void TCPIP_IPV6_DefaultRouterDelete(TCPIP_NET_HANDLE netH);
```

Returns

None.

Description

This function deletes all default routers on a given interface

Remarks

None.

Preconditions

The IPv6 stack is initialized and the interface is up and configured.

Parameters

Parameters	Description
netH	The interface for which to delete the router address.

Function

void TCPIP_IPV6_DefaultRouterDelete(TCPIP_NET_HANDLE netH);

TCPIP_IPV6_DefaultRouterGet Function

Returns the current router address for a specified interface.

File

ipv6.h

C

```
const IPV6_ADDR* TCPIP_IPV6_DefaultRouterGet(TCPIP_NET_HANDLE netH);
```

Returns

- valid IPV6_ADDR pointer - if the interface exists and a valid router address exists
- 0 - if the interface does not exist and a valid router address does not exist

Description

This function returns the current router address for a specified interface.

Remarks

None.

Preconditions

The IPv6 stack is initialized and the interface is up and configured.

Parameters

Parameters	Description
netH	The interface for which to return the router address.

Function

const IPV6_ADDR* TCPIP_IPV6_DefaultRouterGet(TCPIP_NET_HANDLE hNet);

TCPIP_IPV6_Task Function

Standard TCP/IP stack module task function.

File

ipv6.h

C

```
void TCPIP_IPV6_Task();
```

Returns

None.

Description

This function performs IPv6 module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The IPv6 stack is initialized.

Function

void TCPIP_IPV6_Task(void)

b) Data Types and Constants

IP_VERSION_4 Macro

File

ipv6.h

C

```
#define IP_VERSION_4 (0u) // Using IPv4
```

Description

Using IPv4

IP_VERSION_6 Macro

File

ipv6.h

C

```
#define IP_VERSION_6 (1u) // Using IPv6
```

Description

Using IPv6

IPV6_DATA_DYNAMIC_BUFFER Macro

File

ipv6.h

C

```
#define IPV6_DATA_DYNAMIC_BUFFER (0x1u)        // Data to transmit is allocated in dynamically allocated RAM
```

Description

Data to transmit is allocated in dynamically allocated RAM

IPV6_DATA_NETWORK_FIFO Macro

File

ipv6.h

C

```
#define IPV6_DATA_NETWORK_FIFO (0x2u)        // Data to transmit is stored in the Network Controller's FIFOs
```

Description

Data to transmit is stored in the Network Controller's FIFOs

IPV6_DATA_NONE Macro

File

ipv6.h

C

```
#define IPV6_DATA_NONE (0x0u)        // The data segment is unused
```

Description

The data segment is unused

IPV6_DATA_PIC_RAM Macro

File

ipv6.h

C

```
#define IPV6_DATA_PIC_RAM (0x3u)        // Data to transmit is stored in PIC RAM
```

Description

Data to transmit is stored in PIC RAM

IPV6_HEADER_OFFSET_DEST_ADDR Macro

File

ipv6.h

C

```
#define IPV6_HEADER_OFFSET_DEST_ADDR (0x08u + sizeof (IPV6_ADDR))
```

Description

Header offset for destination address

IPV6_HEADER_OFFSET_NEXT_HEADER Macro

File

ipv6.h

C

```
#define IPV6_HEADER_OFFSET_NEXT_HEADER (0x06u)
```

Description

Header offset for next header

IPV6_HEADER_OFFSET_PAYLOAD_LENGTH Macro

File

ipv6.h

C

```
#define IPV6_HEADER_OFFSET_PAYLOAD_LENGTH (0x04u)
```

Description

Header offset for payload length

IPV6_HEADER_OFFSET_SOURCE_ADDR Macro

File

ipv6.h

C

```
#define IPV6_HEADER_OFFSET_SOURCE_ADDR (0x08u)
```

Description

Header offset for source address

IPV6_NO_UPPER_LAYER_CHECKSUM Macro

File

ipv6.h

C

```
#define IPV6_NO_UPPER_LAYER_CHECKSUM (0xFFFFu)    // Value flag for no upper layer checksum
```

Description

Value flag for no upper layer checksum

IPV6_TLV_HBHO_PAYLOAD_JUMBOGRAM Macro

File

ipv6.h

C

```
#define IPV6_TLV_HBHO_PAYLOAD_JUMBOGRAM 0xC2u
```

Description

IPv6 Type-length-value type code for the Hop-by-hop "Jumbo-gram Payload" option

IPV6_TLV_HBHO_ROUTER_ALERT Macro

File

ipv6.h

C

```
#define IPV6_TLV_HBHO_ROUTER_ALERT 0x05u
```

Description

IPv6 Type-length-value type code for the Hop-by-hop "Router Alert" option

IPV6_TLV_PAD_1 Macro

File

ipv6.h

C

```
#define IPV6_TLV_PAD_1 0u
```

Description

IPv6 Type-length-value type code for the Pad 1 option

IPV6_TLV_PAD_N Macro

File

ipv6.h

C

```
#define IPV6_TLV_PAD_N 1u
```

Description

IPv6 Type-length-value type code for the Pad N option

IPV6_TLV_UNREC_OPT_DISCARD_PP Macro

File

ipv6.h

C

```
#define IPV6_TLV_UNREC_OPT_DISCARD_PP 0b10
```

Description

IPv6 action code for the unrecognized option reaction to discard the packet and send an ICMP parameter problem message

IPV6_TLV_UNREC_OPT_DISCARD_PP_NOT_MC Macro

File

ipv6.h

C

```
#define IPV6_TLV_UNREC_OPT_DISCARD_PP_NOT_MC 0b11
```

Description

IPv6 action code for the unrecognized option reaction to discard the packet and send an ICMP parameter problem message is the destination address isn't a multicast address

IPV6_TLV_UNREC_OPT_DISCARD_SILENT Macro

File

ipv6.h

C

```
#define IPV6_TLV_UNREC_OPT_DISCARD_SILENT 0b01
```

Description

IPv6 action code for the unrecognized option reaction to discard the packet silently

IPV6_TLV_UNREC_OPT_SKIP_OPTION Macro

File

ipv6.h

C

```
#define IPV6_TLV_UNREC_OPT_SKIP_OPTION 0b00
```

Description

IPv6 action code for the unrecognized option reaction to skip the option

TCPIP_IPV6_PutArray Macro

Writes data to a packet

File

ipv6.h

C

```
#define TCPIP_IPV6_PutArray(pkt,data,len) TCPIP_IPV6_ArrayPutHelper(pkt, data, IPV6_DATA_PIC_RAM, len)
```

Returns

unsigned short - The number of bytes of data written.

Description

This function writes data to an outgoing packet.

Remarks

None.

Preconditions

TCPIP_IPV6_Initialize is required. TCPIP_IPV6_InterfaceIsReady should be true. The TCPIP_IPV6_TxIsPutReady function must have returned a value greater than or equal to 'len'.

Parameters

Parameters	Description
ptrPacket	The packet
dataSource	Pointer to the data to copy to the packet
len	Length of the data

Function

unsigned short TCPIP_IPV6_PutArray (IPV6_PACKET * ptrPacket,

const void * dataSource, unsigned short len)

IPV6_ACTION Enumeration

Provides a list of possible IPv6 actions.

File

ipv6.h

C

```
typedef enum {
  IPV6_ACTION_NONE = 0,
  IPV6_ACTION_DISCARD_SILENT,
  IPV6_ACTION_DISCARD_PP_0,
  IPV6_ACTION_DISCARD_PP_2,
  IPV6_ACTION_DISCARD_PP_2_NOT_MC,
  IPV6_ACTION_BEGIN_EX_HEADER_PROCESSING
} IPV6_ACTION;
```

Members

Members	Description
IPV6_ACTION_NONE = 0	No action. Skip the option
IPV6_ACTION_DISCARD_SILENT	Discard the packet silently
IPV6_ACTION_DISCARD_PP_0	Discard the packet and send an ICMP parameter problem message with code value 0
IPV6_ACTION_DISCARD_PP_2	Discard the packet and send an ICMP parameter problem message with code value 2
IPV6_ACTION_DISCARD_PP_2_NOT_MC	Discard the packet and send an ICMP parameter problem message with code value 3
IPV6_ACTION_BEGIN_EX_HEADER_PROCESSING	Begin extension processing

Description

Enumeration: IPV6_ACTION

Different actions need to be taken depending on the result of our header processing.

Remarks

None.

IPV6_ADDRESS_POLICY Structure

Data structure for IPv6 address policy.

File

ipv6.h

C

```
typedef struct {
  IPV6_ADDR address;
  unsigned char prefixLength;
  unsigned char precedence;
  unsigned char label;
} IPV6_ADDRESS_POLICY;
```

Members

Members	Description
IPV6_ADDR address;	IPv6 address
unsigned char prefixLength;	IPv6 prefix length
unsigned char precedence;	IPv6 address precedence
unsigned char label;	IPv6 label type

Description

Type: IPV6_ADDRESS_POLICY

The policy table is the longest matching prefix lookup table and is used to select the destination IPv6 Address.

If Precedence(A) > Precedence(B), address A has higher precedence than address B. The label value Label(A) allows for policies that prefer a particular source address prefix for use with a destination address prefix. Default Policy table - Prefix Precedence Label ::1/128 50 0 ::/0 40 1 2002::/16 30 2 ::/96 20 3 ::ffff:0.0.0.0/96 10 4

Remarks

None.

Example

const IPV6_ADDRESS_POLICY gPolicyTable[] = { {{{0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x01}}, 128, 50, 0}, // Loopback address {{{0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00}}, 0, 40, 1}, // Unspecified address {{{0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0xFF, 0xFF, 0x00, 0x00, 0x00, 0x00}}, 96, 35, 4}, // IPv4-mapped address {{{0x20, 0x02, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00}}, 16, 30, 2}, // 2002::/15 - 6to4 {{{0x20, 0x01, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00}}, 32, 5, 5}, // 2001::/32 - Teredo tunneling {{{0xfc, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00}}, 7, 3, 13}, // ULA };

IPV6_ADDRESS_PREFERENCE Enumeration

Provides selection of public versus temporary addresses.

File

ipv6.h

C

```
typedef enum {
  IPV6_PREFER_PUBLIC_ADDRESSES = 0,
  IPV6_PREFER_TEMPORARY_ADDRESSES
} IPV6_ADDRESS_PREFERENCE;
```

Description

Enumeration: IPV6_ADDRESS_PREFERENCE

None

Remarks

None.

IPV6_ADDRESS_TYPE Union

Data structure for IPv6 address types.

File

ipv6.h

C

```
typedef union {
  unsigned char byte;
  struct {
    unsigned scope : 4;
    unsigned type : 2;
  } bits;
} IPV6_ADDRESS_TYPE;
```

Description

Type: IPV6_ADDRESS_TYPE

This type defines the data structure for IPv6 address types.

Remarks

None.

IPV6_DATA_SEGMENT_HEADER Structure

Data structure for IPv6 Data Segment header.

File

ipv6.h

C

```
typedef struct _IPV6_DATA_SEGMENT_HEADER {
  uint8_t* dataLocation;
  unsigned short segmentSize;
  unsigned short segmentLen;
  unsigned char memory;
  unsigned char segmentType;
  struct _IPV6_DATA_SEGMENT_HEADER * nextSegment;
  void * data[0];
} IPV6_DATA_SEGMENT_HEADER;
```

Members

Members	Description
uint8_t* dataLocation;	Location of the data to transmit
unsigned short segmentSize;	Size of this data segment
unsigned short segmentLen;	Number of bytes of data in this segment
unsigned char memory;	Type: IPV6_DATA_NONE, IPV6_DATA_DYNAMIC_BUFFER, IPV6_DATA_NETWORK_FIFO, IPV6_DATA_PIC_RAM
unsigned char segmentType;	Type of segment contents
struct _IPV6_DATA_SEGMENT_HEADER * nextSegment;	Pointer to the next data segment
void * data[0];	Optional buffer space

Description

Structure : IPV6_DATA_SEGMENT_HEADER

Data structure is used to allocate a data segment header and an optional payload.

Remarks

None.

IPV6_EVENT_HANDLER Type

Clients can register a handler with the IPv6 service.

File

ipv6.h

C

```
typedef void (* IPV6_EVENT_HANDLER)(TCPIP_NET_HANDLE hNet, IPV6_EVENT_TYPE evType, const void* evParam,
const void* usrParam);
```

Description

Type: IPV6_EVENT_HANDLER

Once an IPv6 event occurs the IPv6 service will call the registered handler The handler has to be short and fast. It is meant for setting an event flag, not for lengthy processing!

evParam is a parameter that's associated to an IPv6 event

- For an address event (IPV6_EVENT_ADDRESS_ADDED, IPV6_EVENT_ADDRESS_REMOVED) it should typecast to (const IPV6_ADDR_STRUCT*)
- For an IPV6_EVENT_ULA_ADDRESS_GENERATED ULA event it should typecast to (const IPV6_ADDR*)
- For an IPV6_EVENT_ULA_ADDRESS_FAILED ULA event the evParam is an IPV6_ULA_RESULT error code

The evParam is invalid outside of the IPV6_EVENT_HANDLER context call and should not be stored by the caller. Info that's needed has to be copied into caller's own context.

usrParam is a user-supplied parameter

Remarks

For address related events the passed (const IPV6_ADDR_STRUCT*) parameter is invalid after the notification call.

IPV6_EVENT_TYPE Enumeration

This enumeration is used to notify IPv6 client applications.

File

ipv6.h

C

```
typedef enum {
  IPV6_EVENT_ADDRESS_ADDED = 1,
  IPV6_EVENT_ADDRESS_REMOVED,
  IPV6_EVENT_ULA_ADDRESS_GENERATED,
  IPV6_EVENT_ULA_ADDRESS_FAILED
} IPV6_EVENT_TYPE;
```

Members

Members	Description
IPV6_EVENT_ADDRESS_ADDED = 1	Event is generated when IPv6 added to the list
IPV6_EVENT_ADDRESS_REMOVED	Event is generated when IPv6 address removed from the list
IPV6_EVENT_ULA_ADDRESS_GENERATED	Event is generated when IPv6 unique local address included to the list
IPV6_EVENT_ULA_ADDRESS_FAILED	Event is generated when IPv6 unique local address is failed

Description

Enumeration: IPV6_EVENT_TYPE

These events are used while notifying to the registered applications.

Remarks

None.

IPV6_FRAGMENT_HEADER Structure

Data structure for IPv6 fragment header.

File

ipv6.h

C

```
typedef struct {
  uint8_t nextHeader;
  uint8_t reserved;
  union {
    struct {
      uint16_t m : 1;
      uint16_t reserved2 : 2;
      uint16_t fragmentOffset : 13;
    } bits;
    uint16_t w;
  } offsetM;
  uint32_t identification;
} IPV6_FRAGMENT_HEADER;
```

Description

Structure: IPV6_FRAGMENT_HEADER

The Fragment header is used by an IPv6 source to send a packet larger than would fit in the path MTU to its destination. The Fragment header is identified by a Next Header value of 44 in the immediately preceding header.

Remarks

None.

IPV6_HANDLE Type

File

ipv6.h

C

```
typedef const void * IPV6_HANDLE;
```

Description

Pointer to IPv6 object

IPV6_HEADER Structure

IPv6 packet header definition.

File

ipv6.h

C

```
typedef struct {
  unsigned long V_T_F;
  unsigned short PayloadLength;
  unsigned char NextHeader;
  unsigned char HopLimit;
  IPV6_ADDR SourceAddress;
  IPV6_ADDR DestAddress;
} IPV6_HEADER;
```

Members

Members	Description
unsigned long V_T_F;	Version , Traffic class and Flow Label
unsigned short PayloadLength;	Length of IPv6 payload, i.e. the rest of packet following this IPv6 header in octets
unsigned char NextHeader;	Identifies the type of header immediately following IPv6 header
unsigned char HopLimit;	Decremented by 1 by each node that forwards the packet
IPV6_ADDR SourceAddress;	128 bit address of originator
IPV6_ADDR DestAddress;	128 bit address of intended recipient

Description

Structure: IPV6_HEADER

IPv6 packet header definition.

Remarks

Any extension headers present are considered part of the payload length.

IPV6_NEXT_HEADER_TYPE Enumeration

Defines a list of IPv6 next header types.

File

ipv6.h

C

```
typedef enum {
  IPV6_PROT_HOP_BY_HOP_OPTIONS_HEADER = (0u),
  IPV6_PROT_ICMP = (1u),
  IPV6_PROT_TCP = (6u),
  IPV6_PROT_UDP = (17u),
  IPV6_PROT_IPV6 = (41u),
  IPV6_PROT_ROUTING_HEADER = (43u),
  IPV6_PROT_FRAGMENTATION_HEADER = (44u),
  IPV6_PROT_ENCAPSULATING_SECURITY_PAYLOAD_HEADER = (50u),
  IPV6_PROT_AUTHENTICATION_HEADER = (51u),
  IPV6_PROT_ICMPV6 = (58u),
  IPV6_PROT_NONE = (59u),
  IPV6_PROT_DESTINATION_OPTIONS_HEADER = (60u)
} IPV6_NEXT_HEADER_TYPE;
```

Members

Members	Description
IPV6_PROT_HOP_BY_HOP_OPTIONS_HEADER = (0u)	IPv6 Hop-by-Hop Opt. Header
IPV6_PROT_ICMP = (1u)	ICMPv4 Header
IPV6_PROT_TCP = (6u)	TCP protocol Header
IPV6_PROT_UDP = (17u)	UDP protocol Header
IPV6_PROT_IPV6 = (41u)	IPv6 Protocol
IPV6_PROT_ROUTING_HEADER = (43u)	IPv6 Routing Header
IPV6_PROT_FRAGMENTATION_HEADER = (44u)	IPv6 Fragmentation Header
IPV6_PROT_ENCAPSULATING_SECURITY_PAYLOAD_HEADER = (50u)	Encapsulating Security Payload Header
IPV6_PROT_AUTHENTICATION_HEADER = (51u)	Authentication Header
IPV6_PROT_ICMPV6 = (58u)	ICMPv6 Protocol
IPV6_PROT_NONE = (59u)	No next header
IPV6_PROT_DESTINATION_OPTIONS_HEADER = (60u)	Destination Options Header

Description

Enumeration: IPV6_NEXT_HEADER_TYPE

Identifies the type of the next header immediately follows IPv6 header.

Remarks

None

IPV6_PACKET Structure

Packet structure/state tracking for IPv6 packets.

File

ipv6.h

C

```
typedef struct _IPV6_PACKET {
  struct _IPV6_PACKET * next;
  unsigned short payloadLen;
  unsigned short headerLen;
  unsigned short upperLayerHeaderLen;
  unsigned short upperLayerChecksumOffset;
  unsigned char upperLayerHeaderType;
  union {
    struct {
      unsigned char reserved : 3;
      unsigned char useUnspecAddr : 1;
      unsigned char sourceSpecified : 1;
      unsigned char queued : 1;
      unsigned char addressType : 2;
    }
    unsigned char val;
  } flags;
  TCPIP_MAC_ADDR remoteMACAddr;
  IPV6_PACKET_ACK_FNC ackFnc;
  TCPIP_MAC_PACKET_ACK_FUNC macAckFnc;
  void* ackParam;
  void* clientData;
  void * neighbor;
  unsigned short offsetInSegment;
  uint32_t queuedPacketTimeout;
  IPV6_DATA_SEGMENT_HEADER payload;
  TCPIP_NET_HANDLE netIfH;
  IPV6_HEADER ipv6Header;
} IPV6_PACKET;
```

Members

Members	Description
struct _IPV6_PACKET * next;	Next packet in a queue
unsigned short payloadLen;	Amount of data in payload buffer
unsigned short headerLen;	Total header length (IP header + IPv6 Extension headers)
unsigned short upperLayerHeaderLen;	Total length of the upper layer header
unsigned short upperLayerChecksumOffset;	Offset of the upper layer checksum
unsigned char upperLayerHeaderType;	Type definition for the upper-layer header type
unsigned char useUnspecAddr : 1;	This packet should use the unspecified address
unsigned char sourceSpecified : 1;	The upper layer or application layer specified a source address
unsigned char queued : 1;	Packet has been queued
unsigned char addressType : 2;	IP_ADDRESS_TYPE_IPV6 or IP_ADDRESS_TYPE_IPV4
TCPIP_MAC_ADDR remoteMACAddr;	The packet's remote MAC address
IPV6_PACKET_ACK_FNC ackFnc;	function to be called when IPv6 done with the packet
TCPIP_MAC_PACKET_ACK_FUNC macAckFnc;	function to be called when MAC done with a TX packet
void* ackParam;	parameter to be used
void* clientData;	optional packet client data
void * neighbor;	The neighbor that the message was received from
unsigned short offsetInSegment;	Offset used for storing fragment transmission information
uint32_t queuedPacketTimeout;	Time out for IPv6 packets which are queued
IPV6_DATA_SEGMENT_HEADER payload;	IPv6 data segment payload
TCPIP_NET_HANDLE netIfH;	packet network interface
IPV6_HEADER ipv6Header;	IPv6 header definition

Description

Structure: IPV6_PACKET

IPv6 packets are queued for future transmission.queuedPacketTimeout is used to time-out IPv6 queued packets.

Remarks

For IPv6 queuing the time out has to be 0! The queue is processed separately by the NDP.IPV6_PACKET_ACK_FNC is called after the successful removal and inclusion of the packet.

IPV6_PACKET_ACK_FNC Type

Packet allocation and deallocation acknowledgment callback function.

File

ipv6.h

C

```
typedef bool (* IPV6_PACKET_ACK_FNC)(void*, bool, const void*);
```

Returns

-true - if the packet needs the queuing flags removed (it is not deleted and still in use) -false - if the packet does not need the queuing flags removed (either no longer exists or the flags updated)

Description

Type: IPV6_PACKET_ACK_FNC

Packet allocation and deallocation acknowledgment callback function.

Remarks

None.

Parameters

Parameters	Description
void *	Pointer to the packet that was transmitted
bool	True if the packet was sent, false otherwise
const void*	0

IPV6_RX_FRAGMENT_BUFFER Structure

Data structure for IPv6 Received fragmented packet.

File

ipv6.h

C

```
typedef struct _IPV6_RX_FRAGMENT_BUFFER {
  struct _IPV6_RX_FRAGMENT_BUFFER * next;
  uint8_t * ptrPacket;
  uint32_t identification;
  uint16_t bytesInPacket;
  uint16_t packetSize;
  uint16_t firstFragmentLength;
  uint8_t secondsRemaining;
} IPV6_RX_FRAGMENT_BUFFER;
```

Members

Members	Description
struct _IPV6_RX_FRAGMENT_BUFFER * next;	Next fragmented packet
uint8_t * ptrPacket;	Packet information
uint32_t identification;	Fragment id
uint16_t bytesInPacket;	Number of bytes written to packet
uint16_t packetSize;	Packet size (packet is complete when this matches bytesInPacket)
uint16_t firstFragmentLength;	Length of the first fragment
uint8_t secondsRemaining;	Number of seconds remaining during which the fragment can be reassembled

Description

Structure: IPV6_RX_FRAGMENT_BUFFER

Each fragment is composed of unfragmentable Part and fragmentable part. Allocate memory for the fragmented packet w.r.t to TCPIP_IPV6_RX_FRAGMENTED_BUFFER_SIZE. The RFC specifies that the fragments must be reassembled in one minute or less.secondsRemaining is the times remaining for reassemble.

Remarks

None.

IPV6_SEGMENT_TYPE Enumeration

Provides an enumeration of IPv6 segment types.

File

ipv6.h

C

```
typedef enum {
  TYPE_IPV6_HEADER = 1u,
  TYPE_IPV6_EX_HEADER_HOP_BY_HOP_OPTIONS,
  TYPE_IPV6_EX_HEADER_DESTINATION_OPTIONS_1,
  TYPE_IPV6_EX_HEADER_ROUTING,
  TYPE_IPV6_EX_HEADER_FRAGMENT,
  TYPE_IPV6_EX_HEADER_AUTHENTICATION_HEADER,
  TYPE_IPV6_EX_HEADER_ENCAPSULATING_SECURITY_PAYLOAD,
  TYPE_IPV6_EX_HEADER_DESTINATION_OPTIONS_2,
  TYPE_IPV6_UPPER_LAYER_HEADER,
  TYPE_IPV6_UPPER_LAYER_PAYLOAD,
  TYPE_IPV6_BEGINNING_OF_WRITABLE_PART,
  TYPE_IPV6_END_OF_LIST
} IPV6_SEGMENT_TYPE;
```

Description

Enumeration: IPV6_SEGMENT_TYPE

IPv6 extended header.

Remarks

None.

IPV6_TLV_OPTION_TYPE Union

Data structure for IPv6 TLV options.

File

ipv6.h

C

```
typedef union {
  unsigned char b;
  struct {
    unsigned option : 6;
    unsigned unrecognizedAction : 2;
  } bits;
} IPV6_TLV_OPTION_TYPE;
```

Description

Type: IPV6_TLV_OPTION_TYPE

This type defines the data structure for IPv6 TLV options.

Remarks

None.

IPV6_ULA_FLAGS Enumeration

Provides a list of possible ULA action flags.

File

ipv6.h

C

```
typedef enum {
  IPV6_ULA_FLAG_NTPV4 = 0x01,
  IPV6_ULA_FLAG_GENERATE_ONLY = 0x02,
  IPV6_ULA_FLAG_SKIP_DAD = 0x04
} IPV6_ULA_FLAGS;
```

Members

Members	Description
IPV6_ULA_FLAG_NTPV4 = 0x01	use an IPv4 NTP server access in Unique Local Address generation default is an IPv6 server
IPV6_ULA_FLAG_GENERATE_ONLY = 0x02	generate an address only, don't add it to the interface addresses
IPV6_ULA_FLAG_SKIP_DAD = 0x04	when adding the address to the interface, skip the Duplicate Address Detection

Description

Enumeration: IPV6_ULA_FLAGS

This enumeration provides a list of possible flags for the Unique Local Address (ULA) generation.

Remarks

None.

IPV6_ULA_RESULT Enumeration

Provides a list of possible ULA results.

File

ipv6.h

C

```
typedef enum {
  IPV6_ULA_RES_OK,
  IPV6_ULA_RES_BUSY = -1,
  IPV6_ULA_RES_IF_ERR = -2,
  IPV6_ULA_RES_NTP_ACCESS_ERR = -3,
  IPV6_ULA_RES_NTP_TSTAMP_ERR = -4
} IPV6_ULA_RESULT;
```

Members

Members	Description
IPV6_ULA_RES_OK	the address generation was started successfully
IPV6_ULA_RES_BUSY = -1	address generation module is busy
IPV6_ULA_RES_IF_ERR = -2	interface non existent
IPV6_ULA_RES_NTP_ACCESS_ERR = -3	NTP module could not be accessed
IPV6_ULA_RES_NTP_TSTAMP_ERR = -4	wrong NTP time stamp received

Description

Enumeration: IPV6_ULA_RESULT

This enumeration provides a list of possible results for the Unique Local Address (ULA) generation.

Remarks

None.

TCPIP_IPV6_MODULE_CONFIG Structure

Provides a place holder for IPv6 configuration.

File

ipv6.h

C

```
typedef struct {
  uint32_t rxfragmentBufSize;
```

```
  uint32_t fragmentPktRxTimeout;
} TCPIP_IPV6_MODULE_CONFIG;
```

Members

Members	Description
uint32_t rxfragmentBufSize;	RX fragmented buffer size
uint32_t fragmentPktRxTimeout;	fragmented packet time out value

Description

Structure: TCPIP_IPV6_MODULE_CONFIG

IPv6 module runtime configuration and initialization parameters.

Remarks

None.

Files

Files

Name	Description
ipv6.h	IPv6 is the next generation TCP/IP protocol suite.
ipv6_config.h	IPv6 configuration file

Description

This section lists the source and header files used by the library.

ipv6.h

IPv6 is the next generation TCP/IP protocol suite.

Enumerations

	Name	Description
	IPV6_ACTION	Provides a list of possible IPv6 actions.
	IPV6_ADDRESS_PREFERENCE	Provides selection of public versus temporary addresses.
	IPV6_EVENT_TYPE	This enumeration is used to notify IPv6 client applications.
	IPV6_NEXT_HEADER_TYPE	Defines a list of IPv6 next header types.
	IPV6_SEGMENT_TYPE	Provides an enumeration of IPv6 segment types.
	IPV6_ULA_FLAGS	Provides a list of possible ULA action flags.
	IPV6_ULA_RESULT	Provides a list of possible ULA results.

Functions

	Name	Description
	TCPIP_IPV6_AddressUnicastRemove	Removed a configured unicast address from an interface.
	TCPIP_IPV6_ArrayGet	Reads the next byte of data from the specified MAC.
	TCPIP_IPV6_ArrayPutHelper	Helper function to write data to a packet.
	TCPIP_IPV6_DASSourceAddressSelect	Determines the appropriate source address for a given destination address.
	TCPIP_IPV6_DefaultRouterDelete	Deletes the current router list for a specified interface
	TCPIP_IPV6_DefaultRouterGet	Returns the current router address for a specified interface.
	TCPIP_IPV6_DestAddressGet	Gets the destination address for a IPv6 packet.
	TCPIP_IPV6_DestAddressSet	Sets the destination address for a IPv6 packet.
	TCPIP_IPV6_Flush	Flushes a IP TX packet.
	TCPIP_IPV6_Get	Reads the next byte of data from the specified MAC.
	TCPIP_IPV6_HandlerDeregister	Deregisters an IPv6 event handler callback function.
	TCPIP_IPV6_HandlerRegister	Registers an IPv6 event handler callback function.
	TCPIP_IPV6_InterfaceIsReady	Determines if an interface is ready for IPv6 transactions.
	TCPIP_IPV6_MulticastListenerAdd	Adds a multicast listener to an interface.
	TCPIP_IPV6_MulticastListenerRemove	Removes a multicast listener from a given interface.
	TCPIP_IPV6_PacketFree	Frees a TCP/IP Packet structure from dynamic memory.

	TCPIP_IPV6_PayloadSet	Allocates a segment on the end of a packet segment chain and uses it to address prebuffered data.
	TCPIP_IPV6_Put	Writes a character of data to a packet.
	TCPIP_IPV6_RouterAddressAdd	Adds a new router address to a specified interface.
	TCPIP_IPV6_SourceAddressGet	Gets the source address for an IPv6 packet.
	TCPIP_IPV6_SourceAddressSet	Sets the source address for a IPv6 packet.
	TCPIP_IPV6_Task	Standard TCP/IP stack module task function.
	TCPIP_IPV6_TxIsPutReady	Determines whether a TX packet can be written to.
	TCPIP_IPV6_TxPacketAllocate	Dynamically allocates a packet for transmitting IP protocol data.
	TCPIP_IPV6_UnicastAddressAdd	Adds a unicast address to a specified interface
	TCPIP_IPV6_UniqueLocalUnicastAddressAdd	Adds a Unique Local Unicast Address (ULA) to a specified interface.

Macros

	Name	Description
	IP_VERSION_4	Using IPv4
	IP_VERSION_6	Using IPv6
	IPV6_DATA_DYNAMIC_BUFFER	Data to transmit is allocated in dynamically allocated RAM
	IPV6_DATA_NETWORK_FIFO	Data to transmit is stored in the Network Controller's FIFOs
	IPV6_DATA_NONE	The data segment is unused
	IPV6_DATA_PIC_RAM	Data to transmit is stored in PIC RAM
	IPV6_HEADER_OFFSET_DEST_ADDR	Header offset for destination address
	IPV6_HEADER_OFFSET_NEXT_HEADER	Header offset for next header
	IPV6_HEADER_OFFSET_PAYLOAD_LENGTH	Header offset for payload length
	IPV6_HEADER_OFFSET_SOURCE_ADDR	Header offset for source address
	IPV6_NO_UPPER_LAYER_CHECKSUM	Value flag for no upper layer checksum
	IPV6_TLV_HBHO_PAYLOAD_JUMBOGRAM	IPv6 Type-length-value type code for the Hop-by-hop "Jumbo-gram Payload" option
	IPV6_TLV_HBHO_ROUTER_ALERT	IPv6 Type-length-value type code for the Hop-by-hop "Router Alert" option
	IPV6_TLV_PAD_1	IPv6 Type-length-value type code for the Pad 1 option
	IPV6_TLV_PAD_N	IPv6 Type-length-value type code for the Pad N option
	IPV6_TLV_UNREC_OPT_DISCARD_PP	IPv6 action code for the unrecognized option reaction to discard the packet and send an ICMP parameter problem message
	IPV6_TLV_UNREC_OPT_DISCARD_PP_NOT_MC	IPv6 action code for the unrecognized option reaction to discard the packet and send an ICMP parameter problem message is the destination address isn't a multicast address
	IPV6_TLV_UNREC_OPT_DISCARD_SILENT	IPv6 action code for the unrecognized option reaction to discard the packet silently
	IPV6_TLV_UNREC_OPT_SKIP_OPTION	IPv6 action code for the unrecognized option reaction to skip the option
	TCPIP_IPV6_PutArray	Writes data to a packet

Structures

	Name	Description
	_IPV6_DATA_SEGMENT_HEADER	Data structure for IPv6 Data Segment header.
	_IPV6_PACKET	Packet structure/state tracking for IPv6 packets.
	_IPV6_RX_FRAGMENT_BUFFER	Data structure for IPv6 Received fragmented packet.
	IPV6_ADDRESS_POLICY	Data structure for IPv6 address policy.
	IPV6_DATA_SEGMENT_HEADER	Data structure for IPv6 Data Segment header.
	IPV6_FRAGMENT_HEADER	Data structure for IPv6 fragment header.
	IPV6_HEADER	IPv6 packet header definition.
	IPV6_PACKET	Packet structure/state tracking for IPv6 packets.
	IPV6_RX_FRAGMENT_BUFFER	Data structure for IPv6 Received fragmented packet.
	TCPIP_IPV6_MODULE_CONFIG	Provides a place holder for IPv6 configuration.

Types

	Name	Description
	IPV6_EVENT_HANDLER	Clients can register a handler with the IPv6 service.
	IPV6_HANDLE	Pointer to IPv6 object

	IPV6_PACKET_ACK_FNC	Packet allocation and deallocation acknowledgment callback function.

Unions

	Name	Description
	IPV6_ADDRESS_TYPE	Data structure for IPv6 address types.
	IPV6_TLV_OPTION_TYPE	Data structure for IPv6 TLV options.

Description

IPv6 Definitions for the Microchip TCP/IP Stack

Like IPv4 , IPv6 (Internet Protocol Version 6) is the another version of IP protocol. This is the next-generation protocol which works parallel with IPv4. Microchip TCP/IP stack is a dual stack architecture where both Ipv4 and Ipv6 works simultaneously. (RFC - 2460,3484)

File Name

ipv6.h

Company

Microchip Technology Inc.

ipv6_config.h

IPv6 configuration file

Macros

	Name	Description
	TCPIP_IPV6_DEFAULT_ALLOCATION_BLOCK_SIZE	Sets the minimum allocation unit for the payload size
	TCPIP_IPV6_DEFAULT_BASE_REACHABLE_TIME	Default 30 seconds , Router advertisement reachable time
	TCPIP_IPV6_DEFAULT_CUR_HOP_LIMIT	IPv4 Time-to-Live parameter
	TCPIP_IPV6_DEFAULT_LINK_MTU	Default Maximum Transmission Unit
	TCPIP_IPV6_DEFAULT_RETRANSMIT_TIME	1 second, Process the router advertisement's retransmission time
	TCPIP_IPV6_FRAGMENT_PKT_TIMEOUT	Fragmentation packet time-out value. default value is 60 .
	TCPIP_IPV6_INIT_TASK_PROCESS_RATE	IPv6 initialize task processing rate, milliseconds The default value is 32 milliseconds.
	TCPIP_IPV6_MINIMUM_LINK_MTU	Sets the lower bounds of the Maximum Transmission Unit
	TCPIP_IPV6_NEIGHBOR_CACHE_ENTRY_STALE_TIMEOUT	10 minutes
	TCPIP_IPV6_QUEUE_MCAST_PACKET_LIMIT	This option defines the maximum number of multicast queued IPv6 If an additional packet is queued, the oldest packet in the queue will be removed.
	TCPIP_IPV6_QUEUE_NEIGHBOR_PACKET_LIMIT	This option defines the maximum number of queued packets per remote. If an additional packet needs to be queued, the oldest packet in the queue will be removed.
	TCPIP_IPV6_QUEUED_MCAST_PACKET_TIMEOUT	This option defines the number of seconds an IPv6 multicast packet will remain in the queue before being timed out
	TCPIP_IPV6_RX_FRAGMENTED_BUFFER_SIZE	RX fragmented buffer size should be equal to the total original packet size of ICMPv6 ECHO request packets . ex - Let Transmit ICMPv6 Echo request packet whose original packet size is 1500byte from the Global address of HOST1 to the global address of HOST2 and if the packet is going to be fragmented then packet will be broken more than packets. Each packet will have IPv6 header(40 bytes)+ Fragmentation header (8 bytes) + ICMPv6 Echo request header(8 bytes) • Payload (data packet).PING6(1500=40+8+8+1452 bytes). Here data packet size is 1452. If the data packet size is getting changed then this... more
	TCPIP_IPV6_TASK_PROCESS_RATE	IPv6 task processing rate, milliseconds The default value is 1000 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_IPV6_ULA_NTP_ACCESS_TMO	NTP access time-out for the IPv6 ULA address generation, ms

	TCPIP_IPV6_ULA_NTP_VALID_WINDOW	the NTP time stamp validity window, ms if a stamp was obtained outside this interval from the moment of the request a new request will be issued

MAC Driver Module

This section describes the TCP/IP Stack Library MAC Driver module.

Introduction

TCP/IP Stack Library Media Access Control (MAC) Driver Module for Microchip Microcontrollers

This library provides the API of the MAC Driver module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

In the seven-layer OSI model of computer networking, media access control (MAC) data communication protocol is a sub-layer of the data link layer, which itself is layer 2. The MAC sub-layer provides addressing and channel access control mechanisms that make it possible for several terminals or network nodes to communicate within a multiple access network that incorporates a shared medium (e.g., Ethernet). The hardware that implements the MAC is referred to as a medium access controller.

The MAC sub-layer acts as an interface between the logical link control (LLC) sub-layer and the network's physical layer. The MAC layer emulates a full-duplex logical communication channel in a multi-point network. This channel may provide unicast, multicast or broadcast communication service.

Using the Library

This topic describes the basic architecture of the TCP/IP Stack MAC Driver Library and provides information and examples on its use.

Description

Interface Header File: `tcpip_mac.h`

The interface to the TCP/IP Stack MAC Driver Library is defined in the `tcpip_mac.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the TCP/IP Stack MAC Driver Library should include `tcpip.h`.

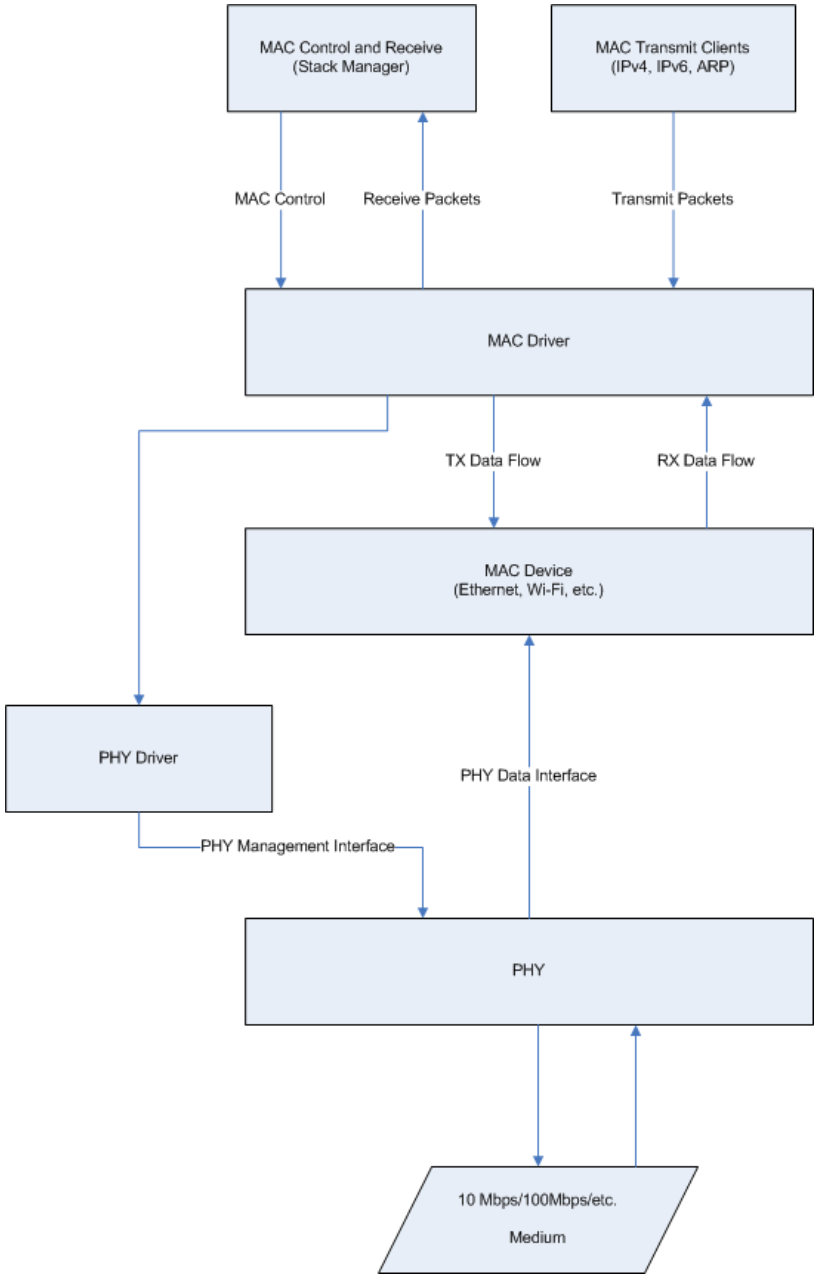
Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

This library provides the API of the TCP/IP Stack MAC module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

MAC Software Abstraction Block Diagram



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the MAC module.

Library Interface Section	Description
Initialization Functions	This section provides routines for configuring the MAC driver
Client Control and Status Functions	This section provides routines for client instance manipulations and MAC status
Event Functions	This section provides routines for control of the MAC driver events
Filter Functions	This section provides routines for controlling the receive MAC filtering
Data Transfer Functions	This section provides routines for transmitting and receiving data packets over the network
Data Types and Constants	This section provides various definitions describing this API

How the Library Works

This topic describes how the TCP/IP Stack MAC Library works.

Description

The MAC layer (together with the Logical Link Control – LLC) is intended to have the functionality described in the OSI model for the Data Link Layer.

There are two important functions to be performed in the MAC layer as part of the Data Link Layer:

Data Encapsulation (Transmit and Receive)

- Framing (frame boundary detection, frame synchronization)
- Addressing (control of the source and destination addresses)
- Error detection (detection of transmission errors occurring in the physical medium)

Media Access Management

- Medium allocation (collision avoidance)
- Contention resolution (collision handling)

Beside this, the receive packet filtering is another important functionality that is usually integrated in the MAC layer.

The functionality previously presented is handled by the hardware itself as an intrinsic part of the data exchange that's performed with the PHY.

From the software point of view the MAC driver exposes an API that's focused on efficient data transfer routines. Control of the driver and access to the transferred data is given by using regular driver client access functions.

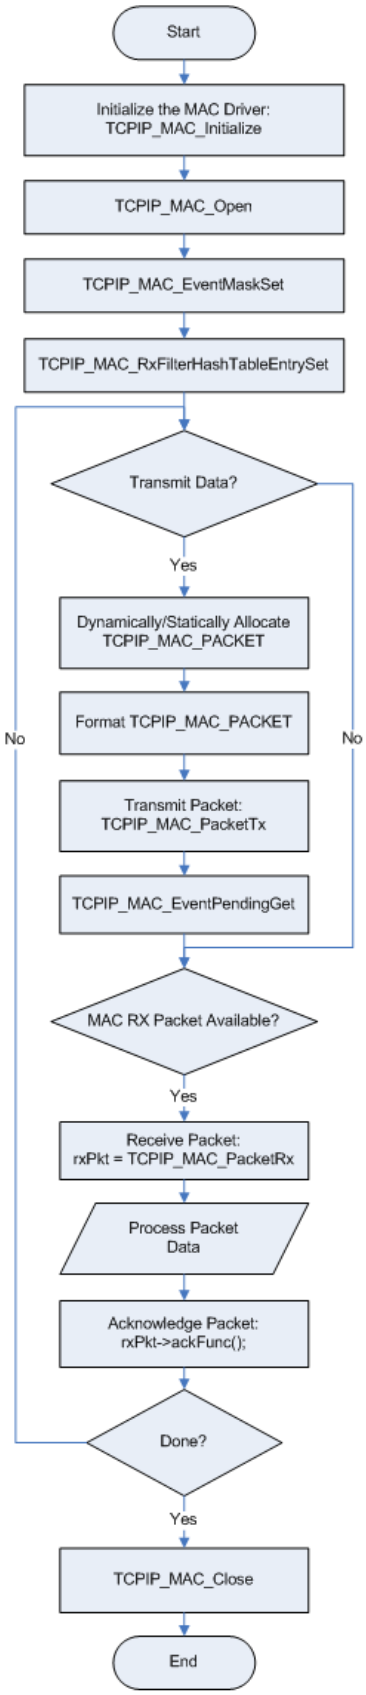
Please note that the MAC model described here corresponds to a virtual MAC driver that the TCP/IP stack uses. All the implementations of the physical MAC drivers (Ethernet, Wi-Fi, etc.) must adhere and implement this API required by the virtual MAC API. This is how the TCP/IP stack achieves virtualization of the operation over multiple network interfaces. The TCP/IP stack makes no assumption about the specifics of an actual implementation and behaves all MACs to behave identically

Core Functionality

This topic describes the core functionality of the TCP/IP Stack MAC Library.

Description

MAC Connection Flow Diagram



The MAC driver is used internally by the TCP/IP Stack Manager and its API is not normally exposed outside the stack. There is little need to interface directly with the MAC from the application level. The TCP/IP Stack provides all the data interface functions to the application by exposing the socket API (TCP and UDP) and also low level IPv4 and IPv6 API. However, the functionality of the MAC driver is important for having a thorough understanding of how the TCP/IP Stack works or for integrating the MPLAB Harmony MAC driver into a third-party TCP/IP Stack.

The MAC driver needs to be initialized by a call to TCPIP_MAC_Initialize() with both stack and module specific initialization data. The stack

initialization data contains absolutely necessary data for the MAC driver to operate (memory allocation functions, packet allocation functions, event notification functions, etc.) Note that the module initialization data could be different from one MAC module to another and, if missing, normally the MAC driver should use some default values specified in the `tcpip_mac_config.h` file.

Once the initialization process succeeds, a MAC client handle is obtained by using TCPIP_MAC_Open.

Other parameters can be set, like the active events and receive filters by calling TCPIP_MAC_EventMaskSet, TCPIP_MAC_RxFilterHashTableEntrySet, etc.

By default the MAC driver operates in interrupts and the events are reported to the TCP/IP stack by using the event notification function that's passed in at the MAC driver initialization. However, by using the TCPIP_MAC_EventPendingGet function, it is possible to use the MAC driver in a polling manner.

To send a packet, a MAC driver client has to obtain a TCPIP_MAC_PACKET data structure, either statically or dynamically. Note that the Harmony TCP/IP Stack uses dynamic packet allocation and has a packet allocation module that the Stack Manager calls for this purpose. The packet has to be properly formatted with all the required fields before being passed to the MAC driver for transmission. The MAC driver will perform a minimum sanity check and will try to transmit the packet over the network. Once the corresponding interrupt signals to the driver that the packet was (successfully/non-successfully) transmitted the MAC driver will call the packet acknowledge function. This will indicate to the owner of the packet (the module that created/allocated the packet) that the packet is no longer in use and it can be reused, discarded, etc.

The receive process is configured as part of the MAC driver initialization procedure. Usually the MAC driver needs some buffers for storing the received network traffic. How exactly this is done is driver specific and not part of this specification. The Harmony Ethernet MAC driver, for example, allocates multiple receive buffers at initialization and uses those for the whole duration of the driver life. Other implementations may choose to free the receive buffers once they are processed and allocate new ones, as needed.

The receive process is initiated by the hardware indicating through an interrupt that a packet is pending. This will trigger a notification event to the MAC client (the TCP/IP stack) and the actual packet receive function can be called. Alternatively the MAC client can call the TCPIP_MAC_EventPendingGet function which can be used in a polling manner.

To actually receive the packet the TCP/IP stack should call the TCPIP_MAC_PacketRx function. This function, besides returning a pointer to the newly received packet will provide additional info about the packet status. Also, some MAC drivers have the possibility to mark the packet being received as being unicast, multicast or broadcast.

Once a packet is obtained, the stack has to dispatch it accordingly, based on the info contained within the packet (ARP, IPv4, IPv6, etc.). Note that in the Harmony TCP/IP stack it's the Stack Manager that performs the receiving and dispatching function of the packets. The recipient of the packet will be called to process the incoming packet and may forward the packet for further processing (TCP, UDP, ICMP). Note that during all this processing time this packet can no longer be used by the MAC driver for storing newly receive data. Therefore once the final recipient of the received packet has processed the data it has to call the packet acknowledge function, so that the packet can be returned to its owner, the AMC driver in this case. If the MAC driver reuses the packet (as the Harmony Ethernet MAC driver does) or simply discards it is driver implementation specific.

Once the data transfer of packets over the network is no longer needed the TCPIP_MAC_Close function can be called and also TCPIP_MAC_Deinitialize. This is part of the normal procedure that the Harmony stack uses for shutting down and restarting a network interface dynamically.

For detailed information about the MAC layer requirements and functionality, please consult the IEEE 802.3 specifications.

Configuring the Library

Macros

	Name	Description
	TCPIP_EMAC_ETH_OPEN_FLAGS	Flags to use for the Ethernet connection A TCPIP_ETH_OPEN_FLAGS value. Set to TCPIP_ETH_OPEN_DEFAULT unless very good reason to use different value
	TCPIP_EMAC_PHY_ADDRESS	The PHY address, as configured on the board. By default all the PHYs respond to address 0
	TCPIP_EMAC_PHY_CONFIG_FLAGS	Flags to configure the MAC ->PHY connection a DRV_ETHPHY_CONFIG_FLAGS This depends on the actual connection (MII/RMII, default/alternate I/O) The DRV_ETHPHY_CFG_AUTO value will use the configuration fuses setting
	TCPIP_EMAC_PHY_LINK_INIT_DELAY	The value of the delay for the link initialization, ms This insures that the PHY is ready to transmit after it is reset A usual value is 500 ms. Adjust to your needs.
	TCPIP_EMAC_RX_BUFF_SIZE	Size of a RX packet buffer. Should be multiple of 16. This is the size of all receive packet buffers processed by the ETHC. The size should be enough to accommodate any network received packet. If the packets are larger, they will have to take multiple RX buffers and the packet manipulation is less efficient. #define TCPIP_EMAC_RX_BUFF_SIZE 512 Together with TCPIP_EMAC_RX_DEDICATED_BUFFERS it has impact on TCPIP_STACK_DRAM_SIZE setting.
	TCPIP_EMAC_RX_DESCRIPTORS	Number of the RX descriptors to be created. If not using the run time replenish mechanism (see below) it should match the number of dedicated buffers: TCPIP_EMAC_RX_DEDICATED_BUFFERS; Otherwise it should be bigger than the sum of dedicated + non-dedicated buffers: TCPIP_EMAC_RX_DESCRIPTORS > TCPIP_EMAC_RX_DEDICATED_BUFFERS + replenish_buffers

	TCPIP_EMAC_RX_FRAGMENTS	MAC maximum number of supported fragments. Based on the values of TCPIP_EMAC_RX_MAX_FRAME and TCPIP_EMAC_RX_BUFF_SIZE an incoming frame may span multiple RX buffers (fragments). Note that excessive fragmentation leads to performance degradation. The default and recommended value should be 1. #define TCPIP_EMAC_RX_FRAGMENTS 1 Alternatively you can use the calculation of the number of fragments based on the selected RX sizes:
	TCPIP_EMAC_RX_MAX_FRAME	Maximum MAC supported RX frame size. Any incoming ETH frame that's longer than this size will be discarded. The default value is 1536 (allows for VLAN tagged frames, although the VLAN tagged frames are discarded). Normally there's no need to touch this value unless you know exactly the maximum size of the frames you want to process or you need to control packets fragmentation (together with the TCPIP_EMAC_RX_BUFF_SIZE).
	TCPIP_EMAC_TX_DESCRIPTORS	Number of the TX descriptors to be created. Because a TCP packet can span at most 3 buffers, the value should always be >= 4 The amount of memory needed per descriptor is not high (around 24 bytes) so when high MAC TX performance is needed make sure that this number is >= 8.
	TCPIP_EMAC_RX_DEDICATED_BUFFERS	Number of MAC dedicated RX packet buffers. These buffers are always owned by the MAC. Note that the MAC driver allocates these buffers for storing the incoming network packets. The bigger the storage capacity, the higher data throughput can be obtained. Note that these packet buffers are allocated from the private TCP/IP heap that is specified by the TCPIP_STACK_DRAM_SIZE setting.
	TCPIP_EMAC_RX_INIT_BUFFERS	Number of non-dedicated buffers for the MAC initialization Buffers allocated at the MAC driver initialization.
	TCPIP_EMAC_RX_LOW_FILL	Number of RX buffers to allocate when below threshold condition is detected. If 0, the MAC driver will allocate (scheduled buffers - rxThres) If !0, the MAC driver will allocate exactly TCPIP_EMAC_RX_LOW_FILL buffers
	TCPIP_EMAC_RX_LOW_THRESHOLD	Minumum threshold for the buffer replenish process. Whenever the number of RX scheduled buffers is <= than this threshold the MAC driver will allocate new non-dedicated buffers (meaning that they will be released to the TCP/IP heap once they are processed). Setting this value to 0 disables the buffer replenishing process.
	TCPIP_EMAC_RX_FILTERS	MAC RX Filters These filters define the packets that are accepted and rejected by the MAC driver Adjust to your needs The default value allows the processing of unicast, multicast and broadcast packets that have a valid CRC

Description

The configuration of the MAC TCP/IP Stack is based on the file `tcpip_config.h`.

This header file contains the configuration selection for the MAC TCP/IP Stack. Based on the selections made, the MAC TCP/IP Stack may support the selected features. These configuration settings will apply to all instances of the MAC TCP/IP Stack.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_EMAC_ETH_OPEN_FLAGS Macro

File

tcpip_mac_config.h

C

```
#define TCPIP_EMAC_ETH_OPEN_FLAGS (TCPIP_ETH_OPEN_DEFAULT)
```

Description

Flags to use for the Ethernet connection A TCPIP_ETH_OPEN_FLAGS value. Set to TCPIP_ETH_OPEN_DEFAULT unless very good reason to use different value

TCPIP_EMAC_PHY_ADDRESS Macro

File

tcpip_mac_config.h

C

```
#define TCPIP_EMAC_PHY_ADDRESS (0)
```

Description

The PHY address, as configured on the board. By default all the PHYs respond to address 0

TCPIP_EMAC_PHY_CONFIG_FLAGS Macro

File

tcpip_mac_config.h

C

```
#define TCPIP_EMAC_PHY_CONFIG_FLAGS (DRV_ETHPHY_CFG_AUTO)
```

Description

Flags to configure the MAC ->PHY connection a DRV_ETHPHY_CONFIG_FLAGS This depends on the actual connection (MII/RMII, default/alternate I/O) The DRV_ETHPHY_CFG_AUTO value will use the configuration fuses setting

TCPIP_EMAC_PHY_LINK_INIT_DELAY Macro

File

tcpip_mac_config.h

C

```
#define TCPIP_EMAC_PHY_LINK_INIT_DELAY (500)
```

Description

The value of the delay for the link initialization, ms This insures that the PHY is ready to transmit after it is reset A usual value is 500 ms. Adjust to your needs.

TCPIP_EMAC_RX_BUFF_SIZE Macro

File

tcpip_mac_config.h

C

```
#define TCPIP_EMAC_RX_BUFF_SIZE 1536
```

Description

Size of a RX packet buffer. Should be multiple of 16. This is the size of all receive packet buffers processed by the ETHC. The size should be enough to accommodate any network received packet. If the packets are larger, they will have to take multiple RX buffers and the packet manipulation is less efficient. #define TCPIP_EMAC_RX_BUFF_SIZE 512 Together with TCPIP_EMAC_RX_DEDICATED_BUFFERS it has impact on TCPIP_STACK_DRAM_SIZE setting.

TCPIP_EMAC_RX_DESCRIPTORS Macro

File

tcpip_mac_config.h

C

```
#define TCPIP_EMAC_RX_DESCRIPTORS 10
```

Description

Number of the RX descriptors to be created. If not using the run time replenish mechanism (see below) it should match the number of dedicated buffers: TCPIP_EMAC_RX_DEDICATED_BUFFERS; Otherwise it should be bigger than the sum of dedicated + non-dedicated buffers: TCPIP_EMAC_RX_DESCRIPTORS > TCPIP_EMAC_RX_DEDICATED_BUFFERS + replenish_buffers

TCPIP_EMAC_RX_FRAGMENTS Macro

File

tcpip_mac_config.h

C

```
#define TCPIP_EMAC_RX_FRAGMENTS ((TCPIP_EMAC_RX_MAX_FRAME + (TCPIP_EMAC_RX_BUFF_SIZE -1 )) /
(TCPIP_EMAC_RX_BUFF_SIZE))
```

Description

MAC maximum number of supported fragments. Based on the values of TCPIP_EMAC_RX_MAX_FRAME and TCPIP_EMAC_RX_BUFF_SIZE an incoming frame may span multiple RX buffers (fragments). Note that excessive fragmentation leads to performance degradation. The default and recommended value should be 1. #define TCPIP_EMAC_RX_FRAGMENTS 1 Alternatively you can use the calculation of the number of fragments based on the selected RX sizes:

TCPIP_EMAC_RX_MAX_FRAME Macro

File

tcpip_mac_config.h

C

```
#define TCPIP_EMAC_RX_MAX_FRAME 1536
```

Description

Maximum MAC supported RX frame size. Any incoming ETH frame that's longer than this size will be discarded. The default value is 1536 (allows for VLAN tagged frames, although the VLAN tagged frames are discarded). Normally there's no need to touch this value unless you know exactly the maximum size of the frames you want to process or you need to control packets fragmentation (together with the TCPIP_EMAC_RX_BUFF_SIZE).

Remarks

Always multiple of 16.

TCPIP_EMAC_TX_DESCRIPTORS Macro

File

tcpip_mac_config.h

C

```
#define TCPIP_EMAC_TX_DESCRIPTORS 8
```

Description

Number of the TX descriptors to be created. Because a TCP packet can span at most 3 buffers, the value should always be >= 4 The amount of memory needed per descriptor is not high (around 24 bytes) so when high MAC TX performance is needed make sure that this number is >= 8.

TCPIP_EMAC_RX_DEDICATED_BUFFERS Macro

File

tcpip_mac_config.h

C

```
#define TCPIP_EMAC_RX_DEDICATED_BUFFERS 4
```

Description

Number of MAC dedicated RX packet buffers. These buffers are always owned by the MAC. Note that the MAC driver allocates these buffers for storing the incoming network packets. The bigger the storage capacity, the higher data throughput can be obtained. Note that these packet buffers are allocated from the private TCP/IP heap that is specified by the TCPIP_STACK_DRAM_SIZE setting.

TCPIP_EMAC_RX_INIT_BUFFERS Macro

File

tcpip_mac_config.h

C

```
#define TCPIP_EMAC_RX_INIT_BUFFERS 0
```

Description

Number of non-dedicated buffers for the MAC initialization Buffers allocated at the MAC driver initialization.

TCPIP_EMAC_RX_LOW_FILL Macro

File

tcpip_mac_config.h

C

```
#define TCPIP_EMAC_RX_LOW_FILL 2
```

Description

Number of RX buffers to allocate when below threshold condition is detected. If 0, the MAC driver will allocate (scheduled buffers - rxThres) If !0, the MAC driver will allocate exactly TCPIP_EMAC_RX_LOW_FILL buffers

TCPIP_EMAC_RX_LOW_THRESHOLD Macro

File

tcpip_mac_config.h

C

```
#define TCPIP_EMAC_RX_LOW_THRESHOLD 1
```

Description

Minumum threshold for the buffer replenish process. Whenever the number of RX scheduled buffers is <= than this threshold the MAC driver will allocate new non-dedicated buffers (meaning that they will be released to the TCP/IP heap once they are processed). Setting this value to 0 disables the buffer replenishing process.

TCPIP_EMAC_RX_FILTERS Macro

File

tcpip_mac_config.h

C

```
#define TCPIP_EMAC_RX_FILTERS (TCPIP_MAC_RX_FILTER_TYPE_DEFAULT)
```

Description

MAC RX Filters These filters define the packets that are accepted and rejected by the MAC driver Adjust to your needs The default value allows the processing of unicast, multicast and broadcast packets that have a valid CRC

Building the Library

This section lists the files that are available in the MAC Driver module of the TCP/IP Stack Library.

Description

The MAC Driver module is part of the core functionality of the TCP/IP Stack Library. Please refer to the Building the Library topic in the TCP/IP Stack Library section for build information.

Library Interface

a) Initialization Functions

	Name	Description
	TCPIP_MAC_Open	MAC driver open function.
	TCPIP_MAC_Close	MAC driver close function.
	TCPIP_MAC_Initialize	MAC driver initialization function.
	TCPIP_MAC_Deinitialize	MAC driver deinitialization function.
	TCPIP_MAC_Reinitialize	MAC driver reinitialization function.

b) Client Control and Status Functions

	Name	Description
	TCPIP_MAC_ParametersGet	MAC parameter get function.
	TCPIP_MAC_StatisticsGet	Gets the current MAC statistics.
	TCPIP_MAC_LinkCheck	MAC link checking function.
	TCPIP_MAC_Status	Provides the current status of the MAC driver module.
	TCPIP_MAC_Tasks	Maintains the MAC driver's state machine.
	TCPIP_MAC_Process	MAC periodic processing function.
	TCPIP_MAC_RegisterStatisticsGet	Gets the current MAC hardware statistics registers.
	TCPIP_MAC_ConfigGet	Gets the current MAC driver configuration.

c) Event Functions

	Name	Description
	TCPIP_MAC_EventAcknowledge	This function acknowledges a previously reported MAC event.
	TCPIP_MAC_EventMaskSet	MAC events report enable/disable function.
	TCPIP_MAC_EventPendingGet	Returns the currently pending MAC events.

d) Filter Functions

	Name	Description
	TCPIP_MAC_RxFilterHashTableEntrySet	Sets the current MAC hash table receive filter.

e) Data Transfer Functions

	Name	Description
	TCPIP_MAC_PacketTx	MAC driver transmit function.
	TCPIP_MAC_PacketRx	A packet is returned if such a pending packet exists.

f) Data Types and Constants

	Name	Description
	TCPIP_MAC_ACTION	Network interface action for initialization/deinitialization
	TCPIP_MAC_ADDR	Definition of a MAC address.
	TCPIP_MAC_DATA_SEGMENT	A data segment that's part of a TX/RX packet.
	TCPIP_MAC_ETHERNET_HEADER	Definition of a MAC frame header.
	TCPIP_MAC_EVENT	Defines the possible MAC event types.
	TCPIP_MAC_EventF	MAC event notification handler.
	TCPIP_MAC_HANDLE	Handle to a MAC driver.
	TCPIP_MAC_HEAP_CallocF	MAC allocation function prototype.
	TCPIP_MAC_HEAP_FreeF	MAC allocation function prototype.
	TCPIP_MAC_HEAP_HANDLE	A handle used for memory allocation functions.
	TCPIP_MAC_HEAP_MallocF	MAC allocation function prototype.
	TCPIP_MAC_MODULE_CTRL	Data structure that's passed to the MAC at the initialization time.
	TCPIP_MAC_PACKET	Forward reference to a MAC packet.
	TCPIP_MAC_PACKET_ACK_FUNC	Prototype of a MAC packet acknowledge function.
	TCPIP_MAC_PACKET_FLAGS	Flags belonging to MAC packet.
	TCPIP_MAC_PACKET_RX_STAT	Status of a received packet.
	TCPIP_MAC_PKT_ACK_RES	List of MAC return codes for a packet acknowledge function.
	TCPIP_MAC_PKT_AckF	MAC packet acknowledge function prototype.
	TCPIP_MAC_PKT_AllocF	MAC packet allocation function prototype.
	TCPIP_MAC_PKT_FreeF	MAC packet free function prototype.
	TCPIP_MAC_POWER_MODE	This is type TCPIP_MAC_POWER_MODE.
	TCPIP_MAC_PROCESS_FLAGS	List of the MAC processing flags.
	TCPIP_MAC_RES	List of return codes from MAC functions.
	TCPIP_MAC_SEGMENT_FLAGS	Flags belonging to MAC data segment.
	TCPIP_MODULE_MAC_MRF24W_CONFIG	This is type TCPIP_MODULE_MAC_MRF24W_CONFIG.
	TCPIP_MODULE_MAC_PIC32INT_CONFIG	Data that's passed to the MAC at initialization time.
	TCPIP_MAC_RX_STATISTICS	MAC receive statistics data gathered at run time.

	TCPIP_MAC_TX_STATISTICS	MAC transmit statistics data gathered at run time.
	TCPIP_MAC_INIT	Contains all the data necessary to initialize the MAC device.
	TCPIP_MAC_PARAMETERS	Data structure that tells the MAC run time parameters.
	TCPIP_MAC_PKT_AckFDbg	This is type TCPIP_MAC_PKT_AckFDbg.
	TCPIP_MAC_PKT_AllocFDbg	This is type TCPIP_MAC_PKT_AllocFDbg.
	TCPIP_MAC_PKT_FreeFDbg	This is type TCPIP_MAC_PKT_FreeFDbg.
	TCPIP_MAC_HEAP_CallocFDbg	This is type TCPIP_MAC_HEAP_CallocFDbg.
	TCPIP_MAC_HEAP_FreeFDbg	This is type TCPIP_MAC_HEAP_FreeFDbg.
	TCPIP_MAC_HEAP_MallocFDbg	This is type TCPIP_MAC_HEAP_MallocFDbg.
	TCPIP_MAC_STATISTICS_REG_ENTRY	Describes a MAC hardware statistics register.
	TCPIP_MAC_TYPE	List of the MAC types.
	TCPIP_MAC_SYNCH_REQUEST	Defines the possible MAC synchronization request types.
	TCPIP_MAC_SynchReqF	MAC synchronization request function definition.
	TCPIP_MODULE_MAC_ID	IDs of the MAC module supported by the stack.
	TCPIP_MODULE_MAC_MRF24WN_CONFIG	This is type TCPIP_MODULE_MAC_MRF24WN_CONFIG.
	TCPIP_MAC_RX_FILTER_TYPE	Defines the possible MAC RX filter types.
	TCPIP_MAC_LINK_MTU	MTU size correspondig to the MAC types.

Description

This section describes the Application Programming Interface (API) functions of the MAC Driver module.

Refer to each section for a detailed description.

a) Initialization Functions

TCPIP_MAC_Open Function

MAC driver open function.

File

tcpip_mac.h

C

```
DRV_HANDLE TCPIP_MAC_Open(const SYS_MODULE_INDEX drvIndex, const DRV_IO_INTENT intent);
```

Returns

- Valid handle - if the open function succeeded
- DRV_HANDLE_INVALID - if an error occurs

Description

This is the function that opens an instance of the MAC. Once a MAC client handle is obtained all the MAC functions can be accessed using that handle.

Remarks

The intent parameter is not used in the current implementation and is maintained only for compatibility with the generic driver Open function signature.

Preconditions

TCPIP_MAC_Initialize should have been called.

Parameters

Parameters	Description
drvIndex	identifier for the driver instance to be opened.
intent	Zero or more of the values from the enumeration DRV_IO_INTENT ORed together to indicate the intended use of the driver

Function

DRV_HANDLE TCPIP_MAC_Open(const SYS_MODULE_INDEX drvIndex, const DRV_IO_INTENT intent);

TCPIP_MAC_Close Function

MAC driver close function.

File

tcpip_mac.h

C

```
void TCPIP_MAC_Close(DRV_HANDLE hMac);
```

Returns

None.

Description

This is the function that closes an instance of the MAC. All per client data is released and the handle can no longer be used after this function is called.

Remarks

None.

Preconditions

TCPIP_MAC_Initialize should have been called. TCPIP_MAC_Open should have been called to obtain a valid handle.

Parameters

Parameters	Description
hMac	MAC client handle obtained by a call to TCPIP_MAC_Open.

Function

void TCPIP_MAC_Close(DRV_HANDLE hMac);

TCPIP_MAC_Initialize Function

MAC driver initialization function.

File

tcpip_mac.h

C

```
SYS_MODULE_OBJ TCPIP_MAC_Initialize(const SYS_MODULE_INDEX index, const SYS_MODULE_INIT * const init);
```

Returns

- Valid handle to a driver object - if successful
- SYS_MODULE_OBJ_INVALID - if initialization failed

Description

MAC Initialize function. SYS_MODULE_OBJ TCPIP_MAC_Initialize(const SYS_MODULE_INDEX index, const SYS_MODULE_INIT * const init);

This is the function that initializes the MAC. It is called by the stack as a result of one interface going up.

Remarks

If this function fails, the stack won't turn up that interface. If the operation needs to wait for the hardware, the initialization function can return a pending code.

The returned object must be passed as argument to TCPIP_MAC_Reinitialize, TCPIP_MAC_Deinitialize, TCPIP_MAC_Tasks and TCPIP_MAC_Status routines.

Preconditions

None.

Parameters

Parameters	Description
index	Index for the MAC driver instance to be initialized

init	pointer to TCPIP_MAC_INIT initialization data containing: • macControl - Stack prepared data. • moduleData - Driver specific. Dependent on the MAC type. For PIC32 MAC driver, the TCPIP_MODULE_MAC_PIC32INT_CONFIG is used.

TCPIP_MAC_Deinitialize Function

MAC driver deinitialization function.

File

tcpip_mac.h

C

```
void TCPIP_MAC_Deinitialize(SYS_MODULE_OBJ object);
```

Returns

None.

Description

MAC De-Initialize function. void TCPIP_MAC_Deinitialize(SYS_MODULE_OBJ object);

This is the function that deinitializes the MAC. It is called by the stack as a result of one interface going down.

Remarks

None.

Preconditions

TCPIP_MAC_Initialize should have been called.

Parameters

Parameters	Description
object	Driver object handle, returned from TCPIP_MAC_Initialize

TCPIP_MAC_Reinitialize Function

MAC driver reinitialization function.

File

tcpip_mac.h

C

```
void TCPIP_MAC_Reinitialize(SYS_MODULE_OBJ object, const SYS_MODULE_INIT * const init);
```

Returns

None.

Description

MAC Re-Initialize function. void TCPIP_MAC_Reinitialize(SYS_MODULE_OBJ object, const SYS_MODULE_INIT * const init);

This is the function that re-initializes the MAC. It is called by the stack as a result of the system changing power modes. Allows reinitialization of the MAC with different power modes, etc.

Remarks

This function is optional and is not currently implemented.

Preconditions

TCPIP_MAC_Initialize should have been called.

Parameters

Parameters	Description
object	Driver object handle, returned from the TCPIP_MAC_Initialize function

init	pointer to TCPIP_MAC_INIT initialization data containing: • macControl - Stack prepared data. • moduleData - Driver specific. Dependent on the MAC type. For PIC32 MAC driver, the TCPIP_MODULE_MAC_PIC32INT_CONFIG is used.

b) Client Control and Status Functions

TCPIP_MAC_ParametersGet Function

MAC parameter get function.

File

tcpip_mac.h

C

```
TCPIP_MAC_RES TCPIP_MAC_ParametersGet(DRV_HANDLE hMac, TCPIP_MAC_PARAMETERS* pMacParams);
```

Returns

- TCPIP_MAC_RES_OK - if pMacParams updated properly
- TCPIP_MAC_RES error code - if processing failed for some reason

Description

This is a function that returns the run time parameters of the MAC driver.

Remarks

None.

Preconditions

TCPIP_MAC_Initialize should have been called. TCPIP_MAC_Open should have been called to obtain a valid handle.

Parameters

Parameters	Description
hMac	handle identifying the MAC driver client
pMacParams	address to store the MAC parameters

Function

TCPIP_MAC_RES TCPIP_MAC_ParametersGet(DRV_HANDLE hMac, TCPIP_MAC_PARAMETERS* pMacParams);

TCPIP_MAC_StatisticsGet Function

Gets the current MAC statistics.

File

tcpip_mac.h

C

```
TCPIP_MAC_RES TCPIP_MAC_StatisticsGet(DRV_HANDLE hMac, TCPIP_MAC_RX_STATISTICS* pRxStatistics,
TCPIP_MAC_TX_STATISTICS* pTxStatistics);
```

Returns

- TCPIP_MAC_RES_OK - if all processing went on OK
- TCPIP_MAC_RES_OP_ERR error code - if function not supported by the driver

Description

This function will get the current value of the statistic counters maintained by the MAC driver.

Remarks

The reported values are info only and change dynamically.

Preconditions

TCPIP_MAC_Initialize should have been called. TCPIP_MAC_Open should have been called to obtain a valid handle.

Parameters

Parameters	Description
hMac	handle identifying the MAC driver client
pRxStatistics	pointer to a TCPIP_MAC_RX_STATISTICS that will receive the current RX statistics counters. Can be NULL if not needed.
pTxStatistics	pointer to a TCPIP_MAC_TX_STATISTICS that will receive the current TX statistics counters. Can be NULL if not needed.

Function

TCPIP_MAC_RES TCPIP_MAC_StatisticsGet(DRV_HANDLE hMac, TCPIP_MAC_RX_STATISTICS* pRxStatistics,
TCPIP_MAC_TX_STATISTICS* pTxStatistics);

TCPIP_MAC_LinkCheck Function

MAC link checking function.

File

tcpip_mac.h

C

```
bool TCPIP_MAC_LinkCheck(DRV_HANDLE hMac);
```

Returns

- true - if the link is up
- false - if the link is down

Description

This is a function that returns the current status of the link.

Remarks

The stack will call this function periodically. Therefore this function is not required to initiate a new PHY transaction and to wait for the result. It can just initiate a new PHY transaction and return immediately the result of the previous transaction.

Preconditions

TCPIP_MAC_Initialize should have been called. TCPIP_MAC_Open should have been called to obtain a valid handle.

Parameters

Parameters	Description
hMac	handle identifying the MAC driver client

Function

bool TCPIP_MAC_LinkCheck(DRV_HANDLE hMac);

TCPIP_MAC_Status Function

Provides the current status of the MAC driver module.

File

tcpip_mac.h

C

```
SYS_STATUS TCPIP_MAC_Status(SYS_MODULE_OBJ object);
```

Returns

- SYS_STATUS_READY - Indicates that any previous module operation for the specified module has completed
- SYS_STATUS_BUSY - Indicates that a previous module operation for the specified module has not yet completed
- SYS_STATUS_ERROR - Indicates that the specified module is in an error state

Description

This function provides the current status of the MAC driver module.

Remarks

Any value greater than SYS_STATUS_READY is also a normal running state in which the driver is ready to accept new operations.

SYS_STATUS_BUSY - Indicates that the driver is busy with a previous system level operation and cannot start another

SYS_STATUS_ERROR - Indicates that the driver is in an error state Any value less than SYS_STATUS_ERROR is also an error state.

SYS_MODULE_DEINITIALIZED - Indicates that the driver has been deinitialized

This operation can be used to determine when any of the driver's module level operations has completed.

If the status operation returns SYS_STATUS_BUSY, then a previous operation has not yet completed. Once the status operation returns SYS_STATUS_READY, any previous operations have completed.

The value of SYS_STATUS_ERROR is negative (-1). Any value less than that is also an error state.

This function will NEVER block waiting for hardware.

If the Status operation returns an error value, the error may be cleared by calling the reinitialize operation. If that fails, the deinitialize operation will need to be called, followed by the initialize operation to return to normal operations.

Preconditions

The TCPIP_MAC_Initialize function must have been called before calling this function.

Example

```
SYS_MODULE_OBJ      object;     // Returned from TCPIP_MAC_Initialize
SYS_STATUS          status;

status = TCPIP_MAC_Status(object);
if (SYS_STATUS_ERROR >= status)
{
    // Handle error
}
```

Parameters

Parameters	Description
object	Driver object handle, returned from TCPIP_MAC_Initialize

Function

SYS_STATUS TCPIP_MAC_Status (SYS_MODULE_OBJ object)

TCPIP_MAC_Tasks Function

Maintains the MAC driver's state machine.

File

tcpip_mac.h

C

```
void TCPIP_MAC_Tasks(SYS_MODULE_OBJ object);
```

Returns

None.

Description

This function is used to maintain the driver's internal state machine

Remarks

This function is normally not called directly by an application. It is called by the system's Tasks routine (SYS_Tasks)

This function will never block or access any resources that may cause it to block.

Preconditions

The TCPIP_MAC_Initialize routine must have been called for the specified MAC driver instance.

Parameters

Parameters	Description
object	Object handle for the specified driver instance (returned from TCPIP_MAC_Initialize)

Function

void TCPIP_MAC_Tasks(SYS_MODULE_OBJ object)

TCPIP_MAC_Process Function

MAC periodic processing function.

File

tcpip_mac.h

C

```
TCPIP_MAC_RES TCPIP_MAC_Process(DRV_HANDLE hMac);
```

Returns

- TCPIP_MAC_RES_OK - if all processing went on OK
- TCPIP_MAC_RES error code - if processing failed for some reason

Description

This is a function that allows for internal processing by the MAC driver. It is meant for processing that cannot be done from within ISR.

Normally this function will be called in response to an TX and/or RX event signaled by the driver. This is specified by the MAC driver using the TCPIP_MAC_PARAMETERS::processFlags.

An alternative approach is that the MAC driver uses a system service to create a timer signal that will call the TCPIP_MAC_Process on a periodic basis.

Remarks

Some of the processing that this function is intended for:

- The MAC driver can process its pending TX queues (although it could do that from within the TX ISR)
- RX buffers replenishing. If the number of packets in the RX queue falls below a specified limit, the MAC driver can use this function to allocate some extra RX packets. Similarly, if there are too many allocated RX packets, the MAC driver can free some of them.

Preconditions

TCPIP_MAC_Initialize should have been called. TCPIP_MAC_Open should have been called to obtain a valid handle.

Parameters

Parameters	Description
hMac	handle identifying the MAC driver client

Function

TCPIP_MAC_RES TCPIP_MAC_Process(DRV_HANDLE hMac);

TCPIP_MAC_RegisterStatisticsGet Function

Gets the current MAC hardware statistics registers.

File

tcpip_mac.h

C

```
TCPIP_MAC_RES TCPIP_MAC_RegisterStatisticsGet(DRV_HANDLE hMac, TCPIP_MAC_STATISTICS_REG_ENTRY* pRegEntries,
int nEntries, int* pHwEntries);
```

Returns

- TCPIP_MAC_RES_OK - if all processing went on OK
- TCPIP_MAC_RES_OP_ERR error code - if function not supported by the driver

Description

This function will get the current value of the statistic registers maintained by the MAC hardware.

Remarks

The reported values are info only and change dynamically.

Preconditions

TCPIP_MAC_Initialize should have been called. TCPIP_MAC_Open should have been called to obtain a valid handle.

Parameters

Parameters	Description
hMac	handle identifying the MAC driver client
pRegStatistics	pointer to a pRegEntries that will receive the current hardware statistics registers values. Can be 0, if only the number of supported hardware registers is requested
nEntries	provides the number of TCPIP_MAC_STATISTICS_REG_ENTRY structures present in pRegEntries Can be 0, if only the number of supported hardware registers is requested The register entries structures will be filled by the driver, up to the supported hardware registers.
pHwEntries	pointer to an address to store the number of the statistics registers that the hardware supports It is updated by the driver. Can be 0 if not needed

Function

TCPIP_MAC_RES TCPIP_MAC_RegisterStatisticsGet(DRV_HANDLE hMac, TCPIP_MAC_STATISTICS_REG_ENTRY* pRegEntries, int nEntries, int* pHwEntries);

TCPIP_MAC_ConfigGet Function

Gets the current MAC driver configuration.

File

tcpip_mac.h

C

```
size_t TCPIP_MAC_ConfigGet(DRV_HANDLE hMac, void* configBuff, size_t buffSize, size_t* pConfigSize);
```

Returns

The number of bytes copied into the supplied storage buffer

Description

This function will get the current MAC driver configuration and store it into a supplied buffer.

Remarks

None.

Preconditions

TCPIP_MAC_Initialize must have been called to set up the driver. TCPIP_MAC_Open should have been called to obtain a valid handle.

Parameters

Parameters	Description
hMac	handle identifying the MAC driver client
configBuff	pointer to a buffer to store the configuration. Can be NULL if not needed.
buffSize	size of the supplied buffer
pConfigSize	address to store the number of bytes needed for the storage of the MAC configuration. Can be NULL if not needed.

Function

size_t TCPIP_MAC_ConfigGet(DRV_HANDLE hMac, void* configBuff, size_t buffSize, size_t* pConfigSize);

c) Event Functions

TCPIP_MAC_EventAcknowledge Function

This function acknowledges a previously reported MAC event.

File

tcpip_mac.h

C

```
bool TCPIP_MAC_EventAcknowledge(DRV_HANDLE hMac, TCPIP_MAC_EVENT macEvents);
```

Returns

- true - if events acknowledged
- false - if no events to be acknowledged

Description

This function acknowledges and re-enables processed events. Multiple events can be "ORed" together as they are processed together. The events acknowledged by this function should be the events that have been retrieved from the MAC by calling TCPIP_MAC_EventPendingGet or have been passed to the MAC client by using the notification handler. Once the events are acknowledged they will be re-enabled.

Remarks

All events should be acknowledged, in order to be re-enabled.

Some events are fatal errors and should not be acknowledged (TCPIP_MAC_EV_RX_BUSERR, TCPIP_MAC_EV_TX_BUSERR). Stack re-initialization is needed under such circumstances.

Some events are just system/application behavior and they are intended only as simple info (TCPIP_MAC_EV_RX_OVFLOW, TCPIP_MAC_EV_RX_BUFNA, TCPIP_MAC_EV_TX_ABORT, TCPIP_MAC_EV_RX_ACT).

The TCPIP_MAC_EV_RX_FWMARK and TCPIP_MAC_EV_RX_EWMARK events are part of the normal flow control operation (if auto flow control was enabled). They should be enabled alternatively, if needed.

The events are persistent. They shouldn't be re-enabled unless they have been processed and the condition that generated them was removed. Re-enabling them immediately without proper processing will have dramatic effects on the system performance.

Preconditions

TCPIP_MAC_Initialize should have been called. TCPIP_MAC_Open should have been called to obtain a valid handle.

Example

```
TCPIP_MAC_EventAcknowledge( hMac, newMacEvents );
```

Parameters

Parameters	Description
hMac	handle identifying the MAC driver client
macEvents	MAC events that are acknowledged and re-enabled

Function

bool TCPIP_MAC_EventAcknowledge(DRV_HANDLE hMac, TCPIP_MAC_EVENT macEvents);

TCPIP_MAC_EventMaskSet Function

MAC events report enable/disable function.

File

tcpip_mac.h

C

```
bool TCPIP_MAC_EventMaskSet(DRV_HANDLE hMac, TCPIP_MAC_EVENT macEvents, bool enable);
```

Returns

- true - if operation succeeded
- false - if some error occurred and the operation failed

Description

This is a function that enables or disables the events to be reported to the MAC client (TCP/IP stack).

All events that are to be enabled will be added to the notification process. All events that are to be disabled will be removed from the notification process. The stack (or stack user) has to catch the events that are notified and process them. After that the stack should call TCPIP_MAC_EventAcknowledge() so that the events can be re-enabled.

Remarks

Multiple events can be "ORed" together.

The event notification system enables the user of the MAC and of the stack to call into the stack for processing only when there are relevant events rather than being forced to periodically call from within a loop.

If the notification events are null the interrupt processing will be disabled. Otherwise the event notification will be enabled and the interrupts relating to the requested events will be enabled.

Note that once an event has been caught by the MAC and reported through the notification handler it may be disabled until the TCPIP_MAC_EventAcknowledge is called.

Preconditions

TCPIP_MAC_Initialize should have been called. TCPIP_MAC_Open should have been called to obtain a valid handle.

Example

```
TCPIP_MAC_EventMaskSet( hMac, TCPIP_MAC_EV_RX_OVFLOW | TCPIP_MAC_EV_RX_BUFNA, true );
```

Parameters

Parameters	Description
hMac	handle identifying the MAC driver client
macEvents	events that the MAC client wants to add/delete for notification
enable	if true, the events will be enabled, else disabled

Function

bool TCPIP_MAC_EventMaskSet(DRV_HANDLE hMac, TCPIP_MAC_EVENT macEvents, bool enable);

TCPIP_MAC_EventPendingGet Function

Returns the currently pending MAC events.

File

tcpip_mac.h

C

```
TCPIP_MAC_EVENT TCPIP_MAC_EventPendingGet(DRV_HANDLE hMac);
```

Returns

The currently stack pending events.

Description

This function returns the currently MAC pending events. Multiple events will be "ORed" together as they accumulate. MAC processing is needed whenever a transmission related event is present (TCPIP_MAC_EV_RX_PKTPEND, TCPIP_MAC_EV_TX_DONE). Other, non critical events, may be passed to an user for informational purposes. All events have to be eventually acknowledged if re-enabling is needed.

Remarks

This is the preferred method to get the current pending MAC events. Even with a notification handler in place it's better to use this function to get the current pending events rather than using the events passed by the notification handler which could be stale.

The returned value is just a momentary value. The pending events can change any time.

Preconditions

TCPIP_MAC_Initialize should have been called. TCPIP_MAC_Open should have been called to obtain a valid handle.

Example

```
TCPIP_MAC_EVENT currEvents = TCPIP_MAC_EventPendingGet( hMac);
```

Parameters

Parameters	Description
hMac	handle identifying the MAC driver client

Function

TCPIP_MAC_EVENT TCPIP_MAC_EventPendingGet(DRV_HANDLE hMac);

d) Filter Functions

TCPIP_MAC_RxFilterHashTableEntrySet Function

Sets the current MAC hash table receive filter.

File

tcpip_mac.h

C

```
TCPIP_MAC_RES TCPIP_MAC_RxFilterHashTableEntrySet(DRV_HANDLE hMac, TCPIP_MAC_ADDR* DestMACAddr);
```

Returns

- TCPIP_MAC_RES_OK - if all processing went on OK.
- TCPIP_MAC_RES error code - if function failed for some reason.

Description

This function sets the MAC hash table filtering to allow packets sent to DestMACAddr to be received. It calculates a CRC-32 using polynomial 0x4C11DB7 over the 6 byte MAC address and then, using bits 28:23 of the CRC, will set the appropriate bits in the hash table filter registers.

The function will enable/disable the Hash Table receive filter if needed.

Remarks

There is no way to individually remove destination MAC addresses from the hash table since it is possible to have a hash collision and therefore multiple MAC addresses relying on the same hash table bit.

A workaround is to have the stack store each enabled MAC address and to perform the comparison at run time.

A call to TCPIP_MAC_RxFilterHashTableEntrySet() using a 00-00-00-00-00-00 destination MAC address, which will clear the entire hash table and disable the hash table filter. This will allow the receive of all packets, regardless of their destination.

Preconditions

TCPIP_MAC_Initialize should have been called. TCPIP_MAC_Open should have been called to obtain a valid handle.

Parameters

Parameters	Description
hMac	handle identifying the MAC driver client
DestMACAddr	destination MAC address (6 bytes) to allow through the Hash Table Filter. If DestMACAddr is set to 00-00-00-00-00-00, then the hash table will be cleared of all entries and the filter will be disabled.

Function

TCPIP_MAC_RES TCPIP_MAC_RxFilterHashTableEntrySet(DRV_HANDLE hMac, TCPIP_MAC_ADDR* DestMACAddr);

e) Data Transfer Functions

TCPIP_MAC_PacketTx Function

MAC driver transmit function.

File

tcpip_mac.h

C

```
TCPIP_MAC_RES TCPIP_MAC_PacketTx(DRV_HANDLE hMac, TCPIP_MAC_PACKET * ptrPacket);
```

Returns

- TCPIP_MAC_RES_OK - if all processing went on OK

- TCPIP_MAC_RES error code - if processing failed for some reason

Description

This is the MAC transmit function. Using this function a packet is submitted to the MAC driver for transmission.

Remarks

A success code returned from this function signals only that the packet was successfully scheduled for transmission over the interface and not that the packet was actually transmitted. An event will be triggered when the packet is transmitted.

The MAC driver has to support internal queuing. Since the TCPIP_MAC_PACKET data structure contains internal queuing members the MAC can queue the packet at no expense. Therefore a packet is to be rejected only if it's not properly formatted. Otherwise it has to be scheduled for transmission in an internal MAC queue.

Once the packet is scheduled for transmission the MAC driver has to set the TCPIP_MAC_PKT_FLAG_QUEUED flag so that the stack is aware that this packet is under processing and cannot be modified.

Once the packet is transmitted, the TCPIP_MAC_PKT_FLAG_QUEUED has to be cleared, the proper packet acknowledgment result (ackRes) has to be set and the packet acknowledgment function (ackFunc) has to be called. It is implementation dependent if all these steps are implemented as part of the ackFunc itself or as discrete steps.

On 32-bit machines, the 1st segment payload of a packet is allocated so that it is always 32-bit aligned and its size is 32 bits multiple. The segLoadOffset adds to the payload address and insures that the network layer data is 32-bit aligned.

PIC32 MAC driver specific : the driver checks that the segLoadOffset >= 2. See notes for the segLoadOffset member.

The packet is not required to contain the Frame Check Sequence (FCS/CRC32) field. The MAC driver/controller will insert that field itself, if it's required.

The MAC driver is required to support the transmission of multiple chained packets.

Preconditions

TCPIP_MAC_Initialize should have been called. TCPIP_MAC_Open should have been called to obtain a valid handle.

Parameters

Parameters	Description
hMac	MAC client handle obtained by a call to TCPIP_MAC_Open.
ptrPacket	pointer to a TCPIP_MAC_PACKET that's completely formatted and ready to be transmitted over the network

Function

TCPIP_MAC_RES TCPIP_MAC_PacketTx(DRV_HANDLE hMac, TCPIP_MAC_PACKET * ptrPacket);

TCPIP_MAC_PacketRx Function

A packet is returned if such a pending packet exists.

File

tcpip_mac.h

C

```
TCPIP_MAC_PACKET* TCPIP_MAC_PacketRx(DRV_HANDLE hMac, TCPIP_MAC_RES* pRes, const TCPIP_MAC_PACKET_RX_STAT**
ppPktStat);
```

Returns

- Valid pointer to an available RX packet
- 0 if no packet pending/available

Description

This is the MAC receive function.

Once a pending packet is available in the MAC driver internal RX queues this function will dequeue the packet and hand it over to the MAC driver's client - i.e., the stack - for further processing.

The flags for a RX packet have to be updated by the MAC driver: TCPIP_MAC_PKT_FLAG_RX has to be set. If the MAC supports it, it should set:

- TCPIP_MAC_PKT_FLAG_UNICAST has to be set if that packet is a unicast packet
- TCPIP_MAC_PKT_FLAG_BCAST has to be set if that packet is a broadcast packet
- TCPIP_MAC_PKT_FLAG_MCAST has to be set if that packet is a multicast packet
- TCPIP_MAC_PKT_FLAG_QUEUED has to be set
- TCPIP_MAC_PKT_FLAG_SPLIT has to be set if the packet has multiple data segments

Additional information about the packet is available by providing the pRes and ppPktStat fields.

Remarks

The MAC driver should dequeue and return to the caller just one single packet, and not multiple chained packets!

Once the higher level layers in the stack are done with processing the RX packet, they have to call the corresponding packet acknowledgment function that tells the owner of that packet that it can resume control of that packet.

Once the stack modules are done processing the RX packets and the acknowledge function is called it is up to the driver design to reuse the RX packets, or simply return them to the pool they were allocated from (assuming that some sort of allocation is implemented). This document makes no requirement about how the MAC RX packets are obtained, using dynamic or static allocation techniques. This is up to the design of the MAC.

The MAC driver can use the TCPIP_MAC_Process() for obtaining new RX packets if needed.

Not all the MACs have hardware support for the received packet status. If the MAC driver cannot supply the TCPIP_MAC_PACKET_RX_STAT info, it should set the ppPktStat to 0.

Preconditions

TCPIP_MAC_Initialize should have been called. TCPIP_MAC_Open should have been called to obtain a valid handle.

Parameters

Parameters	Description
hMac	handle identifying the MAC driver client
pRes	optional pointer to an address that will receive an additional result associated with the operation. Can be 0 if not needed.
ppPktStat	optional pointer to an address that will receive the received packet status. Note that this pointer cannot be used once the packet acknowledgment function was called. Can be 0 if not needed.

Function

TCPIP_MAC_PACKET* TCPIP_MAC_PacketRx (DRV_HANDLE hMac, TCPIP_MAC_RES* pRes,
const TCPIP_MAC_PACKET_RX_STAT** ppPktStat);

f) Data Types and Constants

TCPIP_MAC_ACTION Enumeration

Network interface action for initialization/deinitialization

File

tcpip_mac.h

C

```
typedef enum {
  TCPIP_MAC_ACTION_INIT,
  TCPIP_MAC_ACTION_REINIT,
  TCPIP_MAC_ACTION_DEINIT,
  TCPIP_MAC_ACTION_IF_UP,
  TCPIP_MAC_ACTION_IF_DOWN
} TCPIP_MAC_ACTION;
```

Members

Members	Description
TCPIP_MAC_ACTION_INIT	stack is initialized
TCPIP_MAC_ACTION_REINIT	stack is reinitialized
TCPIP_MAC_ACTION_DEINIT	stack is deinitialized
TCPIP_MAC_ACTION_IF_UP	interface is brought up
TCPIP_MAC_ACTION_IF_DOWN	interface is brought down

Description

TCP/IP MAC Action

This enumeration defines network interface action for initialization and deinitialization.

Remarks

None.

TCPIP_MAC_ADDR Structure

Definition of a MAC address.

File

tcpip_mac.h

C

```
typedef struct {
  uint8_t v[6];
} TCPIP_MAC_ADDR;
```

Description

MAC Address

This structure defines the physical MAC address of an interface.

Remarks

None.

TCPIP_MAC_DATA_SEGMENT Structure

A data segment that's part of a TX/RX packet.

File

tcpip_mac.h

C

```
typedef struct _tag_MAC_DATA_SEGMENT {
  struct _tag_MAC_DATA_SEGMENT* next;
  uint8_t* segLoad;
  uint16_t segLen;
  uint16_t segSize;
  uint16_t segFlags;
  uint16_t segLoadOffset;
  uint8_t segClientData[4];
  uint8_t segClientLoad[0];
} TCPIP_MAC_DATA_SEGMENT;
```

Members

Members	Description
struct _tag_MAC_DATA_SEGMENT* next;	Multi-segment support, next segment in the chain.
uint8_t* segLoad;	Pointer to segment data payload. It specifies the address of the 1st byte to be transmitted.
uint16_t segLen;	Segment payload size; Number of bytes from this segment that has to be transmitted.
uint16_t segSize;	Segment allocated total usable size. This does not include the segLoadOffset (see below).
uint16_t segFlags;	TCPIP_MAC_SEGMENT_FLAGS segment flags: TCPIP_MAC_SEG_FLAG_STATIC, TCPIP_MAC_SEG_FLAG_RX, TCPIP_MAC_SEG_FLAG_RX, TCPIP_MAC_SEG_FLAG_RX_STICKY
uint16_t segLoadOffset;	Note 1: This offset is used as a performance improvement. It allows for the MAC frame to start on an unaligned address but enforces the alignment of the network layer data and improves the IP checksum calculation. The value of this offset is MAC dependent. A typical value for an Ethernet MAC should be 2 bytes (size of the MAC frame is 14 bytes). Note 2: Normally only the 1st segment of a packet needs this extra room at the beginning of the segment buffer. Note 3: The MAC may make use of this space at the beginning of the segment buffer. This is a space reserved for the MAC purposes. Note 4: It is up to the MAC to check that the value of this offset is enforced. PIC32 MAC specific notes: Note 1. The MAC will reject the packet if the load offset is not at least 2 bytes. 2. The PIC32 MAC uses these 2 bytes to calculate the offset between the segLoad and the TCPIP_MAC_PACKET packet it belongs to. That means that the TCPIP_MAC_PACKET* and the segLoad cannot be more than 64 KB apart!
uint8_t segClientData[4];	Additional client segment data. Ignored by the MAC driver.
uint8_t segClientLoad[0];	Additional client segment payload; Ignored by the MAC driver.

Structures

	Name	Description
	_tag_MAC_DATA_SEGMENT	A data segment that's part of a TX/RX packet.

Description

TCPIP MAC Data Segment

Structure of a segment buffer transferred with the MAC. A MAC TX or RX packet can consist of multiple data segments. On TX the MAC has to be able to transmit packets that span multiple data segments. On RX of a network frame the MAC may have to use multiple segments to construct a packet. (For performance reasons, a contiguous MAC packet, with just one segment, if possible, is preferred).

Remarks

See notes for the segLoadOffset member. On 32-bit machines, the segment payload is allocated so that it is always 32-bit aligned and its size is 32-bits multiple. The segLoadOffset adds to the payload address and insures that the network layer data is 32-bit aligned.

_tag_MAC_DATA_SEGMENT Structure

A data segment that's part of a TX/RX packet.

File

tcpip_mac.h

C

```
struct _tag_MAC_DATA_SEGMENT {
  struct _tag_MAC_DATA_SEGMENT* next;
  uint8_t* segLoad;
  uint16_t segLen;
  uint16_t segSize;
  uint16_t segFlags;
  uint16_t segLoadOffset;
  uint8_t segClientData[4];
  uint8_t segClientLoad[0];
};
```

Members

Members	Description
struct _tag_MAC_DATA_SEGMENT* next;	Multi-segment support, next segment in the chain.
uint8_t* segLoad;	Pointer to segment data payload. It specifies the address of the 1st byte to be transmitted.
uint16_t segLen;	Segment payload size; Number of bytes from this segment that has to be transmitted.
uint16_t segSize;	Segment allocated total usable size. This does not include the segLoadOffset (see below).
uint16_t segFlags;	TCPIP_MAC_SEGMENT_FLAGS segment flags: TCPIP_MAC_SEG_FLAG_STATIC, TCPIP_MAC_SEG_FLAG_RX, TCPIP_MAC_SEG_FLAG_RX, TCPIP_MAC_SEG_FLAG_RX_STICKY
uint16_t segLoadOffset;	Note 1: This offset is used as a performance improvement. It allows for the MAC frame to start on an unaligned address but enforces the alignment of the network layer data and improves the IP checksum calculation. The value of this offset is MAC dependent. A typical value for an Ethernet MAC should be 2 bytes (size of the MAC frame is 14 bytes). Note 2: Normally only the 1st segment of a packet needs this extra room at the beginning of the segment buffer. Note 3: The MAC may make use of this space at the beginning of the segment buffer. This is a space reserved for the MAC purposes. Note 4: It is up to the MAC to check that the value of this offset is enforced. PIC32 MAC specific notes: Note 1. The MAC will reject the packet if the load offset is not at least 2 bytes. 2. The PIC32 MAC uses these 2 bytes to calculate the offset between the segLoad and the TCPIP_MAC_PACKET packet it belongs to. That means that the TCPIP_MAC_PACKET* and the segLoad cannot be more than 64 KB apart!
uint8_t segClientData[4];	Additional client segment data. Ignored by the MAC driver.
uint8_t segClientLoad[0];	Additional client segment payload; Ignored by the MAC driver.

Description

TCPIP MAC Data Segment

Structure of a segment buffer transferred with the MAC. A MAC TX or RX packet can consist of multiple data segments. On TX the MAC has to be able to transmit packets that span multiple data segments. On RX of a network frame the MAC may have to use multiple segments to construct a packet. (For performance reasons, a contiguous MAC packet, with just one segment, if possible, is preferred).

Remarks

See notes for the segLoadOffset member. On 32-bit machines, the segment payload is allocated so that it is always 32-bit aligned and its size is 32-bits multiple. The segLoadOffset adds to the payload address and insures that the network layer data is 32-bit aligned.

TCPIP_MAC_ETHERNET_HEADER Structure

Definition of a MAC frame header.

File

tcpip_mac.h

C

```
typedef struct {
  TCPIP_MAC_ADDR DestMACAddr;
  TCPIP_MAC_ADDR SourceMACAddr;
  uint16_t Type;
} TCPIP_MAC_ETHERNET_HEADER;
```

Description

MAC Ethernet Header

This structure defines the generic Ethernet header that starts all the Ethernet frames.

Remarks

None.

TCPIP_MAC_EVENT Enumeration

Defines the possible MAC event types.

File

tcpip_mac.h

C

```
typedef enum {
  TCPIP_MAC_EV_NONE = 0x0000,
  TCPIP_MAC_EV_RX_PKTPEND = 0x0001,
  TCPIP_MAC_EV_RX_OVFLOW = 0x0002,
  TCPIP_MAC_EV_RX_BUFNA = 0x0004,
  TCPIP_MAC_EV_RX_ACT = 0x0008,
  TCPIP_MAC_EV_RX_DONE = 0x0010,
  TCPIP_MAC_EV_RX_FWMARK = 0x0020,
  TCPIP_MAC_EV_RX_EWMARK = 0x0040,
  TCPIP_MAC_EV_RX_BUSERR = 0x0080,
  TCPIP_MAC_EV_TX_DONE = 0x0100,
  TCPIP_MAC_EV_TX_ABORT = 0x0200,
  TCPIP_MAC_EV_TX_BUSERR = 0x0400,
  TCPIP_MAC_EV_CONN_ESTABLISHED = 0x0800,
  TCPIP_MAC_EV_CONN_LOST = 0x1000,
  TCPIP_MAC_EV_RX_ALL = (TCPIP_MAC_EV_RX_PKTPEND|TCPIP_MAC_EV_RX_OVFLOW|
TCPIP_MAC_EV_RX_BUFNA|TCPIP_MAC_EV_RX_ACT| TCPIP_MAC_EV_RX_DONE|TCPIP_MAC_EV_RX_FWMARK|
TCPIP_MAC_EV_RX_EWMARK|TCPIP_MAC_EV_RX_BUSERR),
  TCPIP_MAC_EV_TX_ALL = (TCPIP_MAC_EV_TX_DONE|TCPIP_MAC_EV_TX_ABORT|TCPIP_MAC_EV_TX_BUSERR),
  TCPIP_MAC_EV_RXTX_ERRORS = (TCPIP_MAC_EV_RX_OVFLOW|TCPIP_MAC_EV_RX_BUFNA|
TCPIP_MAC_EV_RX_BUSERR|TCPIP_MAC_EV_TX_ABORT| TCPIP_MAC_EV_TX_BUSERR),
  TCPIP_MAC_EV_CONN_ALL = (TCPIP_MAC_EV_CONN_ESTABLISHED|TCPIP_MAC_EV_CONN_LOST)
} TCPIP_MAC_EVENT;
```

Members

Members	Description
TCPIP_MAC_EV_NONE = 0x0000	no event
TCPIP_MAC_EV_RX_PKTPEND = 0x0001	RX triggered events: A receive packet is pending
TCPIP_MAC_EV_RX_OVFLOW = 0x0002	RX triggered events: RX FIFO overflow (system level latency, no descriptors, etc.)
TCPIP_MAC_EV_RX_BUFNA = 0x0004	RX triggered events: no RX descriptor available to receive a new packet

TCPIP_MAC_EV_RX_ACT = 0x0008	RX triggered events: There's RX data available
TCPIP_MAC_EV_RX_DONE = 0x0010	RX triggered events: A packet was successfully received
TCPIP_MAC_EV_RX_FWMARK = 0x0020	RX triggered events: the number of received packets is greater than or equal to than the RX Full Watermark
TCPIP_MAC_EV_RX_EWMARK = 0x0040	RX triggered events: the number of received packets is less than or equal to than the RX Empty Watermark
TCPIP_MAC_EV_RX_BUSERR = 0x0080	RX triggered events: a bus error encountered during an RX transfer
TCPIP_MAC_EV_TX_DONE = 0x0100	TX triggered events: A packet was transmitted and its status is available
TCPIP_MAC_EV_TX_ABORT = 0x0200	TX triggered events: a TX packet was aborted by the MAC (jumbo/system underrun/excessive defer/late collision/excessive collisions)
TCPIP_MAC_EV_TX_BUSERR = 0x0400	TX triggered events: a bus error encountered during a TX transfer
TCPIP_MAC_EV_CONN_ESTABLISHED = 0x0800	Connection triggered events: Connection established
TCPIP_MAC_EV_CONN_LOST = 0x1000	Connection triggered events: Connection lost
TCPIP_MAC_EV_RX_ALL = (TCPIP_MAC_EV_RX_PKTPEND|TCPIP_MAC_EV_RX_OVFLOW| TCPIP_MAC_EV_RX_BUFNA|TCPIP_MAC_EV_RX_ACT| TCPIP_MAC_EV_RX_DONE|TCPIP_MAC_EV_RX_FWMARK| TCPIP_MAC_EV_RX_EWMARK|TCPIP_MAC_EV_RX_BUSERR)	Useful Masks: all RX related events
TCPIP_MAC_EV_TX_ALL = (TCPIP_MAC_EV_TX_DONE|TCPIP_MAC_EV_TX_ABORT|TCPIP_MAC_EV_TX_BUSERR)	Useful Masks: all TX related events
TCPIP_MAC_EV_RXTX_ERRORS = (TCPIP_MAC_EV_RX_OVFLOW|TCPIP_MAC_EV_RX_BUFNA| TCPIP_MAC_EV_RX_BUSERR|TCPIP_MAC_EV_TX_ABORT| TCPIP_MAC_EV_TX_BUSERR)	abnormal traffic/system events: Action should be taken accordingly by the stack (or the stack user)
TCPIP_MAC_EV_CONN_ALL = (TCPIP_MAC_EV_CONN_ESTABLISHED|TCPIP_MAC_EV_CONN_LOST)	Mask of all Connection related events

Description

TCP/IP MAC Event

TCP/IP MAC Events Codes.

This enumeration defines all the possible events that can be reported by the MAC to the stack.

Depending on the type of the hardware Ethernet/Wi-Fi interface, etc., not all events are possible.

Remarks

None.

TCPIP_MAC_EventF Type

MAC event notification handler.

File

tcpip_mac.h

C

```
typedef void (* TCPIP_MAC_EventF)(TCPIP_MAC_EVENT event, const void* eventParam);
```

Returns

None

Description

Event notification Function: typedef void (*TCPIP_MAC_EventF)(TCPIP_MAC_EVENT event, const void* eventParam);

This function describes the MAC event notification handler. This is a handler specified by the user of the MAC (the TCP/IP stack). The stack can use the handler to be notified of MAC events. Whenever a notification occurs the passed events have to be eventually processed:

- Stack should process the TCPIP_EV_RX_PKTPEND/TCPIP_EV_RX_DONE, TCPIP_EV_TX_DONE events
- Process the specific (error) condition

- Acknowledge the events by calling TCPIP_MAC_EventAcknowledge() so that they can be re-enabled.

Remarks

The notification handler will be called from the ISR which detects the corresponding event. The event notification handler has to be kept as short as possible and non-blocking. Mainly useful for RTOS integration where this handler will wake-up a thread that waits for a MAC event to occur. The event notification system also enables the user of the TCPIP stack to call into the stack for processing only when there are relevant events rather than being forced to periodically call from within a loop at unknown moments. Without a notification handler the stack user can still call TCPIP_MAC_EventPendingGet to see if processing by the stack needed. This is a default way of adding MAC interrupt processing to the TCP/IP stack.

Parameters

Parameters	Description
event	event that's reported (multiple events can be OR-ed)
eventParam	user parameter that's used in the notification handler

TCPIP_MAC_HANDLE Type

Handle to a MAC driver.

File

tcpip_mac.h

C

```
typedef DRV_HANDLE TCPIP_MAC_HANDLE;
```

Description

MAC Handle

This data type defines a MAC client handle.

Remarks

Another name for the DRV_HANDLE.

TCPIP_MAC_HEAP_CallocF Type

MAC allocation function prototype.

File

tcpip_mac.h

C

```
typedef void* (* TCPIP_MAC_HEAP_CallocF)(TCPIP_MAC_HEAP_HANDLE heapH, size_t nElems, size_t elemSize);
```

Returns

- valid pointer - if the allocation request succeeded
- 0 - if the allocation request failed

Description

Memory Allocation Function: typedef void* (*TCPIP_MAC_HEAP_CallocF)(TCPIP_MAC_HEAP_HANDLE heapH, size_t nElems, size_t elemSize);

This calloc style function is used by the MAC to allocate memory.

Remarks

The debug version adds the module identifier and source file line number.

Parameters

Parameters	Description
heapH	heap handle to be used in call
nElems	number of identical elements requested
elemSize	size of one element, in bytes

TCPIP_MAC_HEAP_FreeF Type

MAC allocation function prototype.

File

tcpip_mac.h

C

```
typedef size_t (* TCPIP_MAC_HEAP_FreeF)(TCPIP_MAC_HEAP_HANDLE heapH, const void* pBuff);
```

Returns

- Non-zero number - if the free request succeeded
- 0 - if the free request failed

Description

Memory Allocation Function: typedef size_t (*TCPIP_MAC_HEAP_FreeF)(TCPIP_MAC_HEAP_HANDLE heapH, const void* pBuff);

This free style function is used by the MAC to free allocated memory.

Remarks

The debug version adds the module identifier and source file line number.

TCPIP_MAC_HEAP_HANDLE Type

A handle used for memory allocation functions.

File

tcpip_mac.h

C

```
typedef const void* TCPIP_MAC_HEAP_HANDLE;
```

Description

Handle to a heap

This is the handle that's required for accessing memory allocation functions.

Remarks

None

TCPIP_MAC_HEAP_MallocF Type

MAC allocation function prototype.

File

tcpip_mac.h

C

```
typedef void* (* TCPIP_MAC_HEAP_MallocF)(TCPIP_MAC_HEAP_HANDLE heapH, size_t nBytes);
```

Returns

- valid pointer - if the allocation request succeeded
- 0 - if the allocation request failed

Description

Memory Allocation Function: typedef void* (*TCPIP_MAC_HEAP_MallocF)(TCPIP_MAC_HEAP_HANDLE heapH, size_t nBytes);

This malloc style function is used by the MAC to allocate memory.

Remarks

The debug version adds the module identifier and source file line number.

TCPIP_MAC_MODULE_CTRL Structure

Data structure that's passed to the MAC at the initialization time.

File

tcpip_mac.h

C

```
typedef struct {
  int nIfs;
  TCPIP_MAC_HEAP_MallocF mallocF;
  TCPIP_MAC_HEAP_CallocF callocF;
  TCPIP_MAC_HEAP_FreeF freeF;
  TCPIP_MAC_HEAP_HANDLE memH;
  TCPIP_MAC_PKT_AllocF pktAllocF;
  TCPIP_MAC_PKT_FreeF pktFreeF;
  TCPIP_MAC_PKT_AckF pktAckF;
  TCPIP_MAC_SynchReqF synchF;
  TCPIP_MAC_EventF eventF;
  const void* eventParam;
  unsigned int moduleId;
  int netIx;
  TCPIP_MAC_ACTION macAction;
  TCPIP_MAC_POWER_MODE powerMode;
  TCPIP_MAC_ADDR ifPhyAddress;
} TCPIP_MAC_MODULE_CTRL;
```

Members

Members	Description
int nIfs;	number of the interfaces supported in this session
TCPIP_MAC_HEAP_MallocF mallocF;	malloc type allocation function
TCPIP_MAC_HEAP_CallocF callocF;	calloc type allocation function
TCPIP_MAC_HEAP_FreeF freeF;	free type allocation free function
TCPIP_MAC_HEAP_HANDLE memH;	handle to be used in the stack allocation service calls
TCPIP_MAC_PKT_AllocF pktAllocF;	packet allocation function
TCPIP_MAC_PKT_FreeF pktFreeF;	packet free function
TCPIP_MAC_PKT_AckF pktAckF;	packet allocation function
TCPIP_MAC_SynchReqF synchF;	Synchronization object request function
TCPIP_MAC_EventF eventF;	Event notification function. used by the MAC for event reporting.
const void* eventParam;	Parameter to be used when the event function is called.
unsigned int moduleId;	Module identifier. Allows multiple channels/ports, etc. MAC support.
int netIx;	index of the current interface
TCPIP_MAC_ACTION macAction;	current action for the MAC/stack
TCPIP_MAC_POWER_MODE powerMode;	The power mode for this interface to go to. Valid only if stackAction == init/reinit. Ignored for deinitialize operation.
TCPIP_MAC_ADDR ifPhyAddress;	Physical address of the interface. MAC sets this field as part of the initialization function. The stack will use this data as the interface address.

Description

MAC Initialization Data

This is the data structure that the MAC user (TCP/IP stack) passes on to the MAC driver at the MAC initialization time. It contains all the data needed for the MAC to initialize itself and to start processing packets.

Remarks

Most of the data that's passed in this structure is permanent data. It is maintained by the stack for one full session i.e., across Initialize() -> DeInitialize() calls.

Some fields are module specific though (like the memory allocation handle, allocation functions, etc.) that could be different from one module to the other.

TCPIP_MAC_PACKET Type

Forward reference to a MAC packet.

File

tcpip_mac.h

C

```
typedef struct _tag_TCPIP_MAC_PACKET TCPIP_MAC_PACKET;
```

Structures

	Name	Description
	_tag_TCPIP_MAC_PACKET	A TX/RX packet descriptor.

Description

MAC Packet forward reference

Forward reference needed in the MAC packet acknowledge function.

Remarks

None.

_tag_TCPIP_MAC_PACKET Structure

A TX/RX packet descriptor.

File

tcpip_mac.h

C

```
struct _tag_TCPIP_MAC_PACKET {
  struct _tag_TCPIP_MAC_PACKET* next;
  struct _tag_TCPIP_MAC_PACKET* pkt_next;
  TCPIP_MAC_PACKET_ACK_FUNC ackFunc;
  const void* ackParam;
  TCPIP_MAC_DATA_SEGMENT* pDSeg;
  uint8_t* pMacLayer;
  uint8_t* pNetLayer;
  uint8_t* pTransportLayer;
  uint16_t totTransportLen;
  uint16_t pktFlags;
  uint32_t tStamp;
  const void* pktIf;
  int16_t ackRes;
  uint16_t pktClientData;
  uint32_t pktClientLoad[0];
};
```

Members

Members	Description
struct _tag_TCPIP_MAC_PACKET* next;	Multi-packet/queuing support. This field is used for chaining/queuing packets.
struct _tag_TCPIP_MAC_PACKET* pkt_next;	Multi-packet/queuing support. This field is used for chaining packet fragments, etc.
TCPIP_MAC_PACKET_ACK_FUNC ackFunc;	Packet acknowledgment function. On TX: A stack module owns the packet. Once the MAC is done transmitting the packet (success or failure) it has to set an appropriate acknowledge result in the ackRes field (a TCPIP_MAC_PKT_ACK_RES) adjust some packet flags (see TCPIP_MAC_PKT_FLAG_QUEUED) and call the packet acknowledge function (ackFunc). This call informs the packet owner that the MAC is done with using that packet. It is up to the implementation what action the ackFunc takes: reuse, free, discard the packet or if some of the above steps are included in the ackFunc itself. On RX: The packet is under the MAC control and it's passed to the stack when it contains valid data. Once the recipient of the packet (IP, ICMP, UDP, TCP, etc.) is done with the packet processing it has to set an appropriate acknowledge result in the ackRes field (a TCPIP_MAC_PKT_ACK_RES) adjust some packet flags (see TCPIP_MAC_PKT_FLAG_QUEUED) and call the packet acknowledge function (ackFunc). This call informs the packet owner (the MAC) that the processing of the packet is completed. It is up to the implementation what action the ackFunc takes: reuse, free, discard the packet or if some of the above steps are included in the ackFunc itself.
const void* ackParam;	Associated acknowledgment parameter to be used when ackFunc is called. For TX packets: this is a client supplied parameter and is not used by the MAC driver. For RX: If the MAC owns the RX packet then the MAC driver can use this field for further dispatching in the MAC driver owned acknowledgment function.

TCPIP_MAC_DATA_SEGMENT* pDSeg;	Data (root) segment associated to this packet. It is up to the design if the root data segment associated with a packet is contiguous in memory with the packet itself. It can be 0 if the packet has no associated data.
uint8_t* pMacLayer;	Pointer to the MAC frame. On TX: the sending higher layer protocol updates this field. On RX: the MAC driver updates this field before handing over the packet. (MCHP TCP/IP stack note: The packet allocation function update this field automatically).
uint8_t* pNetLayer;	Pointer to the network layer data. On TX: the sending higher layer protocol updates this field. The MAC driver shouldn't need this field. On RX: the MAC driver updates this field before handing over the packet. (MCHP TCP/IP stack note: The packet allocation function updates this field automatically. But not for IPv6!).
uint8_t* pTransportLayer;	Pointer to the transport layer. On TX: the sending higher layer protocol updates this field. The MAC driver shouldn't need this field. On RX: the MAC driver updates this field before handing over the packet. (MCHP TCP/IP stack note: The packet allocation function updates this field automatically. But not for IPv6!).
uint16_t totTransportLen;	Total length of the transport layer. The MAC driver shouldn't need this field.
uint16_t pktFlags;	TCPIP_MAC_PACKET_FLAGS associated packet flags. On TX: the MAC driver has to set: TCPIP_MAC_PKT_FLAG_QUEUED - if the driver needs to queue the packet On RX: the MAC driver updates this field before handing over the packet. Flags that the MAC driver has to set/clear: TCPIP_MAC_PKT_FLAG_RX and TCPIP_MAC_PKT_FLAG_UNICAST, TCPIP_MAC_PKT_FLAG_BCAST and TCPIP_MAC_PKT_FLAG_MCAST TCPIP_MAC_PKT_FLAG_QUEUED TCPIP_MAC_PKT_FLAG_SPLIT
uint32_t tStamp;	Time stamp value. Statistics, info. On TX: the sending higher layer protocol updates this field. The MAC driver shouldn't need this field On RX: the MAC driver updates this field before handing over the packet.
const void* pktIf;	The packet interface. On TX: the sending higher layer protocol updates this field. The MAC driver doesn't use this field. On RX: the receiving higher level protocol updates this value. The MAC driver doesn't use this field.
int16_t ackRes;	A TCPIP_MAC_PKT_ACK_RES code associated with the packet. On TX: The MAC driver sets this field when calling the packet ackFunc. On RX: The higher level protocol which is the recipient of the packet sets this field when calling the packet ackFunc.
uint16_t pktClientData;	Client/padding data; ignored by the MAC driver. It can be used by the packet client.
uint32_t pktClientLoad[0];	Additional client packet payload, variable packet data. Ignored by the MAC driver.

Description

MAC Packet

Structure of a packet transferred with the MAC. This is the structure used for both TX and RX. See the description of each individual field.

Remarks

Specific TCP/IP stack implementations might offer packet support functions to assist in driver development. (For the MCHP TCP/IP stack see tcpip_packet.h)

Since the packets may be dynamically allocated, an acknowledge function can result in data deallocation (blocking). Therefore, the acknowledgment function should NOT be called from within an interrupt context.

TCPIP_MAC_PACKET_ACK_FUNC Type

Prototype of a MAC packet acknowledge function.

File

tcpip_mac.h

C

```
typedef bool (* TCPIP_MAC_PACKET_ACK_FUNC)(TCPIP_MAC_PACKET* pkt, const void* param);
```

Returns

- true - if the packet needs the queuing flags removed (it is not deleted and still in use)
- false - if the packet does not need the queuing flags removed (either no longer exists or the flags updated)

Description

MAC Acknowledge Function

This is the prototype of the function that the MAC calls once the TX/RX packet processing is done.

Remarks

None.

TCPIP_MAC_PACKET_FLAGS Enumeration

Flags belonging to MAC packet.

File

tcpip_mac.h

C

```
typedef enum {
  TCPIP_MAC_PKT_FLAG_STATIC = 0x0001,
  TCPIP_MAC_PKT_FLAG_TX = 0x0002,
  TCPIP_MAC_PKT_FLAG_SPLIT = 0x0004,
  TCPIP_MAC_PKT_FLAG_QUEUED = 0x0008,
  TCPIP_MAC_PKT_FLAG_UNICAST = 0x0010,
  TCPIP_MAC_PKT_FLAG_BCAST = 0x0020,
  TCPIP_MAC_PKT_FLAG_MCAST = 0x0040,
  TCPIP_MAC_PKT_FLAG_CAST_MASK = 0x0070,
  TCPIP_MAC_PKT_FLAG_CAST_DISABLED = 0x0000,
  TCPIP_MAC_PKT_FLAG_USER = 0x0100
} TCPIP_MAC_PACKET_FLAGS;
```

Members

Members	Description
TCPIP_MAC_PKT_FLAG_STATIC = 0x0001	Packet can not be dynamically deallocated. Set when the packet is allocated.
TCPIP_MAC_PKT_FLAG_TX = 0x0002	If set, it is a TX packet/segment. Otherwise, it is a RX packet.
TCPIP_MAC_PKT_FLAG_SPLIT = 0x0004	Packet data spans multiple segments - ZC functionality. If not set then the packet has only one data segment. It is set by the MAC driver when a RX packet spans multiple data segments.
TCPIP_MAC_PKT_FLAG_QUEUED = 0x0008	Packet data is queued somewhere, cannot be freed. The flag is set by a module processing the packet to show that the packet is in use and queued for further processing (normally the MAC driver does that). Cleared by the packet destination when the packet processing was completed.
TCPIP_MAC_PKT_FLAG_UNICAST = 0x0010	RX flag, MAC updated. Specifies an unicast packet.
TCPIP_MAC_PKT_FLAG_BCAST = 0x0020	RX flag, MAC updated. Specifies a broadcast packet.
TCPIP_MAC_PKT_FLAG_MCAST = 0x0040	RX flag, MAC updated. Specifies an multicast packet.
TCPIP_MAC_PKT_FLAG_CAST_MASK = 0x0070	Packet cast mask bits.
TCPIP_MAC_PKT_FLAG_CAST_DISABLED = 0x0000	Packet cast mask. Specifies a packet where the MCAST/BCAST fields are not updated by the MAC RX process.
TCPIP_MAC_PKT_FLAG_USER = 0x0100	Available user flags.

Description

MAC Packet Flags

This enumeration contains the definitions of MAC packet flags: packet allocation flags and general purpose flags.

Remarks

16 bits only packet flags are supported.

TCPIP_MAC_PACKET_RX_STAT Structure

Status of a received packet.

File

tcpip_mac.h

C

```
typedef struct {
  unsigned chksumOk : 1;
  unsigned pktChecksum : 16;
  unsigned runtPkt : 1;
  unsigned notMeUcast : 1;
  unsigned htMatch : 1;
  unsigned magicMatch : 1;
  unsigned pmMatch : 1;
```

```
  unsigned uMatch : 1;
  unsigned bMatch : 1;
  unsigned mMatch : 1;
  unsigned rxBytes : 16;
  unsigned crcError : 1;
  unsigned lenError : 1;
  unsigned lenRange : 1;
  unsigned rxOk : 1;
  unsigned mcast : 1;
  unsigned bcast : 1;
  unsigned rxCtrl : 1;
  unsigned rxVLAN : 1;
} TCPIP_MAC_PACKET_RX_STAT;
```

Members

Members	Description
unsigned chksumOk : 1;	correct checksum filled in
unsigned pktChecksum : 16;	Packet payload checksum
unsigned runtPkt : 1;	Runt packet received
unsigned notMeUcast : 1;	Unicast, not me packet,
unsigned htMatch : 1;	Hash table match
unsigned magicMatch : 1;	Magic packet match
unsigned pmMatch : 1;	Pattern match match
unsigned uMatch : 1;	Unicast match
unsigned bMatch : 1;	Broadcast match
unsigned mMatch : 1;	Multicast match
unsigned rxBytes : 16;	Received bytes
unsigned crcError : 1;	CRC error in packet
unsigned lenError : 1;	Receive length check error
unsigned lenRange : 1;	Receive length out of range
unsigned rxOk : 1;	Receive OK
unsigned mcast : 1;	Multicast packet
unsigned bcast : 1;	Broadcast packet
unsigned rxCtrl : 1;	Control frame received
unsigned rxVLAN : 1;	Received VLAN tagged frame

Description

Received Packet Status

This structure contains the status of a received packet.

Remarks

Not all the MACs have hardware support for the received packet status.

TCPIP_MAC_PKT_ACK_RES Enumeration

List of MAC return codes for a packet acknowledge function.

File

tcpip_mac.h

C

```
typedef enum {
  TCPIP_MAC_PKT_ACK_NONE = 0,
  TCPIP_MAC_PKT_ACK_TX_OK = 1,
  TCPIP_MAC_PKT_ACK_RX_OK = 2,
  TCPIP_MAC_PKT_ACK_LINK_DOWN = -1,
  TCPIP_MAC_PKT_ACK_NET_DOWN = -2,
  TCPIP_MAC_PKT_ACK_BUFFER_ERR = -3,
  TCPIP_MAC_PKT_ACK_ARP_TMO = -4,
  TCPIP_MAC_PKT_ACK_ARP_NET_ERR = -5,
  TCPIP_MAC_PKT_ACK_MAC_REJECT_ERR = -6,
  TCPIP_MAC_PKT_ACK_CHKSUM_ERR = -10,
  TCPIP_MAC_PKT_ACK_SOURCE_ERR = -11,
  TCPIP_MAC_PKT_ACK_TYPE_ERR = -12,
```

```
  TCPIP_MAC_PKT_ACK_STRUCT_ERR = -13,
  TCPIP_MAC_PKT_ACK_PROTO_DEST_ERR = -14,
  TCPIP_MAC_PKT_ACK_FRAGMENT_ERR = -15,
  TCPIP_MAC_PKT_ACK_PROTO_DEST_CLOSE = -16,
  TCPIP_MAC_PKT_ACK_ALLOC_ERR = -17
} TCPIP_MAC_PKT_ACK_RES;
```

Members

Members	Description
TCPIP_MAC_PKT_ACK_NONE = 0	packet result unknown, unspecified
TCPIP_MAC_PKT_ACK_TX_OK = 1	TX success code - packet was transmitted successfully
TCPIP_MAC_PKT_ACK_RX_OK = 2	RX success code - packet was received/processed successfully
TCPIP_MAC_PKT_ACK_LINK_DOWN = -1	TX:packet was dropped because the link was down
TCPIP_MAC_PKT_ACK_NET_DOWN = -2	TX:packet was dropped because the network is down
TCPIP_MAC_PKT_ACK_BUFFER_ERR = -3	TX:packet was dropped because the buffer type is not supported
TCPIP_MAC_PKT_ACK_ARP_TMO = -4	TX:packet was dropped because of an ARP timeout
TCPIP_MAC_PKT_ACK_ARP_NET_ERR = -5	TX:packet associated interface is down or non existent
TCPIP_MAC_PKT_ACK_MAC_REJECT_ERR = -6	TX:packet rejected by MAC
TCPIP_MAC_PKT_ACK_CHKSUM_ERR = -10	RX: packet was dropped because the checksum was incorrect
TCPIP_MAC_PKT_ACK_SOURCE_ERR = -11	RX: packet was dropped because of wrong interface source address
TCPIP_MAC_PKT_ACK_TYPE_ERR = -12	RX: packet was dropped because the type was unknown
TCPIP_MAC_PKT_ACK_STRUCT_ERR = -13	RX: internal packet structure error
TCPIP_MAC_PKT_ACK_PROTO_DEST_ERR = -14	RX: the packet protocol couldn't find a destination for it
TCPIP_MAC_PKT_ACK_FRAGMENT_ERR = -15	RX: the packet too fragmented
TCPIP_MAC_PKT_ACK_PROTO_DEST_CLOSE = -16	RX: the packet destination is closing
TCPIP_MAC_PKT_ACK_ALLOC_ERR = -17	RX: memory allocation error

Description

MAC Packet Acknowledge Result

This enumeration contains the list of MAC codes used for a packet acknowledgment.

Remarks

16 bits only acknowledge results are supported. Positive codes indicate success. Negative codes indicate a failure of some sort.

TCPIP_MAC_PKT_AckF Type

MAC packet acknowledge function prototype.

File

tcpip_mac.h

C

```
typedef void (* TCPIP_MAC_PKT_AckF)(TCPIP_MAC_PACKET* pPkt, TCPIP_MAC_PKT_ACK_RES ackRes);
```

Returns

None.

Description

Packet Acknowledgment Function: typedef void (*TCPIP_MAC_PKT_AckF)(TCPIP_MAC_PACKET* pPkt, TCPIP_MAC_PKT_ACK_RES ackRes);

This function is used by the MAC to acknowledge a TCPIP_MAC_PACKET packet when the packet processing is completed.

Remarks

A TCPIP_MAC_PACKET packet always has an acknowledgment function. This function should clear the TCPIP_MAC_PKT_FLAG_QUEUED flag. The packet's ackRes is updated only if the parameter ackRes != TCPIP_MAC_PKT_ACK_NONE. The debug version adds the module identifier.

Parameters

Parameters	Description
pPkt	pointer to a valid TCPIP_MAC_PACKET packet.

ackRes	the result of the packet processing

TCPIP_MAC_PKT_AllocF Type

MAC packet allocation function prototype.

File

tcpip_mac.h

C

```
typedef TCPIP_MAC_PACKET* (* TCPIP_MAC_PKT_AllocF)(uint16_t pktLen, uint16_t segLoadLen,
TCPIP_MAC_PACKET_FLAGS flags);
```

Returns

- Valid packet pointer - if the allocation request succeeded
- 0 - if the allocation request failed

Description

Packet Allocation Function: typedef TCPIP_MAC_PACKET* (*TCPIP_MAC_PKT_AllocF)(uint16_t pktLen, uint16_t segLoadLen, TCPIP_MAC_PACKET_FLAGS flags);

This function is used by the MAC to allocate a TCPIP_MAC_PACKET packet.

Remarks

The returned allocated packet should always have the TCPIP_MAC_ETHERNET_HEADER added to the packet.

The debug version adds the module identifier.

Parameters

Parameters	Description
pktLen	the size of the packet (it will be 32 bits rounded up)
segLoadLen	the payload size for the segment associated to this packet. Payload is always 32 bit aligned. If 0 no segment is created/attached to the packet.
flags	packet flags

TCPIP_MAC_PKT_FreeF Type

MAC packet free function prototype.

File

tcpip_mac.h

C

```
typedef void (* TCPIP_MAC_PKT_FreeF)(TCPIP_MAC_PACKET* pPkt);
```

Returns

None.

Description

Packet Allocation Function: typedef void (*TCPIP_MAC_PKT_FreeF)(TCPIP_MAC_PACKET* pPkt);

This function is used by the MAC to free a previously allocated TCPIP_MAC_PACKET packet.

Remarks

The function will free a previously allocated packet. However packets or segments marked with TCPIP_MAC_PKT_FLAG_STATIC/TCPIP_MAC_SEG_FLAG_STATIC are not freed.

Also note that this function does not free explicitly the external segment payload. A payload that was created contiguously when the segment was created will be automatically freed by this function.

The debug version adds the module identifier.

Parameters

Parameters	Description
pPkt	pointer to a previously allocated packet.

TCPIP_MAC_POWER_MODE Enumeration

File

tcpip_mac.h

C

```
typedef enum {
  TCPIP_MAC_POWER_NONE,
  TCPIP_MAC_POWER_FULL,
  TCPIP_MAC_POWER_LOW,
  TCPIP_MAC_POWER_DOWN
} TCPIP_MAC_POWER_MODE;
```

Members

Members	Description
TCPIP_MAC_POWER_NONE	unknown power mode
TCPIP_MAC_POWER_FULL	up and running; valid for init/reinit
TCPIP_MAC_POWER_LOW	low power mode; valid for init/reinit
TCPIP_MAC_POWER_DOWN	interface is down

Description

This is type TCPIP_MAC_POWER_MODE.

TCPIP_MAC_PROCESS_FLAGS Enumeration

List of the MAC processing flags.

File

tcpip_mac.h

C

```
typedef enum {
  TCPIP_MAC_PROCESS_FLAG_NONE = 0x0000,
  TCPIP_MAC_PROCESS_FLAG_RX = 0x0001,
  TCPIP_MAC_PROCESS_FLAG_TX = 0x0002,
  TCPIP_MAC_PROCESS_FLAG_ANY = 0x0100
} TCPIP_MAC_PROCESS_FLAGS;
```

Members

Members	Description
TCPIP_MAC_PROCESS_FLAG_NONE = 0x0000	the stack never has to call the TCPIP_MAC_Process function
TCPIP_MAC_PROCESS_FLAG_RX = 0x0001	the stack has to call the TCPIP_MAC_Process after an RX signal
TCPIP_MAC_PROCESS_FLAG_TX = 0x0002	the stack has to call the TCPIP_MAC_Process after an TX signal
TCPIP_MAC_PROCESS_FLAG_ANY = 0x0100	the stack has to call the TCPIP_MAC_Process after any type of signal

Description

MAC Process Flags

List of specific MAC processing flags that indicate to the user of the MAC (TCP/IP stack) the processing that is expected by the MAC driver.

Remarks

Multiple flags can be "ORed".

TCPIP_MAC_RES Enumeration

List of return codes from MAC functions.

File

tcpip_mac.h

C

```
typedef enum {
  TCPIP_MAC_RES_OK = 0,
  TCPIP_MAC_RES_PENDING = 1,
  TCPIP_MAC_RES_TYPE_ERR = -1,
  TCPIP_MAC_RES_IS_BUSY = -2,
  TCPIP_MAC_RES_INIT_FAIL = -3,
  TCPIP_MAC_RES_PHY_INIT_FAIL = -4,
  TCPIP_MAC_RES_EVENT_INIT_FAIL = -5,
  TCPIP_MAC_RES_OP_ERR = -6,
  TCPIP_MAC_RES_ALLOC_ERR = -7,
  TCPIP_MAC_RES_INSTANCE_ERR = -8,
  TCPIP_MAC_RES_FRAGMENT_ERR = -9,
  TCPIP_MAC_RES_PACKET_ERR = -10,
  TCPIP_MAC_RES_QUEUE_TX_FULL = -11,
  TCPIP_MAC_RES_SYNCH_LOCK_FAIL = -12
} TCPIP_MAC_RES;
```

Members

Members	Description
TCPIP_MAC_RES_OK = 0	operation successful
TCPIP_MAC_RES_PENDING = 1	operation is pending upon some hardware resource. call again to completion
TCPIP_MAC_RES_TYPE_ERR = -1	unsupported type
TCPIP_MAC_RES_IS_BUSY = -2	device is in use
TCPIP_MAC_RES_INIT_FAIL = -3	generic initialization failure
TCPIP_MAC_RES_PHY_INIT_FAIL = -4	PHY initialization failure
TCPIP_MAC_RES_EVENT_INIT_FAIL = -5	Event system initialization failure
TCPIP_MAC_RES_OP_ERR = -6	unsupported operation
TCPIP_MAC_RES_ALLOC_ERR = -7	memory allocation error
TCPIP_MAC_RES_INSTANCE_ERR = -8	already instantiated, initialized error
TCPIP_MAC_RES_FRAGMENT_ERR = -9	too fragmented, RX buffer too small
TCPIP_MAC_RES_PACKET_ERR = -10	unsupported/corrupted packet error
TCPIP_MAC_RES_QUEUE_TX_FULL = -11	TX queue exceeded the limit
TCPIP_MAC_RES_SYNCH_LOCK_FAIL = -12	Synchronization object lock failed Could not get a lock

Description

MAC Result Enumeration

This is the list of codes that the MAC uses to specify the outcome of a MAC function.

Remarks

Benign operation results - always have positive values. Error codes - always have negative values.

TCPIP_MAC_SEGMENT_FLAGS Enumeration

Flags belonging to MAC data segment.

File

tcpip_mac.h

C

```
typedef enum {
  TCPIP_MAC_SEG_FLAG_STATIC = 0x0001,
  TCPIP_MAC_SEG_FLAG_TX = 0x0002,
  TCPIP_MAC_SEG_FLAG_RX_STICKY = 0x0004,
  TCPIP_MAC_SEG_FLAG_USER_PAYLOAD = 0x0008,
  TCPIP_MAC_SEG_FLAG_USER = 0x0100
} TCPIP_MAC_SEGMENT_FLAGS;
```

Members

Members	Description
TCPIP_MAC_SEG_FLAG_STATIC = 0x0001	Segment can not be dynamically deallocated. Set when the segment is allocated
TCPIP_MAC_SEG_FLAG_TX = 0x0002	If set, it's a TX segment; otherwise, is a RX packet.

TCPIP_MAC_SEG_FLAG_RX_STICKY = 0x0004	a MAC RX dedicated/sticky segment; otherwise, a non-dedicated/float segment
TCPIP_MAC_SEG_FLAG_USER_PAYLOAD = 0x0008	Segment carrying user payload Higher level protocols (TCP, UDP, etc.) may use it
TCPIP_MAC_SEG_FLAG_USER = 0x0100	User available segment flags.

Description

MAC Segment Flags

This enumeration contains the definitions of MAC segment flags: segment allocation flags and general purpose flags.

Remarks

16 bits only segment flags are supported.

TCPIP_MODULE_MAC_MRF24W_CONFIG Structure

File

tcpip_mac.h

C

```
typedef struct {
} TCPIP_MODULE_MAC_MRF24W_CONFIG;
```

Description

This is type TCPIP_MODULE_MAC_MRF24W_CONFIG.

TCPIP_MODULE_MAC_PIC32INT_CONFIG Structure

Data that's passed to the MAC at initialization time.

File

tcpip_mac.h

C

```
typedef struct {
  uint16_t nTxDescriptors;
  uint16_t rxBuffSize;
  uint16_t nRxDescriptors;
  uint16_t nRxDedicatedBuffers;
  uint16_t nRxInitBuffers;
  uint16_t rxLowThreshold;
  uint16_t rxLowFill;
  TCPIP_ETH_OPEN_FLAGS ethFlags;
  DRV_ETHPHY_CONFIG_FLAGS phyFlags;
  uint16_t linkInitDelay;
  uint16_t phyAddress;
  ETH_MODULE_ID ethModuleId;
  const DRV_ETHPHY_OBJECT* pPhyObject;
  const DRV_ETHPHY_OBJECT_BASE* pPhyBase;
} TCPIP_MODULE_MAC_PIC32INT_CONFIG;
```

Members

Members	Description
uint16_t nTxDescriptors;	number of TX descriptors
uint16_t rxBuffSize;	size of the corresponding RX buffer
uint16_t nRxDescriptors;	Number of RX descriptors Has to be high enough to accommodate both dedicated and non-dedicated RX buffers
uint16_t nRxDedicatedBuffers;	Number of MAC dedicated RX buffers These buffers/packets are owned by the MAC and are not returned to the packet pool They are allocated at MAC initialization time using pktAllocF and freed at MAC deinitialize time using pktFreeF Could be 0, if only not dedicated buffers are needed. For best performance usually it's best to have some dedicated buffers so as to minimize the run time allocations
uint16_t nRxInitBuffers;	Number of MAC non dedicated RX buffers allocated at the MAC initialization pktAllocF Note that these buffers are allocated in addition of the nRxDedicatedBuffers Freed at run time using pktFreeF

uint16_t rxLowThreshold;	Minimum threshold for the buffer replenish process Whenever the number of RX scheduled buffers is <= than this threshold the MAC driver will allocate new non-dedicated buffers that will be freed at run time using pktFreeF Setting this value to 0 disables the buffer replenishing process
uint16_t rxLowFill;	Number of RX buffers to allocate when below threshold condition is detected If 0, the MAC driver will allocate (scheduled buffers - rxThres) If !0, the MAC driver will allocate exactly rxLowFill buffers
TCPIP_ETH_OPEN_FLAGS ethFlags;	flags to use for the ETH connection
DRV_ETHPHY_CONFIG_FLAGS phyFlags;	PHY configuration
uint16_t linkInitDelay;	PHYs initialization delay (milliseconds) for insuring that the PHY is ready to transmit data.
uint16_t phyAddress;	PHY address, as configured on the board. All PHYs respond to address 0
ETH_MODULE_ID ethModuleId;	Ethernet module ID for this driver instance
const DRV_ETHPHY_OBJECT* pPhyObject;	Non-volatile pointer to the PHY vendor object associated with this MAC
const DRV_ETHPHY_OBJECT_BASE* pPhyBase;	Non-volatile pointer to the PHY basic object associated with this MAC

Description

MAC Initialization Data

This structure defines the MAC initialization data for the PIC32 MAC/Ethernet controller.

Remarks

- Each supported MAC has its own specific init/configuration data

TCPIP_MAC_RX_STATISTICS Structure

MAC receive statistics data gathered at run time.

File

tcpip_mac.h

C

```
typedef struct {
  int nRxOkPackets;
  int nRxPendBuffers;
  int nRxSchedBuffers;
  int nRxErrorPackets;
  int nRxFragmentErrors;
} TCPIP_MAC_RX_STATISTICS;
```

Members

Members	Description
int nRxOkPackets;	number of OK RX packets
int nRxPendBuffers;	number of unacknowledged pending RX buffers in the driver queues. If each incoming packet fits within a RX buffer (the RX buffer is large enough) than this corresponds to the number of unacknowledged pending RX packets. Otherwise the number of packets is less than the pending buffers.
int nRxSchedBuffers;	number of currently scheduled RX buffers in the driver queues. These are available buffers, ready to receive data
int nRxErrorPackets;	number of RX packets with errors
int nRxFragmentErrors;	number of RX fragmentation errors

Description

MAC RX Statistics Data

This structure defines the RX statistics data for the MAC driver.

Remarks

This statistics are recorded by the driver, not by the hardware.

TCPIP_MAC_TX_STATISTICS Structure

MAC transmit statistics data gathered at run time.

File

tcpip_mac.h

C

```
typedef struct {
  int nTxOkPackets;
  int nTxPendBuffers;
  int nTxErrorPackets;
  int nTxQueueFull;
} TCPIP_MAC_TX_STATISTICS;
```

Members

Members	Description
int nTxOkPackets;	number of OK transmitted packets
int nTxPendBuffers;	number of unacknowledged pending TX buffers in the driver queues. This is equal with pending TX packets when each packet is contained within a TX buffer.
int nTxErrorPackets;	number of packets that could not be transmitted
int nTxQueueFull;	number of times the TX queue was full this may signal that the number of TX descriptors is too small

Description

MAC TX Statistics Data

This structure defines the TX statistics data for the MAC driver.

Remarks

This statistics are recorded by the driver, not by the hardware.

TCPIP_MAC_INIT Structure

Contains all the data necessary to initialize the MAC device.

File

tcpip_mac.h

C

```
typedef struct {
  SYS_MODULE_INIT moduleInit;
  const TCPIP_MAC_MODULE_CTRL* const macControl;
  const void* const moduleData;
} TCPIP_MAC_INIT;
```

Members

Members	Description
SYS_MODULE_INIT moduleInit;	System module initialization
const TCPIP_MAC_MODULE_CTRL* const macControl;	Stack prepared data
const void* const moduleData;	Driver specific initialization data

Description

MAC Device Driver Initialization Data

This data structure contains all the data necessary to initialize the MAC device.

Remarks

A pointer to a structure of this format containing the desired initialization data must be passed into the TCPIP_MAC_Initialize routine.

TCPIP_MAC_PARAMETERS Structure

Data structure that tells the MAC run time parameters.

File

tcpip_mac.h

C

```
typedef struct {
  TCPIP_MAC_ADDR ifPhyAddress;
  TCPIP_MAC_PROCESS_FLAGS processFlags;
  TCPIP_MAC_TYPE macType;
  TCPIP_MAC_LINK_MTU linkMtu;
} TCPIP_MAC_PARAMETERS;
```

Members

Members	Description
TCPIP_MAC_ADDR ifPhyAddress;	Physical address of the interface. MAC sets this field as part of the initialization process.
TCPIP_MAC_PROCESS_FLAGS processFlags;	MAC process flags. The stack will use this value to call into the MAC process function after receiving a MAC event.
TCPIP_MAC_TYPE macType;	MAC type: ETH, Wi-Fi, etc.
TCPIP_MAC_LINK_MTU linkMtu;	MAC link MTU size

Description

MAC Run time parameters

This is the data structure that the MAC user (TCP/IP stack) passes on to the MAC driver after the MAC initialization time to retrieve the settings resulted.

Remarks

None.

TCPIP_MAC_PKT_AckFDbg Type

File

tcpip_mac.h

C

```
typedef void (* TCPIP_MAC_PKT_AckFDbg)(TCPIP_MAC_PACKET* pPkt, TCPIP_MAC_PKT_ACK_RES ackRes, int moduleId);
```

Description

This is type TCPIP_MAC_PKT_AckFDbg.

TCPIP_MAC_PKT_AllocFDbg Type

File

tcpip_mac.h

C

```
typedef TCPIP_MAC_PACKET* (* TCPIP_MAC_PKT_AllocFDbg)(uint16_t pktLen, uint16_t segLoadLen,
TCPIP_MAC_PACKET_FLAGS flags, int moduleId);
```

Description

This is type TCPIP_MAC_PKT_AllocFDbg.

TCPIP_MAC_PKT_FreeFDbg Type

File

tcpip_mac.h

C

```
typedef void (* TCPIP_MAC_PKT_FreeFDbg)(TCPIP_MAC_PACKET* pPkt, int moduleId);
```

Description

This is type TCPIP_MAC_PKT_FreeFDbg.

TCPIP_MAC_HEAP_CallocFDbg Type

File

tcpip_mac.h

C

```
typedef void* (* TCPIP_MAC_HEAP_CallocFDbg)(TCPIP_MAC_HEAP_HANDLE heapH, size_t nElems, size_t elemSize,
int moduleId, int lineNo);
```

Description

This is type TCPIP_MAC_HEAP_CallocFDbg.

TCPIP_MAC_HEAP_FreeFDbg Type

File

tcpip_mac.h

C

```
typedef size_t (* TCPIP_MAC_HEAP_FreeFDbg)(TCPIP_MAC_HEAP_HANDLE heapH, const void* pBuff, int moduleId,
int lineNo);
```

Description

This is type TCPIP_MAC_HEAP_FreeFDbg.

TCPIP_MAC_HEAP_MallocFDbg Type

File

tcpip_mac.h

C

```
typedef void* (* TCPIP_MAC_HEAP_MallocFDbg)(TCPIP_MAC_HEAP_HANDLE heapH, size_t nBytes, int moduleId, int
lineNo);
```

Description

This is type TCPIP_MAC_HEAP_MallocFDbg.

TCPIP_MAC_STATISTICS_REG_ENTRY Structure

Describes a MAC hardware statistics register.

File

tcpip_mac.h

C

```
typedef struct {
  char registerName[8];
  uint32_t registerValue;
} TCPIP_MAC_STATISTICS_REG_ENTRY;
```

Members

Members	Description
char registerName[8];	name of the hardware register
uint32_t registerValue;	value of the hardware register

Description

MAC Hardware Statistics Register Entry

This structure defines an interface for gathering the MAC hardware statistics registers data.

Remarks

None

TCPIP_MAC_TYPE Enumeration

List of the MAC types.

File

tcpip_mac.h

C

```
typedef enum {
  TCPIP_MAC_TYPE_NONE = 0,
  TCPIP_MAC_TYPE_ETH,
  TCPIP_MAC_TYPE_WLAN,
  TCPIP_MAC_TYPES
} TCPIP_MAC_TYPE;
```

Members

Members	Description
TCPIP_MAC_TYPE_NONE = 0	invalid/unknown MAC type
TCPIP_MAC_TYPE_ETH	wired Ethernet MAC type
TCPIP_MAC_TYPE_WLAN	wireless, Wi-Fi type MAC
TCPIP_MAC_TYPES	supported types

Description

MAC Types

List of specific MAC types that indicate to the user of the MAC (TCP/IP stack) the actual type of the MAC driver.

Remarks

Other types will be eventually added.

TCPIP_MAC_SYNCH_REQUEST Enumeration

Defines the possible MAC synchronization request types.

File

tcpip_mac.h

C

```
typedef enum {
  TCPIP_MAC_SYNCH_REQUEST_NONE = 0,
  TCPIP_MAC_SYNCH_REQUEST_OBJ_CREATE,
  TCPIP_MAC_SYNCH_REQUEST_OBJ_DELETE,
  TCPIP_MAC_SYNCH_REQUEST_OBJ_LOCK,
  TCPIP_MAC_SYNCH_REQUEST_OBJ_UNLOCK,
  TCPIP_MAC_SYNCH_REQUEST_CRIT_ENTER,
  TCPIP_MAC_SYNCH_REQUEST_CRIT_LEAVE
} TCPIP_MAC_SYNCH_REQUEST;
```

Members

Members	Description
TCPIP_MAC_SYNCH_REQUEST_NONE = 0	no request
TCPIP_MAC_SYNCH_REQUEST_OBJ_CREATE	request to create a synchronization object usually a binary semaphore
TCPIP_MAC_SYNCH_REQUEST_OBJ_DELETE	request to delete a previously created synchronization object
TCPIP_MAC_SYNCH_REQUEST_OBJ_LOCK	request to lock access using a previously created synchronization object
TCPIP_MAC_SYNCH_REQUEST_OBJ_UNLOCK	request to unlock/release access using a previously created synchronization object
TCPIP_MAC_SYNCH_REQUEST_CRIT_ENTER	request to enter a critical section
TCPIP_MAC_SYNCH_REQUEST_CRIT_LEAVE	request to exit from a critical section

Description

TCP/IP MAC Synchronization object request

TCP/IP MAC synchronization request codes.

This enumeration defines all the possible synchronization actions that can be requested by the MAC to the stack at run time.

Remarks

None.

TCPIP_MAC_SynchReqF Type

MAC synchronization request function definition.

File

tcpip_mac.h

C

```
typedef bool (* TCPIP_MAC_SynchReqF)(void* synchHandle, TCPIP_MAC_SYNCH_REQUEST request);
```

Returns

- true - if the call is successful
- false - if the call failed

Description

Synchronization request Function: typedef bool (*TCPIP_MAC_SynchReqF)(void* synchHandle, TCPIP_MAC_SYNCH_REQUEST request);

This function describes the MAC synchronization request function. The MAC driver will call this function whenever it needs to create, delete, lock or unlock a synchronization object.

Remarks

None.

Parameters

Parameters	Description
synchHandle	• pointer to a valid storage area • for TCPIP_MAC_SYNCH_REQUEST_OBJ_CREATE it is an address that will store a handle to identify the synchronization object to the OS (OSAL). • for other synchronization object request types the handle has to be valid and identify the synchronization object to the OS (OSAL). • for Critical sections it maintains OS passed info
request	a TCPIP_MAC_SYNCH_REQUEST type

TCPIP_MODULE_MAC_ID Enumeration

IDs of the MAC module supported by the stack.

File

tcpip_mac.h

C

```
typedef enum {
  TCPIP_MODULE_MAC_NONE = 0x1000,
  TCPIP_MODULE_MAC_ENCJ60 = 0x1010,
  TCPIP_MODULE_MAC_ENCJ60_0 = 0x1010,
  TCPIP_MODULE_MAC_ENCJ600 = 0x1020,
  TCPIP_MODULE_MAC_ENCJ600_0 = 0x1020,
  TCPIP_MODULE_MAC_97J60 = 0x1030,
  TCPIP_MODULE_MAC_97J60_0 = 0x1030,
  TCPIP_MODULE_MAC_PIC32INT = 0x1040,

TCPIP_MODULE_MAC_EXTERNAL = 0x4000	External, non MCHP, MAC modules

Description

MAC Modules ID

This type defines the supported MAC types.

Remarks

Not all types listed in this enumeration are supported. New MAC types will be added as needed.

TCPIP_MODULE_MAC_MRF24WN_CONFIG Structure

File

tcpip_mac.h

C

```
typedef struct {
} TCPIP_MODULE_MAC_MRF24WN_CONFIG;
```

Description

This is type TCPIP_MODULE_MAC_MRF24WN_CONFIG.

TCPIP_MAC_RX_FILTER_TYPE Enumeration

Defines the possible MAC RX filter types.

File

tcpip_mac.h

C

```
typedef enum {
  TCPIP_MAC_RX_FILTER_TYPE_BCAST_ACCEPT,
  TCPIP_MAC_RX_FILTER_TYPE_MCAST_ACCEPT,
  TCPIP_MAC_RX_FILTER_TYPE_UCAST_ACCEPT,
  TCPIP_MAC_RX_FILTER_TYPE_UCAST_OTHER_ACCEPT,
  TCPIP_MAC_RX_FILTER_TYPE_RUNT_REJECT,
  TCPIP_MAC_RX_FILTER_TYPE_RUNT_ACCEPT,
  TCPIP_MAC_RX_FILTER_TYPE_CRC_ERROR_REJECT,
  TCPIP_MAC_RX_FILTER_TYPE_CRC_ERROR_ACCEPT,
  TCPIP_MAC_RX_FILTER_TYPE_DEFAULT
} TCPIP_MAC_RX_FILTER_TYPE;
```

Members

Members	Description
TCPIP_MAC_RX_FILTER_TYPE_BCAST_ACCEPT	Broadcast packets are accepted
TCPIP_MAC_RX_FILTER_TYPE_MCAST_ACCEPT	Multicast packets are accepted
TCPIP_MAC_RX_FILTER_TYPE_UCAST_ACCEPT	Unicast packets to a this host are accepted
TCPIP_MAC_RX_FILTER_TYPE_UCAST_OTHER_ACCEPT	Unicast packets to a different host are accepted
TCPIP_MAC_RX_FILTER_TYPE_RUNT_REJECT	Runt packets (< 64 bytes) are rejected
TCPIP_MAC_RX_FILTER_TYPE_RUNT_ACCEPT	Runt packets (< 64 bytes) are accepted
TCPIP_MAC_RX_FILTER_TYPE_CRC_ERROR_REJECT	Packets with CRC errors are rejected
TCPIP_MAC_RX_FILTER_TYPE_CRC_ERROR_ACCEPT	Packets with CRC errors are accepted
TCPIP_MAC_RX_FILTER_TYPE_DEFAULT	Default RX filter: will accept most valid packets

Description

MAC RX Filter Types

This enumeration defines the RX filtering capabilities for the TCP/IP MAC driver.

Remarks

The Ethernet/Wi-Fi controllers have an RX filter module that takes part in the packet acceptance decision.

Multiple values can be OR-ed together.

There usually is a priority in the RX filter processing for a MAC module. In order for a packet to be accepted, it has to be specifically accepted by a filter. Once a filter accepts or rejects a packet, further filters are not tried. If a packet isn't rejected/accepted after all filters are tried, it will be rejected by default!

Not all MACs support all the RX filter types.

Current implementation does not suport more than 16 filters.

TCPIP_MAC_LINK_MTU Enumeration

MTU size correspondig to the MAC types.

File

tcpip_mac.h

C

```
typedef enum {
  TCPIP_MAC_LINK_MTU_DEFAULT = 1500,
  TCPIP_MAC_LINK_MTU_ETH = 1500,
  TCPIP_MAC_LINK_MTU_WLAN = 1500
} TCPIP_MAC_LINK_MTU;
```

Members

Members	Description
TCPIP_MAC_LINK_MTU_DEFAULT = 1500	default MTU link
TCPIP_MAC_LINK_MTU_ETH = 1500	wired Ethernet MAC type
TCPIP_MAC_LINK_MTU_WLAN = 1500	wireless, Wi-Fi type MAC

Description

Link MTU per MAC Type

Lists the Maximum Transmission Unit corresponding to a MAC type.

Remarks

The MTU is usually set by the standards. For special links the values can be updated.

The default value is normally used. However the individual MAC drivers can use the specific symols

Enumerations

	Name	Description
	TCPIP_MAC_ACTION	Network interface action for initialization/deinitialization
	TCPIP_MAC_EVENT	Defines the possible MAC event types.
	TCPIP_MAC_LINK_MTU	MTU size correspondig to the MAC types.
	TCPIP_MAC_PACKET_FLAGS	Flags belonging to MAC packet.
	TCPIP_MAC_PKT_ACK_RES	List of MAC return codes for a packet acknowledge function.
	TCPIP_MAC_POWER_MODE	This is type TCPIP_MAC_POWER_MODE.
	TCPIP_MAC_PROCESS_FLAGS	List of the MAC processing flags.
	TCPIP_MAC_RES	List of return codes from MAC functions.
	TCPIP_MAC_RX_FILTER_TYPE	Defines the possible MAC RX filter types.
	TCPIP_MAC_SEGMENT_FLAGS	Flags belonging to MAC data segment.
	TCPIP_MAC_SYNCH_REQUEST	Defines the possible MAC synchronization request types.
	TCPIP_MAC_TYPE	List of the MAC types.
	TCPIP_MODULE_MAC_ID	IDs of the MAC module supported by the stack.

Functions

	Name	Description
	TCPIP_MAC_Close	MAC driver close function.
	TCPIP_MAC_ConfigGet	Gets the current MAC driver configuration.
	TCPIP_MAC_Deinitialize	MAC driver deinitialization function.
	TCPIP_MAC_EventAcknowledge	This function acknowledges a previously reported MAC event.
	TCPIP_MAC_EventMaskSet	MAC events report enable/disable function.
	TCPIP_MAC_EventPendingGet	Returns the currently pending MAC events.
	TCPIP_MAC_Initialize	MAC driver initialization function.
	TCPIP_MAC_LinkCheck	MAC link checking function.
	TCPIP_MAC_Open	MAC driver open function.
	TCPIP_MAC_PacketRx	A packet is returned if such a pending packet exists.
	TCPIP_MAC_PacketTx	MAC driver transmit function.
	TCPIP_MAC_ParametersGet	MAC parameter get function.
	TCPIP_MAC_Process	MAC periodic processing function.
	TCPIP_MAC_RegisterStatisticsGet	Gets the current MAC hardware statistics registers.
	TCPIP_MAC_Reinitialize	MAC driver reinitialization function.
	TCPIP_MAC_RxFilterHashTableEntrySet	Sets the current MAC hash table receive filter.
	TCPIP_MAC_StatisticsGet	Gets the current MAC statistics.
	TCPIP_MAC_Status	Provides the current status of the MAC driver module.
	TCPIP_MAC_Tasks	Maintains the MAC driver's state machine.

Structures

	Name	Description
	_tag_MAC_DATA_SEGMENT	A data segment that's part of a TX/RX packet.
	_tag_TCPIP_MAC_PACKET	A TX/RX packet descriptor.
	TCPIP_MAC_ADDR	Definition of a MAC address.
	TCPIP_MAC_DATA_SEGMENT	A data segment that's part of a TX/RX packet.
	TCPIP_MAC_ETHERNET_HEADER	Definition of a MAC frame header.
	TCPIP_MAC_INIT	Contains all the data necessary to initialize the MAC device.
	TCPIP_MAC_MODULE_CTRL	Data structure that's passed to the MAC at the initialization time.
	TCPIP_MAC_PACKET_RX_STAT	Status of a received packet.

	TCPIP_MAC_PARAMETERS	Data structure that tells the MAC run time parameters.
	TCPIP_MAC_RX_STATISTICS	MAC receive statistics data gathered at run time.
	TCPIP_MAC_STATISTICS_REG_ENTRY	Describes a MAC hardware statistics register.
	TCPIP_MAC_TX_STATISTICS	MAC transmit statistics data gathered at run time.
	TCPIP_MODULE_MAC_MRF24W_CONFIG	This is type TCPIP_MODULE_MAC_MRF24W_CONFIG.
	TCPIP_MODULE_MAC_MRF24WN_CONFIG	This is type TCPIP_MODULE_MAC_MRF24WN_CONFIG.
	TCPIP_MODULE_MAC_PIC32INT_CONFIG	Data that's passed to the MAC at initialization time.

Types

	Name	Description
	TCPIP_MAC_EventF	MAC event notification handler.
	TCPIP_MAC_HANDLE	Handle to a MAC driver.
	TCPIP_MAC_HEAP_CallocF	MAC allocation function prototype.
	TCPIP_MAC_HEAP_CallocFDbg	This is type TCPIP_MAC_HEAP_CallocFDbg.
	TCPIP_MAC_HEAP_FreeF	MAC allocation function prototype.
	TCPIP_MAC_HEAP_FreeFDbg	This is type TCPIP_MAC_HEAP_FreeFDbg.
	TCPIP_MAC_HEAP_HANDLE	A handle used for memory allocation functions.
	TCPIP_MAC_HEAP_MallocF	MAC allocation function prototype.
	TCPIP_MAC_HEAP_MallocFDbg	This is type TCPIP_MAC_HEAP_MallocFDbg.
	TCPIP_MAC_PACKET	Forward reference to a MAC packet.
	TCPIP_MAC_PACKET_ACK_FUNC	Prototype of a MAC packet acknowledge function.
	TCPIP_MAC_PKT_AckF	MAC packet acknowledge function prototype.
	TCPIP_MAC_PKT_AckFDbg	This is type TCPIP_MAC_PKT_AckFDbg.
	TCPIP_MAC_PKT_AllocF	MAC packet allocation function prototype.
	TCPIP_MAC_PKT_AllocFDbg	This is type TCPIP_MAC_PKT_AllocFDbg.
	TCPIP_MAC_PKT_FreeF	MAC packet free function prototype.
	TCPIP_MAC_PKT_FreeFDbg	This is type TCPIP_MAC_PKT_FreeFDbg.
	TCPIP_MAC_SynchReqF	MAC synchronization request function definition.

Description

MAC Module Definitions for the Microchip TCP/IP Stack

File Name

tcpip_mac.h

Company

Microchip Technology Inc.

tcpip_mac_config.h

Configuration file

Macros

	Name	Description
	TCPIP_EMAC_ETH_OPEN_FLAGS	Flags to use for the Ethernet connection A TCPIP_ETH_OPEN_FLAGS value. Set to TCPIP_ETH_OPEN_DEFAULT unless very good reason to use different value
	TCPIP_EMAC_PHY_ADDRESS	The PHY address, as configured on the board. By default all the PHYs respond to address 0
	TCPIP_EMAC_PHY_CONFIG_FLAGS	Flags to configure the MAC ->PHY connection a DRV_ETHPHY_CONFIG_FLAGS This depends on the actual connection (MII/RMII, default/alternate I/O) The DRV_ETHPHY_CFG_AUTO value will use the configuration fuses setting
	TCPIP_EMAC_PHY_LINK_INIT_DELAY	The value of the delay for the link initialization, ms This insures that the PHY is ready to transmit after it is reset A usual value is 500 ms. Adjust to your needs.

	TCPIP_EMAC_RX_BUFF_SIZE	Size of a RX packet buffer. Should be multiple of 16. This is the size of all receive packet buffers processed by the ETHC. The size should be enough to accommodate any network received packet. If the packets are larger, they will have to take multiple RX buffers and the packet manipulation is less efficient. #define TCPIP_EMAC_RX_BUFF_SIZE 512 Together with TCPIP_EMAC_RX_DEDICATED_BUFFERS it has impact on TCPIP_STACK_DRAM_SIZE setting.
	TCPIP_EMAC_RX_DEDICATED_BUFFERS	Number of MAC dedicated RX packet buffers. These buffers are always owned by the MAC. Note that the MAC driver allocates these buffers for storing the incoming network packets. The bigger the storage capacity, the higher data throughput can be obtained. Note that these packet buffers are allocated from the private TCP/IP heap that is specified by the TCPIP_STACK_DRAM_SIZE setting.
	TCPIP_EMAC_RX_DESCRIPTORS	Number of the RX descriptors to be created. If not using the run time replenish mechanism (see below) it should match the number of dedicated buffers: TCPIP_EMAC_RX_DEDICATED_BUFFERS; Otherwise it should be bigger than the sum of dedicated + non-dedicated buffers: TCPIP_EMAC_RX_DESCRIPTORS > TCPIP_EMAC_RX_DEDICATED_BUFFERS + replenish_buffers
	TCPIP_EMAC_RX_FILTERS	MAC RX Filters These filters define the packets that are accepted and rejected by the MAC driver Adjust to your needs The default value allows the processing of unicast, multicast and broadcast packets that have a valid CRC
	TCPIP_EMAC_RX_FRAGMENTS	MAC maximum number of supported fragments. Based on the values of TCPIP_EMAC_RX_MAX_FRAME and TCPIP_EMAC_RX_BUFF_SIZE an incoming frame may span multiple RX buffers (fragments). Note that excessive fragmentation leads to performance degradation. The default and recommended value should be 1. #define TCPIP_EMAC_RX_FRAGMENTS 1 Alternatively you can use the calculation of the number of fragments based on the selected RX sizes:
	TCPIP_EMAC_RX_INIT_BUFFERS	Number of non-dedicated buffers for the MAC initialization Buffers allocated at the MAC driver initialization.
	TCPIP_EMAC_RX_LOW_FILL	Number of RX buffers to allocate when below threshold condition is detected. If 0, the MAC driver will allocate (scheduled buffers - rxThres) If !0, the MAC driver will allocate exactly TCPIP_EMAC_RX_LOW_FILL buffers
	TCPIP_EMAC_RX_LOW_THRESHOLD	Minumum threshold for the buffer replenish process. Whenever the number of RX scheduled buffers is <= than this threshold the MAC driver will allocate new non-dedicated buffers (meaning that they will be released to the TCP/IP heap once they are processed). Setting this value to 0 disables the buffer replenishing process.
	TCPIP_EMAC_RX_MAX_FRAME	Maximum MAC supported RX frame size. Any incoming ETH frame that's longer than this size will be discarded. The default value is 1536 (allows for VLAN tagged frames, although the VLAN tagged frames are discarded). Normally there's no need to touch this value unless you know exactly the maximum size of the frames you want to process or you need to control packets fragmentation (together with the TCPIP_EMAC_RX_BUFF_SIZE).
	TCPIP_EMAC_TX_DESCRIPTORS	Number of the TX descriptors to be created. Because a TCP packet can span at most 3 buffers, the value should always be >= 4 The amount of memory needed per descriptor is not high (around 24 bytes) so when high MAC TX performance is needed make sure that this number is >= 8.

Manager Module

This section describes the TCP/IP Stack Library Manager module.

Introduction

TCP/IP Stack Library Manager Module for Microchip Microcontrollers

This library provides the API of the Manager module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

The TCP/IP manager provides access to the stack initialization, configuration and status functions.

It also process the packets received from different network interfaces (MAC drivers) and dispatches them based on their type to the proper higher layer in the stack.

Using the Library

This topic describes the basic architecture of the Manager TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `tcpip_manager.h`

The interface to the Manager TCP/IP Stack library is defined in the `tcpip_manager.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the Manager TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

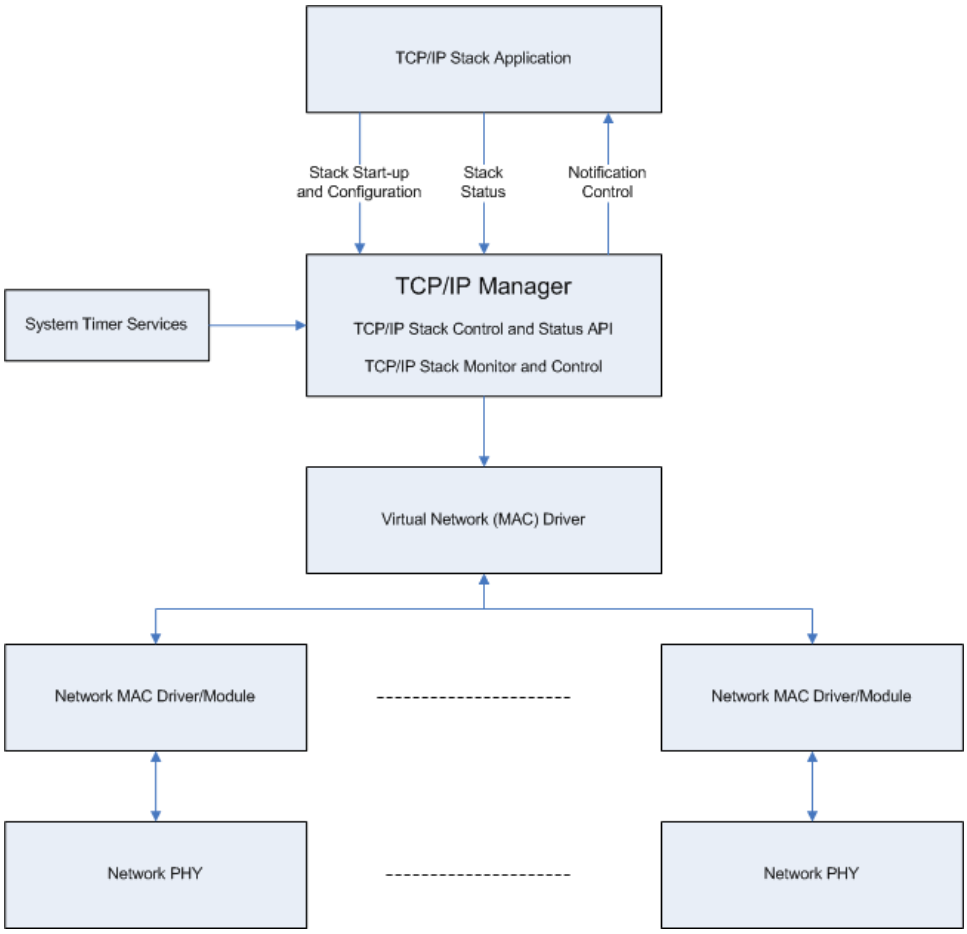
This library provides the API of the Manager TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

The TCP/IP manager allows the user of the stack to initialize, control and get current status of the TCP/IP stack.

It is also responsible for the receiving of the network packets and their dispatch to the stack processing layers.

Manager Software Abstraction Block Diagram



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Manager module.

Library Interface Section	Description
Task and Initialize Functions	Routines to Initialize and Deinitialize this Module
Network Up/Down/Linked Functions	Routines to Set and Get the Network's Up/Down Status
Network Status and Control Functions	Routines to Set and Get the Various Network Controls
Network Address Status and Control Functions	Routines to Set and Get the Network's Address Status
Network Structure Storage Functions	Network Information Routines
Data Types and Constants	This section provides various definitions describing this API

How the Library Works

This topic describes how the TCP/IP Stack Library Manager module operates.

Description

The Manager module of the TCP/IP stack is the central module in the stack. It is the module that allows the client to configure and initialize the stack and also to get current status and parameters of the network interfaces that the stack supports.

The stack manager controls the communication to the underlying virtual MAC driver that implements the interface to a specific network channel. The various network interfaces that the TCP/IP stack supports are brought up or torn down by the stack manager in response to the stack client commands.

The manager is also responsible for providing the TCP/IP client with notifications of the events that occur in the stack at the network interface level. A dynamic registration mechanism is provided for this.

Another important functionality of the stack manager is the dispatch of the incoming network packets. The manager is notified by the underlying interface drivers of the traffic related event (transmit, receive, errors, etc.) As a response to those events the manager gets the pending receive packets from the virtual MAC driver and, based on their type, dispatches them to the appropriate higher level protocol for further processing (IPv4, ARP, IPv6).

As part of the event notification provided by the MAC driver the TCP/IP stack manager calls back into the MAC driver when this one needs processing time and can maintain statistics counters, link status, etc.

The MPLAB Harmony framework on the system running the TCP/IP stack interfaces to the stack manager mainly by using three functions, TCPIP_STACK_Initialize and TCPIP_STACK_Deinitialize for TCP/IP stack initialization, and TCPIP_STACK_Task for periodic processing and the advance of the stack state machine.

The stack is capable of running either under an Operating System (RTOS) or in a bare-metal environment. When running in a bare-metal environment a "cooperative multi-tasking" approach is needed by the TCP/IP stack, meaning that control has to reach the TCPIP_STACK_Task function. That is the system will make periodic calls to this function which allows the TCP/IP stack to dequeue incoming packets and the corresponding state machines in the stack to advance. The application has to be aware that it cannot monopolize the processor for long periods of time, and needs to relinquish control so that the system loops perform their tasks.

In an RTOS environment it is preferred to have the stack manager run in its own thread. This thread will be blocked waiting for network interface events and when such an event occurs it will wake up and process the data. This is a more efficient way of using the CPU resources.

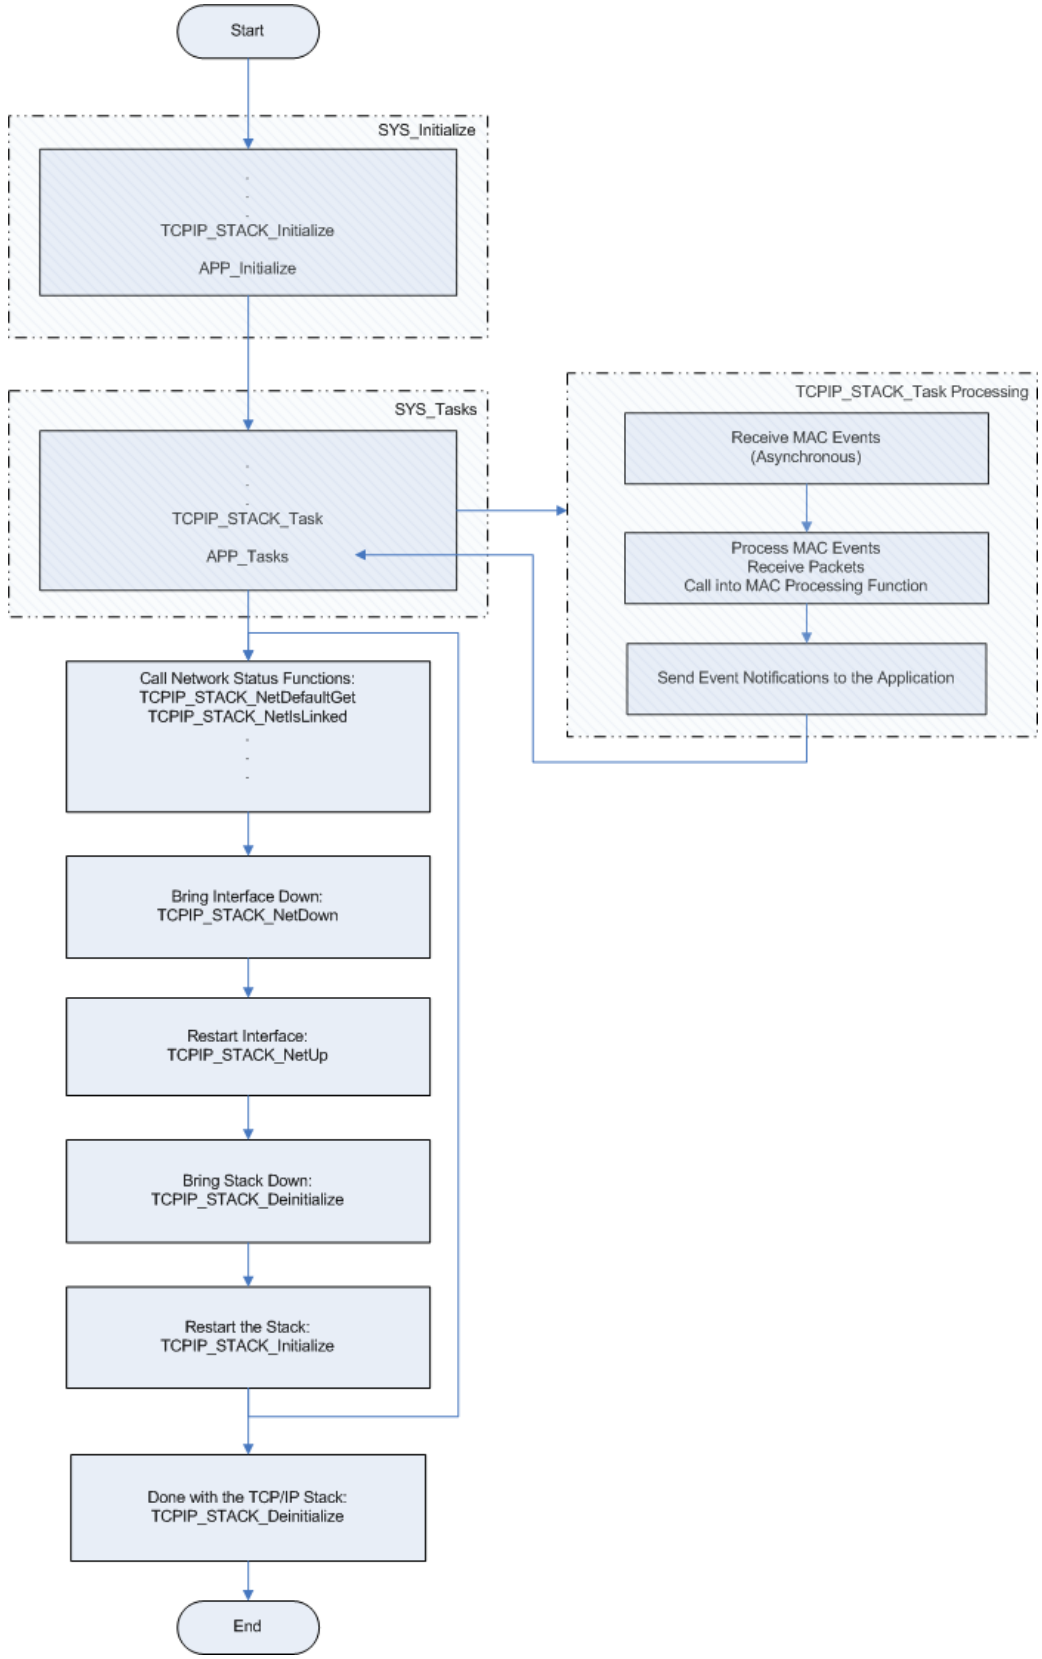
Refer to Volume IV: MPLAB Harmony Framework Reference for information on configuring the MPLAB Harmony framework to run in a RTOS or bare-metal environment.

Core Functionality

This topic describes the core functionality of the TCP/IP Stack Library Manager module.

Description

The following diagram provides an overview for the operation and use of the Manager module in a typical MPLAB Harmony framework (bare-metal, non-OS environment).



The TCP/IP stack is initialized as a part of the system initialization by a call to TCPIP_STACK_Initialize. By configuring the stack, the application can pass run-time initialization data to the stack to select both the network parameters of the interfaces (network addresses, masks, physical addresses, NetBIOS names, DHCP operation, etc.) and the parameters for the modules contained in the stack (TCP, UDP, ARP, IPv4, IPv6, etc.).

Once the stack is initialized the application can use the stack manager calls to inquire about the stack current settings (current addresses obtained by DHCP or IPv6 advertisements messages, etc.), to check the physical link status or to set new parameters to the stack.

It should be noted that different interfaces can be stopped and restarted dynamically (TCPIP_STACK_NetDown, TCPIP_STACK_NetUp) without the stack being killed. When a particular interface is brought up only the network parameters for that interface need to be supplied (no parameters

for the TCP/IP stack modules are needed).

The entire stack can be stopped and restarted (TCPIP_STACK_Deinitialize, TCPIP_STACK_Initialize). Reinitializing the stack allows the stack initialization with a complete new set of network and/or module parameters.

The stack processing is done in the TCPIP_STACK_Task function. As explained in the previous paragraph, processing time is required by the stack, meaning that periodic calls have to be made by the system/framework to the TCPIP_STACK_Task function. When execution reaches this function the stack maintains and advances its internal state machine. The most important part of this is the processing of the events that are reported by the underlying MAC drivers (through the use of the virtual MAC driver, which provides an interrupt signaling/event notification mechanism). As a response to the MAC events, the stack manager will retrieve packets from the internal MAC receive queues and dispatch them for processing. It will also call into MAC processing functions if required and provide processing for the stack modules that are the recipients of the dispatched network packets. The stack manager will also notify the application of the network events if the application dynamically registered an event notification handler with the stack.

It should be noted that the stack manager also requires a periodic tick signal for which it uses the MPLAB Harmony system timer services (see Timer System Service Library).

If the application no longer uses the TCP/IP stack, it is important that it calls the TCPIP_STACK_Deinitialize function. This function closes any open network connections (sockets, etc.), closes the underlying MAC and PHY drivers and all of the modules in the stack, and frees all of the resources that were internally allocated by the stack as part of the initialization and run-time processing.

Configuring the Library

The configuration of the Manager TCP/IP Stack is based on the file `system_config.h`, which may include `tcpip_config.h`.

This header file contains the configuration of the stack and the modules that are included in the current build of the stack.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

Building the Library

This section lists the files that are available in the Manager module of the TCP/IP Stack Library.

Description

The Manager module is part of the core functionality of the TCP/IP Stack Library. Please refer to the Building the Library topic in the TCP/IP Stack Library section for build information.

Library Interface

a) Helper Functions

	Name	Description
	TCPIP_Helper_FormatNetBIOSName	Formats a string to a valid NetBIOS name.
	TCPIP_Helper_htonl	Conversion routines from network order to host order and reverse.
	TCPIP_Helper_htons	This is function TCPIP_Helper_htons.
	TCPIP_Helper_IPAddressToString	Converts an IPV4 address to an ASCII string.
	TCPIP_Helper_IPv6AddressToString	Converts an IPv6 address to a string representation.
	TCPIP_Helper_IsBcastAddress	Checks if an IPv4 address is a broadcast address.
	TCPIP_Helper_IsMcastAddress	Checks if an IPv4 address is a multicast address.
	TCPIP_Helper_IsPrivateAddress	Detects a private (non-routable) address.
	TCPIP_Helper_MACAddressToString	Converts a MAC address to a string.
	TCPIP_Helper_ntohl	!defined(__PIC32MX__)
	TCPIP_Helper_ntohs	This is function TCPIP_Helper_ntohs.
	TCPIP_Helper_StringToIPAddress	Converts an ASCII string to an IPV4 address.
	TCPIP_Helper_StringToIPv6Address	Converts a string to an IPv6 address.
	TCPIP_Helper_StringToMACAddress	Converts a string to an MAC address.
	TCPIP_Helper_htonll	This is function TCPIP_Helper_htonll.
	TCPIP_Helper_ntohll	This is function TCPIP_Helper_ntohll.
	TCPIP_Helper_SecurePortGetByIndex	Returns the secure port belonging to a specified index.
	TCPIP_Helper_SecurePortSet	Sets the required port secure connection status.
	TCPIP_Helper_TCPSecurePortGet	Checks if the required TCP port is a secure port.
	TCPIP_Helper_UDPSecurePortGet	Checks if the required UDP port is a secure port.
	TCPIP_Helper_Base64Decode	Helper function to decode a Base-64 encoded array.
	TCPIP_Helper_Base64Encode	Helper function to encode to Base-64.

b) Task and Initialize Functions

	Name	Description
	TCPIP_STACK_SetLocalMasks	Sets the local/non-local masks for network interface.
	TCPIP_STACK_SetLocalMasksType	Sets the local/non-local masks type for network interface.
	TCPIP_STACK_HandlerDeregister	Deregisters an event notification handler.
	TCPIP_STACK_HandlerRegister	Sets a new event notification handler.
	TCPIP_STACK_Initialize	Stack initialization function.
	TCPIP_STACK_Deinitialize	Stack deinitialization function.
	TCPIP_STACK_Task	TCP/IP Stack task function.
	TCPIP_STACK_VersionGet	Gets the TCP/IP stack version in numerical format.
	TCPIP_STACK_VersionStrGet	Gets the TCP/IP stack version in string format.
	TCPIP_STACK_MACObjectGet	Returns the network MAC driver object of this interface.
	TCPIP_MODULE_SignalFunctionDeregister	Deregisters a signal function for a stack module.
	TCPIP_MODULE_SignalFunctionRegister	Registers a new signal function for a stack module.
	TCPIP_MODULE_SignalGet	Returns the current signals for a TCP/IP module.

c) Network Status and Control Functions

	Name	Description
	TCPIP_STACK_IndexToNet	Network interface handle from interface number.
	TCPIP_STACK_NetBIOSName	Network interface NetBIOS name.
	TCPIP_STACK_NetBiosNameSet	Sets network interface NetBIOS name.
	TCPIP_STACK_NetDefaultGet	Default network interface handle.
	TCPIP_STACK_NetDefaultSet	Sets the default network interface handle.
	TCPIP_STACK_NetHandleGet	Network interface handle from a name.
	TCPIP_STACK_NetIndexGet	Network interface number from interface handle.
	TCPIP_STACK_NetMask	Network interface IPv4 address mask.
	TCPIP_STACK_NetNameGet	Network interface name from a handle.
	TCPIP_STACK_NumberOfNetworksGet	Number of network interfaces in the stack.
	TCPIP_STACK_EventsPendingGet	Returns the currently pending events.
	TCPIP_STACK_NetIsReady	Gets the network interface configuration status.
	TCPIP_STACK_NetMACRegisterStatisticsGet	Get the MAC statistics register data.
	TCPIP_STACK_NetAliasNameGet	Network interface alias name from a handle.
	TCPIP_STACK_InitializeDataGet	Get the TCP/IP stack initialization data.

d) Network Up/Down/Linked Functions

	Name	Description
	TCPIP_STACK_NetIsLinked	Gets the network interface link status.
	TCPIP_STACK_NetIsUp	Gets the network interface up or down status.
	TCPIP_STACK_NetUp	Turns up a network interface. As part of this process, the corresponding MAC driver is initialized.
	TCPIP_STACK_NetDown	Turns down a network interface.

e) Network Address Status and Control Functions

	Name	Description
	TCPIP_STACK_NetAddress	Network interface IPv4 address.
	TCPIP_STACK_NetAddressBcast	Network interface broadcast address.
	TCPIP_STACK_NetAddressDnsPrimary	Network interface DNS address.
	TCPIP_STACK_NetAddressDnsPrimarySet	Sets network interface IPv4 DNS address.
	TCPIP_STACK_NetAddressDnsSecond	Network interface secondary DNS address.
	TCPIP_STACK_NetAddressDnsSecondSet	Sets network interface IPv4 secondary DNS address.
	TCPIP_STACK_NetAddressGateway	Network interface IPv4 gateway address.
	TCPIP_STACK_NetAddressGatewaySet	Sets network interface IPv4 gateway address.
	TCPIP_STACK_NetAddressMac	Network interface MAC address.
	TCPIP_STACK_NetAddressMacSet	Sets network interface MAC address.
	TCPIP_STACK_NetAddressSet	Sets network interface IPv4 address.

	TCPIP_STACK_NetIPv6AddressGet	Gets network interface IPv6 address.
	TCPIP_STACK_ModuleConfigGet	Get stack module configuration data.
	TCPIP_STACK_NetMACIdGet	Get the MAC ID of the network interface.
	TCPIP_STACK_NetMACStatisticsGet	Get the MAC statistics data.
	TCPIP_STACK_Status	Provides the current status of the TCPIP stack module.

f) Network Structure Storage Functions

	Name	Description
	TCPIP_STACK_NetConfigGet	Get stack network interface configuration data.
	TCPIP_STACK_NetConfigSet	Restores stack network interface configuration data.

g) Data Types and Constants

	Name	Description
	TCPIP_LOCAL_MASK_TYPE	Mask operation for local/non-local network interface.
	TCPIP_NET_HANDLE	Defines a network interface handle.
	TCPIP_EVENT	Defines the possible TCPIP event types.
	TCPIP_EVENT_HANDLE	Defines a TCPIP stack event handle.
	TCPIP_STACK_EVENT_HANDLER	Pointer to a function(handler) that will get called to process an event.
	TCPIP_Helper_ntohl	This is macro TCPIP_Helper_ntohl.
	TCPIP_Helper_ntohs	This is macro TCPIP_Helper_ntohs.
	TCPIP_STACK_IF_NAME_ALIAS_ETH	alias for Ethernet interface
	TCPIP_STACK_IF_NAME_ALIAS_UNK	alias for unknown interface
	TCPIP_STACK_IF_NAME_ALIAS_WLAN	alias for Wi-Fi interface
	_IPV6_ADDR_STRUCT	COmplex type to represent an IPv6 address.
	IP_ADDR	Backward compatible definition to represent an IPv4 address.
	IP_ADDRESS_TYPE	Definition of the TCP/IP supported address types.
	IP_MULTI_ADDRESS	Definition to represent multiple IP addresses.
	IPV4_ADDR	Definition to represent an IPv4 address
	IPV6_ADDR	Definition to represent an IPv6 address.
	IPV6_ADDR_HANDLE	Definition to represent an IPv6 address.
	IPV6_ADDR_SCOPE	Definition to represent the scope of an IPv6 address.
	IPV6_ADDR_STRUCT	COmplex type to represent an IPv6 address.
	IPV6_ADDR_TYPE	Definition to represent the type of an IPv6 address.
	TCPIP_NETWORK_CONFIG	Defines the data required to initialize the network configuration.
	TCPIP_NETWORK_CONFIG_FLAGS	Definition of network configuration start-up flags.
	TCPIP_STACK_INIT	Definition to represent the TCP/IP stack initialization/configuration structure.
	TCPIP_STACK_MODULE	List of the TCP/IP stack supported modules.
	TCPIP_STACK_MODULE_CONFIG	Definition to represent a TCP/IP module initialization/configuration structure.
	TCPIP_MODULE_SIGNAL	Lists the signals that are generated by the TCP/IP stack manager and processed by the stack modules.
	TCPIP_MODULE_SIGNAL_FUNC	Pointer to a function(handler) that will get called when a stack internal signal occurred.
	TCPIP_MODULE_SIGNAL_HANDLE	Defines a TCPIP stack signal function handle.
	TCPIP_STACK_IF_NAME_97J60	This is macro TCPIP_STACK_IF_NAME_97J60.
	TCPIP_STACK_IF_NAME_ENCJ60	This is macro TCPIP_STACK_IF_NAME_ENCJ60.
	TCPIP_STACK_IF_NAME_ENCJ600	This is macro TCPIP_STACK_IF_NAME_ENCJ600.
	TCPIP_STACK_IF_NAME_MRF24W	This is macro TCPIP_STACK_IF_NAME_MRF24W.
	TCPIP_STACK_IF_NAME_NONE	Defines the TCP/IP stack supported network interfaces.
	TCPIP_STACK_IF_NAME_PIC32INT	This is macro TCPIP_STACK_IF_NAME_PIC32INT.
	TCPIP_STACK_IF_POWER_DOWN	powered down, not started
	TCPIP_STACK_IF_POWER_FULL	up and running;
	TCPIP_STACK_IF_POWER_LOW	low power mode; not supported now
	TCPIP_STACK_IF_POWER_NONE	unsupported, invalid
	TCPIP_STACK_VERSION_MAJOR	TCP/IP stack version
	TCPIP_STACK_VERSION_MINOR	This is macro TCPIP_STACK_VERSION_MINOR.
	TCPIP_STACK_VERSION_PATCH	This is macro TCPIP_STACK_VERSION_PATCH.

	TCPIP_STACK_VERSION_STR	This is macro TCPIP_STACK_VERSION_STR.
	TCPIP_Helper_ntohll	This is macro TCPIP_Helper_ntohll.
	TCPIP_STACK_IF_NAME_MRF24WN	This is macro TCPIP_STACK_IF_NAME_MRF24WN.

Description

This section describes the Application Programming Interface (API) functions of the Manager module.

Refer to each section for a detailed description.

a) Helper Functions

TCPIP_Helper_FormatNetBIOSName Function

Formats a string to a valid NetBIOS name.

File

tcpip_helpers.h

C

```
void TCPIP_Helper_FormatNetBIOSName(uint8_t Name[]);
```

Returns

None.

Description

This function formats a string to a valid NetBIOS name. Names will be exactly 16 characters, as defined by the NetBIOS spec. The 16th character will be a 0x00 byte, while the other 15 will be the provided string, padded with spaces as necessary.

Preconditions

None.

Parameters

Parameters	Description
Name	the string to format as a NetBIOS name. This parameter must have at least 16 bytes allocated.

Function

void TCPIP_Helper_FormatNetBIOSName(uint8_t Name[])

TCPIP_Helper_htonl Function

Conversion routines from network order to host order and reverse.

File

tcpip_helpers.h

C

```
inline uint32_t TCPIP_Helper_htonl(uint32_t hLong);
```

Returns

The converted 16/32-bit quantity.

Description

These functions will convert a long or short quantity from the network order (big endian) to host order (little endian on PIC32).

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
hLong/nLong	long value (32 bits) to convert
hShort/nShort	short value (16 bits) to convert

Function

uint64_t TCPIP_Helper_htonll(uint64_t hLLong);
uint32_t TCPIP_Helper_htonl(uint32_t hLong);
uint16_t TCPIP_Helper_htons(uint16_t hShort);
uint64_t TCPIP_Helper_ntohll(uint64_t nLLong);
uint32_t TCPIP_Helper_ntohl(uint32_t nLong);
uint16_t TCPIP_Helper_ntohs(uint16_t nShort);

TCPIP_Helper_htons Function

File

tcpip_helpers.h

C

```
inline uint16_t TCPIP_Helper_htons(uint16_t hShort);
```

Description

This is function TCPIP_Helper_htons.

TCPIP_Helper_IPAddressToString Function

Converts an IPV4 address to an ASCII string.

File

tcpip_helpers.h

C

```
bool TCPIP_Helper_IPAddressToString(const IPV4_ADDR* IPAddress, char* buff, size_t buffSize);
```

Returns

- true - an IP address was successfully converted
- false - supplied buffer was not large enough

Description

This function converts IPV4_ADDR to a dotted-quad decimal IP address string

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
IPAddress	Pointer to IPV4_ADDR to convert
buff	buffer to store the converted dotted-quad IP address string
buffSize	buffer size

Function

bool TCPIP_Helper_IPAddressToString(const IPV4_ADDR* IPAddress, char* buff, size_t buffSize);

TCPIP_Helper_IPv6AddressToString Function

Converts an IPv6 address to a string representation.

File

tcpip_helpers.h

C

```
bool TCPIP_Helper_IPv6AddressToString(const IPV6_ADDR * addr, char* buff, size_t buffSize);
```

Returns

- true - an IPv6 address was successfully converted
- false - supplied buffer was not large enough

Description

This function converts an IPV6_ADDR to a text representation of an IPv6 address.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
addr	Pointer to IPV6_ADDR to convert
buff	Pointer to a buffer to store the text representation
buffSize	buffer size

Function

bool TCPIP_Helper_IPv6AddressToString (const IPV6_ADDR * addr, char* buff, size_t buffSize);

TCPIP_Helper_IsBcastAddress Function

Checks if an IPv4 address is a broadcast address.

File

tcpip_helpers.h

C

```
__inline__ bool TCPIP_Helper_IsBcastAddress(const IPV4_ADDR* IPAddress);
```

Returns

- true - if the IPv4 address is a broadcast address
- false - if the IPv4 address is not a broadcast address

Description

This function verifies if the supplied IPv4 address is a broadcast address.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
IPAddress	Pointer to IPV4_ADDR to check

Function

bool TCPIP_Helper_IsBcastAddress(const IPV4_ADDR* IPAddress);

TCPIP_Helper_IsMcastAddress Function

Checks if an IPv4 address is a multicast address.

File

tcpip_helpers.h

C

```
__inline__ bool TCPIP_Helper_IsMcastAddress(const IPV4_ADDR* IPAddress);
```

Returns

- true - if the IPv4 address is a multicast address
- false - if the IPv4 address is not a multicast address

Description

This function verifies if the supplied IPv4 address is a multicast address.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
IPAddress	Pointer to IPV4_ADDR to check

Function

bool TCPIP_Helper_IsMcastAddress(const IPV4_ADDR* IPAddress)

TCPIP_Helper_IsPrivateAddress Function

Detects a private (non-routable) address.

File

tcpip_helpers.h

C

```
bool TCPIP_Helper_IsPrivateAddress(uint32_t ipv4Address);
```

Returns

- true - the IPv4 address is a private address
- false - the IPv4 address is a routable address

Description

This function checks if the passed in IPv4 address is a private or a routable address.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
ipv4Address	IPv4 address to check, network order

Function

bool TCPIP_Helper_IsPrivateAddress(uint32_t ipv4Address);

TCPIP_Helper_MACAddressToString Function

Converts a MAC address to a string.

File

tcpip_helpers.h

C

```
bool TCPIP_Helper_MACAddressToString(const TCPIP_MAC_ADDR* macAddr, char* buff, size_t buffSize);
```

Returns

- true - a MAC address was successfully decoded
- false - no MAC address could be found, or the format was incorrect

Description

This function will convert a MAC address to a string representation.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
macAddr	Pointer to address to convert
buff	buffer to store the string representation
buffSize	size of the buffer

Function

bool TCPIP_Helper_MACAddressToString(const TCPIP_MAC_ADDR* macAddr, char* buff, size_t buffSize);

TCPIP_Helper_ntohl Function

File

tcpip_helpers.h

C

```
uint32_t TCPIP_Helper_ntohl(uint32_t nLong);
```

Description

!defined(__PIC32MX__)

TCPIP_Helper_ntohs Function

File

tcpip_helpers.h

C

```
uint16_t TCPIP_Helper_ntohs(uint16_t nShort);
```

Description

This is function TCPIP_Helper_ntohs.

TCPIP_Helper_StringToIPAddress Function

Converts an ASCII string to an IPV4 address.

File

tcpip_helpers.h

C

```
bool TCPIP_Helper_StringToIPAddress(const char* str, IPV4_ADDR* IPAddress);
```

Returns

- true - an IP address was successfully decoded
- false - no IP address could be found, or the format was incorrect

Description

This function parses a dotted-quad decimal IP address string into an IPV4_ADDR struct. The output result is big-endian.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
str	Pointer to a dotted-quad IP address string
IPAddress	Pointer to IPV4_ADDR in which to store the result

Function

bool TCPIP_Helper_StringToIPAddress(const char* str, IPV4_ADDR* IPAddress);

TCPIP_Helper_StringToIPv6Address Function

Converts a string to an IPv6 address.

File

tcpip_helpers.h

C

```
bool TCPIP_Helper_StringToIPv6Address(const char * str, IPV6_ADDR * addr);
```

Description

This function parses the text representation of an IPv6 address to an IPV6_ADDR struct. The output result is big-endian.

Remarks

None.

Preconditions

None

Example

1111:2222:3333:4444:5555:6666:AAAA:FFFF 1111:2222::FFFF 1111:2222:3333:4444:5555:6666:192.168.1.20 addr - Pointer to IPV6_ADDR in which to store the result

Parameters

Parameters	Description
str	Pointer to an RFC3513, Section 2.2 text representation of an IPv6 address

Function

bool TCPIP_Helper_StringToIPv6Address (const char * str, IPV6_ADDR * addr);

TCPIP_Helper_StringToMACAddress Function

Converts a string to an MAC address.

File

tcpip_helpers.h

C

```
bool TCPIP_Helper_StringToMACAddress(const char* str, uint8_t macAddr[6]);
```

Returns

- true - a MAC address was successfully decoded
- false - no MAC address could be found, or the format was incorrect

Description

This function parses a MAC address string "aa:bb:cc:dd:ee:ff" or "aa-bb-cc-dd-ee-ff" into an hex MAC address.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
str	Pointer to a colon separated MAC address string
macAddr	Pointer to buffer to store the result

Function

bool TCPIP_Helper_StringToMACAddress(const char* str, uint8_t macAddr[6]);

TCPIP_Helper_htonll Function

File

tcpip_helpers.h

C

```
uint64_t TCPIP_Helper_htonll(uint64_t hLLong);
```

Description

This is function TCPIP_Helper_htonll.

TCPIP_Helper_ntohll Function

File

tcpip_helpers.h

C

```
uint64_t TCPIP_Helper_ntohll(uint64_t nLLong);
```

Description

This is function TCPIP_Helper_ntohll.

TCPIP_Helper_SecurePortGetByIndex Function

Returns the secure port belonging to a specified index.

File

tcpip_helpers.h

C

```
uint16_t TCPIP_Helper_SecurePortGetByIndex(int index, bool streamSocket, int* pnIndexes);
```

Returns

- a port number corresponding to the required index
- 0 if the corresponding slot is free or the port is not associated with the requested stream/datagram flag.

Description

This function returns the secure TCP/UDP port situated at the internal port table requested index. It also returns the number of indexes currently in the table.

Preconditions

TCP/IP stack properly initialized.

Parameters

Parameters	Description
index	The port index to query. 0 should always be a valid index
streamSocket	if true, a stream/TCP port is queried else a datagram/UDP port is queried
pnIndexes	pointer to store the number of indexes that the table currntly has. Could be NULL if not needed.

Function

uint16_t TCPIP_Helper_SecurePortGetByIndex(int index, bool streamSocket, int* pnIndexes);

TCPIP_Helper_SecurePortSet Function

Sets the required port secure connection status.

File

tcpip_helpers.h

C

```
bool TCPIP_Helper_SecurePortSet(uint16_t port, bool streamSocket, bool isSecure);
```

Returns

- true - the port status successfuly changed
- false - the port status could not be changed (no more slots in the table, port not found, etc.)

Description

This function sets the internal data for deciding if the required port is a secure port or not. A secure port is one that requires secure connections. The TCP/IP internally maintained table with the ports that require secure connections is manipulated with this function. This table can be queried using the TCPIP_Helper_TCPSecurePortGet() function.

Remarks

Currently there is no protection for multi-threaded accessing and modifying the entries in the secure port table. It is thus recommended that the updates to the table occur just once at initialization time and after that all threads perform read-only accesses.

Preconditions

TCP/IP stack properly initialized.

Parameters

Parameters	Description
port	The TCP port to set
streamSocket	if true, a stream/TCP port is queried else a datagram/UDP port is queried
isSecure	if true, the port is set as requiring secure connection if false, the port is set as not requiring a secure connection and it will be removed from the secure ports table

Function

bool TCPIP_Helper_SecurePortSet(uint16_t port, bool streamSocket, bool isSecure);

TCPIP_Helper_TCPSecurePortGet Function

Checks if the required TCP port is a secure port.

File

tcpip_helpers.h

C

```
bool TCPIP_Helper_TCPSecurePortGet(uint16_t tcpPort);
```

Returns

- true - if the port is a secure connection port
- false - if port is not secure (the port is not found in the internal secure ports table)

Description

This function checks the internal data for detecting if the required TCP port is a secure port or not. A secure port is one that requires secure connections. The TCP/IP stack maintains an internal table with the ports that require secure connections. This table can be maintained using the TCPIP_Helper_SecurePortSet() function.

Remarks

The TCP/IP stack populates the internal secure port table with default values as part of the stack power up procedure. The table is not re-initialized when the stack is brought down and then restarted.

Preconditions

TCP/IP stack properly initialized.

Parameters

Parameters	Description
tcpPort	The TCP port to query

Function

bool TCPIP_Helper_TCPSecurePortGet(uint16_t tcpPort);

TCPIP_Helper_UDPSecurePortGet Function

Checks if the required UDP port is a secure port.

File

tcpip_helpers.h

C

```
bool TCPIP_Helper_UDPSecurePortGet(uint16_t udpPort);
```

Returns

- true - if the port is a secure connection port
- false - if port is not secure (the port is not found in the internal secure ports table)

Description

This function checks the internal data for detecting if the required UDP port is a secure port or not. A secure port is one that requires secure connections. The TCP/IP stack maintains an internal table with the ports that require secure connections. This table can be maintained using the TCPIP_Helper_SecurePortSet() function.

Remarks

The TCP/IP stack populates the internal secure port table with default values as part of the stack power up procedure. The table is not re-initialized when the stack is brought down and then restarted.

Preconditions

TCP/IP stack properly initialized.

Parameters

Parameters	Description
udpPort	The UDP port to query

Function

bool TCPIP_Helper_UDPSecurePortGet(uint16_t udpPort);

TCPIP_Helper_Base64Decode Function

Helper function to decode a Base-64 encoded array.

File

tcpip_helpers.h

C

```
uint16_t TCPIP_Helper_Base64Decode(const uint8_t* sourceData, uint16_t sourceLen, uint8_t* destData,
uint16_t destLen);
```

Returns

Number of decoded bytes written to destData.

Description

Decodes a Base-64 array to its literal representation.

Remarks

This function will ignore invalid Base-64 characters (CR, LF, etc). If sourceData is equal to destData, the data will be converted in-place. If sourceData is not equal to destData, but the regions overlap, the behavior is undefined.

Decoded data size is 3 / 4 the size of the encoded source data.

Preconditions

None

Parameters

Parameters	Description
sourceData	Pointer to a string of Base-64 encoded data
sourceLen	Length of the Base-64 source data Maximum length that can be written to destData
destData	Pointer to write the decoded data

Function

uint16_t TCPIP_Helper_Base64Decode(const uint8_t* sourceData, uint16_t sourceLen,

uint8_t* destData, uint16_t destLen)

TCPIP_Helper_Base64Encode Function

Helper function to encode to Base-64.

File

tcpip_helpers.h

C

```
uint16_t TCPIP_Helper_Base64Encode(const uint8_t* sourceData, uint16_t sourceLen, uint8_t* destData,
uint16_t destLen);
```

Returns

Number of encoded bytes written to destData. This will always be a multiple of 4.

Description

This function encodes a binary array to Base-64.

Remarks

Encoding cannot be performed in-place. If surceData overlaps with destData, the behavior is undefined.

The source data is padded wit 1 or 2 bytes, if needed, to make the source size a multiple of 3 bytes. Then for each 3 bytes tuple in the source 4 output bytes are generated. The output size needed is pad(sourceLen) * 4 / 3 bytes.

Preconditions

None

Parameters

Parameters	Description
sourceData	Pointer to a string of binary data
sourceLen	Length of the binary source data
destData	Pointer to write the Base-64 encoded data
destLen	Maximum length that can be written to destData

Function

uint16_t TCPIP_Helper_Base64Encode(const uint8_t* sourceData, uint16_t sourceLen,

uint8_t* destData, uint16_t destLen)

b) Task and Initialize Functions

TCPIP_STACK_SetLocalMasks Function

Sets the local/non-local masks for network interface.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_SetLocalMasks(TCPIP_NET_HANDLE netH, uint32_t andMask, uint32_t orMask);
```

Returns

- true - if interface exists and is enabled
- false - if an error occurred

Description

This function sets the masks used in the stack decision of a destination address being a local or non-local address. These masks will be used when the corresponding mask type is set to TCPIP_LOCAL_MASK_SET.

Remarks

None

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("PIC32INT");
TCPIP_STACK_SetLocalMasks(netH, 0x0101a0c0, 0x0);
```

Parameters

Parameters	Description
netH	handle of the interface to use
andMask	AND mask to use for local network detection, big endian (BE) format
orType	OR mask to use for local network detection , BE format

Function

bool TCPIP_STACK_SetLocalMasks(TCPIP_NET_HANDLE netH,

uint32_t andMask, uint32_t orMask)

TCPIP_STACK_SetLocalMasksType Function

Sets the local/non-local masks type for network interface.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_SetLocalMasksType(TCPIP_NET_HANDLE netH, TCPIP_LOCAL_MASK_TYPE andType,
TCPIP_LOCAL_MASK_TYPE orType);
```

Returns

- true - if the interface exists and is enabled
- false - if an error occurred

Description

This function sets the types of masks used in the stack decision of a destination address being a local or non-local address. For example, when a TCP connection is made, the advertised MSS usually has different values for local versus non-local networks.

To decide if a destination IP address (destAdd) is local to a network interface (having the netAdd address) the following calculation is performed: if(((destAdd & andMask) | orMask) == ((netAdd & andMask) | orMask)), the destination address is considered to be a local address; otherwise, the destination address is non-local.

This function sets the types of masks used for the AND and OR operations, as follows:

- TCPIP_LOCAL_MASK_ZERO: use the all 0's mask (0x00000000)
- TCPIP_LOCAL_MASK_ONE: use the all 1's mask (0xffffffff)
- TCPIP_LOCAL_MASK_NET: use the current network mask
- TCPIP_LOCAL_MASK_SET: use a mask that's set by the application There are operations to set a specific AND and OR masks

Using different values for the AND and OR masks an application can select various destination networks to be considered as local/non-local:

- only their own network
- any network
- no network
- specific (range of) networks
- etc.

Remarks

The default value for both AND and OR masks is set to TCPIP_LOCAL_MASK_ZERO so that any destination network is considered to be local!

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("PIC32INT");
TCPIP_STACK_SetLocalMasksType(netH, TCPIP_LOCAL_MASK_NET, TCPIP_LOCAL_MASK_ZERO);
```

Parameters

Parameters	Description
netH	handle of the interface to use
andType	AND type of mask to use for local network detection
orType	OR type of mask to use for local network detection

Function

bool TCPIP_STACK_SetLocalMasksType(TCPIP_NET_HANDLE netH, TCPIP_LOCAL_MASK_TYPE andType,
TCPIP_LOCAL_MASK_TYPE orType)

TCPIP_STACK_HandlerDeregister Function

Deregisters an event notification handler.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_HandlerDeregister(TCPIP_EVENT_HANDLE hEvent);
```

Returns

- true - if the operation succeeded
- false - if the operation failed

Description

This function removes an event notification handler.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Example

```
TCPIP_EVENT_HANDLE myHandle = TCPIP_STACK_HandlerRegister( hNet, TCPIP_EV_CONN_ALL, myEventHandler, myParam
);
// do something else
// now we're done with it
TCPIP_STACK_HandlerDeregister(myHandle);
```

Parameters

Parameters	Description
hEvent	TCPIP event handle obtained by a call to TCPIP_STACK_HandlerRegister

Function

bool TCPIP_STACK_HandlerDeregister(TCPIP_EVENT_HANDLE hEvent);

TCPIP_STACK_HandlerRegister Function

Sets a new event notification handler.

File

tcpip_manager.h

C

```
TCPIP_EVENT_HANDLE TCPIP_STACK_HandlerRegister(TCPIP_NET_HANDLE hNet, TCPIP_EVENT evMask,
TCPIP_STACK_EVENT_HANDLER notifyHandler, const void* notifyfParam);
```

Returns

- a valid TCPIP_EVENT_HANDLE - if the operation succeeded
- NULL - if the operation failed

Description

This function sets a new event notification handler. The caller can use the handler to be notified of stack events.

Remarks

The notification handler may be called from the ISR which detects the corresponding event. The event notification handler has to be kept as short as possible and non-blocking.

Without a notification handler the stack user can still call TCPIP_STACK_GetPending() to see if processing by the stack needed.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_EVENT_HANDLE myHandle = TCPIP_STACK_HandlerRegister( hNet, TCPIP_EV_CONN_ALL, myEventHandler, myParam
);
```

Parameters

Parameters	Description
hNet	network handle
evMask	mask of events to be notified of
notifyHandler	the event notification handler
notifyfParam	notification handler parameter

Function

TCPIP_EVENT_HANDLE TCPIP_STACK_HandlerRegister(TCPIP_NET_HANDLE hNet,
TCPIP_EVENT evMask, TCPIP_STACK_EVENT_HANDLER notifyHandler, const void* notifyfParam)

TCPIP_STACK_Initialize Function

Stack initialization function.

File

tcpip_manager.h

C

```
SYS_MODULE_OBJ TCPIP_STACK_Initialize(const SYS_MODULE_INDEX index, const SYS_MODULE_INIT * const init);
```

Returns

- Valid handle to a driver object, if successful.
- SYS_MODULE_OBJ_INVALID if initialization failed.

Description

The function initializes the stack. If an error occurs, the SYS_ERROR() is called and the function deinitialize itself.

Remarks

This function must be called before any of the stack or its component routines are used.

New TCPIP_NETWORK_CONFIG types could be added/removed at run time for implementations that support dynamic network interface creation.

Only one instance of the TCP/IP stack can run in the system and the index parameter is irrelevant

If this call is made after the stack is successfully initialized, the current TCP/IP stack object handle will be returned.

Preconditions

None

Parameters

Parameters	Description
index	index of the TCP/IP stack to be initialized
init	Pointer to initialization data.
It should be a TCPIP_STACK_INIT structure carrying the following data	• pNetConf - pointer to an array of TCPIP_NETWORK_CONFIG to support • nNets - number of network configurations in the array • pModConfig - pointer to an array of TCPIP_STACK_MODULE_CONFIG • nModules - number of modules to initialize

Function

SYS_MODULE_OBJ TCPIP_STACK_Initialize(const SYS_MODULE_INDEX index,
const SYS_MODULE_INIT * const init);

TCPIP_STACK_Deinitialize Function

Stack deinitialization function.

File

tcpip_manager.h

C

```
void TCPIP_STACK_Deinitialize(SYS_MODULE_OBJ object);
```

Returns

None.

Description

This function performs the deinitialization of the TCPIP stack. All allocated resources are released.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize.

Parameters

Parameters	Description
object	Object handle, returned from TCPIP_STACK_Initialize call

Function

void TCPIP_STACK_Deinitialize(SYS_MODULE_OBJ object)

TCPIP_STACK_Task Function

TCP/IP Stack task function.

File

tcpip_manager.h

C

```
void TCPIP_STACK_Task(SYS_MODULE_OBJ object);
```

Returns

None.

Description

TCP/IP stack execution state machine. Stack Finite-state Machine (FSM) is executed.

Remarks

This FSM checks for new incoming packets, and routes it to appropriate stack components. It also performs timed operations.

This function must be called periodically to ensure timely responses.

This function continues the stack initialization process after the TCPIP_STACK_Initialize was called. The TCPIP_STACK_Status will report SYS_STATUS_BUSY while the initialization is in progress.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize.

Parameters

Parameters	Description
object	Object handle returned by TCPIP_STACK_Initialize

Function

void TCPIP_STACK_Task(SYS_MODULE_OBJ object)

TCPIP_STACK_VersionGet Function

Gets the TCP/IP stack version in numerical format.

File

tcpip_manager.h

C

```
unsigned int TCPIP_STACK_VersionGet(const SYS_MODULE_INDEX index);
```

Returns

Current driver version in numerical format.

Description

This function gets the TCP/IP stack version. The version is encoded as major * 10000 + minor * 100 + patch. The stringed version can be obtained using TCPIP_STACK_VersionStrGet()

Remarks

None.

Preconditions

None.

Example

```
unsigned int version;

version = TCPIP_STACK_VersionGet( TCPIP_STACK_INDEX_1 );

if(version < 110200)
{
    // Do Something
}
```

Parameters

Parameters	Description
index	Identifier for the object instance to get the version for

Function

unsigned int TCPIP_STACK_VersionGet (const SYS_MODULE_INDEX index)

TCPIP_STACK_VersionStrGet Function

Gets the TCP/IP stack version in string format.

File

tcpip_manager.h

C

```
char * TCPIP_STACK_VersionStrGet(const SYS_MODULE_INDEX index);
```

Returns

Current TCP/IP stack version in the string format.

Description

This function gets the TCP/IP stack version. The version is returned as major.minor.path[type], where type is optional. The numerical version can be obtained using TCPIP_STACK_VersionGet.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the object instance to get the version for.

Function

char * TCPIP_STACK_VersionStrGet (const SYS_MODULE_INDEX index)

TCPIP_STACK_MACObjectGet Function

Returns the network MAC driver object of this interface.

File

tcpip_manager.h

C

```
const TCPIP_MAC_OBJECT* TCPIP_STACK_MACObjectGet(TCPIP_NET_HANDLE netH);
```

Returns

It returns a valid MAC driver object pointer if success. Returns 0 if no such interface or there is no MAC object.

Description

This function returns the MAC driver object that's associated with the interface handle.

Remarks

The MAC driver object is the one that's passed at the stack/interface initialization.

The MAC driver is not a true multi-client driver. Under normal circumstances the MAC driver has only one client, the TCP/IP stack. To have the TCPIP_MAC_Open() succeed after the MAC driver has been initialized by the TCP/IP stack, the configuration symbol DRV_ETHMAC_CLIENTS_NUMBER has to be > 1! But the returned handle is the same one as the TCP/IP stack uses.

Access to the MAC driver in this way is allowed mainly for debugging, diagnostic and statistics purposes. It is possible though to transmit packets this way. But it's not possible to be signalled about incoming RX packets while the stack is running because only the TCP/IP dispatcher will be notified by the RX events.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Example

```
 TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("eth0");
 const TCPIP_MAC_OBJECT* pEthMacObject = TCPIP_STACK_MACObjectGet(netH);
 if(pEthMacObject != 0)
 {    // valid MAC object pointer
      DRV_HANDLE hMac = (*pEthMacObject->TCPIP_MAC_Open)(pEthMacObject->macId, DRV_IO_INTENT_READWRITE);
      if(hMac != DRV_HANDLE_INVALID)
      {   // can use the MAC handle to access a MAC function
          TCPIP_MAC_RX_STATISTICS rxStatistics;
          TCPIP_MAC_TX_STATISTICS txStatistics;
          TCPIP_MAC_RES macRes = (*pEthMacObject->TCPIP_MAC_StatisticsGet)(hMac, &rxStatistics,
&txStatistics);
      }
 }
```

Parameters

Parameters	Description
netH	Interface handle to get the name of.

Function

const TCPIP_MAC_OBJECT* TCPIP_STACK_MACObjectGet(TCPIP_NET_HANDLE netH);

TCPIP_MODULE_SignalFunctionDeregister Function

Deregisters a signal function for a stack module.

File

tcpip_manager.h

C

```
bool TCPIP_MODULE_SignalFunctionDeregister(TCPIP_MODULE_SIGNAL_HANDLE signalHandle);
```

Returns

- true - if the operation succeeded
- false - if the operation failed (i.e., no such module, invalid handle, etc.)

Description

This function deregisters a previous signal function. The caller will no longer be notified of stack internal signals.

Remarks

See the remarks for TCPIP_MODULE_SignalFunctionRegister.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.
signalHandle - a valid signal handle

Example

```
void appSignalFunc(TCPIP_STACK_MODULE moduleId, TCPIP_MODULE_SIGNAL signal)
{
    // process incoming signal for the incoming module
}

TCPIP_MODULE_SIGNAL_HANDLE signalH = TCPIP_MODULE_SignalFunctionRegister( TCPIP_MODULE_HTTP_SERVER,
appSignalFunc);

// when done with this signal notification
TCPIP_MODULE_SignalFunctionDeregister(signalH);
```

Parameters

Parameters	Description
signalHandle	signal handle obtained from a registration call

Function

bool TCPIP_MODULE_SignalFunctionDeregister(TCPIP_MODULE_SIGNAL_HANDLE signalHandle);

TCPIP_MODULE_SignalFunctionRegister Function

Registers a new signal function for a stack module.

File

tcpip_manager.h

C

```
TCPIP_MODULE_SIGNAL_HANDLE TCPIP_MODULE_SignalFunctionRegister(TCPIP_STACK_MODULE moduleId,
TCPIP_MODULE_SIGNAL_FUNC signalF);
```

Returns

- valid handle - if the operation succeeded,
- 0/invalid handle - if the operation failed (i.e., no such module, signal already set, etc.)

Description

This function registers a new signal function. This function will be called and the user notified when a stack internal signal occurs.

Remarks

There is no support for multiple signal functions now. Each module supports just one signal function. A call to register a new module signal function will fail if a function is already registered. TCPIP_MODULE_SignalFunctionDeregister needs to be called first

By default all stack modules, including the stack manager (TCPIP_MODULE_MANAGER) are initialized with a null signal function. Explicit call is needed for setting a module signal function.

A signal handler can be registered for the stack manager itself (TCPIP_MODULE_MANAGER). This will report RX and TMO signals.

The stack internal signaling mechanism is always active and cannot be disabled. This function is called on top of the normal stack signaling mechanism for a module that has a registered signal function.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Example

```
void appSignalFunc(TCPIP_STACK_MODULE moduleId, TCPIP_MODULE_SIGNAL signal)
{
    // process incoming signal for the incoming module
}

TCPIP_MODULE_SIGNAL_HANDLE signalH = TCPIP_MODULE_SignalFunctionRegister( TCPIP_MODULE_HTTP_SERVER,
appSignalFunc);
```

Parameters

Parameters	Description
moduleId	module ID
signalF	signal function to be called when an internal signal occurs

Function

TCPIP_MODULE_SIGNAL_HANDLE TCPIP_MODULE_SignalFunctionRegister(TCPIP_STACK_MODULE moduleId,
TCPIP_MODULE_SIGNAL_FUNC signalF);

TCPIP_MODULE_SignalGet Function

Returns the current signals for a TCP/IP module.

File

tcpip_manager.h

C

```
TCPIP_MODULE_SIGNAL TCPIP_MODULE_SignalGet(TCPIP_STACK_MODULE moduleId);
```

Returns

The current value of the module's signals.

Description

This function provides a read only value of the current signals for a stack module.

Remarks

The signals are processed and cleared inside the stack. It is not possible to clear a signal that's pending using this API.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Example

```
TCPIP_MODULE_SIGNAL currSIgnal = TCPIP_MODULE_SignalGet(TCPIP_MODULE_HTTP_SERVER);
```

Parameters

Parameters	Description
moduleId	module ID

Function

TCPIP_MODULE_SIGNAL TCPIP_MODULE_SignalGet(TCPIP_STACK_MODULE moduleId);

c) Network Status and Control Functions

TCPIP_STACK_IndexToNet Function

Network interface handle from interface number.

File

tcpip_manager.h

C

```
TCPIP_NET_HANDLE TCPIP_STACK_IndexToNet(int netIx);
```

Returns

Network interface handle.

Description

This function converts an interface number to a network interface handle.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Parameters

Parameters	Description
netIx	Interface index.

Function

TCPIP_NET_HANDLE TCPIP_STACK_IndexToNet(int netIx)

TCPIP_STACK_NetBIOSName Function

Network interface NetBIOS name.

File

tcpip_manager.h

C

```
const char* TCPIP_STACK_NetBIOSName(TCPIP_NET_HANDLE netH);
```

Returns

pointer to the NetBIOS name of that interface

Description

The function returns the network interface NetBIOS name.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("PIC32INT");
const char* biosName = TCPIP_STACK_NetBIOSName(netH);
```

Parameters

Parameters	Description
netH	Interface handle to get name of.

Function

const char* TCPIP_STACK_NetBIOSName(TCPIP_NET_HANDLE netH)

TCPIP_STACK_NetBiosNameSet Function

Sets network interface NetBIOS name.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_NetBiosNameSet(TCPIP_NET_HANDLE netH, const char* biosName);
```

Returns

- true - if the NetBIOS name of the interface is set
- false - if no such interface or interface is not enabled

Description

This function sets the network interface NetBIOS name.

Remarks

Exercise extreme caution when using these functions to change the settings of a running network interface. Changing these parameters at runtime can lead to unexpected behavior or loss of network connectivity. The preferred way to change the parameters for a running interface is to do so as part of the network configuration passed at the stack initialization.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("PIC32INT");
TCPIP_STACK_NetBiosNameSet(netH, myBiosName);
```

Parameters

Parameters	Description
netH	Interface handle to set name of.

Function

bool TCPIP_STACK_NetBiosNameSet(TCPIP_NET_HANDLE netH, const char* biosName);

TCPIP_STACK_NetDefaultGet Function

Default network interface handle.

File

tcpip_manager.h

C

```
TCPIP_NET_HANDLE TCPIP_STACK_NetDefaultGet();
```

Returns

The default network interface.

Description

The function returns the current default network interface in the TCP/IP stack. This is the interface on which packets will be transmitted when the internal routing algorithm cannot detect a match for an outgoing packet.

Remarks

This function is intended for multi-homed hosts, with the TCP/IP stack running multiple interfaces.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Function

TCPIP_NET_HANDLE TCPIP_STACK_NetDefaultGet(void)

TCPIP_STACK_NetDefaultSet Function

Sets the default network interface handle.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_NetDefaultSet(TCPIP_NET_HANDLE netH);
```

Returns

- true - if success
- false - if failed (the old interface does not change)

Description

The function sets the current default network interface in the TCP/IP stack.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Parameters

Parameters	Description
netH	Interface handle.

Function

bool TCPIP_STACK_NetDefaultSet(TCPIP_NET_HANDLE netH)

TCPIP_STACK_NetHandleGet Function

Network interface handle from a name.

File

tcpip_manager.h

C

```
TCPIP_NET_HANDLE TCPIP_STACK_NetHandleGet(const char* interface);
```

Returns

Network handle.

Description

This function resolves a network interface name to a handle.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Example

```
TCPIP_NET_HANDLE hNet = TCPIP_STACK_NetHandleGet("PIC32INT");
 or
TCPIP_NET_HANDLE hNet = TCPIP_STACK_NetHandleGet("eth0");
```

Parameters

Parameters	Description
interface	The names specified in TCPIP_NETWORK_CONFIG.

Function

TCPIP_NET_HANDLE TCPIP_STACK_NetHandleGet(const char* interface)

TCPIP_STACK_NetIndexGet Function

Network interface number from interface handle.

File

tcpip_manager.h

C

```
int TCPIP_STACK_NetIndexGet(TCPIP_NET_HANDLE hNet);
```

Returns

Index of this network handle in the stack. -1 if invalid.

Description

This function converts a network interface handle to an interface number.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Parameters

Parameters	Description
hNet	Interface handle.

Function

int TCPIP_STACK_NetIndexGet(TCPIP_NET_HANDLE hNet);

TCPIP_STACK_NetMask Function

Network interface IPv4 address mask.

File

tcpip_manager.h

C

```
uint32_t TCPIP_STACK_NetMask(TCPIP_NET_HANDLE netH);
```

Returns

- IPv4 address mask of that interface
- 0 if interface is disabled/non-existent

Description

The function returns the IPv4 address mask of the specified interface. If the interface is enabled then it returns the IP address mask of that interface.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("PIC32INT");
uint32_t subMask = TCPIP_STACK_NetMask(netH);
```

Parameters

Parameters	Description
netH	Interface handle to get mask of.

Function

uint32_t TCPIP_STACK_NetMask(TCPIP_NET_HANDLE netH)

TCPIP_STACK_NetNameGet Function

Network interface name from a handle.

File

tcpip_manager.h

C

```
const char* TCPIP_STACK_NetNameGet(TCPIP_NET_HANDLE netH);
```

Returns

It returns the name associated to that interface handle. Returns 0 if no such name.

Description

This function returns the name associated with the interface handle.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_IndexToNet(0);
const char* netName = TCPIP_STACK_NetNameGet(netH);
```

Parameters

Parameters	Description
netH	Interface handle to get the name of.

Function

const char* TCPIP_STACK_NetNameGet(TCPIP_NET_HANDLE netH)

TCPIP_STACK_NumberOfNetworksGet Function

Number of network interfaces in the stack.

File

tcpip_manager.h

C

```
int TCPIP_STACK_NumberOfNetworksGet();
```

Returns

Number of network interfaces.

Description

This function returns the number of interfaces currently active in the TCP/IP stack.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Function

int TCPIP_STACK_NumberOfNetworksGet(void)

TCPIP_STACK_EventsPendingGet Function

Returns the currently pending events.

File

tcpip_manager.h

C

```
TCPIP_EVENT TCPIP_STACK_EventsPendingGet(TCPIP_NET_HANDLE hNet);
```

Returns

The currently TCPIP pending events.

Description

This function returns the currently pending events Multiple events can be ORed together as they accumulate.

Remarks

This is the preferred method to get the current pending stack events.

Even with a notification handler in place it's better to use this function to get the current pending events

The returned value is just a momentary value. The pending events can change any time.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_EVENT currEvents = TCPIP_STACK_EventsPendingGet( hNet);
```

Parameters

Parameters	Description
hNet	network handle

Function

TCPIP_EVENT TCPIP_STACK_EventsPendingGet(TCPIP_NET_HANDLE hNet)

TCPIP_STACK_NetIsReady Function

Gets the network interface configuration status.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_NetIsReady(TCPIP_NET_HANDLE hNet);
```

Returns

- true - if interface exists, the corresponding MAC is linked and the interface is properly configured and ready for transfers
- false - if the interface does not exist or interface not ready

Description

This function returns the network interface configuration status.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Parameters

Parameters	Description
hNet	Interface handle.

Function

bool TCPIP_STACK_NetIsReady(TCPIP_NET_HANDLE hNet);

TCPIP_STACK_NetMACRegisterStatisticsGet Function

Get the MAC statistics register data.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_NetMACRegisterStatisticsGet(TCPIP_NET_HANDLE netH, TCPIP_MAC_STATISTICS_REG_ENTRY*
pRegEntries, int nEntries, int* pHwEntries);
```

Returns

- true - if the call succeeded
- false - if the call failed (the corresponding MAC does not implement hardware statistics counters).

Description

This function returns the hardware statistics register data of the MAC that is attached to the specified network interface.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_MAC_REG_STATISTICS regStatistics;
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("PIC32INT");
if(TCPIP_STACK_NetMACRegisterStatisticsGet(netH, &regStatistics))
```

```
{
    // display the hardware statistics registers for the internal PIC32 MAC attached to this interface
}
```

Parameters

Parameters	Description
netH	handle of the interface to use
pRegStatistics	pointer to a pRegEntries that will receive the current hardware statistics registers values. Can be 0, if only the number of supported hardware registers is requested
nEntries	provides the number of TCPIP_MAC_STATISTICS_REG_ENTRY structures present in pRegEntries Can be 0, if only the number of supported hardware registers is requested The register entries structures will be filled by the driver, up to the supported hardware registers.
pHwEntries	pointer to an address to store the number of the statistics registers that the hardware supports It is updated by the driver. Can be 0 if not needed

Function

bool TCPIP_STACK_NetMACRegisterStatisticsGet(TCPIP_NET_HANDLE netH,
TCPIP_MAC_STATISTICS_REG_ENTRY* pRegEntries, int nEntries, int* pHwEntries);

TCPIP_STACK_NetAliasNameGet Function

Network interface alias name from a handle.

File

tcpip_manager.h

C

```
int TCPIP_STACK_NetAliasNameGet(TCPIP_NET_HANDLE netH, char* nameBuffer, int buffSize);
```

Returns

It returns the number of characters of the interface alias name. Returns 0 if no such interface.

Description

This function returns the alias name associated with the interface handle.

Remarks

The aliases names are:

- "eth0", "eth1", etc. for Ethernet interfaces
- "wlan0", "wlan1", etc. for Wi-Fi interfaces

See the TCPIP_STACK_IF_NAME_ALIAS_ETH, TCPIP_STACK_IF_NAME_ALIAS_WLAN in tcpip.h for the aliases names.

Alias interface names are at most 8 characters long.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_IndexToNet(0);
char ifName[8];
TCPIP_STACK_NetAliasNameGet(netH, ifName, sizeof(ifName));
```

Parameters

Parameters	Description
netH	Interface handle name to obtain
nameBuffer	buffer to receive the name; could be 0 if only name size is needed
buffSize	size of the provided buffer

Function

int TCPIP_STACK_NetAliasNameGet(TCPIP_NET_HANDLE netH,
char* nameBuffer, int buffSize)

TCPIP_STACK_InitializeDataGet Function

Get the TCP/IP stack initialization data.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_InitializeDataGet(SYS_MODULE_OBJ object, TCPIP_STACK_INIT* pStackInit);
```

Returns

- true - if the stack is up and running and the stack init data has been copied
- false - if the stack is down or an error has occurred

Description

This function returns the data that was used for the last call to the TCPIP_STACK_Initialize().

Remarks

The stack does not make a persistent copy of the TCPIP_NETWORK_CONFIG and TCPIP_STACK_MODULE_CONFIG data that are passed in the TCPIP_STACK_INIT at the moment of the stack initialization! It is up to the application to insure that the initialization data is still available after the TCPIP_STACK_Initialize() has been called if this API is used.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Example

```
TCPIP_STACK_INIT initData;
TCPIP_STACK_InitializeDataGet(tcpipObject, &initData);
```

Parameters

Parameters	Description
object	Object handle, returned from TCPIP_STACK_Initialize call
pStackInit	Pointer to an address to store the stack initialization data

Function

bool TCPIP_STACK_InitializeDataGet(SYS_MODULE_OBJ object,
TCPIP_STACK_INIT* pStackInit)

d) Network Up/Down/Linked Functions

TCPIP_STACK_NetIsLinked Function

Gets the network interface link status.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_NetIsLinked(TCPIP_NET_HANDLE hNet);
```

Returns

- true - if interface exists and the corresponding MAC is linked
- false - if the interface does not exist or the link is down

Description

This function returns the network interface link status.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Parameters

Parameters	Description
hNet	Interface handle.

Function

bool TCPIP_STACK_NetIsLinked(TCPIP_NET_HANDLE hNet);

TCPIP_STACK_NetIsUp Function

Gets the network interface up or down status.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_NetIsUp(TCPIP_NET_HANDLE hNet);
```

Returns

- true - if interface exists and is enabled
- false - if the interface does not exist or is disabled

Description

This function returns the network interface up or down (enabled) status.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Parameters

Parameters	Description
hNet	Interface handle.

Function

bool TCPIP_STACK_NetIsUp(TCPIP_NET_HANDLE hNet);

TCPIP_STACK_NetUp Function

Turns up a network interface. As part of this process, the corresponding MAC driver is initialized.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_NetUp(TCPIP_NET_HANDLE netH, const TCPIP_NETWORK_CONFIG* pUsrConfig);
```

Returns

- true - if success
- false - if no such network or an error occurred

Description

This function brings a network interface up and perform its initialization.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Parameters

Parameters	Description
netH	Interface handle.
pUsrConfig	pointer to a TCPIP_NETWORK_CONFIG for the interface initialization

Function

bool TCPIP_STACK_NetUp(TCPIP_NET_HANDLE netH, const TCPIP_NETWORK_CONFIG*
pUsrConfig)

TCPIP_STACK_NetDown Function

Turns down a network interface.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_NetDown(TCPIP_NET_HANDLE netH);
```

Returns

- true - if success
- false - if no such network interface or the interface is already down

Description

This function performs the deinitialization of a net interface. As part of this process, the corresponding MAC driver is deinitialized.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Parameters

Parameters	Description
netH	Interface handle.

Function

bool TCPIP_STACK_NetDown(TCPIP_NET_HANDLE netH)

e) Network Address Status and Control Functions

TCPIP_STACK_NetAddress Function

Network interface IPv4 address.

File

tcpip_manager.h

C

```
uint32_t TCPIP_STACK_NetAddress(TCPIP_NET_HANDLE netH);
```

Returns

If interface is enabled, it returns the IP address of that interface; otherwise 0 is returned.

Description

If interface is enabled then the function will return the IPv4 address of the network interface.

Remarks

None

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("eth0");
uint32_t ipAdd = TCPIP_STACK_NetAddress(netH);
```

Parameters

Parameters	Description
netH	Interface handle to get address of.

Function

uint32_t TCPIP_STACK_NetAddress(TCPIP_NET_HANDLE netH)

TCPIP_STACK_NetAddressBcast Function

Network interface broadcast address.

File

tcpip_manager.h

C

```
uint32_t TCPIP_STACK_NetAddressBcast(TCPIP_NET_HANDLE netH);
```

Returns

- Broadcast IP address of that interface
- 0 if no such interface

Description

The function returns the network interface broadcast address. The interface should be enabled for this function to work.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Parameters

Parameters	Description
netH	Interface handle to get address of.

Function

uint32_t TCPIP_STACK_NetAddressBcast(TCPIP_NET_HANDLE netH)

TCPIP_STACK_NetAddressDnsPrimary Function

Network interface DNS address.

File

tcpip_manager.h

C

```
uint32_t TCPIP_STACK_NetAddressDnsPrimary(TCPIP_NET_HANDLE netH);
```

Returns

- IPv4 address of the primary DNS server
- 0 if no such interface or interface is down

Description

If interface is enabled then the function will return the IPv4 address of the primary DNS of the network interface.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("PIC32INT");
myIPAddress = TCPIP_STACK_NetAddressDnsPrimary(netH);
```

Parameters

Parameters	Description
netH	Interface handle to get the DNS address of.

Function

uint32_t TCPIP_STACK_NetAddressDnsPrimary(TCPIP_NET_HANDLE netH)

TCPIP_STACK_NetAddressDnsPrimarySet Function

Sets network interface IPv4 DNS address.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_NetAddressDnsPrimarySet(TCPIP_NET_HANDLE netH, IPV4_ADDR* ipAddress);
```

Returns

- true - if success
- false - if no such interface or interface is not enabled

Description

This function sets the network interface primary IPv4 DNS address.

Remarks

Exercise extreme caution when using these functions to change the settings of a running network interface. Changing these parameters at runtime can lead to unexpected behavior or loss of network connectivity. The preferred way to change the parameters for a running interface is to do so as part of the network configuration passed at the stack initialization.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The

network interface should be up and running.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("PIC32INT");
TCPIP_STACK_NetAddressDnsPrimarySet(netH, &myIPAddress);
```

Parameters

Parameters	Description
netH	Interface handle to set the DNS address of.
ipAddress	IP address to set

Function

bool TCPIP_STACK_NetAddressDnsPrimarySet(TCPIP_NET_HANDLE netH, IPV4_ADDR* ipAddress)

TCPIP_STACK_NetAddressDnsSecond Function

Network interface secondary DNS address.

File

tcpip_manager.h

C

```
uint32_t TCPIP_STACK_NetAddressDnsSecond(TCPIP_NET_HANDLE netH);
```

Returns

- The secondary DNS address if success.
- 0 if no such interface or interface is down

Description

If interface is enabled then the function will return the IPv4 address of the secondary DNS of the network interface.

Remarks

None

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("PIC32INT");
myIPAddress = TCPIP_STACK_NetAddressDnsSecond(netH);
```

Parameters

Parameters	Description
netH	Interface handle to get the DNS address of.

Function

uint32_t TCPIP_STACK_NetAddressDnsSecond(TCPIP_NET_HANDLE netH)

TCPIP_STACK_NetAddressDnsSecondSet Function

Sets network interface IPv4 secondary DNS address.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_NetAddressDnsSecondSet(TCPIP_NET_HANDLE netH, IPV4_ADDR* ipAddress);
```

Returns

- true - if success
- false - if no such interface or interface is not enabled

Description

This function sets the network interface secondary IPv4 DNS address.

Remarks

Exercise extreme caution when using these functions to change the settings of a running network interface. Changing these parameters at runtime can lead to unexpected behavior or loss of network connectivity. The preferred way to change the parameters for a running interface is to do so as part of the network configuration passed at the stack initialization.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("PIC32INT");
TCPIP_STACK_NetAddressDnsSecondSet(netH, &myIPAddress);
```

Parameters

Parameters	Description
netH	Interface handle to set the secondary DNS address of.
ipAddress	IP address to set

Function

bool TCPIP_STACK_NetAddressDnsSecondSet(TCPIP_NET_HANDLE netH, IPV4_ADDR* ipAddress)

TCPIP_STACK_NetAddressGateway Function

Network interface IPv4 gateway address.

File

tcpip_manager.h

C

```
uint32_t TCPIP_STACK_NetAddressGateway(TCPIP_NET_HANDLE netH);
```

Returns

If interface is enabled then it returns the gateway address of that interface. Otherwise, 0 is returned.

Description

If interface is enabled then the function will return the IPv4 gateway address of the network interface.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("eth0");
uint32_t ipAdd = TCPIP_STACK_NetAddressGateway(netH);
```

Parameters

Parameters	Description
netH	Interface handle to get address of.

Function

uint32_t TCPIP_STACK_NetAddressGateway(TCPIP_NET_HANDLE netH)

TCPIP_STACK_NetAddressGatewaySet Function

Sets network interface IPv4 gateway address.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_NetAddressGatewaySet(TCPIP_NET_HANDLE netH, IPV4_ADDR* ipAddress);
```

Returns

- true - if success
- false - if no such interface or interface is not enabled

Description

This function sets the network interface IPv4 gateway address.

Remarks

Exercise extreme caution when using these functions to change the settings of a running network interface. Changing these parameters at runtime can lead to unexpected behavior or loss of network connectivity. The preferred way to change the parameters for a running interface is to do so as part of the network configuration passed at the stack initialization.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("PIC32INT");
TCPIP_STACK_NetAddressGatewaySet(netH, &myIPAddress);
```

Parameters

Parameters	Description
netH	Interface handle to set the gateway address of.
ipAddress	IP address to set

Function

bool TCPIP_STACK_NetAddressGatewaySet(TCPIP_NET_HANDLE netH, IPV4_ADDR* ipAddress)

TCPIP_STACK_NetAddressMac Function

Network interface MAC address.

File

tcpip_manager.h

C

```
const uint8_t* TCPIP_STACK_NetAddressMac(TCPIP_NET_HANDLE netH);
```

Returns

- Constant pointer to the MAC address
- 0 if no such interface

Description

The function returns the network interface physical (MAC) address. The interface should be enabled for this function to work.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("PIC32INT");
const TCPIP_MAC_ADDR* pAdd = TCPIP_STACK_NetAddressMac(netH);
```

Parameters

Parameters	Description
netH	Interface handle to get the address of.

Function

const uint8_t* TCPIP_STACK_NetAddressMac(TCPIP_NET_HANDLE netH)

TCPIP_STACK_NetAddressMacSet Function

Sets network interface MAC address.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_NetAddressMacSet(TCPIP_NET_HANDLE netH, const TCPIP_MAC_ADDR* pAddr);
```

Returns

- true - if the MAC address of the interface is set
- false - if no such interface or interface is not enabled

Description

This function sets the network interface physical MAC address.

Remarks

One should use extreme caution when using these functions to change the settings of a running network interface. Changing these parameters at runtime can lead to unexpected behavior or loss of network connectivity. The preferred way to change the parameters for a running interface is to do so as part of the network configuration passed at the stack initialization.

This function updates the MAC address in the stack data structures. It does not re-program the MAC with the new address. The MAC programming is done only at MAC initialization for now.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("PIC32INT");
TCPIP_STACK_NetAddressMacSet(netH, &myMacAddress);
```

Parameters

Parameters	Description
netH	Interface handle to set the address of.
pAddr	pointer to a valid physical (MAC) address.

Function

bool TCPIP_STACK_NetAddressMacSet(TCPIP_NET_HANDLE netH, const TCPIP_MAC_ADDR* pAddr)

TCPIP_STACK_NetAddressSet Function

Sets network interface IPv4 address.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_NetAddressSet(TCPIP_NET_HANDLE netH, IPV4_ADDR* ipAddress, IPV4_ADDR* mask, bool
setDefault);
```

Returns

- true - if success
- false - if no such interface or interface is not enabled

Description

This function sets the associated network IP address and/or mask. If you're changing the network then it's preferred that you set both these values simultaneously to avoid having the stack running with a mismatch between its IP address and mask.

Remarks

Exercise extreme caution when using these functions to change the settings of a running network interface. Changing these parameters at runtime can lead to unexpected behavior or loss of network connectivity. The preferred way to change the parameters for a running interface is to do so as part of the network configuration passed at the stack initialization.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("PIC32INT");
TCPIP_STACK_NetAddressSet(netH, &myIPAddress, &myIPMask, false);
```

Parameters

Parameters	Description
netH	Interface handle to set address of.
ipAddress	IP address to set (could be NULL to set only the mask)
mask	corresponding network mask to set (could be NULL to set only the IP address)
setDefault	if true, the interface default address/mask is also set

Function

bool TCPIP_STACK_NetAddressSet(TCPIP_NET_HANDLE netH, IPV4_ADDR* ipAddress,
IPV4_ADDR* mask, bool setDefault)

TCPIP_STACK_NetIPv6AddressGet Function

Gets network interface IPv6 address.

File

tcpip_manager.h

C

```
IPV6_ADDR_HANDLE TCPIP_STACK_NetIPv6AddressGet(TCPIP_NET_HANDLE netH, IPV6_ADDR_TYPE addType,
IPV6_ADDR_STRUCT* pAddStruct, IPV6_ADDR_HANDLE addHandle);
```

Returns

- Non-NULL IPV6_ADDR_HANDLE - if an valid IPv6 address was found and the pAddStruct structure was filled with data
- 0 - if no other IPv6 exists or if the supplied IPV6_ADDR_HANDLE is invalid

Description

This function allows the listing of the IPv6 addresses associated with an interface.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
IPV6_ADDR_STRUCT currAddr;
IPV6_ADDR_HANDLE currHandle;
TCPIP_NET_HANDLE hNet = TCPIP_STACK_NetHandleGet("PIC32INT");
char    ipv6AddBuff[44];

currHandle = 0;
do
{
     currHandle = TCPIP_STACK_NetIPv6AddressGet(netH, IPV6_ADDR_TYPE_UNICAST, &currAddr, currHandle);
     if(currHandle)
     {   // have a valid address; display it
         TCPIP_HELPER_IPv6AddressToString(&currAddr.address, ipv6AddBuff, sizeof(ipv6AddBuff));
     }
}while(currHandle != 0);
```

Parameters

Parameters	Description
netH	handle of the interface to retrieve the addresses for
addType	type of address to request IPV6_ADDR_TYPE_UNICAST and IPV6_ADDR_TYPE_MULTICAST supported for now
pAddStruct	structure provided by the user that will be filled with corresponding IPV6_ADDR_STRUCT data
addHandle	an address handle that allows iteration across multiple IPv6 addresses.
On the first call	has to be 0; it will begin the listing of the IPv6 addresses
On subsequent calls	has to be a handle previously returned by a call to this function

Function

IPV6_ADDR_HANDLE TCPIP_STACK_NetIPv6AddressGet(TCPIP_NET_HANDLE netH,

IPV6_ADDR_TYPE addType, IPV6_ADDR_STRUCT* pAddStruct, IPV6_ADDR_HANDLE addHandle);

TCPIP_STACK_ModuleConfigGet Function

Get stack module configuration data.

File

tcpip_manager.h

C

```
size_t TCPIP_STACK_ModuleConfigGet(TCPIP_STACK_MODULE modId, void* configBuff, size_t buffSize, size_t*
pNeededSize);
```

Returns

The number of bytes copied to the user buffer:

- -1 - if the module ID is invalid
- 0 - if the configBuff is NULL or buffSize is less than required
- > 0 - if the call succeeded and the configuration was copied

Description

This function returns the current configuration data of the stack module specified by the corresponding module ID.

Remarks

Currently, only the MAC modules implement this function.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Example

```
uint8_t configBuffer[200];
size_t configSize;
size_t copiedSize;
copiedSize = TCPIP_STACK_ModuleConfigGet(TCPIP_MODULE_MAC_MRF24W, configBuffer,
                                         sizeof(configBuffer), &configSize);
```

Parameters

Parameters	Description
modId	the ID that identifies the requested module
configBuff	pointer to a buffer that will receive the configuration data If this pointer is 0, just the pNeededSize will be updated
buffSize	size of the provided buffer
pNeededSize	pointer to an address to store the number of bytes needed to store this module configuration data. Can be NULL if not needed.

Function

size_t TCPIP_STACK_ModuleConfigGet(TCPIP_STACK_MODULE modId, void* configBuff,

size_t buffSize, size_t* pNeededSize)

TCPIP_STACK_NetMACIdGet Function

Get the MAC ID of the network interface.

File

tcpip_manager.h

C

```
TCPIP_STACK_MODULE TCPIP_STACK_NetMACIdGet(TCPIP_NET_HANDLE netH);
```

Returns

A TCPIP_STACK_MODULE ID that belongs to the MAC of that network interface.

Description

This function returns the module ID of the MAC that's attached to the specified network interface.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("PIC32INT");
TCPIP_STACK_MODULE modId = TCPIP_STACK_NetMACIdGet(netH);
if(modId == TCPIP_MODULE_MAC_PIC32INT)
{
     // an internal PIC32 MAC attached to this interface
}
```

Parameters

Parameters	Description
netH	handle of the interface to use

Function

TCPIP_STACK_MODULE TCPIP_STACK_NetMACIdGet(TCPIP_NET_HANDLE netH)

TCPIP_STACK_NetMACStatisticsGet Function

Get the MAC statistics data.

File

tcpip_manager.h

C

```
bool TCPIP_STACK_NetMACStatisticsGet(TCPIP_NET_HANDLE netH, TCPIP_MAC_RX_STATISTICS* pRxStatistics,
TCPIP_MAC_TX_STATISTICS* pTxStatistics);
```

Returns

- true - if the call succeeded
- false - if the call failed (the corresponding MAC does not implement statistics counters)

Description

This function returns the statistics data of the MAC that's attached to the specified network interface.

Remarks

None.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY. The network interface should be up and running.

Example

```
TCPIP_MAC_RX_STATISTICS rxStatistics;
TCPIP_MAC_TX_STATISTICS txStatistics;
TCPIP_NET_HANDLE netH = TCPIP_STACK_NetHandleGet("PIC32INT");
if(TCPIP_STACK_NetMACStatisticsGet(netH, &rxStatistics, &txStatistics))
{
     // display the statistics for the internal PIC32 MAC attached to this interface
}
```

Parameters

Parameters	Description
netH	handle of the interface to use
pRxStatistics	pointer to a TCPIP_MAC_RX_STATISTICS that will receive the current RX statistics counters. Can be NULL if not needed.
pTxStatistics	pointer to a TCPIP_MAC_TX_STATISTICS that will receive the current TX statistics counters. Can be NULL if not needed.

Function

bool TCPIP_STACK_NetMACStatisticsGet(TCPIP_NET_HANDLE netH,
TCPIP_MAC_RX_STATISTICS* pRxStatistics, TCPIP_MAC_TX_STATISTICS* pTxStatistics)

TCPIP_STACK_Status Function

Provides the current status of the TCPIP stack module.

File

tcpip_manager.h

C

```
SYS_STATUS TCPIP_STACK_Status(SYS_MODULE_OBJ object);
```

Returns

- SYS_STATUS_READY - Indicates that any previous initialization operation for the stack has completed
- SYS_STATUS_BUSY - Indicates that a previous initialization operation for the stack has not yet completed

- SYS_STATUS_ERROR - Indicates that the initialization operation has failed and the stack is in an error state

Description

This function provides the current status of the TCPIP stack module.

Remarks

After calling TCPIP_STACK_Initialize, the stack will contiue its initialization process in the TCPIP_STACK_Task routine. This that may take some time. The stack is ready to use only when the TCPIP_STACK_Status returned SYS_STATUS_READY.

Preconditions

The TCPIP_STACK_Initialize function must have been called before calling this function.

Parameters

Parameters	Description
object	Object handle, returned from TCPIP_STACK_Initialize

Function

SYS_STATUS TCPIP_STACK_Status (SYS_MODULE_OBJ object)

f) Network Structure Storage Functions

TCPIP_STACK_NetConfigGet Function

Get stack network interface configuration data.

File

tcpip_manager.h

C

```
size_t TCPIP_STACK_NetConfigGet(TCPIP_NET_HANDLE netH, void* configStoreBuff, size_t configStoreSize,
size_t* pNeededSize);
```

Returns

- -1 - if the interface is invalid or the stack is not initialized
- 0 - if no data is copied (no supplied buffer of buffer too small)
- > 0 - for success, indicating the amount of data copied.

Description

This function dumps the current configuration data of the network interface specified by the corresponding network handle into the supplied buffer.

Remarks

The function is a helper for retrieving the network configuration data. Its companion function, TCPIP_STACK_NetConfigSet, restores the TCPIP_NETWORK_CONFIG from the dump buffer.

Currently, the data is saved in plain binary format into the supplied buffer. However, the application must not make use of this assumption as it may change in a future release (some compression scheme may be implemented).

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Example

```
uint8_t currConfig[100];
size_t neededSize, result;
TCPIP_NET_HANDLE hNet = TCPIP_STACK_NetHandleGet("PIC32INT");
result = TCPIP_STACK_NetConfigGet(hNet, currConfig, sizeof(currConfig), &neededSize);
if(result > 0)
{
     // store the currConfig to some external storage
}
```

Parameters

Parameters	Description
netH	the handle that identifies the requested interface
configStoreBuff	pointer to a buffer that will receive the current configuration data. All the data that's needed to restore a TCPIP_NETWORK_CONFIG structure is stored in this buffer. Can be NULL if only the storage size is needed.
configStoreSize	size of the supplied buffer
pNeededSize	pointer to store the size needed for storage; Can be NULL if not needed

Function

size_t TCPIP_STACK_NetConfigGet(TCPIP_NET_HANDLE netH, void* configStoreBuff,

size_t configStoreSize, size_t* pNeededSize)

TCPIP_STACK_NetConfigSet Function

Restores stack network interface configuration data.

File

tcpip_manager.h

C

```
TCPIP_NETWORK_CONFIG* TCPIP_STACK_NetConfigSet(void* configStoreBuff, void* netConfigBuff, size_t buffSize,
size_t* pNeededSize);
```

Returns

- valid TCPIP_NETWORK_CONFIG pointer (netConfigBuff) if netConfigBuff was successfully updated
- 0 if the netConfigBuff is not supplied or is not large enough

Description

This function restores data from a previously dump buffer and updates the supplied interface configuration. All the data is recovered and constructed into the netConfigBuff (supposing this buffer is large enough). If this operation succeeded, the netConfigBuff can be safely cast to a (TCPIP_NETWORK_CONFIG*).

The structure of the netConfigBuff is as follows:

- A TCPIP_NETWORK_CONFIG structure is created at the very beginning of the buffer.
- All of the necessary fields that are part of the TCPIP_NETWORK_CONFIG will be placed in the buffer itself.

Remarks

The function is a helper for being able to restore the configuration data. Its companion function, TCPIP_STACK_NetConfigGet, saves the TCPIP_NETWORK_CONFIG to a dump buffer.

Preconditions

The TCP/IP stack should have been initialized by TCPIP_STACK_Initialize and the TCPIP_STACK_Status returned SYS_STATUS_READY.

Example

```
uint8_t currConfig[100];
uint8_t restoreBuff[100];
size_t neededSize, result;
TCPIP_NET_HANDLE hNet = TCPIP_STACK_NetHandleGet("PIC32INT");
result = TCPIP_STACK_NetConfigGet(hNet, currConfig, sizeof(currConfig), &neededSize);
if(result > 0)
{
     // store the currConfig buffer to some external storage (neededSize bytes needed)

     // later on restore the configuration
     TCPIP_NETWORK_CONFIG* netConfig;
     // extract the network configuration from the previously saved buffer
     netConfig = TCPIP_STACK_NetConfigSet(currConfig, restoreBuff, sizeof(restoreBuff), neededSize);
     if(netConfig)
     {
         // use this netConfig to initialize a network interface
         TCPIP_STACK_NetUp(hNet, netConfig);
```

```
        }
    }
```

Parameters

Parameters	Description
configStoreBuff	pointer to a buffer that received configuration data from a TCPIP_STACK_NetConfigGet call.
netConfigBuff	pointer to a buffer that will receive the TCPIP_NETWORK_CONFIG data
buffSize	size of the supplied netConfigBuff buffer
pNeededSize	pointer to store the size needed for storage; can be NULL if not needed. If supplied, the pNeededSize will be updated with the actual size that's needed for the netConfigBuff.

Function

TCPIP_NETWORK_CONFIG* TCPIP_STACK_NetConfigSet(void* configStoreBuff, void* netConfigBuff, size_t buffSize, size_t* pNeededSize);

g) Data Types and Constants

TCPIP_LOCAL_MASK_TYPE Enumeration

Mask operation for local/non-local network interface.

File

tcpip_manager.h

C

```
typedef enum {
  TCPIP_LOCAL_MASK_ZERO,
  TCPIP_LOCAL_MASK_ONE,
  TCPIP_LOCAL_MASK_NET,
  TCPIP_LOCAL_MASK_SET
} TCPIP_LOCAL_MASK_TYPE;
```

Members

Members	Description
TCPIP_LOCAL_MASK_ZERO	use an all zero network mask
TCPIP_LOCAL_MASK_ONE	use an all ones network mask
TCPIP_LOCAL_MASK_NET	use the current network mask
TCPIP_LOCAL_MASK_SET	use the set value for the network mask

Description

Enumeration: TCPIP_LOCAL_MASK_TYPE

These are the available operations that set the local/non-local detection network mask.

TCPIP_NET_HANDLE Type

Defines a network interface handle.

File

tcpip_manager.h

C

```
typedef const void* TCPIP_NET_HANDLE;
```

Description

Type: TCPIP_NET_HANDLE

Definition of the network handle which clients use to get access to control the interfaces.

TCPIP_EVENT Enumeration

Defines the possible TCPIP event types.

File

tcpip_manager.h

C

```
typedef enum {
  TCPIP_EV_NONE = 0x0000,
  TCPIP_EV_RX_PKTPEND = 0x0001,
  TCPIP_EV_RX_OVFLOW = 0x0002,
  TCPIP_EV_RX_BUFNA = 0x0004,
  TCPIP_EV_RX_ACT = 0x0008,
  TCPIP_EV_RX_DONE = 0x0010,
  TCPIP_EV_RX_FWMARK = 0x0020,
  TCPIP_EV_RX_EWMARK = 0x0040,
  TCPIP_EV_RX_BUSERR = 0x0080,
  TCPIP_EV_TX_DONE = 0x0100,
  TCPIP_EV_TX_ABORT = 0x0200,
  TCPIP_EV_TX_BUSERR = 0x0400,
  TCPIP_EV_CONN_ESTABLISHED = 0x0800,
  TCPIP_EV_CONN_LOST = 0x1000,
  TCPIP_EV_RX_ALL = (TCPIP_EV_RX_PKTPEND|TCPIP_EV_RX_OVFLOW|TCPIP_EV_RX_BUFNA|TCPIP_EV_RX_ACT|
TCPIP_EV_RX_DONE|TCPIP_EV_RX_FWMARK|TCPIP_EV_RX_EWMARK|TCPIP_EV_RX_BUSERR),
  TCPIP_EV_TX_ALL = (TCPIP_EV_TX_DONE|TCPIP_EV_TX_ABORT|TCPIP_EV_TX_BUSERR),
  TCPIP_EV_RXTX_ERRORS = (TCPIP_EV_RX_OVFLOW|TCPIP_EV_RX_BUFNA|TCPIP_EV_RX_BUSERR|
TCPIP_EV_TX_ABORT|TCPIP_EV_TX_BUSERR),
  TCPIP_EV_CONN_ALL = (TCPIP_EV_CONN_ESTABLISHED|TCPIP_EV_CONN_LOST)
} TCPIP_EVENT;
```

Members

Members	Description
TCPIP_EV_NONE = 0x0000	no event
TCPIP_EV_RX_PKTPEND = 0x0001	A receive packet is pending
TCPIP_EV_RX_OVFLOW = 0x0002	RX FIFO overflow (system level latency, no descriptors, etc.)
TCPIP_EV_RX_BUFNA = 0x0004	no RX descriptor available to receive a new packet
TCPIP_EV_RX_ACT = 0x0008	There's RX data available
TCPIP_EV_RX_DONE = 0x0010	A packet was successfully received
TCPIP_EV_RX_FWMARK = 0x0020	the number of received packets is >= than the RX Full Watermark
TCPIP_EV_RX_EWMARK = 0x0040	the number of received packets is <= than the RX Empty Watermark
TCPIP_EV_RX_BUSERR = 0x0080	a bus error encountered during an RX transfer
TCPIP_EV_TX_DONE = 0x0100	A packet was transmitted and it's status is available
TCPIP_EV_TX_ABORT = 0x0200	a TX packet was aborted by the MAC (jumbo/system under-run/excessive defer/late collision/excessive collisions)
TCPIP_EV_TX_BUSERR = 0x0400	a bus error encountered during a TX transfer
TCPIP_EV_CONN_ESTABLISHED = 0x0800	Connection Established
TCPIP_EV_CONN_LOST = 0x1000	Connection Lost
TCPIP_EV_RX_ALL = (TCPIP_EV_RX_PKTPEND|TCPIP_EV_RX_OVFLOW|TCPIP_EV_RX_BUFNA|TCPIP_EV_RX_ACT| TCPIP_EV_RX_DONE|TCPIP_EV_RX_FWMARK|TCPIP_EV_RX_EWMARK|TCPIP_EV_RX_BUSERR)	Mask of all RX related events
TCPIP_EV_TX_ALL = (TCPIP_EV_TX_DONE|TCPIP_EV_TX_ABORT|TCPIP_EV_TX_BUSERR)	Mask of all TX related events
TCPIP_EV_RXTX_ERRORS = (TCPIP_EV_RX_OVFLOW|TCPIP_EV_RX_BUFNA|TCPIP_EV_RX_BUSERR| TCPIP_EV_TX_ABORT|TCPIP_EV_TX_BUSERR)	All events showing some abnormal traffic/system condition Action should be taken accordingly by the stack (or the stack user)
TCPIP_EV_CONN_ALL = (TCPIP_EV_CONN_ESTABLISHED|TCPIP_EV_CONN_LOST)	Mask of all Connection related events

Description

TCPIP Stack Events Codes

This enumeration defines all the possible events that can be reported by the TCPIP stack. These are events received by the stack from the network interfaces. They are reported by the MAC driver of the network interface.

Remarks

Depending on the type of the hardware interface, not all events are possible.

Note that specific interfaces can offer specific events and functions to retrieve those events.

TCPIP_EVENT_HANDLE Type

Defines a TCPIP stack event handle.

File

tcpip_manager.h

C

```
typedef const void* TCPIP_EVENT_HANDLE;
```

Description

Type: TCPIP_EVENT_HANDLE

Definition of an event handle used for event registration by the stack clients.

TCPIP_STACK_EVENT_HANDLER Type

Pointer to a function(handler) that will get called to process an event.

File

tcpip_manager.h

C

```
typedef void (* TCPIP_STACK_EVENT_HANDLER)(TCPIP_NET_HANDLE hNet, TCPIP_EVENT, const void* fParam);
```

Returns

None.

Description

TCPIP event notification handler Pointer

Pointer to a function that may be called from within an ISR when a TCP/IP event is available.

Remarks

This function may be invoked from within an ISR. It should be kept as short as possible and it should not include blocking or polling code.

Preconditions

None

Parameters

Parameters	Description
hNet	network handle
tcpEvent	ORed mask of events that occurred
fParam	user passed parameter

Function

void* (TCPIP_NET_HANDLE hNet, TCPIP_EVENT tcpEvent, void* fParam)

TCPIP_Helper_ntohl Macro

File

tcpip_helpers.h

C

```
#define TCPIP_Helper_ntohl(n) TCPIP_Helper_htonl(n)
```

Description

This is macro TCPIP_Helper_ntohl.

TCPIP_Helper_ntohs Macro

File

tcpip_helpers.h

C

```
#define TCPIP_Helper_ntohs(n) TCPIP_Helper_htons(n)
```

Description

This is macro TCPIP_Helper_ntohs.

TCPIP_STACK_IF_NAME_ALIAS_ETH Macro

File

tcpip.h

C

```
#define TCPIP_STACK_IF_NAME_ALIAS_ETH "eth"
```

Description

alias for Ethernet interface

TCPIP_STACK_IF_NAME_ALIAS_UNK Macro

File

tcpip.h

C

```
#define TCPIP_STACK_IF_NAME_ALIAS_UNK "unk"
```

Description

alias for unknown interface

TCPIP_STACK_IF_NAME_ALIAS_WLAN Macro

File

tcpip.h

C

```
#define TCPIP_STACK_IF_NAME_ALIAS_WLAN "wlan"
```

Description

alias for Wi-Fi interface

IP_ADDR Type

Backward compatible definition to represent an IPv4 address.

File

tcpip.h

C

```
typedef IPV4_ADDR IP_ADDR;
```

Description

IPv4 Address backward compatible type

This type describes the backward compatible IPv4 address type.

Remarks

None.

IP_ADDRESS_TYPE Enumeration

Definition of the TCP/IP supported address types.

File

tcpip.h

C

```
typedef enum {
  IP_ADDRESS_TYPE_ANY,
  IP_ADDRESS_TYPE_IPV4,
  IP_ADDRESS_TYPE_IPV6
} IP_ADDRESS_TYPE;
```

Members

Members	Description
IP_ADDRESS_TYPE_ANY	either IPv4 or IPv6, unspecified;
IP_ADDRESS_TYPE_IPV4	IPv4 address type
IP_ADDRESS_TYPE_IPV6	IPv6 address type

Description

TCP/IP IP Address type

This type describes the supported IP address types.

Remarks

None.

IP_MULTI_ADDRESS Union

Definition to represent multiple IP addresses.

File

tcpip.h

C

```
typedef union {
  IPV4_ADDR v4Add;
  IPV6_ADDR v6Add;
} IP_MULTI_ADDRESS;
```

Description

TCP/IP multiple Address type

This type describes the TCP/IP multiple address type.

Remarks

None.

IPV4_ADDR Union

Definition to represent an IPv4 address

File

tcpip.h

C

```
typedef union {
  uint32_t Val;
  uint16_t w[2];
  uint8_t v[4];
} IPV4_ADDR;
```

Description

IPv4 Address type

This type describes the IPv4 address type.

Remarks

None.

IPV6_ADDR Union

Definition to represent an IPv6 address.

File

tcpip.h

C

```
typedef union {
  uint8_t v[16];
  uint16_t w[8];
  uint32_t d[4];
} IPV6_ADDR;
```

Description

IPv6 Address type

This type describes the IPv6 address type.

Remarks

None.

IPV6_ADDR_HANDLE Type

Definition to represent an IPv6 address.

File

tcpip.h

C

```
typedef const void* IPV6_ADDR_HANDLE;
```

Description

IPv6 Address handle

This type describes an IPv6 address handle.

Remarks

None.

IPV6_ADDR_SCOPE Enumeration

Definition to represent the scope of an IPv6 address.

File

tcpip.h

C

```
typedef enum {
  IPV6_ADDR_SCOPE_UNKNOWN,
  IPV6_ADDR_SCOPE_INTERFACE_LOCAL,
  IPV6_ADDR_SCOPE_LINK_LOCAL,
  IPV6_ADDR_SCOPE_ADMIN_LOCAL,
  IPV6_ADDR_SCOPE_SITE_LOCAL,
  IPV6_ADDR_SCOPE_ORG_LOCAL,
  IPV6_ADDR_SCOPE_GLOBAL
} IPV6_ADDR_SCOPE;
```

Description

IPv6 Address scope

This type describes the IPv6 address scope.

Remarks

None.

IPV6_ADDR_STRUCT Structure

COmplex type to represent an IPv6 address.

File

tcpip.h

C

```
typedef struct _IPV6_ADDR_STRUCT {
  struct _IPV6_ADDR_STRUCT * next;
  struct _IPV6_ADDR_STRUCT * prev;
  IPV6_ADDR address;
  unsigned long validLifetime;
  unsigned long preferredLifetime;
  unsigned long lastTickTime;
  unsigned char prefixLen;
  struct {
    unsigned char precedence;
    unsigned scope : 4;
    unsigned label : 4;
    unsigned type : 2;
    unsigned temporary : 1;
  } flags;
} IPV6_ADDR_STRUCT;
```

Members

Members	Description
unsigned char precedence;	Allow preferences
unsigned scope : 4;	Link-local, site-local, global.
unsigned label : 4;	Policy label
unsigned type : 2;	Uni-, Any-, Multi-cast
unsigned temporary : 1;	Indicates that the address is temporary (not public)

Description

IPv6 Address Structure

This type defines all the fields of an IPv6 address.

Remarks

None.

IPV6_ADDR_TYPE Enumeration

Definition to represent the type of an IPv6 address.

File

tcpip.h

C

```
typedef enum {
  IPV6_ADDR_TYPE_UNKNOWN,
  IPV6_ADDR_TYPE_UNICAST,
  IPV6_ADDR_TYPE_ANYCAST,
  IPV6_ADDR_TYPE_MULTICAST,
  IPV6_ADDR_TYPE_SOLICITED_NODE_MULTICAST,
  IPV6_ADDR_TYPE_UNICAST_TENTATIVE
} IPV6_ADDR_TYPE;
```

Members

Members	Description
IPV6_ADDR_TYPE_UNKNOWN	Invalid/unknown address type
IPV6_ADDR_TYPE_UNICAST	Only link-local and global are currently valid for unicast

Description

IPv6 Address type

This type describes the possible type of an IPv6 address.

Remarks

None.

TCPIP_NETWORK_CONFIG Structure

Defines the data required to initialize the network configuration.

File

tcpip.h

C

```
typedef struct {
  char* interface;
  char* hostName;
  char* macAddr;
  char* ipAddr;
  char* ipMask;
  char* gateway;
  char* priDNS;
  char* secondDNS;
  char* powerMode;
  TCPIP_NETWORK_CONFIG_FLAGS startFlags;
  const struct TCPIP_MAC_OBJECT_TYPE* pMacObject;
  char* ipv6Addr;
  int ipv6PrefixLen;
  char* ipv6Gateway;
} TCPIP_NETWORK_CONFIG;
```

Members

Members	Description
char* interface;	Pointer to the interface name; could be NULL.
char* hostName;	Valid Host name for this interface to use. Ex: "MCHPBOARD
char* macAddr;	MAC address to use for this interface. Use "00:04:a3:00:00:00" or 0 for the factory preprogrammed address
char* ipAddr;	Static IP address to use. Ex: "169.254.1.1
char* ipMask;	Netmask to use. Ex: "255.255.0.0
char* gateway;	Static Gateway to use. Ex: "169.254.1.1
char* priDNS;	Primary DNS to use. Ex: "169.254.1.1
char* secondDNS;	Secondary DNS to use. Use "0.0.0.0" for none
char* powerMode;	Power Mode to use. Use TCPIP_STACK_IF_POWER_NONE, TCPIP_STACK_IF_POWER_FULL, TCPIP_STACK_IF_POWER_LOW, or TCPIP_STACK_IF_POWER_DOWN
TCPIP_NETWORK_CONFIG_FLAGS startFlags;	flags for interface start-up

const struct TCPIP_MAC_OBJECT_TYPE* pMacObject;	Non-volatile pointer to the MAC driver object associated with this network interface This is the MAC driver that this interface will use
char* ipv6Addr;	static IPv6 address; only if TCPIP_NETWORK_CONFIG_IPV6_ADDRESS specified can be NULL if not needed
int ipv6PrefixLen;	subnet prefix length; only if TCPIP_NETWORK_CONFIG_IPV6_ADDRESS specified 0 means default value (64) should probably always be 64 as requested by the RFC
char* ipv6Gateway;	default IPv6 gateway address; only if TCPIP_NETWORK_CONFIG_IPV6_ADDRESS specified can be NULL if not needed

Description

Multi-Homed Hosts Network Addressing Configuration Data

This data type defines the data required to initialize the network configuration for a specific interface.

Remarks

None.

TCPIP_NETWORK_CONFIG_FLAGS Enumeration

Definition of network configuration start-up flags.

File

tcpip.h

C

```
typedef enum {
  TCPIP_NETWORK_CONFIG_IP_STATIC,
  TCPIP_NETWORK_CONFIG_DHCP_CLIENT_ON,
  TCPIP_NETWORK_CONFIG_ZCLL_ON,
  TCPIP_NETWORK_CONFIG_DHCP_SERVER_ON,
  TCPIP_NETWORK_CONFIG_DNS_CLIENT_ON,
  TCPIP_NETWORK_CONFIG_DNS_SERVER_ON,
  TCPIP_NETWORK_CONFIG_IPV6_ADDRESS
} TCPIP_NETWORK_CONFIG_FLAGS;
```

Members

Members	Description
TCPIP_NETWORK_CONFIG_IP_STATIC	Start the interface with a static IP address No address service is enabled on this interface (DHCPc, ZCLL or DHCPs)
TCPIP_NETWORK_CONFIG_DHCP_CLIENT_ON	DHCP client enabled on this interface
TCPIP_NETWORK_CONFIG_ZCLL_ON	ZeroConf LinkLocal enabled on this interface
TCPIP_NETWORK_CONFIG_DHCP_SERVER_ON	DHCP server enabled on this interface
TCPIP_NETWORK_CONFIG_DNS_CLIENT_ON	DNS CLIENT enabled on this interface
TCPIP_NETWORK_CONFIG_DNS_SERVER_ON	DNS Server Enabled on this Interface
TCPIP_NETWORK_CONFIG_IPV6_ADDRESS	the network configuration contains an IPv6 static address and subnet prefix length

Description

Network Configuration start-up flags

This enumerated type describes the list of the supported TCP/IP network configuration start-up flags.

Remarks

DHCPc, DHCPs and ZCLL are conflicting and cannot be more than one enabled on the same interface! The order of priorities is: DHCPc, ZCLL, DHCPs in case of conflict

Only one of either DNS server or client can be enabled per interface.

Valid values are 0x0001 - 0x8000; 16 bits are maintained only.

TCPIP_STACK_INIT Structure

Definition to represent the TCP/IP stack initialization/configuration structure.

File

tcpip.h

C

```
typedef struct {
  SYS_MODULE_INIT moduleInit;
  const TCPIP_NETWORK_CONFIG* pNetConf;
  int nNets;
  const TCPIP_STACK_MODULE_CONFIG* pModConfig;
  int nModules;
} TCPIP_STACK_INIT;
```

Members

Members	Description
SYS_MODULE_INIT moduleInit;	system module initialization
const TCPIP_NETWORK_CONFIG* pNetConf;	pointer to array of network configurations
int nNets;	number of networks in the configuration array
const TCPIP_STACK_MODULE_CONFIG* pModConfig;	pointer to array of module configurations
int nModules;	number of modules in the array

Description

TCP/IP stack initialization/configuration structure

This type describes the TCP/IP stack initialization/configuration data type that's passed to the TCP/IP stack at the initialization time.

Remarks

This data structure will be passed to the stack initialization function, TCPIP_STACK_Initialize.

TCPIP_STACK_MODULE Enumeration

List of the TCP/IP stack supported modules.

File

tcpip.h

C

```
typedef enum {
  TCPIP_MODULE_NONE = 0,
  TCPIP_MODULE_IPV4,
  TCPIP_MODULE_IPV6,
  TCPIP_MODULE_LLDP,
  TCPIP_MODULE_ICMPV6,
  TCPIP_MODULE_NDP,
  TCPIP_MODULE_UDP,
  TCPIP_MODULE_TCP,
  TCPIP_MODULE_IGMP,
  TCPIP_MODULE_DHCP_SERVER,
  TCPIP_MODULE_ANNOUNCE,
  TCPIP_MODULE_DNS_CLIENT,
  TCPIP_MODULE_DNS_SERVER,
  TCPIP_MODULE_ZCLL,
  TCPIP_MODULE_MDNS,
  TCPIP_MODULE_NBNS,
  TCPIP_MODULE_SMTP_CLIENT,
  TCPIP_MODULE_SNTP,
  TCPIP_MODULE_FTP_SERVER,
  TCPIP_MODULE_HTTP_SERVER,
  TCPIP_MODULE_HTTP_NET_SERVER,
  TCPIP_MODULE_TELNET_SERVER,
  TCPIP_MODULE_SNMP_SERVER,
  TCPIP_MODULE_SNMPV3_SERVER,
  TCPIP_MODULE_DYNDNS_CLIENT,
  TCPIP_MODULE_BERKELEY,
  TCPIP_MODULE_REBOOT_SERVER,
  TCPIP_MODULE_COMMAND,
  TCPIP_MODULE_IPERF,
  TCPIP_MODULE_TFTP_CLIENT,
  TCPIP_MODULE_DHCPV6_CLIENT,
  TCPIP_MODULE_SMTPC,
  TCPIP_MODULES_NUMBER,
```

```
  TCPIP_MODULE_MAC_START
} TCPIP_STACK_MODULE;
```

Members

Members	Description
TCPIP_MODULE_NONE = 0	unspecified/unknown module
TCPIP_MODULE_LLDP	LLDP module
TCPIP_MODULE_IGMP	IGMP host module
TCPIP_MODULE_ZCLL	Zero Config Link Local
TCPIP_MODULE_MDNS	Bonjour/mDNS
TCPIP_MODULE_TFTP_CLIENT	TFTP client module
TCPIP_MODULE_DHCPV6_CLIENT	DHCPV6 client
TCPIP_MODULE_SMTPC	SMTP (new) client
TCPIP_MODULES_NUMBER	number of modules in the TCP/IP stack itself starting here is list of supported MAC modules and are defined in the tcpip_mac.h

Description

TCP/IP stack supported modules

The following enumeration lists all the modules supported by the TCP/IP stack.

Remarks

None.

TCPIP_STACK_MODULE_CONFIG Structure

Definition to represent a TCP/IP module initialization/configuration structure.

File

tcpip.h

C

```
typedef struct {
  TCPIP_STACK_MODULE moduleId;
  const void * const configData;
} TCPIP_STACK_MODULE_CONFIG;
```

Description

TCP/IP module initialization/configuration structure

This type describes a TCP/IP module initialization/configuration data type that's passed to a TCP/IP module at the stack initialization time.

Remarks

Each stack module will be configured with a user-defined initialization/configuration structure.

TCPIP_MODULE_SIGNAL Enumeration

Lists the signals that are generated by the TCP/IP stack manager and processed by the stack modules.

File

tcpip_manager.h

C

```
typedef enum {
  TCPIP_MODULE_SIGNAL_NONE = 0x0000,
  TCPIP_MODULE_SIGNAL_RX_PENDING = 0x0001,
  TCPIP_MODULE_SIGNAL_TMO = 0x0002,
  TCPIP_MODULE_SIGNAL_ASYNC = 0x0100,
  TCPIP_MODULE_SIGNAL_MASK_ALL = (TCPIP_MODULE_SIGNAL_RX_PENDING | TCPIP_MODULE_SIGNAL_TMO)
} TCPIP_MODULE_SIGNAL;
```

Members

Members	Description
TCPIP_MODULE_SIGNAL_NONE = 0x0000	no pending signal

TCPIP_MODULE_SIGNAL_RX_PENDING = 0x0001	RX packet pending for processing
TCPIP_MODULE_SIGNAL_TMO = 0x0002	module timeout has occurred for modules that implement a state machine advancing on timer signals
TCPIP_MODULE_SIGNAL_ASYNC = 0x0100	Special signals module asynchronous attention required this is a signal that's requested by modules that need special attention module is required to clear this flag when out of the critical processing
TCPIP_MODULE_SIGNAL_MASK_ALL = (TCPIP_MODULE_SIGNAL_RX_PENDING | TCPIP_MODULE_SIGNAL_TMO)	All processing signals mask Note that TCPIP_MODULE_SIGNAL_ASYNC has to be cleared explicitly

Description

Enumeration: TCPIP_MODULE_SIGNAL

These signals are generated by the stack manager towards the internal stack modules; A stack app could use them to provide wake up conditions for a thread waiting for a signal to occur. This is mainly useful when the stack modules tasks functions are executed at the app level and the app needs a way to identify that a module needs attention.

Remarks

Multiple signals could be ORed.

Only 16-bit values are maintained for this type of signal.

TCPIP_MODULE_SIGNAL_FUNC Type

Pointer to a function(handler) that will get called when a stack internal signal occurred.

File

tcpip_manager.h

C

```
typedef void (* TCPIP_MODULE_SIGNAL_FUNC)(TCPIP_MODULE_SIGNAL_HANDLE sigHandle, TCPIP_STACK_MODULE
moduleId, TCPIP_MODULE_SIGNAL signal);
```

Returns

None.

Description

TCPIP module signal function

Pointer to a function that will be called from within the TCP/IP stack when a signal is delivered to a stack module.

Remarks

This function should be kept as short as possible and it should not include blocking or polling code. It's for setting flags/signaling purposes only.

Preconditions

None.

Parameters

Parameters	Description
sigHandle	signal handle obtained from a registration call
moduleId	module that receives the signal
signal	the occurring signal

Function

void* (TCPIP_MODULE_SIGNAL_HANDLE sigHandle, TCPIP_STACK_MODULE moduleId,
TCPIP_MODULE_SIGNAL signal)

TCPIP_MODULE_SIGNAL_HANDLE Type

Defines a TCPIP stack signal function handle.

File

tcpip_manager.h

C

```
typedef const void* TCPIP_MODULE_SIGNAL_HANDLE;
```

Description

Type: TCPIP_MODULE_SIGNAL_HANDLE

Definition of an signal function handle used for signal registration by the stack clients.

TCPIP_STACK_IF_NAME_97J60 Macro

File

tcpip.h

C

```
#define TCPIP_STACK_IF_NAME_97J60 "97J60"
```

Description

This is macro TCPIP_STACK_IF_NAME_97J60.

TCPIP_STACK_IF_NAME_ENCJ60 Macro

File

tcpip.h

C

```
#define TCPIP_STACK_IF_NAME_ENCJ60 "ENCJ60"
```

Description

This is macro TCPIP_STACK_IF_NAME_ENCJ60.

TCPIP_STACK_IF_NAME_ENCJ600 Macro

File

tcpip.h

C

```
#define TCPIP_STACK_IF_NAME_ENCJ600 "ENCJ600"
```

Description

This is macro TCPIP_STACK_IF_NAME_ENCJ600.

TCPIP_STACK_IF_NAME_MRF24W Macro

File

tcpip.h

C

```
#define TCPIP_STACK_IF_NAME_MRF24W "MRF24W"
```

Description

This is macro TCPIP_STACK_IF_NAME_MRF24W.

TCPIP_STACK_IF_NAME_NONE Macro

Defines the TCP/IP stack supported network interfaces.

File

tcpip.h

C

```
#define TCPIP_STACK_IF_NAME_NONE 0
```

Description

TCP/IP stack supported network interfaces

The following enumeration lists the names of all the interfaces supported by the TCP/IP stack and aliases.

Remarks

None.

TCPIP_STACK_IF_NAME_PIC32INT Macro

File

tcpip.h

C

```
#define TCPIP_STACK_IF_NAME_PIC32INT "PIC32INT"
```

Description

This is macro TCPIP_STACK_IF_NAME_PIC32INT.

TCPIP_STACK_IF_POWER_DOWN Macro

File

tcpip.h

C

```
#define TCPIP_STACK_IF_POWER_DOWN "down"
```

Description

powered down, not started

TCPIP_STACK_IF_POWER_FULL Macro

File

tcpip.h

C

```
#define TCPIP_STACK_IF_POWER_FULL "full"
```

Description

up and running;

TCPIP_STACK_IF_POWER_LOW Macro

File

tcpip.h

C

```
#define TCPIP_STACK_IF_POWER_LOW "low"
```

Description

low power mode; not supported now

TCPIP_STACK_IF_POWER_NONE Macro

File

tcpip.h

C

```
#define TCPIP_STACK_IF_POWER_NONE 0
```

Description

unsupported, invalid

TCPIP_STACK_VERSION_MAJOR Macro

File

tcpip.h

C

```
#define TCPIP_STACK_VERSION_MAJOR 7
```

Description

TCP/IP stack version

TCPIP_STACK_VERSION_MINOR Macro

File

tcpip.h

C

```
#define TCPIP_STACK_VERSION_MINOR 25
```

Description

This is macro TCPIP_STACK_VERSION_MINOR.

TCPIP_STACK_VERSION_PATCH Macro

File

tcpip.h

C

```
#define TCPIP_STACK_VERSION_PATCH 0
```

Description

This is macro TCPIP_STACK_VERSION_PATCH.

TCPIP_STACK_VERSION_STR Macro

File

tcpip.h

C

```
#define TCPIP_STACK_VERSION_STR "7.26"
```

Description

This is macro TCPIP_STACK_VERSION_STR.

TCPIP_Helper_ntohll Macro

File

tcpip_helpers.h

C

```
#define TCPIP_Helper_ntohll(ll) TCPIP_Helper_htonll(ll)
```

Description

This is macro TCPIP_Helper_ntohll.

TCPIP_STACK_IF_NAME_MRF24WN Macro

File

tcpip.h

C

```
#define TCPIP_STACK_IF_NAME_MRF24WN "MRF24WN"
```

Description

This is macro TCPIP_STACK_IF_NAME_MRF24WN.

Files

Files

Name	Description
tcpip_manager.h	This is the TCP/IP stack manager.
tcpip_helpers.h	TCP/IP Stack helpers header file.
tcpip.h	TCP/IP API definitions.

Description

This section lists the source and header files used by the library.

tcpip_manager.h

This is the TCP/IP stack manager.

Enumerations

	Name	Description
	TCPIP_EVENT	Defines the possible TCPIP event types.
	TCPIP_LOCAL_MASK_TYPE	Mask operation for local/non-local network interface.
	TCPIP_MODULE_SIGNAL	Lists the signals that are generated by the TCP/IP stack manager and processed by the stack modules.

Functions

	Name	Description
	TCPIP_MODULE_SignalFunctionDeregister	Deregisters a signal function for a stack module.
	TCPIP_MODULE_SignalFunctionRegister	Registers a new signal function for a stack module.
	TCPIP_MODULE_SignalGet	Returns the current signals for a TCP/IP module.
	TCPIP_STACK_Deinitialize	Stack deinitialization function.
	TCPIP_STACK_EventsPendingGet	Returns the currently pending events.
	TCPIP_STACK_HandlerDeregister	Deregisters an event notification handler.
	TCPIP_STACK_HandlerRegister	Sets a new event notification handler.
	TCPIP_STACK_IndexToNet	Network interface handle from interface number.
	TCPIP_STACK_Initialize	Stack initialization function.
	TCPIP_STACK_InitializeDataGet	Get the TCP/IP stack initialization data.
	TCPIP_STACK_MACObjectGet	Returns the network MAC driver object of this interface.
	TCPIP_STACK_ModuleConfigGet	Get stack module configuration data.
	TCPIP_STACK_NetAddress	Network interface IPv4 address.
	TCPIP_STACK_NetAddressBcast	Network interface broadcast address.
	TCPIP_STACK_NetAddressDnsPrimary	Network interface DNS address.
	TCPIP_STACK_NetAddressDnsPrimarySet	Sets network interface IPv4 DNS address.
	TCPIP_STACK_NetAddressDnsSecond	Network interface secondary DNS address.
	TCPIP_STACK_NetAddressDnsSecondSet	Sets network interface IPv4 secondary DNS address.

	TCPIP_STACK_NetAddressGateway	Network interface IPv4 gateway address.
	TCPIP_STACK_NetAddressGatewaySet	Sets network interface IPv4 gateway address.
	TCPIP_STACK_NetAddressMac	Network interface MAC address.
	TCPIP_STACK_NetAddressMacSet	Sets network interface MAC address.
	TCPIP_STACK_NetAddressSet	Sets network interface IPv4 address.
	TCPIP_STACK_NetAliasNameGet	Network interface alias name from a handle.
	TCPIP_STACK_NetBIOSName	Network interface NetBIOS name.
	TCPIP_STACK_NetBiosNameSet	Sets network interface NetBIOS name.
	TCPIP_STACK_NetConfigGet	Get stack network interface configuration data.
	TCPIP_STACK_NetConfigSet	Restores stack network interface configuration data.
	TCPIP_STACK_NetDefaultGet	Default network interface handle.
	TCPIP_STACK_NetDefaultSet	Sets the default network interface handle.
	TCPIP_STACK_NetDown	Turns down a network interface.
	TCPIP_STACK_NetHandleGet	Network interface handle from a name.
	TCPIP_STACK_NetIndexGet	Network interface number from interface handle.
	TCPIP_STACK_NetIPv6AddressGet	Gets network interface IPv6 address.
	TCPIP_STACK_NetIsLinked	Gets the network interface link status.
	TCPIP_STACK_NetIsReady	Gets the network interface configuration status.
	TCPIP_STACK_NetIsUp	Gets the network interface up or down status.
	TCPIP_STACK_NetMACIdGet	Get the MAC ID of the network interface.
	TCPIP_STACK_NetMACRegisterStatisticsGet	Get the MAC statistics register data.
	TCPIP_STACK_NetMACStatisticsGet	Get the MAC statistics data.
	TCPIP_STACK_NetMask	Network interface IPv4 address mask.
	TCPIP_STACK_NetNameGet	Network interface name from a handle.
	TCPIP_STACK_NetUp	Turns up a network interface. As part of this process, the corresponding MAC driver is initialized.
	TCPIP_STACK_NumberOfNetworksGet	Number of network interfaces in the stack.
	TCPIP_STACK_SetLocalMasks	Sets the local/non-local masks for network interface.
	TCPIP_STACK_SetLocalMasksType	Sets the local/non-local masks type for network interface.
	TCPIP_STACK_Status	Provides the current status of the TCPIP stack module.
	TCPIP_STACK_Task	TCP/IP Stack task function.
	TCPIP_STACK_VersionGet	Gets the TCP/IP stack version in numerical format.
	TCPIP_STACK_VersionStrGet	Gets the TCP/IP stack version in string format.

Types

	Name	Description
	TCPIP_EVENT_HANDLE	Defines a TCPIP stack event handle.
	TCPIP_MODULE_SIGNAL_FUNC	Pointer to a function(handler) that will get called when a stack internal signal occurred.
	TCPIP_MODULE_SIGNAL_HANDLE	Defines a TCPIP stack signal function handle.
	TCPIP_NET_HANDLE	Defines a network interface handle.
	TCPIP_STACK_EVENT_HANDLER	Pointer to a function(handler) that will get called to process an event.

Description

Microchip TCP/IP Stack Definitions

The TCP/IP manager provides access to the stack initialization, configuration and status. It also process the packets received from different network interfaces (MAC drivers) and dispatches them accordingly based on their type to the proper higher layer in the stack.

File Name

tcpip_manager.h

Company

Microchip Technology Inc.

tcpip_helpers.h

TCP/IP Stack helpers header file.

Functions

	Name	Description
	TCPIP_Helper_Base64Decode	Helper function to decode a Base-64 encoded array.
	TCPIP_Helper_Base64Encode	Helper function to encode to Base-64.
	TCPIP_Helper_FormatNetBIOSName	Formats a string to a valid NetBIOS name.
	TCPIP_Helper_htonl	Conversion routines from network order to host order and reverse.
	TCPIP_Helper_htonll	This is function TCPIP_Helper_htonll.
	TCPIP_Helper_htons	This is function TCPIP_Helper_htons.
	TCPIP_Helper_IPAddressToString	Converts an IPV4 address to an ASCII string.
	TCPIP_Helper_IPv6AddressToString	Converts an IPv6 address to a string representation.
	TCPIP_Helper_IsBcastAddress	Checks if an IPv4 address is a broadcast address.
	TCPIP_Helper_IsMcastAddress	Checks if an IPv4 address is a multicast address.
	TCPIP_Helper_IsPrivateAddress	Detects a private (non-routable) address.
	TCPIP_Helper_MACAddressToString	Converts a MAC address to a string.
	TCPIP_Helper_ntohl	!defined(__PIC32MX__)
	TCPIP_Helper_ntohll	This is function TCPIP_Helper_ntohll.
	TCPIP_Helper_ntohs	This is function TCPIP_Helper_ntohs.
	TCPIP_Helper_SecurePortGetByIndex	Returns the secure port belonging to a specified index.
	TCPIP_Helper_SecurePortSet	Sets the required port secure connection status.
	TCPIP_Helper_StringToIPAddress	Converts an ASCII string to an IPV4 address.
	TCPIP_Helper_StringToIPv6Address	Converts a string to an IPv6 address.
	TCPIP_Helper_StringToMACAddress	Converts a string to an MAC address.
	TCPIP_Helper_TCPSecurePortGet	Checks if the required TCP port is a secure port.
	TCPIP_Helper_UDPSecurePortGet	Checks if the required UDP port is a secure port.

Macros

	Name	Description
	TCPIP_Helper_ntohl	This is macro TCPIP_Helper_ntohl.
	TCPIP_Helper_ntohll	This is macro TCPIP_Helper_ntohll.
	TCPIP_Helper_ntohs	This is macro TCPIP_Helper_ntohs.

Description

Header file for tcpip_stack_helpers

This file provides the APIs for the TCP/IP Stack helpers.

File Name

tcpip_helpers.h

Company

Microchip Technology Inc.

tcpip.h

TCP/IP API definitions.

Enumerations

	Name	Description
	IP_ADDRESS_TYPE	Definition of the TCP/IP supported address types.
	IPV6_ADDR_SCOPE	Definition to represent the scope of an IPv6 address.
	IPV6_ADDR_TYPE	Definition to represent the type of an IPv6 address.
	TCPIP_NETWORK_CONFIG_FLAGS	Definition of network configuration start-up flags.
	TCPIP_STACK_MODULE	List of the TCP/IP stack supported modules.

Macros

	Name	Description
	TCPIP_STACK_IF_NAME_97J60	This is macro TCPIP_STACK_IF_NAME_97J60.

	TCPIP_STACK_IF_NAME_ALIAS_ETH	alias for Ethernet interface
	TCPIP_STACK_IF_NAME_ALIAS_UNK	alias for unknown interface
	TCPIP_STACK_IF_NAME_ALIAS_WLAN	alias for Wi-Fi interface
	TCPIP_STACK_IF_NAME_ENCJ60	This is macro TCPIP_STACK_IF_NAME_ENCJ60.
	TCPIP_STACK_IF_NAME_ENCJ600	This is macro TCPIP_STACK_IF_NAME_ENCJ600.
	TCPIP_STACK_IF_NAME_MRF24W	This is macro TCPIP_STACK_IF_NAME_MRF24W.
	TCPIP_STACK_IF_NAME_MRF24WN	This is macro TCPIP_STACK_IF_NAME_MRF24WN.
	TCPIP_STACK_IF_NAME_NONE	Defines the TCP/IP stack supported network interfaces.
	TCPIP_STACK_IF_NAME_PIC32INT	This is macro TCPIP_STACK_IF_NAME_PIC32INT.
	TCPIP_STACK_IF_POWER_DOWN	powered down, not started
	TCPIP_STACK_IF_POWER_FULL	up and running;
	TCPIP_STACK_IF_POWER_LOW	low power mode; not supported now
	TCPIP_STACK_IF_POWER_NONE	unsupported, invalid
	TCPIP_STACK_VERSION_MAJOR	TCP/IP stack version
	TCPIP_STACK_VERSION_MINOR	This is macro TCPIP_STACK_VERSION_MINOR.
	TCPIP_STACK_VERSION_PATCH	This is macro TCPIP_STACK_VERSION_PATCH.
	TCPIP_STACK_VERSION_STR	This is macro TCPIP_STACK_VERSION_STR.

Structures

	Name	Description
	_IPV6_ADDR_STRUCT	COmplex type to represent an IPv6 address.
	IPV6_ADDR_STRUCT	COmplex type to represent an IPv6 address.
	TCPIP_NETWORK_CONFIG	Defines the data required to initialize the network configuration.
	TCPIP_STACK_INIT	Definition to represent the TCP/IP stack initialization/configuration structure.
	TCPIP_STACK_MODULE_CONFIG	Definition to represent a TCP/IP module initialization/configuration structure.

Types

	Name	Description
	IP_ADDR	Backward compatible definition to represent an IPv4 address.
	IPV6_ADDR_HANDLE	Definition to represent an IPv6 address.

Unions

	Name	Description
	IP_MULTI_ADDRESS	Definition to represent multiple IP addresses.
	IPV4_ADDR	Definition to represent an IPv4 address
	IPV6_ADDR	Definition to represent an IPv6 address.

Description

Microchip TCP/IP Stack Include File

This is the global TCP/IP header file that any user of the TCP/IP API should include. It contains the basic TCP/IP types and data structures and includes all the of the TCP/IP stack modules.

File Name

tcpip.h

Company

Microchip Technology Inc.

NBNS Module

This section describes the TCP/IP Stack Library NBNS module.

Introduction

TCP/IP Stack Library NetBIOS (NBNS) Module for Microchip Microcontrollers

This library provides the API of the NBNS module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

The NetBIOS Name Service protocol associates host names with IP addresses, similarly to DNS, but on the same IP subnet. Practically, this allows the assignment of human-name hostnames to access boards on the same subnet. For example. in the "TCP/IP Demo App" demonstration project, the development board is programmed with the human name 'mchpboard' so it can be accessed directly instead of with its IP address.

Using the Library

This topic describes the basic architecture of the NBNS TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `nbns.h`

The interface to the NBNS TCP/IP Stack library is defined in the `nbns.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the NBNS TCP/IP Stack library should include `tcpip.h`.

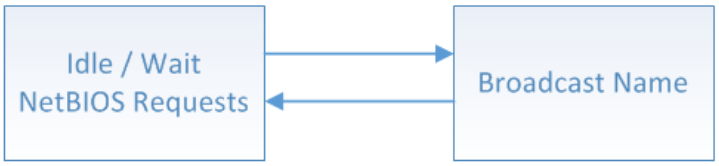
Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

This library provides the API of the NBNS TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

NBNS Software Abstraction Block Diagram



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the NBNS module.

Library Interface Section	Description
Functions	This section provides a routine that performs NBNS module tasks in the TCP/IP stack.
Data Types and Constants	This section provides various definitions describing This API

Configuring the Library

Macros

	Name	Description
	TCPIP_NBNS_TASK_TICK_RATE	NBNS task processing rate The default value is 110 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

Description

The configuration of the NBNS TCP/IP Stack is based on the `file tcpip_config.h`.

This header file contains the configuration selection for the NBNS TCP/IP Stack. Based on the selections made, the NBNS TCP/IP Stack may support the selected features. These configuration settings will apply to all instances of the NBNS TCP/IP Stack.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_NBNS_TASK_TICK_RATE Macro

File

nbns_config.h

C

```
#define TCPIP_NBNS_TASK_TICK_RATE 110
```

Description

NBNS task processing rate The default value is 110 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

Building the Library

This section lists the files that are available in the NBNS module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/nbns.c`	NBNS implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The NBNS module depends on the following modules:

- TCP/IP Stack Library
- UDP Module

Library Interface

a) Functions

	Name	Description
	TCPIP_NBNS_Task	Standard TCP/IP stack module task function.

b) Data Types and Constants

	Name	Description
	TCPIP_NBNS_MODULE_CONFIG	Placeholder for NBNS configuration upgrades.

Description

This section describes the Application Programming Interface (API) functions of the NBNS module.

Refer to each section for a detailed description.

a) Functions

TCPIP_NBNS_Task Function

Standard TCP/IP stack module task function.

File

nbns.h

C

```
void TCPIP_NBNS_Task();
```

Returns

None.

Description

This function performs NBNS module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The NBNS module should have been initialized.

Function

void TCPIP_NBNS_Task(void)

b) Data Types and Constants

TCPIP_NBNS_MODULE_CONFIG Structure

Placeholder for NBNS configuration upgrades.

File

nbns.h

C

```
typedef struct {
} TCPIP_NBNS_MODULE_CONFIG;
```

Description

TCPIP_NBNS_MODULE_CONFIG Structure Typedef

This type definition provides a placeholder for NBNS configuration upgrades.

Remarks

None.

NDP Module

This section describes the TCP/IP Stack Library NDP module.

Introduction

TCP/IP Stack Library NDP Module for Microchip Microcontrollers

This library provides the API of the NDP (Neighbor Discovery Protocol) module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

This document provides NDP (Neighbor Discovery Protocol) for IP version 6. IPv6 nodes on the same link use neighbor discovery to discover each other's presence. RFC - 4861.

It is responsible for:

- Address Auto configuration of nodes

- Discovery of other nodes in the link (It can be a Router Discovery or Neighbor Discovery)
- Determining the link-layer address of other nodes
- Duplicate address detection (DAD)
- Finding available routers and Domain Name System (DNS) servers
- Address Prefix discovery
- Parameter Discovery (Such as Link MTU or Hop limit)

Comparing with IPv4:

- NDP is a substitute of ARP (Address Resolution protocol). This new mechanism uses a mix of ICMPv6 and multicast addresses to discover the IPv6 node on same link.
- NDP includes Neighbor Unreachability Detection (NUD) , thus improving the robustness of packet delivery.
- Unlike IPv4 broadcast addresses, IPv6 address resolution multicasts are spread over 4 billion (2^32) multicast addresses, greatly reducing address resolution-related interrupts on nodes other than the target. Moreover, non-IPv6 machines should not be interrupted at all.
- Neighbor Discovery defines five different ICMPv6 packet types.

Five Different ICMPv6 Packet Types:

- **Router Solicitation** - Hosts inquire with Router Solicitation message to locate routers on the attached link
- **Router Advertisement** - Router advertise their presence periodically to all the nodes or in response to the Router Solicitation message
- **Neighbor Solicitation** - Neighbor solicitations are used by nodes to determine the Link Layer address of a neighbor, or to verify that a neighbor is still reachable via a cached Link Layer address
- **Neighbor Advertisement** - Neighbor advertisements are used by nodes to respond to a Neighbor Solicitation message
- **Redirect** - Routers may inform hosts of a better first hop router for a destination

Using the Library

This topic describes the basic architecture of the NDP TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `ndp.h`

The interface to the NDP TCP/IP Stack Library is defined in the `ndp.h` header file. Any C language source (`.c`) file that uses the NDP TCP/IP library should include `ipv6.h`, `icmpv6.h`, and `ndp.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack Library interacts with the framework.

Abstraction Model

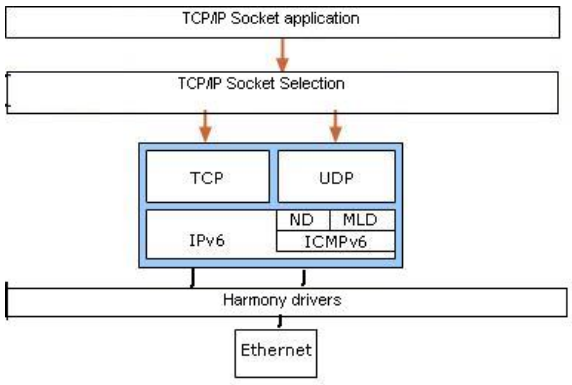
This library provides the API of the NDP TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

NDP with IPv6 Software Abstraction Block Diagram

This module provides software abstraction of the IPv6 module existent in any TCP/IP Stack implementation. It removes the overhead of address resolution from all other modules in the stack.

IPv6 Block Diagram



Link Layer Neighbor Discovery

1) Using the address FEC0::1:0:0:1 :A, node A wants to deliver packets to destination node B using the IPv6 address FEC0::1 :0:0:1 :B on the

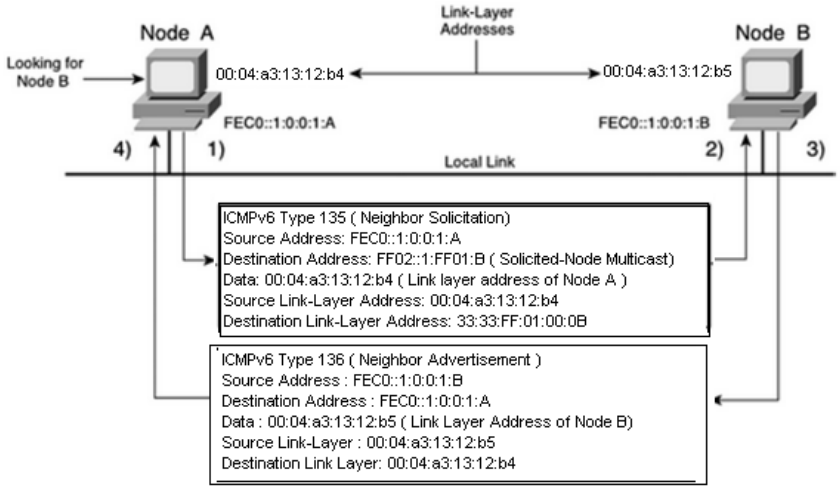
same local link. However, node A does not know node B's link-layer address. Node A sends an ICMPv6 Type

135 message (neighbor solicitation) on the local link using its site-local address FEC0::1:0:0:1:A as the IPv6 source address, the solicited-node multicast address FF02::1 :FF01:B corresponding to the target address FEC0::1 :0:0:1 :B as the destination IPv6 address, and the source link-layer address 00:04:a3:13:12:b4 of the sender, node A, as data of the ICMPv6 message. The source link-layer address of this frame is the link-layer address 00:04:a3:13:12:b4 of node A. The destination link-layer address 33:33:FF:01 :00:0B of this frame uses multicast mapping of the destination IPv6 address FF02::1 :FF01 :B.

2) Node B, which is listening to the local link for multicast addresses, intercepts the neighbor solicitation message because the destination IPv6 address FF02::1:FF01:B represents the solicited-node multicast address corresponding to its IPv6 address FEC0::1:0:0:1:B.

3) Node B replies by sending a neighbor advertisement message using its site-local address FEC0::1 :0:0:1 :B as the IPv6 source address and the site-local address FEC0::1 :0:0:1 :A as the destination IPv6 address. It also includes its link-layer address 00:04:a3:13:12:b5 in the ICMPv6 message. After receiving neighbor solicitation and neighbor advertisement messages, node A and node B know each other's link-layer addresses.

Learned link-layer addresses are kept in a neighbor discovery table (neighbor cache). Therefore, the nodes can communicate on the local link. The neighbor solicitation message is also used by nodes to verify the reachability of neighbor nodes in the neighbor discovery table (neighbor cache). However, the unicast addresses of the neighbor nodes are used as destination IPv6 addresses in ICMPv6 messages instead of solicited-node multicast addresses in this situation. It is possible for a node that changes its link-layer address to inform all other neighbor nodes on the local link by sending a neighbor advertisement message using the all-nodes multicast address FF02::1 . The neighbor discovery table of the nodes on the local link is updated with the new link-layer address.



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the IPv6, ICMPv6, and NDP module.

Library Interface Section	Description
Reachability Functions	Reachability routine functionality

Configuring the Library

Macros

	Name	Description
	TCPIP_IPV6_MTU_INCREASE_TIMEOUT	600 seconds
	TCPIP_IPV6_NDP_DELAY_FIRST_PROBE_TIME	5 s
	TCPIP_IPV6_NDP_MAX_ANYCAST_DELAY_TIME	1 s
	TCPIP_IPV6_NDP_MAX_MULTICAST_SOLICIT	3 transmissions

Reboot Module

This section describes the TCP/IP Stack Library Reboot module.

Introduction

TCP/IP Stack Library Reboot Module for Microchip Microcontrollers

This library provides the API of the Reboot module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

The Reboot module will allow a user to remotely reboot the PIC microcontroller that is running the TCP/IP stack. This feature is primarily used for bootloader applications, which must reset the microcontroller to enter the bootloader code section. This module will execute a task that listens on a specified UDP port for a packet, and then reboots if it receives one.

Using the Library

This topic describes the basic architecture of the Reboot TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `tcpip_reboot_config.h`

The interface to the Reboot TCP/IP Stack library is defined in the `tcpip_reboot_config.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the Reboot TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

This library provides the API of the Reboot TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

	Name	Description
	TCPIP_REBOOT_MESSAGE	the mesage needed to be sent accross the net to reboot the machine
	TCPIP_REBOOT_SAME_SUBNET_ONLY	For improved security, you might want to limit reboot capabilities to only users on the same IP subnet. Define TCPIP_REBOOT_SAME_SUBNET_ONLY to enable this access restriction.
	TCPIP_REBOOT_TASK_TICK_RATE	the periodic rate of the Reboot task The default value is 1130 milliseconds. This module listens for incoming reboot requests and a high operation frequency is not required. The value cannot be lower than the TCPIP_STACK_TICK_RATE.

Description

Reboot Configuration file

SMTP Module

This section describes the TCP/IP Stack Library SMTP module.

Introduction

TCP/IP Stack Library Simple Mail Transfer Protocol (SMTP) Module for Microchip Microcontrollers

This library provides the API of the SMTP module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

The SMTP client module in the TCP/IP Stack lets applications send e-mails to any recipient worldwide. These message could include status information or important alerts. Using the e-mail to SMS gateways provided by most cell phone carriers, these messages can also be delivered directly to cell phone handsets.

Using the SMTP client requires access to a local mail server (such as `mail.yourdomain.com`) for reliable operation. Your MPLAB Harmony or network administrator can provide the correct address, but end-user applications will need an interface to provide this data.

Using the Library

This topic describes the basic architecture of the SMTP TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `smtp.h`

The interface to the SMTP TCP/IP Stack library is defined in the `smtp.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the SMTP TCP/IP Stack library should include `tcpip.h`.

Library File:

The SMTP TCP/IP Stack library archive (`.a`) file is installed with MPLAB Harmony.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

This library provides the API of the SMTP TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

SMTP Software Abstraction Block Diagram

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the SMTP module.

Library Interface Section	Description
Functions	Routines to configure this module
Data Types and Constants	This section provides various definitions describing this API

SMTP Client Examples

SMTP Client examples.

Description

The following two examples demonstrate the use of the SMTP client in different scenarios. The first, and simpler example, sends a short message whose contents are all located in RAM at once.

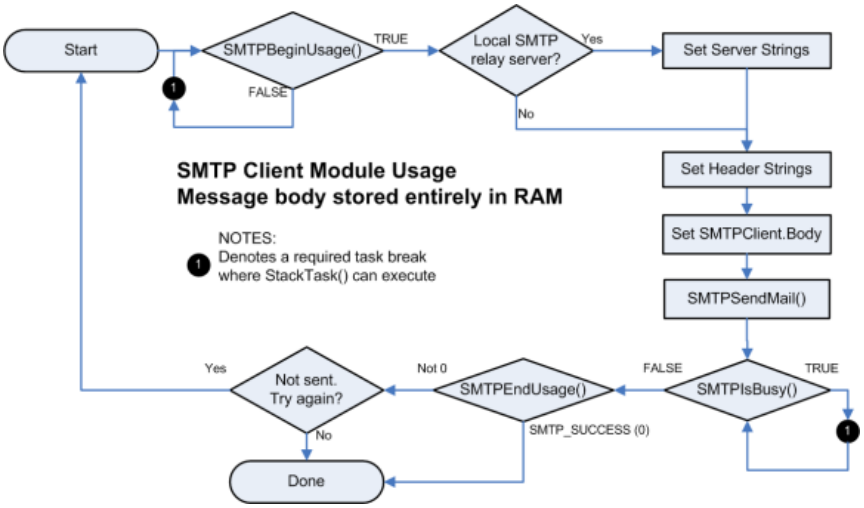
The second example is more involved and demonstrates generating a message on the fly in the case where the entire message cannot fit into RAM at once. The SMTPDemo example provided in `MainDemo.c` sends a brief e-mail message indicating the current status of the board's buttons.

SMTP Client Short Message Example

The SMTP client API is simplified when messages can be buffered entirely in RAM. The SMTPDemo example provided in `MainDemo.c` sends a brief e-mail message indicating the current status of the board's buttons. This document will walk through that example.

Make sure STACK_USE_SMTP_CLIENT is uncommented in `tcpip_config.h` before continuing.

The following diagram provides an overview of the process:



1. First, call SMTPBeginUsage to verify that the SMTP client is available and to begin a new message. If FALSE is returned, the SMTP client is busy and the application must return to the main loop to allow StackTask to execute again.
2. Next, set the local relay server to use as SMTPClient.Server. If the local relay server requires a user name and password, set SMTPClient.Username and SMTPClient.Password to the appropriate credentials. If server parameters are not set, the stack will attempt to deliver the message directly to its destination host. This will likely fail due to SPAM prevention measures put in place by most ISPs and network administrators.
3. Continue on to set the header strings as necessary for the message. This includes the subject line, from address, and any recipients you need

to add. Finally, set SMTPClient.Body to the message to be sent.

4. At this point, verify that SMTPClient.ROMPointers is correctly configured for any strings that are stored in program memory. Once the message is ready to send, call SMTPSendMail to instruct the SMTP client to begin transmission.
5. The application must now call SMTPIsBusy until it returns FALSE. Each time TRUE is returned, return to the main loop and wait for StackTask to execute again. This allows the SMTP server to continue its work in a cooperative multitasking manner. Once FALSE is returned, call SMTPEndUsage to release the SMTP client. Check the return value of this function to determine if the message was successfully sent.

The example in `MainDemo.c` needs minor modifications to use your e-mail address. The Server and To fields must be set in SMTPDemo in order for the message to be properly delivered. Once this is done, holding down BUTTON2 and BUTTON3 simultaneously (the left-most two buttons) will begin sending the message. LED1 will light as the message is being processed, and will extinguish when the SMTP state machine completes. If the transmission was successful LED2 will light, otherwise it will remain dark.

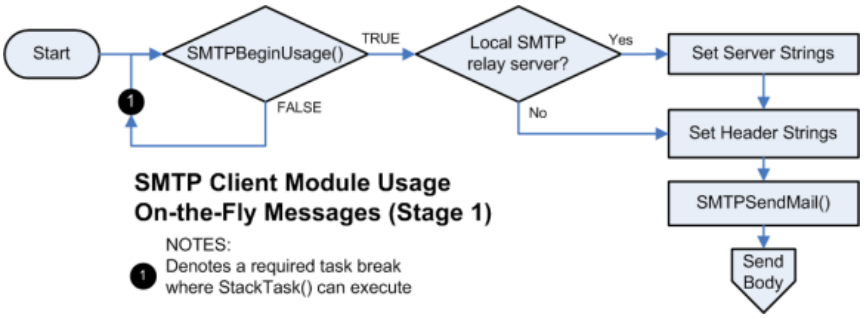
SMTP Client Long Message Example

The SMTP client API is capable of sending messages that do not fit entirely in RAM. To do so, the application must manage its output state and only write as many bytes as are available in the buffer at a time. The second SMTPDemo example provided in `MainDemo.c` sends a message that is a dump of all contents of the PIC microcontroller's RAM. This example is currently commented out. Comment out the previous Short Message Example and uncomment the Long Message Example. This document will walk through sending a longer message.

Make sure STACK_USE_SMTP_CLIENT is uncommented in `tcpip_config.h` before continuing.

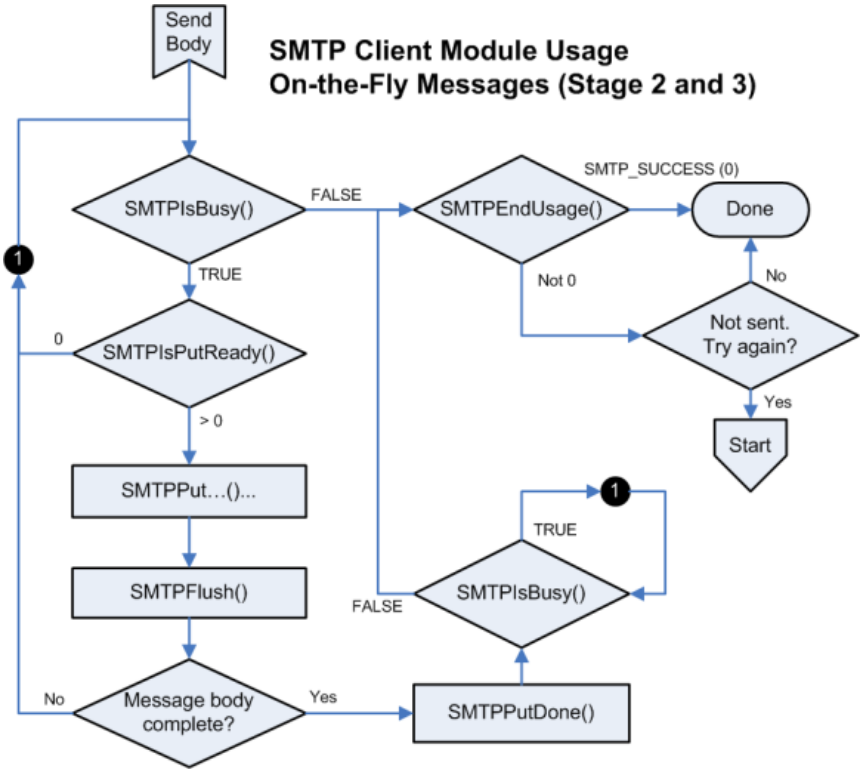
Sending longer messages is divided into three stages. The first stage configures the SMTP client to send the message. The second stage sends the message in small chunks as buffer space is available. The final stage finishes the transmission and determines whether or not the message was successful.

The following diagram illustrates the first stage:



1. The first stage is largely similar to the first few steps in sending a short message. First, call SMTPBeginUsage to verify that the SMTP client is available and to begin a new message. If FALSE is returned, the SMTP client is busy and the application must return to the main loop to allow StackTask to execute again.
2. Next, set the local relay server to use as SMTPClient.Server. If the local relay server requires a user name and password, set SMTPClient.Username and SMTPClient.Password to the appropriate credentials. If server parameters are not set, the stack will attempt to deliver the message directly to its destination host. This will likely fail due to SPAM prevention measures put in place by most ISPs and network administrators.
3. Continue on to set the header strings as necessary for the message. This includes the subject line, from address, and any recipients you need to add.
4. The next portion of the process differs. Ensure that SMTPClient.Body remains set to its default (NULL). At this point, call SMTPSendMail to open a connection to the remote server and transmit the headers. The application is now ready to proceed to the second stage and send the message body.

The following diagram provides an overview of stage two and three:



1. Upon entering stage two, the application should call SMTPIsBusy to verify that the connection to the remote server is active and has not been lost. If the call succeeds, call SMTPIsPutReady to determine how many bytes are available in the TX buffer. If no bytes are available, return to the main loop so that StackTask can transmit the data to the remote node and free up the buffer.
2. If space is available, any combination of the SMTPPut, SMTPPutArray, SMTPPutROMArray, SMTPPutString, and SMTPPutROMString functions may be called to transmit the message. These functions return the number of bytes successfully written. Use this value, along with the value originally returned from SMTPIsPutReady to track how much free space remains in the TX buffer. Once the buffer is depleted, call SMTPFlush to force the data written to be sent.
3. The SMTP client module can accept as much data as the TCP TX FIFO can hold. This is determined by the socket initializer for TCP_PURPOSE_DEFAULT type sockets in `tcpip_config.h`, which defaults to 200 bytes.
4. If the TX buffer is exhausted before the message is complete, return to the main loop so that StackTask may transmit the data to the remote node and free up the buffer. Upon return, go to the beginning of the second stage to transmit the next portion of the message.

Once the message is complete, the application will move to the third stage. Call SMTPPutDone to inform the SMTP client that no more data remains. Then call SMTPIsBusy repeatedly. Each time TRUE is returned, return to the main loop and wait for StackTask to execute again. Once FALSE is returned, the message transmission has completed and the application must call SMTPEndUsage to release the SMTP client. Check the return value of this function to determine if the message was successfully sent.

The example in `MainDemo.c` needs minor modifications to use your e-mail address. Set the Server and To fields in SMTPDemo, and ensure that these fields are being properly assigned to SMTPClient struct. The demonstration works exactly the same way as the previous one, with BUTTON2 and BUTTON3 held down simultaneously (the left-most two buttons) kicking off the state machine. LED1 will light as the message is being processed, and will extinguish when the SMTP state machine completes. If the transmission was successful LED2 will turn ON; otherwise, it will remain OFF.

Configuring the Library

Macros

	Name	Description
	TCPIP_SMTP_SERVER_REPLY_TIMEOUT	How long to wait before assuming the connection has been dropped (default 8 seconds)
	TCPIP_SMTP_TASK_TICK_RATE	SMTP task rate, milliseconds The default value is 55 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_SMTP_WRITE_READY_SPACE	the minimum amount of data to ask from the transport/encryption layer when querying the write space
	TCPIP_SMTP_MAX_WRITE_SIZE	the max size of data to be written in a discrete string/array email operation: TCPIP_SMTP_StringPut/TCPIP_SMTP_ArrayPut. Excess characters will be discarded. Note that the higher this value, the greater the size of the underlying TCP socket TX buffer Adjust as needed. Normally should not exceed 512 characters.

Description

The configuration of the SMPT TCP/IP Stack Library is based on the file `tcpip_config.h`.

This header file contains the configuration selection for the SMTP TCP/IP Stack Library. Based on the selections made, the SMTP TCP/IP Stack Library may support the selected features. These configuration settings will apply to all instances of the SMTP TCP/IP Stack Library.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_SMTP_SERVER_REPLY_TIMEOUT Macro

File

smtp_config.h

C

```
#define TCPIP_SMTP_SERVER_REPLY_TIMEOUT (8)
```

Description

How long to wait before assuming the connection has been dropped (default 8 seconds)

TCPIP_SMTP_TASK_TICK_RATE Macro

File

smtp_config.h

C

```
#define TCPIP_SMTP_TASK_TICK_RATE (55)
```

Description

SMTP task rate, milliseconds The default value is 55 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

TCPIP_SMTP_WRITE_READY_SPACE Macro

File

smtp_config.h

C

```
#define TCPIP_SMTP_WRITE_READY_SPACE 150
```

Description

the minimum amount of data to ask from the transport/encryption layer when querying the write space

TCPIP_SMTP_MAX_WRITE_SIZE Macro

File

smtp_config.h

C

```
#define TCPIP_SMTP_MAX_WRITE_SIZE 512
```

Description

the max size of data to be written in a discrete string/array email operation: TCPIP_SMTP_StringPut/TCPIP_SMTP_ArrayPut. Excess characters will be discarded. Note that the higher this value, the greater the size of the underlying TCP socket TX buffer Adjust as needed. Normally should not exceed 512 characters.

Building the Library

This section lists the files that are available in the SMTP module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/smtp.c`	SMTP implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The SMTP module depends on the following modules:

- TCP/IP Stack Library
- DNS Module
- TCP Module

Library Interface

a) Functions

	Name	Description
	TCPIP_SMTP_ArrayPut	Writes a series of bytes to the SMTP client.
	TCPIP_SMTP_Flush	Flushes the SMTP socket and forces all data to be sent.
	TCPIP_SMTP_IsBusy	Determines if the SMTP client is busy.
	TCPIP_SMTP_IsPutReady	Determines how much data can be written to the SMTP client.
	TCPIP_SMTP_Put	Writes a single byte to the SMTP client.
	TCPIP_SMTP_PutIsDone	Indicates that the on-the-fly message is complete.
	TCPIP_SMTP_StringPut	Writes a string to the SMTP client.
	TCPIP_SMTP_UsageBegin	Requests control of the SMTP client module.
	TCPIP_SMTP_UsageEnd	Releases control of the SMTP client module.
	TCPIP_SMTP_MailSend	Initializes the message sending process.
	TCPIP_SMTP_ClientTask	Standard TCP/IP stack module task function.

b) Data Types and Functions

	Name	Description
	SMTP_CONNECT_ERROR	Connection to SMTP server failed
	SMTP_RESOLVE_ERROR	DNS lookup for SMTP server failed
	SMTP_SUCCESS	Message was successfully sent
	TCPIP_SMTP_CLIENT_MODULE_CONFIG	This is type TCPIP_SMTP_CLIENT_MODULE_CONFIG.
	TCPIP_SMTP_CLIENT_MESSAGE	Configures the SMTP client to send a message.

Description

This section describes the Application Programming Interface (API) functions of the SMTP module.

Refer to each section for a detailed description.

a) Functions

TCPIP_SMTP_ArrayPut Function

Writes a series of bytes to the SMTP client.

File

smtp.h

C

```
uint16_t TCPIP_SMTP_ArrayPut(uint8_t* Data, uint16_t Len);
```

Returns

The number of bytes written. If less than Len, then the TX FIFO became full before all bytes could be written.

Description

This function writes a series of bytes to the SMTP client.

Remarks

This function should only be called externally when the SMTP client is generating an on-the-fly message (i.e., TCPIP_SMTP_MailSend was called with SMTPClient.Body set to NULL).

Preconditions

TCPIP_SMTP_UsageBegin returned true on a previous call.

Parameters

Parameters	Description
Data	The data to be written
Len	How many bytes should be written

Function

uint16_t TCPIP_SMTP_ArrayPut(uint8_t* Data, uint16_t Len)

TCPIP_SMTP_Flush Function

Flushes the SMTP socket and forces all data to be sent.

File

smtp.h

C

```
void TCPIP_SMTP_Flush();
```

Returns

None.

Description

This function flushes the SMTP socket and forces all data to be sent.

Remarks

This function should only be called externally when the SMTP client is generating an on-the-fly message (i.e., TCPIP_SMTP_MailSend was called with SMTPClient.Body set to NULL).

Preconditions

TCPIP_SMTP_UsageBegin returned true on a previous call.

Function

void TCPIP_SMTP_Flush(void)

TCPIP_SMTP_IsBusy Function

Determines if the SMTP client is busy.

File

smtp.h

C

```
bool TCPIP_SMTP_IsBusy();
```

Description

Call this function to determine if the SMTP client is busy performing background tasks. This function should be called after any call to TCPIP_SMTP_MailSend, TCPIP_SMTP_PutIsDone to determine if the stack has finished performing its internal tasks. It should also be called prior to any call to TCPIP_SMTP_IsPutReady to verify that the SMTP client has not prematurely disconnected. When this function returns false, the next call should be to TCPIP_SMTP_UsageEnd to release the module and obtain the status code for the operation.

Preconditions

TCPIP_SMTP_UsageBegin returned true on a previous call.

Function

bool TCPIP_SMTP_IsBusy(void)

TCPIP_SMTP_IsPutReady Function

Determines how much data can be written to the SMTP client.

File

smtp.h

C

```
uint16_t TCPIP_SMTP_IsPutReady();
```

Returns

The number of free bytes the SMTP TX FIFO.

Description

Use this function to determine how much data can be written to the SMTP client when generating an on-the-fly message.

Remarks

This function should only be called externally when the SMTP client is generating an on-the-fly message (i.e., TCPIP_SMTP_MailSend was called with SMTPClient.Body set to NULL).

Preconditions

TCPIP_SMTP_UsageBegin returned true on a previous call, and an on-the-fly message is being generated. This requires that TCPIP_SMTP_MailSend was called with SMTPClient.Body set to NULL.

Function

uint16_t TCPIP_SMTP_IsPutReady(void)

TCPIP_SMTP_Put Function

Writes a single byte to the SMTP client.

File

smtp.h

C

```
bool TCPIP_SMTP_Put(char c);
```

Description

This function writes a single byte to the SMTP client.

Remarks

This function is obsolete and will be eventually removed. TCPIP_SMTP_ArrayPut and TCPIP_SMTP_StringPut should be used.

This function cannot be used on an encrypted connection. It is difficult to estimate the amount of TX buffer space needed when transmitting byte by byte, which could cause intermediary write operations to the underlying TCP socket.

This function should only be called externally when the SMTP client is generating an on-the-fly message (i.e., TCPIP_SMTP_MailSend was called with SMTPClient.Body set to NULL).

Preconditions

TCPIP_SMTP_UsageBegin returned true on a previous call.

Parameters

Parameters	Description
c	The byte to be written

Function

bool TCPIP_SMTP_Put(char c)

TCPIP_SMTP_PutIsDone Function

Indicates that the on-the-fly message is complete.

File

smtp.h

C

```
void TCPIP_SMTP_PutIsDone();
```

Returns

None.

Description

This function indicates that the on-the-fly message is complete.

Preconditions

TCPIP_SMTP_UsageBegin returned true on a previous call, and the SMTP client is generated an on-the-fly message (i.e., TCPIP_SMTP_MailSend was called with SMTPClient.Body set to NULL).

Function

void TCPIP_SMTP_PutIsDone(void)

TCPIP_SMTP_StringPut Function

Writes a string to the SMTP client.

File

smtp.h

C

```
uint16_t TCPIP_SMTP_StringPut(char* Data);
```

Returns

The number of bytes written. If less than the length of Data, then the TX FIFO became full before all bytes could be written.

Description

This function writes a string to the SMTP client.

Remarks

This function should only be called externally when the SMTP client is generating an on-the-fly message. (That is, TCPIP_SMTP_MailSend was

called with SMTPClient.Body set to NULL.)

Preconditions

TCPIP_SMTP_UsageBegin returned true on a previous call.

Parameters

Parameters	Description
Data	The data to be written

Function

uint16_t TCPIP_SMTP_StringPut(char* Data)

TCPIP_SMTP_UsageBegin Function

Requests control of the SMTP client module.

File

smtp.h

C

```
bool TCPIP_SMTP_UsageBegin();
```

Description

Call this function before calling any other SMTP Client APIs. This function obtains a lock on the SMTP Client, which can only be used by one stack application at a time. Once the application is finished with the SMTP client, it must call TCPIP_SMTP_UsageEnd to release control of the module to any other waiting applications.

This function initializes all the SMTP state machines and variables back to their default state.

Preconditions

None.

Function

bool TCPIP_SMTP_UsageBegin(void)

TCPIP_SMTP_UsageEnd Function

Releases control of the SMTP client module.

File

smtp.h

C

```
uint16_t TCPIP_SMTP_UsageEnd();
```

Description

Call this function to release control of the SMTP client module once an application is finished using it. This function releases the lock obtained by TCPIP_SMTP_UsageBegin, and frees the SMTP client to be used by another application.

Preconditions

TCPIP_SMTP_UsageBegin returned true on a previous call.

Function

uint16_t TCPIP_SMTP_UsageEnd(void)

TCPIP_SMTP_MailSend Function

Initializes the message sending process.

File

smtp.h

C

```
void TCPIP_SMTP_MailSend(TCPIP_SMTP_CLIENT_MESSAGE* smtpClientMessage);
```

Returns

None.

Description

This function starts the state machine that performs the actual transmission of the message. Call this function after all the fields in SMTPClient have been set.

Remarks

The fields pointed by the smtpClientMessage have to be non-volatile until the SMTP send mail process is completed!

Preconditions

TCPIP_SMTP_UsageBegin returned true on a previous call.

Parameters

Parameters	Description
smtpClientMessage	pointer to a TCPIP_SMTP_CLIENT_MESSAGE structure that configures the message to send

Function

void TCPIP_SMTP_MailSend(TCPIP_SMTP_CLIENT_MESSAGE* smtpClientMessage)

TCPIP_SMTP_ClientTask Function

Standard TCP/IP stack module task function.

File

smtp.h

C

```
void TCPIP_SMTP_ClientTask();
```

Returns

None.

Description

this function performs SMTP module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

SMTP module should have been initialized.

Function

void TCPIP_SMTP_ClientTask(void)

b) Data Types and Functions

SMTP_CONNECT_ERROR Macro

File

smtp.h

C

```
#define SMTP_CONNECT_ERROR (0x8001u)    // Connection to SMTP server failed
```

Description

Connection to SMTP server failed

SMTP_RESOLVE_ERROR Macro

File

smtp.h

C

```
#define SMTP_RESOLVE_ERROR (0x8000u)    // DNS lookup for SMTP server failed
```

Description

DNS lookup for SMTP server failed

SMTP_SUCCESS Macro

File

smtp.h

C

```
#define SMTP_SUCCESS (0x0000u)    // Message was successfully sent
```

Description

Message was successfully sent

TCPIP_SMTP_CLIENT_MODULE_CONFIG Structure

File

smtp.h

C

```
typedef struct {
} TCPIP_SMTP_CLIENT_MODULE_CONFIG;
```

Description

This is type TCPIP_SMTP_CLIENT_MODULE_CONFIG.

TCPIP_SMTP_CLIENT_MESSAGE Structure

Configures the SMTP client to send a message.

File

smtp.h

C

```
typedef struct {
  char* Server;
  char* Username;
  char* Password;
  char* To;
  char* CC;
  char* BCC;
  char* From;
  char* Subject;
  char* OtherHeaders;
  char* Body;
  bool UseSSL;
  uint16_t ServerPort;
} TCPIP_SMTP_CLIENT_MESSAGE;
```

Description

This structure of pointers configures the SMTP Client to send an e-mail message.

Remarks

When formatting an e-mail address, the SMTP standard format for associating a printable name may be used. This format places the printable name in quotation marks, with the address following in pointed brackets, such as "John Smith" .

Parameters

Parameters	Description
Server	the SMTP server to relay the message through
Username	the user name to use when logging into the SMTP server, if any is required
Password	the password to supply when logging in, if any is required
To	the destination address for this message. May be a comma-separated list of address, and/or formatted.
CC	The CC addresses for this message, if any. May be a comma-separated list of address, and/or formatted.
BCC	The BCC addresses for this message, if any. May be a comma-separated list of address, and/or formatted.
From	The From address for this message. May be formatted.
Subject	The Subject header for this message.
OtherHeaders	Any additional headers for this message. Each additional header, including the last one, must be terminated with a CRLF pair.
Body	When sending a message from memory, the location of the body of this message in memory. Leave as NULL to build a message on-the-fly.
UseSSL	This flag causes the SMTP client to make a secure connection to the server.
ServerPort	(uint16_t value) Indicates the port on which to connect to the remote SMTP server.

Function

typedef struct TCPIP_SMTP_CLIENT_MESSAGE

SMTPC Module

This section describes the TCP/IP Stack Library SMTPC module.

Introduction

TCP/IP Stack Library Simple Mail Transfer Protocol Client (SMTPC) Module for Microchip Microcontrollers

This library provides the API of the SMTPC Client module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

The SMTPC module in the TCP/IP Stack lets applications send e-mails to any recipient worldwide. These message could include status information or important alerts. Using the e-mail to SMS gateways provided by most cell phone carriers, these messages can also be delivered directly to cell phone handsets.

Using the SMTPC client requires access to a local mail server (such as `mail.yourdomain.com`) for reliable operation. Your MPLAB Harmony or network administrator can provide the correct address, but end-user applications will need an interface to provide this data.

Using the Library

This topic describes the basic architecture of the SMTPC TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `smtpc.h`

The interface to the SMTPC TCP/IP Stack library is defined in the `smtpc.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the SMTPC TCP/IP Stack library should include `tcpip.h`.

Library File:

The SMTPC TCP/IP Stack library archive (`.a`) file is installed with MPLAB Harmony.

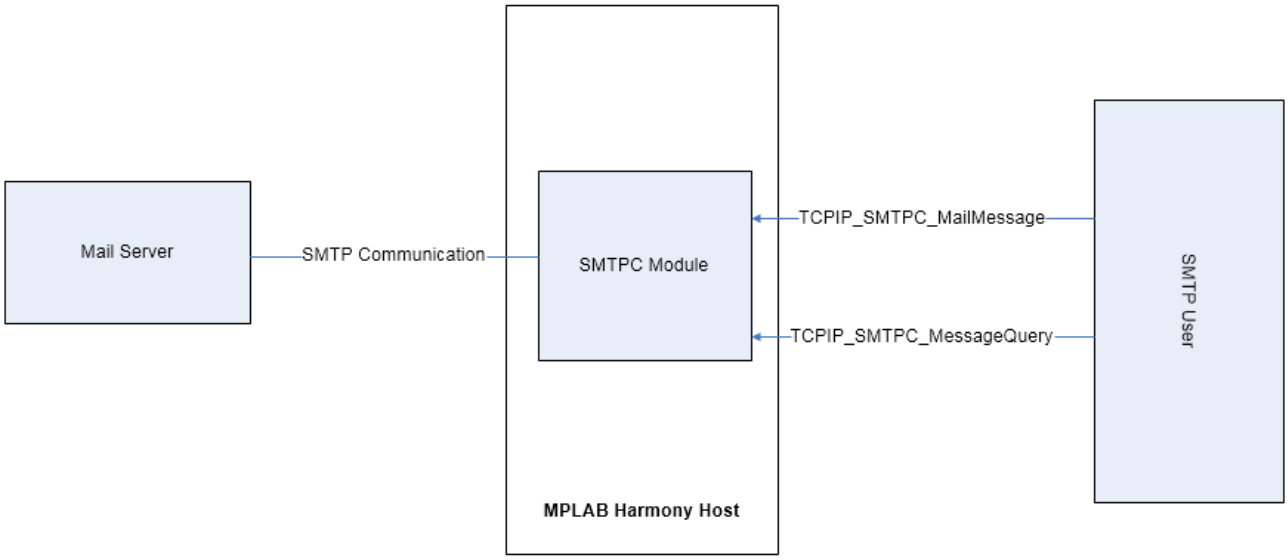
Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

This library provides the API of the SMTPC TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

SMTPC Software Abstraction Block Diagram



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the SMTPC module.

Library Interface Section	Description
Functions	Routines to configure this module
Data Types and Constants	This section provides various definitions describing this API

Configuring the Library

Macros

	Name	Description
	TCPIP_SMTPC_CLIENT_ADDR_BUFFER_SIZE	size of a buffer that can hold an email address: user@domain.smth
	TCPIP_SMTPC_CLIENT_AUTH_BUFFER_SIZE	size of a buffer that can hold the 2* username and password
	TCPIP_SMTPC_CLIENT_MESSAGE_DATE	default string that identifies the SMTPC client mail date Currently there is no date/time service available The mail server will update with the current date Keep the current data/time format that's accepted by the SMTP servers
	TCPIP_SMTPC_INTERNAL_RETRY_TIMEOUT	The retry interval because of a SMTPC temporary error, in seconds. These include temporary errors related to: DNS, socket connection, TLS.
	TCPIP_SMTPC_MAIL_CONNECTIONS	number of mail connections (sockets) to be created each mail message requires a mail connection adjust based on the number of simultaneous mail messages in transit
	TCPIP_SMTPC_MAIL_RETRIES	How many times to retry sending a mail message Retries occur only for server reported transient errors or for internal temporary errors (DNS, socket errors, etc.)
	TCPIP_SMTPC_PLAIN_LINE_BUFF_SIZE	size of an email line when sending the email body as plain text SMTP lines are recommended to be 78 chars long and MUST not exceed 998 characters! This implementation limits the line size to TCPIP_SMTPC_PLAIN_LINE_BUFF_SIZE (usually 256 or 512). So any mail line longer that this size will have inserted an artificial end of line sequence (CRLF) after this many characters.
	TCPIP_SMTPC_SERVER_DATA_TIMEOUT	server acknowledgment of the mail data: body, attachments et all; seconds Should be adjusted according to the server responsivity RFC specifies it as 10 min Default is 1 minute, which should normally be enough
	TCPIP_SMTPC_SERVER_REPLY_BUFFER_SIZE	size of the RX buffer for processing the server replies Usually the server replies are not very long so a 512 bytes buffer will normally do
	TCPIP_SMTPC_SERVER_REPLY_TIMEOUT	general server response timeout, seconds Should be adjusted according to the server responsivity RFC specifies it as 5 min Default is 1 minute, which should normally be enough
	TCPIP_SMTPC_SERVER_TRANSIENT_RETRY_TIMEOUT	The retry interval because of a server transient error, in seconds. RFC specifies it should be at least 30 min!
	TCPIP_SMTPC_SKT_RX_BUFF_SIZE	Define the size of the RX buffer for the SMTPC socket Use 0 for default TCP socket value The SMTPC RX does not need high throughput so the default value is usually fine.
	TCPIP_SMTPC_SKT_TX_BUFF_SIZE	Define the size of the TX buffer for the SMTPC socket Use 0 for default TCP socket value The SMTPC TX does not need high throughput so the default value is usually fine. For transferring large files increase this value as needed.
	TCPIP_SMTPC_TASK_TICK_RATE	SMTPC task rate, milliseconds The default value is 55 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_SMTPC_TLS_HANDSHAKE_TIMEOUT	the timeout for the TLS handshake to complete, seconds when a secure connection is established to the mail server Adjust based on the processing speed, key size, etc.
	TCPIP_SMTPC_USE_MAIL_COMMAND	Use the sample tcpip console "mail" command for sending email from the console

Description

The configuration of the SMPT TCP/IP Stack Library is based on the file `tcpip_config.h`.

This header file contains the configuration selection for the SMTPC TCP/IP Stack Library. Based on the selections made, the SMTPC TCP/IP Stack Library may support the selected features. These configuration settings will apply to all instances of the SMTPC TCP/IP Stack Library.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_SMTPC_CLIENT_ADDR_BUFFER_SIZE Macro

File

smtpc_config.h

C

```
#define TCPIP_SMTPC_CLIENT_ADDR_BUFFER_SIZE 80
```

Description

size of a buffer that can hold an email address: user@domain.smth

Remarks

this buffer is automatic, created on the stack Check your project stack settings if you need a large buffer here! If buffer not long enough this could generate TCPIP_SMTPC_RES_MESSAGE_ADDR_LEN_ERROR.

TCPIP_SMTPC_CLIENT_AUTH_BUFFER_SIZE Macro

File

smtpc_config.h

C

```
#define TCPIP_SMTPC_CLIENT_AUTH_BUFFER_SIZE 100
```

Description

size of a buffer that can hold the 2* username and password

Remarks

this buffer is automatic, created on the stack Check your project stack settings if you need a large buffer here! If buffer not long enough this could generate TCPIP_SMTPC_RES_MESSAGE_AUTH_LEN_ERROR.

TCPIP_SMTPC_CLIENT_MESSAGE_DATE Macro

File

smtpc_config.h

C

```
#define TCPIP_SMTPC_CLIENT_MESSAGE_DATE "Thu, 14 July 2016 14:55:06 -0600"
```

Description

default string that identifies the SMTPC client mail date Currently there is no date/time service available The mail server will update with the current date Keep the current data/time format that's accepted by the SMTP servers

TCPIP_SMTPC_INTERNAL_RETRY_TIMEOUT Macro

File

smtpc_config.h

C

```
#define TCPIP_SMTPC_INTERNAL_RETRY_TIMEOUT 10
```

Description

The retry interval because of a SMTPC temporary error, in seconds. These include temporary errors related to: DNS, socket connection, TLS.

TCPIP_SMTPC_MAIL_CONNECTIONS Macro

File

smtpc_config.h

C

```
#define TCPIP_SMTPC_MAIL_CONNECTIONS 3
```

Description

number of mail connections (sockets) to be created each mail message requires a mail connection adjust based on the number of simultaneous mail messages in transit

TCPIP_SMTPC_MAIL_RETRIES Macro

File

smtpc_config.h

C

```
#define TCPIP_SMTPC_MAIL_RETRIES 3
```

Description

How many times to retry sending a mail message Retries occur only for server reported transient errors or for internal temporary errors (DNS, socket errors, etc.)

TCPIP_SMTPC_PLAIN_LINE_BUFF_SIZE Macro

File

smtpc_config.h

C

```
#define TCPIP_SMTPC_PLAIN_LINE_BUFF_SIZE 256
```

Description

size of an email line when sending the email body as plain text SMTP lines are recommended to be 78 chars long and MUST not exceed 998 characters! This implementation limits the line size to TCPIP_SMTPC_PLAIN_LINE_BUFF_SIZE (usually 256 or 512). So any mail line longer that this size will have inserted an artificial end of line sequence (CRLF) after this many characters.

Remarks

this buffer is automatic, created on the stack Check your project stack settings if you need a large buffer here!

Lines are sent out as a whole so the line cannot be longer than the TCP socket TX buffer! SMTPC will ensure that this symbol does not exceed the size of the socket TX buffer by allocating a larger TX buffer, if needed

TCPIP_SMTPC_SERVER_DATA_TIMEOUT Macro

File

smtpc_config.h

C

```
#define TCPIP_SMTPC_SERVER_DATA_TIMEOUT 60
```

Description

server acknowledgment of the mail data: body, attachments et all; seconds Should be adjusted according to the server responsivity RFC specifies it as 10 min Default is 1 minute, which should normally be enough

TCPIP_SMTPC_SERVER_REPLY_BUFFER_SIZE Macro

File

smtpc_config.h

C

```
#define TCPIP_SMTPC_SERVER_REPLY_BUFFER_SIZE 512
```

Description

size of the RX buffer for processing the server replies Usually the server replies are not very long so a 512 bytes buffer will normally do

TCPIP_SMTPC_SERVER_REPLY_TIMEOUT Macro

File

smtpc_config.h

C

```
#define TCPIP_SMTPC_SERVER_REPLY_TIMEOUT 60
```

Description

general server response timeout, seconds Should be adjusted according to the server responsivity RFC specifies it as 5 min Default is 1 minute, which should normally be enough

TCPIP_SMTPC_SERVER_TRANSIENT_RETRY_TIMEOUT Macro

File

smtpc_config.h

C

```
#define TCPIP_SMTPC_SERVER_TRANSIENT_RETRY_TIMEOUT (10 * 60)
```

Description

The retry interval because of a server transient error, in seconds. RFC specifies it should be at least 30 min!

TCPIP_SMTPC_SKT_RX_BUFF_SIZE Macro

File

smtpc_config.h

C

```
#define TCPIP_SMTPC_SKT_RX_BUFF_SIZE 0
```

Description

Define the size of the RX buffer for the SMTPC socket Use 0 for default TCP socket value The SMTPC RX does not need high throughput so the default value is usually fine.

TCPIP_SMTPC_SKT_TX_BUFF_SIZE Macro

File

smtpc_config.h

C

```
#define TCPIP_SMTPC_SKT_TX_BUFF_SIZE 0
```

Description

Define the size of the TX buffer for the SMTPC socket Use 0 for default TCP socket value The SMTPC TX does not need high throughput so the default value is usually fine. For transferring large files increase this value as needed.

TCPIP_SMTPC_TASK_TICK_RATE Macro

File

smtpc_config.h

C

```
#define TCPIP_SMTPC_TASK_TICK_RATE (55)
```

Description

SMTPC task rate, milliseconds The default value is 55 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

TCPIP_SMTPC_TLS_HANDSHAKE_TIMEOUT Macro

File

smtpc_config.h

C

```
#define TCPIP_SMTPC_TLS_HANDSHAKE_TIMEOUT 10
```

Description

the timeout for the TLS handshake to complete, seconds when a secure connection is established to the mail server Adjust based on the processing speed, key size, etc.

TCPIP_SMTPC_USE_MAIL_COMMAND Macro

File

smtpc_config.h

C

```
#define TCPIP_SMTPC_USE_MAIL_COMMAND 0
```

Description

Use the sample tcpip console "mail" command for sending email from the console

Building the Library

This section lists the files that are available in the SMTPC module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/smtpc.c`	SMTPC implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The SMTPC module depends on the following modules:

- TCP/IP Stack Library
- DNS Module
- TCP Module

Library Interface

a) Functions

	Name	Description
	TCPIP_SMTPC_MailMessage	SMTPC mail message function.
	TCPIP_SMTPC_MessageQuery	SMTPC mail message query function.
	TCPIP_SMTPC_Task	Standard TCP/IP stack module task function.

b) Data Types and Functions

	Name	Description
	TCPIP_SMTPC_ATTACH_BUFFER	Buffer attachment to the mail.
	TCPIP_SMTPC_ATTACH_FILE	File attachment to the mail.
	TCPIP_SMTPC_ATTACH_TYPE	SMTPC attachment type
	TCPIP_SMTPC_ENCODE_TYPE	SMTPC encoding type
	TCPIP_SMTPC_MAIL_FLAGS	Mail message flags
	TCPIP_SMTPC_MAIL_MESSAGE	Mail message descriptor.
	TCPIP_SMTPC_MESSAGE_CALLBACK	Defines a mail message callback
	TCPIP_SMTPC_MESSAGE_HANDLE	Defines a handle to a mail message
	TCPIP_SMTPC_MESSAGE_QUERY	Structure defining a run time query for a mail message
	TCPIP_SMTPC_MESSAGE_REPORT	Structure defining a mail message report
	TCPIP_SMTPC_MESSAGE_RESULT	SMTPC result code
	TCPIP_SMTPC_MESSAGE_STATUS	SMTPC message status
	TCPIP_SMTPC_MESSAGE_WARNING	SMTPC warning type
	TCPIP_SMTPC_MODULE_CONFIG	SMTPC configuration data.
	TCPIP_SMTPC_SERVER_REPLY_CALLBACK	Defines a mail server reply callback

Description

This section describes the Application Programming Interface (API) functions of the SMTPC module.

Refer to each section for a detailed description.

a) Functions

TCPIP_SMTPC_MailMessage Function

SMTPC mail message function.

File

smtpc.h

C

```
TCPIP_SMTPC_MESSAGE_HANDLE TCPIP_SMTPC_MailMessage(const TCPIP_SMTPC_MAIL_MESSAGE* pMailMessage,
TCPIP_SMTPC_MESSAGE_RESULT* pRes);
```

Returns

a valid handle (!= 0) - if mail message scheduled successfully 0 - if call failed

an error code otherwise

Description

This function sends a mail message to the specified server.

Remarks

The returned handle is valid until the final mail notification function is called (TCPIP_SMTPC_MESSAGE_CALLBACK) if exists, or until the mail transaction is completed. After that the messageHandle is no longer valid and should not be used again.

Preconditions

SMTPC module should have been initialized.

Parameters

Parameters	Description
pMailMessage	pointer to a TCPIP_SMTPC_MAIL_MESSAGE describing the mail message to be sent
pRes	address to store the operation result If the call failed, additional info will be reported with this result Can be NULL if not needed.

Function

TCPIP_SMTPC_MESSAGE_HANDLE TCPIP_SMTPC_MailMessage(const TCPIP_SMTPC_MAIL_MESSAGE* pMailMessage, TCPIP_SMTPC_MESSAGE_RESULT* pRes);

TCPIP_SMTPC_MessageQuery Function

SMTPC mail message query function.

File

smtpc.h

C

```
TCPIP_SMTPC_MESSAGE_RESULT TCPIP_SMTPC_MessageQuery(TCPIP_SMTPC_MESSAGE_HANDLE messageHandle,
TCPIP_SMTPC_MESSAGE_QUERY* pQuery);
```

Returns

TCPIP_SMTPC_RES_OK - if message query updated successfully TCPIP_SMTPC_RES_MESSAGE_ERROR - if no such message exists

Description

This function allows the query of a mail message at run time.

Remarks

The message status is for info purposes only. The message status changes as is processed by the SMTPC module.

Once the mail transfer is complete and the corresponding notification function is called, the messageHandle is no longer valid and should not be used again.

Preconditions

SMTPC module should have been initialized.

Parameters

Parameters	Description
messageHandle	handle identifying the message. This handle was obtained with a call to TCPIP_SMTPC_MailMessage().
pQuery	pointer to a TCPIP_SMTPC_MESSAGE_QUERY structure that will be updated with the current status of the mail message

Function

TCPIP_SMTPC_MESSAGE_RESULT TCPIP_SMTPC_MessageQuery(TCPIP_SMTPC_MESSAGE_HANDLE messageHandle, TCPIP_SMTPC_MESSAGE_QUERY* pQuery);

TCPIP_SMTPC_Task Function

Standard TCP/IP stack module task function.

File

smtpc.h

C

```
void TCPIP_SMTPC_Task();
```

Returns

None.

Description

this function performs SMTPC module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

SMTPC module should have been initialized.

Function

void TCPIP_SMTPC_Task(void)

b) Data Types and Functions

TCPIP_SMTPC_ATTACH_BUFFER Structure

Buffer attachment to the mail.

File

smtpc.h

C

```
typedef struct {
  TCPIP_SMTPC_ATTACH_TYPE attachType;
  TCPIP_SMTPC_ENCODE_TYPE attachEncode;
  const char* attachName;
  const uint8_t* attachBuffer;
  size_t attachSize;
} TCPIP_SMTPC_ATTACH_BUFFER;
```

Members

Members	Description
TCPIP_SMTPC_ATTACH_TYPE attachType;	type of the contained data
TCPIP_SMTPC_ENCODE_TYPE attachEncode;	preferred encoding
const char* attachName;	file name to be used for the attachment
const uint8_t* attachBuffer;	buffer containing the data
size_t attachSize;	buffer size

Description

Structure: TCPIP_SMTPC_ATTACH_BUFFER

This data structure describes a mail buffer attachment.

Remarks

A buffer attachment is attached to the email just like a file. But data is taken from the persistent user buffer rather than from a file.

If the attach type is application octet stream then the suggested encoding will be overwritten and BASE64 encoding will be used.

The user supplied buffer has to be persistent until the mail completion callback will be called.

TCPIP_SMTPC_ATTACH_FILE Structure

File attachment to the mail.

File

smtpc.h

C

```
typedef struct {
  TCPIP_SMTPC_ATTACH_TYPE attachType;
  TCPIP_SMTPC_ENCODE_TYPE attachEncode;
  const char* fileName;
} TCPIP_SMTPC_ATTACH_FILE;
```

Members

Members	Description
TCPIP_SMTPC_ATTACH_TYPE attachType;	type of the contained data
TCPIP_SMTPC_ENCODE_TYPE attachEncode;	preferred encoding
const char* fileName;	name of the file to be opened

Description

Structure: TCPIP_SMTPC_ATTACH_FILE

This data structure describes a mail file attachment.

Remarks

The specified file will be opened for reading and attached to the email.

If the attach type is application octet stream then the suggested encoding will be overwritten and BASE64 encoding will be used.

The file has to be persistent until the mail completion callback will be called.

If file could not be opened when the mail is sent a warning will be issued and the file will be ignored.

TCPIP_SMTPC_ATTACH_TYPE Enumeration

SMTPC attachment type

File

smtpc.h

C

```
typedef enum {
  TCPIP_SMTPC_ATTACH_TYPE_UNKNOWN = 0x0000,
  TCPIP_SMTPC_ATTACH_TYPE_APPLICATION = 0x0001,
  TCPIP_SMTPC_ATTACH_TYPE_TEXT = 0x0002,
  TCPIP_SMTPC_ATTACH_TYPE_INLINE = 0x8000
} TCPIP_SMTPC_ATTACH_TYPE;
```

Members

Members	Description
TCPIP_SMTPC_ATTACH_TYPE_UNKNOWN = 0x0000	unknown attachment type; will default to binary
TCPIP_SMTPC_ATTACH_TYPE_APPLICATION = 0x0001	application octet stream, binary Use this attachment type when sending binary data
TCPIP_SMTPC_ATTACH_TYPE_TEXT = 0x0002	plain text Use this attachment type when sending ASCII text other supported types will be added here
TCPIP_SMTPC_ATTACH_TYPE_INLINE = 0x8000	flag for sending the data as inline instead of attachment

Description

Enumeration: TCPIP_SMTPC_ATTACH_TYPE

Enumeration describing the possible attachment types supported by the SMTPC client.

Remarks

Only one attachment type should be set at a time.

TCPIP_SMTPC_ENCODE_TYPE Enumeration

SMTPC encoding type

File

smtpc.h

C

```
typedef enum {
  TCPIP_SMTPC_ENCODE_TYPE_UNKNOWN,
  TCPIP_SMTPC_ENCODE_TYPE_7BIT,
  TCPIP_SMTPC_ENCODE_TYPE_BASE64
```

```
} TCPIP_SMTPC_ENCODE_TYPE;
```

Members

Members	Description
TCPIP_SMTPC_ENCODE_TYPE_UNKNOWN	unknown encoding type; defaults to base64
TCPIP_SMTPC_ENCODE_TYPE_7BIT	7bit encoding type: no encoding done, 7 bit ASCII This doesn't do any encoding. Use it for plain text.
TCPIP_SMTPC_ENCODE_TYPE_BASE64	base64 encoding applied Mandatory for binary data; could be used for plain data as well. other supported types will be added here

Description

Enumeration: TCPIP_SMTPC_ENCODE_TYPE

Enumeration describing the possible encoding types supported by the SMTPC client.

Remarks

Normally plain text should be sen using the 7bit encoding type, i.e. plain ASCII. However, selecting base64 encoding has the advantage that the lines are not limited in length and any sequence of characters can be present in the email body without the need of the SMTPC to search and replace the SMTP forbidden characters.

TCPIP_SMTPC_MAIL_FLAGS Enumeration

Mail message flags

File

smtpc.h

C

```
typedef enum {
  TCPIP_SMTPC_MAIL_FLAG_USE_IPV6 = 0x0001,
  TCPIP_SMTPC_MAIL_FLAG_BODY_TYPE_BINARY = 0x0002,
  TCPIP_SMTPC_MAIL_FLAG_BODY_ENCODE_ASCII = 0x0004,
  TCPIP_SMTPC_MAIL_FLAG_CONNECT_TLS = 0x0010,
  TCPIP_SMTPC_MAIL_FLAG_SKIP_TLS = 0x0020,
  TCPIP_SMTPC_MAIL_FLAG_FORCE_TLS = 0x0040,
  TCPIP_SMTPC_MAIL_FLAG_AUTH_PLAIN = 0x0100
} TCPIP_SMTPC_MAIL_FLAGS;
```

Members

Members	Description
TCPIP_SMTPC_MAIL_FLAG_USE_IPV6 = 0x0001	use IPv6 connection to the server, rather than default IPv4
TCPIP_SMTPC_MAIL_FLAG_BODY_TYPE_BINARY = 0x0002	mail body is binary rather then standard plain text
TCPIP_SMTPC_MAIL_FLAG_BODY_ENCODE_ASCII = 0x0004	send mail body as plain ASCII encoding rather than default BASE64
TCPIP_SMTPC_MAIL_FLAG_CONNECT_TLS = 0x0010	connect with TLS from the very beginning This flag is useful if the server accepts encrypted connections on port 465, for example Note that port 465 is not really a SMTP port, although supported by many servers!
TCPIP_SMTPC_MAIL_FLAG_SKIP_TLS = 0x0020	skip TLS even if the server supports it most servers won't accept mail if TLS is skipped though
TCPIP_SMTPC_MAIL_FLAG_FORCE_TLS = 0x0040	start TLS even if the server does not indicate support for it
TCPIP_SMTPC_MAIL_FLAG_AUTH_PLAIN = 0x0100	favor PLAIN authentication, if supported by default the LOGIN authentication is selected

Description

Enumeration: TCPIP_SMTPC_MAIL_FLAGS

Enumeration describing the possible mail message flags supported by the SMTPC client.

Remarks

Multiple flags can be set

Only 16 bit flags supported

If no flags are set, then the default settings are used for the mail message.

Normally the mail body is plain text. Using these flags, a binary mail body can be sent.

Normally the mail body is plain text so a standard ASCII encoding is used. Using these flags, a BASE64 encoding for the mail body can be

selected. Note that if the mail body is selected to be binary then the BASE64 encoding is automatically selected.

BASE64 encoding has the advantage that the mail body lines are not limited in length and any sequence of characters can be present in the email body without the need of the SMTPC to search and replace the SMTP forbidden characters.

Normally the connection to the server occurs on a standard SMTP port: 25 or (preferred) 587 as a plain/non-encrypted connection. Once the server replies with TLS support, the encryption is started. Using the flags you can force the connection to be TLS from the very beginning. Or you can avoid engaging in TLS even if the server supports it. Or try to start TLS even if the server didn't advertise support for it.

TCPIP_SMTPC_MAIL_MESSAGE Structure

Mail message descriptor.

File

smtpc.h

C

```
typedef struct {
  const char* from;
  const char* to;
  const char* sender;
  const char* cc;
  const char* bcc;
  const char* date;
  const char* subject;
  const uint8_t* body;
  size_t bodySize;
  int nBuffers;
  const TCPIP_SMTPC_ATTACH_BUFFER* attachBuffers;
  int nFiles;
  const TCPIP_SMTPC_ATTACH_FILE* attachFiles;
  const char* username;
  const char* password;
  const char* smtpServer;
  uint16_t serverPort;
  TCPIP_SMTPC_MAIL_FLAGS messageFlags;
  TCPIP_SMTPC_MESSAGE_CALLBACK messageCallback;
  TCPIP_SMTPC_SERVER_REPLY_CALLBACK replyCallback;
} TCPIP_SMTPC_MAIL_MESSAGE;
```

Members

Members	Description
const char* from;	Mandatory Mail Fields recipient return address
const char* to;	destination address
const char* sender;	Optional Mail Fields if sent on behalf of someone else
const char* cc;	carbon copy destination address
const char* bcc;	blind carbon copy destination address
const char* date;	date for the mail message Should be formatted like: "Wed, 20 July 2016 14:55:06 -0600" if NULL, then the TCPIP_SMTPC_CLIENT_MESSAGE_DATE will be used
const char* subject;	Regular Mail Fields mail subject line
const uint8_t* body;	mail body; main body of the mail
int nBuffers;	Mail Attachments number of attached buffers
const TCPIP_SMTPC_ATTACH_BUFFER* attachBuffers;	array of buffer attachments
int nFiles;	number of attached files
const TCPIP_SMTPC_ATTACH_FILE* attachFiles;	array of file attachments
const char* username;	Mail Authentication username to be presented when the mail server requires authentication
const char* password;	associated password to be presented when the mail server requires authentication
const char* smtpServer;	Mail Server address or name of a server to send the mail to (smtp.gmail.com, 74.125.23.109, etc.)

uint16_t serverPort;	port on which the SMTP server listens on Standard SMTP ports are 25 or 587 For servers supporting TLS (gmail, yahoo, etc.), the recommended port is 587
TCPIP_SMTPC_MAIL_FLAGS messageFlags;	Additional message flags
TCPIP_SMTPC_MESSAGE_CALLBACK messageCallback;	Mail Notifications message completion notification could be NULL if not needed
TCPIP_SMTPC_SERVER_REPLY_CALLBACK replyCallback;	server reply notification could be NULL if not needed

Description

Structure: TCPIP_SMTPC_MAIL_MESSAGE

This data structure describes a mail message

Remarks

SMTPC does NOT make private copies of the strings, buffers, etc. presented in a TCPIP_SMTPC_MAIL_MESSAGE data structure. All fields that are pointers to strings, buffers, files names, etc. MUST be persistent until the mail complete notification is received.

The TCPIP_SMTPC_MAIL_MESSAGE data structure itself does not need to be persistent.

The mail body is not a char* but uint8_t* to allow sending binary data as well as part of the mail body. This requires though that the bodySize member is present.

If some file could not be opened when the mail is sent a warning will be issued and the file will be ignored.

Currently the fields: "sender", "cc" and "bcc" are not used. They will be eventually added.

TCPIP_SMTPC_MESSAGE_CALLBACK Type

Defines a mail message callback

File

smtpc.h

C

```
typedef void (* TCPIP_SMTPC_MESSAGE_CALLBACK)(TCPIP_SMTPC_MESSAGE_HANDLE messageHandle, const
TCPIP_SMTPC_MESSAGE_REPORT* pMailReport);
```

Description

Type: TCPIP_SMTPC_MESSAGE_CALLBACK

Data type describing a function that will be called by the SMTPC module upon completion of the mail message.

Remarks

A message handle is used rather than the user's TCPIP_SMTPC_MAIL_MESSAGE. This allows sending multiple copies of the message without waiting for a previous copy to be done.

This notification can be called multiple times if the delivery attempt failed for a transient reson. The number of left retries tells if another attempt will be retried.

Once this final notification function is called (left retries == 0), the SMTPC no longer uses the TCPIP_SMTPC_MAIL_MESSAGE data (unless there are other copies of this message in transit). This messageHandle is no longer valid and should not be used again.

The pMailReport points to a SMTPC owned read only data structure. It should be used only to inspect the message delivery result.

Parameters

Parameters	Description
messageHandle	handle identifying the message. This handle was obtained with a call to TCPIP_SMTPC_MailMessage().
pMailReport	pointer to a TCPIP_SMTPC_MESSAGE_REPORT data structure containing the
result of the message delivery	messageRes - the result of the message
errorStat	error status
messageWarn	warnings
leftRetries	number of times the delivery will be re-attempted.

TCPIP_SMTPC_MESSAGE_HANDLE Type

Defines a handle to a mail message

File

smtpc.h

C

```
typedef const void* TCPIP_SMTPC_MESSAGE_HANDLE;
```

Description

Type: TCPIP_SMTPC_MESSAGE_HANDLE

Data type describing a handle that identifies a mail message that's scheduled for transmission. This handle is to be used for retrieving the message status. This handle will be part of the callback that the SMTP client will use to notify the user of the mail completion.

A valid handle is != 0.

Remarks

None

TCPIP_SMTPC_MESSAGE_QUERY Structure

Structure defining a run time query for a mail message

File

smtpc.h

C

```
typedef struct {
  TCPIP_SMTPC_MESSAGE_STATUS messageStat;
  TCPIP_SMTPC_MESSAGE_WARNING messageWarn;
  int messageRetries;
  NET_PRES_SKT_HANDLE_T messageSkt;
} TCPIP_SMTPC_MESSAGE_QUERY;
```

Members

Members	Description
TCPIP_SMTPC_MESSAGE_STATUS messageStat;	the current status of the mail message
TCPIP_SMTPC_MESSAGE_WARNING messageWarn;	the current warnings encountered during the message transmission
int messageRetries;	the current number of retries for this message
NET_PRES_SKT_HANDLE_T messageSkt;	the socket associated with this message

Description

Structure: TCPIP_SMTPC_MESSAGE_QUERY

This data structure describes a mail message query at run time.

Remarks

The message status is for info purposes only. The message status changes as is processed by the SMTPC module.

TCPIP_SMTPC_MESSAGE_REPORT Structure

Structure defining a mail message report

File

smtpc.h

C

```
typedef struct {
  TCPIP_SMTPC_MESSAGE_RESULT messageRes;
  TCPIP_SMTPC_MESSAGE_STATUS errorStat;
  TCPIP_SMTPC_MESSAGE_WARNING messageWarn;
  int leftRetries;
} TCPIP_SMTPC_MESSAGE_REPORT;
```

Members

Members	Description
TCPIP_SMTPC_MESSAGE_RESULT messageRes;	the result of the message TCPIP_SMTPC_RES_OK if the message was successfully transmited else some error were encountered
TCPIP_SMTPC_MESSAGE_STATUS errorStat;	the mail message status in which the error occurred, if any Else the TCPIP_SMTPC_MESSAGE_STAT_NONE will be used
TCPIP_SMTPC_MESSAGE_WARNING messageWarn;	warnings encountered during the message transmission, if any
int leftRetries;	the number of retries that will still be attempted if error was a transient, not fatal

Description

Structure: TCPIP_SMTPC_MESSAGE_REPORT

This data structure describes a mail message report. It is used by the SMTPC to report an mail delivery result.

Remarks

None

TCPIP_SMTPC_MESSAGE_RESULT Enumeration

SMTPC result code

File

smtpc.h

C

```
typedef enum {
  TCPIP_SMTPC_RES_OK = 0,
  TCPIP_SMTPC_RES_PENDING = 1,
  TCPIP_SMTPC_RES_MESSAGE_ERROR = -1,
  TCPIP_SMTPC_RES_MESSAGE_SERVER_ERROR = -2,
  TCPIP_SMTPC_RES_MESSAGE_RCPT_ERROR = -3,
  TCPIP_SMTPC_RES_MESSAGE_BUFFER_ERROR = -4,
  TCPIP_SMTPC_RES_MESSAGE_FILE_ERROR = -5,
  TCPIP_SMTPC_RES_MESSAGE_AUTH_REQUIRED = -6,
  TCPIP_SMTPC_RES_MESSAGE_AUTH_LEN_ERROR = -7,
  TCPIP_SMTPC_RES_MESSAGE_ADDR_LEN_ERROR = -8,

} TCPIP_SMTPC_MESSAGE_RESULT;
```

Members

Members	Description
TCPIP_SMTPC_RES_OK = 0	OK, operation successful
TCPIP_SMTPC_RES_PENDING = 1	operation in progress
TCPIP_SMTPC_RES_MESSAGE_ERROR = -1	mail message error

TCPIP_SMTPC_RES_MESSAGE_SERVER_ERROR = -2	message indicated wrong mail server
TCPIP_SMTPC_RES_MESSAGE_RCPT_ERROR = -3	message mail recipient error: from, to, etc.
TCPIP_SMTPC_RES_MESSAGE_BUFFER_ERROR = -4	attachment buffer error
TCPIP_SMTPC_RES_MESSAGE_FILE_ERROR = -5	attachment file error
TCPIP_SMTPC_RES_MESSAGE_AUTH_REQUIRED = -6	server requires authentication but username or password haven't been provided
TCPIP_SMTPC_RES_MESSAGE_AUTH_LEN_ERROR = -7	provided credentials are too long, buffer overflow
TCPIP_SMTPC_RES_MESSAGE_ADDR_LEN_ERROR = -8	email address too long, buffer overflow
TCPIP_SMTPC_RES_MAIL_BUSY = -9	all mail connections are busy; try later
TCPIP_SMTPC_RES_DNS_ERROR = -10	failure to resolve server name
TCPIP_SMTPC_RES_SKT_OPEN_ERROR = -11	failure to open a communication socket
TCPIP_SMTPC_RES_SKT_BIND_ERROR = -12	failure to bind a socket to the mail server
TCPIP_SMTPC_RES_SKT_CONNECT_TMO = -13	connection to mail server timeout
TCPIP_SMTPC_RES_SKT_TLS_ERROR = -14	TLS is required but failed to start TLS on the communication socket
TCPIP_SMTPC_RES_SERVER_TMO = -15	server timeout
TCPIP_SMTPC_RES_CONNECTION_REJECT = -16	server rejected the connection
TCPIP_SMTPC_RES_CONNECTION_CLOSE = -17	server closed the connection
TCPIP_SMTPC_RES_HELLO_REJECT = -18	server rejected the hello greeting
TCPIP_SMTPC_RES_AUTH_UNKNOWN = -19	server requires authentication mechanism unsupported by SMTPC Currently LOGIN and PLAIN authentications are supported
TCPIP_SMTPC_RES_AUTH_LOGIN_REJECT = -20	server rejected the login authentication request
TCPIP_SMTPC_RES_AUTH_LOGIN_SERVER_ERROR = -21	unexpected server reply to login authentication request
TCPIP_SMTPC_RES_AUTH_REJECT = -22	server rejected the supplied authentication
TCPIP_SMTPC_RES_TLS_REJECT = -23	server rejected the TLS start
TCPIP_SMTPC_RES_TLS_FAILED = -24	TLS session negotiation failed
TCPIP_SMTPC_RES_TLS_TMO = -25	TLS session timeout
TCPIP_SMTPC_RES_MAIL_FROM_REJECT = -26	server rejected the "from" address
TCPIP_SMTPC_RES_MAIL_RCPT_REJECT = -27	server rejected the "recipient" address
TCPIP_SMTPC_RES_MAIL_DATA_REJECT = -28	server rejected the "data" field
TCPIP_SMTPC_RES_MAIL_BODY_REJECT = -29	server rejected the mail body
TCPIP_SMTPC_RES_INITIALIZE_ERROR = -40	module is not properly initialized, API call is invalid
TCPIP_SMTPC_RES_INTERNAL_ERROR = -41	internal failure, should not happen

Description

Enumeration: TCPIP_SMTPC_MESSAGE_RESULT

Enumeration describing the possible result codes returned by the SMTPC client.

Remarks

None

TCPIP_SMTPC_MESSAGE_STATUS Enumeration

SMTPC message status

File

smtpc.h

C

```
typedef enum {
  TCPIP_SMTPC_MESSAGE_STAT_NONE,
  TCPIP_SMTPC_MESSAGE_STAT_DNS,
  TCPIP_SMTPC_MESSAGE_STAT_CONNECT,
  TCPIP_SMTPC_MESSAGE_STAT_HELLO,
  TCPIP_SMTPC_MESSAGE_STAT_TLS,
```

```
  TCPIP_SMTPC_MESSAGE_STAT_AUTH,
  TCPIP_SMTPC_MESSAGE_STAT_MAIL_ENVELOPE,
  TCPIP_SMTPC_MESSAGE_STAT_MAIL_BODY,
  TCPIP_SMTPC_MESSAGE_STAT_MAIL_BUFFERS,
  TCPIP_SMTPC_MESSAGE_STAT_MAIL_FILES,
  TCPIP_SMTPC_MESSAGE_STAT_MAIL_ACKNOWLEDGE,
  TCPIP_SMTPC_MESSAGE_STAT_MAIL_REPORT,
  TCPIP_SMTPC_MESSAGE_STAT_CLOSING,
  TCPIP_SMTPC_MESSAGE_STAT_WAIT_RETRY
} TCPIP_SMTPC_MESSAGE_STATUS;
```

Members

Members	Description
TCPIP_SMTPC_MESSAGE_STAT_NONE	there is no transaction started
TCPIP_SMTPC_MESSAGE_STAT_DNS	doing the DNS resolution
TCPIP_SMTPC_MESSAGE_STAT_CONNECT	connecting to the server
TCPIP_SMTPC_MESSAGE_STAT_HELLO	saying hello to the server
TCPIP_SMTPC_MESSAGE_STAT_TLS	starting the TLS communication with the server
TCPIP_SMTPC_MESSAGE_STAT_AUTH	authenticating to the server
TCPIP_SMTPC_MESSAGE_STAT_MAIL_ENVELOPE	sending mail envelope
TCPIP_SMTPC_MESSAGE_STAT_MAIL_BODY	sending mail body
TCPIP_SMTPC_MESSAGE_STAT_MAIL_BUFFERS	sending mail buffers
TCPIP_SMTPC_MESSAGE_STAT_MAIL_FILES	sending mail files
TCPIP_SMTPC_MESSAGE_STAT_MAIL_ACKNOWLEDGE	waiting for the mail acknowledge
TCPIP_SMTPC_MESSAGE_STAT_MAIL_REPORT	reporting the mail outcome
TCPIP_SMTPC_MESSAGE_STAT_CLOSING	closing the mail transaction
TCPIP_SMTPC_MESSAGE_STAT_WAIT_RETRY	waiting for a retry

Description

Enumeration: TCPIP_SMTPC_MESSAGE_STATUS

Enumeration describing the possible states of a mail message during a mail transmission. The message progresses through various states until complete mail transfer or error

Remarks

TCPIP_SMTPC_MESSAGE_STAT_HELLO will occur twice if TLS is supported by the server. Once the connection is secured, another HELLO message will be sent to the server.

TCPIP_SMTPC_MESSAGE_WARNING Enumeration

SMTPC warning type

File

smtpc.h

C

```
typedef enum {
  TCPIP_SMTPC_WARN_REPLY_BUFFER_SMALL = 0x0001,
  TCPIP_SMTPC_WARN_WRONG_FORMAT = 0x0002,
  TCPIP_SMTPC_WARN_UNEXPECTED_REPLY = 0x0004,
  TCPIP_SMTPC_WARN_FILE_NOT_FOUND = 0x0008,
  TCPIP_SMTPC_WARN_AUTH_LOGIN_LEN = 0x0010
} TCPIP_SMTPC_MESSAGE_WARNING;
```

Members

Members	Description
TCPIP_SMTPC_WARN_REPLY_BUFFER_SMALL = 0x0001	the reply buffer allocated for the server replies is too small server reply exceeded the size of the buffer it should be increased
TCPIP_SMTPC_WARN_WRONG_FORMAT = 0x0002	server reply was not properly formatted
TCPIP_SMTPC_WARN_UNEXPECTED_REPLY = 0x0004	unexpected server replied received
TCPIP_SMTPC_WARN_FILE_NOT_FOUND = 0x0008	file attachment not found; ignored

TCPIP_SMTPC_WARN_AUTH_LOGIN_LEN = 0x0010	provided credentials for LOGIN authentication are too long and were truncated (buffer overflow) this most likely will result in a server authentication rejection

Description

Enumeration: TCPIP_SMTPC_MESSAGE_WARNING

Enumeration describing the possible warning types occurring during a mail transmission. These events are not fatal and SMTPC client will try to complete the mail transfer.

Remarks

Multiple warnings could be set during a mail transmission

TCPIP_SMTPC_MODULE_CONFIG Structure

SMTPC configuration data.

File

smtpc.h

C

```
typedef struct {
  int nMailConnections;
  uint32_t serverReplyTmo;
  uint32_t serverDataTmo;
  uint32_t tlsHandshakeTmo;
  int nMailRetries;
  uint32_t serverRetryTmo;
  uint32_t smtpcRetryTmo;
  uint16_t sktTxBuffSize;
  uint16_t sktRxBuffSize;
} TCPIP_SMTPC_MODULE_CONFIG;
```

Members

Members	Description
int nMailConnections;	number of mail connections to be created each mail message to be sent requires a mail connection adjust based on the number of simultaneous mail messages in transit
uint32_t serverReplyTmo;	general server response timeout, seconds Should be adjusted according to the server responsivity RFC specifies it as 5 min
uint32_t serverDataTmo;	server response timeout to acknowledge a received mail body/data, seconds Should be adjusted according to the server responsivity RFC specifies it as 10 min
uint32_t tlsHandshakeTmo;	secure connection establishment timeout, seconds usually few seconds
int nMailRetries;	how many times to retry sending a mail message Retries occur only for server reported transient errors
uint32_t serverRetryTmo;	The retry interval because of a server transient error, in seconds. RFC specifies it should be at least 30 min!
uint32_t smtpcRetryTmo;	The retry interval because of a SMTPC temporary error, in seconds. These include temporary errors related to: DNS, socket connection, TLS.
uint16_t sktTxBuffSize;	size of TX buffer for the associated socket; leave 0 for default
uint16_t sktRxBuffSize;	size of RX buffer for the associated socket; leave 0 for default

Description

Structure: TCPIP_SMTPC_MODULE_CONFIG

This data structure describes the SMTPC configuration data. It is presented to the module as part of the module initialization.

Remarks

None

TCPIP_SMTPC_SERVER_REPLY_CALLBACK Type

Defines a mail server reply callback

File

smtpc.h

C

```
typedef void (* TCPIP_SMTPC_SERVER_REPLY_CALLBACK)(TCPIP_SMTPC_MESSAGE_HANDLE messageHandle,
TCPIP_SMTPC_MESSAGE_STATUS currStat, const char* serverReply);
```

Description

Type: TCPIP_SMTPC_SERVER_REPLY_CALLBACK

Data type describing a function that will be called by the SMTPC module upon receiving a message from the mail server. SMTPC will parse and process the server messages anyway but it can optionally pass the server replies to the user.

Remarks

None

Parameters

Parameters	Description
messageHandle	handle identifying the message. This handle was obtained with a call to TCPIP_SMTPC_MailMessage().
currStat	the current status for the mail message
serverReply	the reply sent by the server

Files

Files

Name	Description
smtpc.h	Module for Microchip TCP/IP Stack.
smtpc_config.h	SMTPC configuration file

Description

This section lists the source and header files used by the library.

smtpc.h

Module for Microchip TCP/IP Stack.

Enumerations

	Name	Description
	TCPIP_SMTPC_ATTACH_TYPE	SMTPC attachment type
	TCPIP_SMTPC_ENCODE_TYPE	SMTPC encoding type
	TCPIP_SMTPC_MAIL_FLAGS	Mail message flags
	TCPIP_SMTPC_MESSAGE_RESULT	SMTPC result code
	TCPIP_SMTPC_MESSAGE_STATUS	SMTPC message status
	TCPIP_SMTPC_MESSAGE_WARNING	SMTPC warning type

Functions

	Name	Description
	TCPIP_SMTPC_MailMessage	SMTPC mail message function.
	TCPIP_SMTPC_MessageQuery	SMTPC mail message query function.
	TCPIP_SMTPC_Task	Standard TCP/IP stack module task function.

Structures

	Name	Description
	TCPIP_SMTPC_ATTACH_BUFFER	Buffer attachment to the mail.
	TCPIP_SMTPC_ATTACH_FILE	File attachment to the mail.
	TCPIP_SMTPC_MAIL_MESSAGE	Mail message descriptor.
	TCPIP_SMTPC_MESSAGE_QUERY	Structure defining a run time query for a mail message
	TCPIP_SMTPC_MESSAGE_REPORT	Structure defining a mail message report
	TCPIP_SMTPC_MODULE_CONFIG	SMTPC configuration data.

Types

	Name	Description
	TCPIP_SMTPC_MESSAGE_CALLBACK	Defines a mail message callback
	TCPIP_SMTPC_MESSAGE_HANDLE	Defines a handle to a mail message
	TCPIP_SMTPC_SERVER_REPLY_CALLBACK	Defines a mail server reply callback

Description

Simple Mail Transfer Protocol Client - SMTPC

The SMTPC client module in the TCP/IP Stack lets applications send e-mails to any recipient worldwide. These message could include status information or important alerts. Using the e-mail to SMS gateways provided by most cell phone carriers, these messages can also be delivered directly to cell phone handsets.

File Name

smtpc.h

Company

Microchip Technology Inc.

smtpc_config.h

SMTPC configuration file

Macros

	Name	Description
	TCPIP_SMTPC_CLIENT_ADDR_BUFFER_SIZE	size of a buffer that can hold an email address: user@domain.smth
	TCPIP_SMTPC_CLIENT_AUTH_BUFFER_SIZE	size of a buffer that can hold the 2* username and password
	TCPIP_SMTPC_CLIENT_MESSAGE_DATE	default string that identifies the SMTPC client mail date Currently there is no date/time service available The mail server will update with the current date Keep the current data/time format that's accepted by the SMTP servers
	TCPIP_SMTPC_INTERNAL_RETRY_TIMEOUT	The retry interval because of a SMTPC temporary error, in seconds. These include temporary errors related to: DNS, socket connection, TLS.
	TCPIP_SMTPC_MAIL_CONNECTIONS	number of mail connections (sockets) to be created each mail message requires a mail connection adjust based on the number of simultaneous mail messages in transit
	TCPIP_SMTPC_MAIL_RETRIES	How many times to retry sending a mail message Retries occur only for server reported transient errors or for internal temporary errors (DNS, socket errors, etc.)
	TCPIP_SMTPC_PLAIN_LINE_BUFF_SIZE	size of an email line when sending the email body as plain text SMTP lines are recommended to be 78 chars long and MUST not exceed 998 characters! This implementation limits the line size to TCPIP_SMTPC_PLAIN_LINE_BUFF_SIZE (usually 256 or 512). So any mail line longer that this size will have inserted an artificial end of line sequence (CRLF) after this many characters.
	TCPIP_SMTPC_SERVER_DATA_TIMEOUT	server acknowledgment of the mail data: body, attachments et all; seconds Should be adjusted according to the server responsivity RFC specifies it as 10 min Default is 1 minute, which should normally be enough
	TCPIP_SMTPC_SERVER_REPLY_BUFFER_SIZE	size of the RX buffer for processing the server replies Usually the server replies are not very long so a 512 bytes buffer will normally do
	TCPIP_SMTPC_SERVER_REPLY_TIMEOUT	general server response timeout, seconds Should be adjusted according to the server responsivity RFC specifies it as 5 min Default is 1 minute, which should normally be enough
	TCPIP_SMTPC_SERVER_TRANSIENT_RETRY_TIMEOUT	The retry interval because of a server transient error, in seconds. RFC specifies it should be at least 30 min!
	TCPIP_SMTPC_SKT_RX_BUFF_SIZE	Define the size of the RX buffer for the SMTPC socket Use 0 for default TCP socket value The SMTPC RX does not need high throughput so the default value is usually fine.
	TCPIP_SMTPC_SKT_TX_BUFF_SIZE	Define the size of the TX buffer for the SMTPC socket Use 0 for default TCP socket value The SMTPC TX does not need high throughput so the default value is usually fine. For transferring large files increase this value as needed.

	TCPIP_SMTPC_TASK_TICK_RATE	SMTPC task rate, milliseconds The default value is 55 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_SMTPC_TLS_HANDSHAKE_TIMEOUT	the timeout for the TLS handshake to complete, seconds when a secure connection is established to the mail server Adjust based on the processing speed, key size, etc.
	TCPIP_SMTPC_USE_MAIL_COMMAND	Use the sample tcpip console "mail" command for sending email from the console

SNMP Module

This section describes the TCP/IP Stack Library SNMP module.

Introduction

TCP/IP Stack Library Simple Network Management Protocol (SNMP) Module for Microchip Microcontrollers

This library provides the API of the SNMP module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

SNMP is one of the key components of a Network Management System (NMS). SNMP is an application layer protocol that facilitates the exchange of management information among network devices. It is a part of the TCP/IP protocol suite.

SNMP is an Internet protocol that was originally designed to manage different network devices, such as file servers, hubs, routers and so on. It can also be used to manage and control an ever increasing number of small embedded systems connected to one another over any IP network. Systems can communicate with each other using SNMP to transfer control and status information, creating a truly distributed system.

SNMP is used in a variety of applications where remote monitoring and controlling of the network node is desired, such as a network printer, online Uninterrupted Power Supply (UPS), security cameras, home and industrial appliances monitor and control, automatic energy meter readings, etc.

Unlike more familiar human-oriented protocols, like HTTP, SNMP is considered a machine-to-machine protocol.

Note: The related application note, AN870 *"SNMP V2c Agent for Microchip TCP/IP Stack"* (DS8000870) is available for download from the Microchip web site at: http://ww1.microchip.com/downloads/en/AppNotes/00870b.pdf

Using the Library

This topic describes the basic architecture of the SNMP TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `snmp.h`

The interface to the SNMP TCP/IP Stack library is defined in the `snmp.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the SNMP TCP/IP Stack library should include `tcpip.h`.

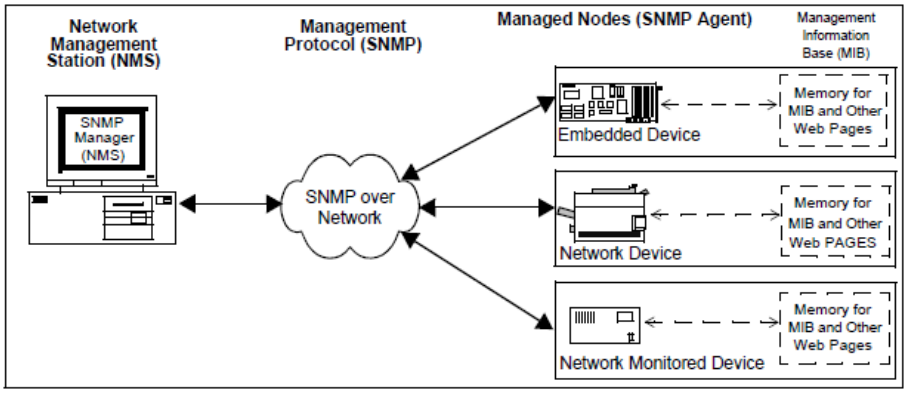
Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

This library provides the API of the SNMP TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

SNMP Software Abstraction Block Diagram



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the SNMP module.

Library Interface Section	Description
SNMP Module Functions	Routines to configure this module
SNMPv3 Module Functions	Routines to configure this module
SNMP Application Functions	Routines to configure an application
SNMPv3 Application Functions	Routines to configure an application
SNMP Data Types and Constants	This section provides various definitions describing this API
SNMPv3 Data Types and Constants	This section provides various definitions describing this API

Configuring the Library

Macros

	Name	Description
	TCPIP_SNMP_BIB_FILE_NAME	The Microchip mib2bib.jar compiler is used to convert the Microchip MIB script to binary format and it is compatible with the Microchip SNMP agent. which is written in ASCII format. Name of the bib file for SNMP is snmp.bib.
	TCPIP_SNMP_COMMUNITY_MAX_LEN	This is the maximum length for community string. Application must ensure that this length is observed. SNMP module adds one byte extra after TCPIP_SNMP_COMMUNITY_MAX_LEN for adding '0' NULL character.
	TCPIP_SNMP_MAX_COMMUNITY_SUPPORT	Specifying more strings than TCPIP_SNMP_MAX_COMMUNITY_SUPPORT will result in the later strings being ignored (but still wasting program memory). Specifying fewer strings is legal, as long as at least one is present.
	TCPIP_SNMP_MAX_MSG_SIZE	The maximum length in octets of an SNMP message which this SNMP agent able to process. As per RFC 3411 snmpEngineMaxMessageSize and RFC 1157 (section 4- protocol specification) and implementation supports more than 480 whenever feasible. It should be divisible by 16

	TCPIP_SNMP_MAX_NON_REC_ID_OID	Update the Non record id OID value which is part of CustomSnmpDemoApp.c file. This is the maximum size for gSnmpNonMibRecInfo[] which is the list of static variable Parent OIDs which are not part of mib.h file. This structure is used to restrict access to static variables of SNMPv3 OIDs from SNMPv2c and SNMPv1 version. With SNMPv3 all the OIDs accessible but when we are using SNMPv2c version , static variables of the SNMPv3 cannot be accessible with SNMP version v2c. SNMP agent supports both SMIv1 and SMIv2 standard and snmp.mib has been updated with respect to SMIV2 standard and it... more
	TCPIP_SNMP_NOTIFY_COMMUNITY_LEN	Maximum length for SNMP Trap community name
	TCPIP_SNMP_OID_MAX_LEN	Maximum length for the OID String. Change this to match your OID string length.
	TCPIP_SNMP_TASK_PROCESS_RATE	SNMP task processing rate, in milli-seconds. The SNMP module will process a timer event with this rate for processing its own state machine, etc. The default value is 200 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_SNMP_TRAP_COMMUNITY_MAX_LEN	The maximum size of TRAP community string length
	TCPIP_SNMP_TRAP_COMMUNITY_MAX_LEN_MEM_USE	Trap information. This macro will be used to avoid SNMP OID memory buffer corruption
	TCPIP_SNMP_TRAP_TABLE_SIZE	This table maintains list of interested receivers who should receive notifications when some interesting event occurs.
	TCPIP_SNMPV3_AUTH_LOCALIZED_PASSWORD_KEY_LEN	SNMPv3 Authentication Localized password key length size
	TCPIP_SNMPV3_AUTH_LOCALIZED_PASSWORD_KEY_LEN_MEM_USE	SNMPv3 authentication localized Key length for memory validation
	TCPIP_SNMPV3_PRIV_LOCALIZED_PASSWORD_KEY_LEN	SNMPv3 Privacy Password key length size
	TCPIP_SNMPV3_PRIV_LOCALIZED_PASSWORD_KEY_LEN_MEM_USE	SNMPv3 privacy key length size for memory validation
	TCPIP_SNMPV3_USER_SECURITY_NAME_LEN	Maximum size for SNMPv3 User Security Name length.
	TCPIP_SNMPV3_USER_SECURITY_NAME_LEN_MEM_USE	User security name length for memory validation
	TCPIP_SNMPV3_USM_MAX_USER	Maximum number of SNMPv3 users. User Security Model should have at least 1 user. Default is 3.

Description

The configuration of the SNMP TCP/IP Stack Library is based on the file `tcpip_config.h`.

This header file contains the configuration selection for the SNMP TCP/IP Stack Library. Based on the selections made, the SNMP TCP/IP Stack Library may support the selected features. These configuration settings will apply to all instances of the SNMP TCP/IP Stack Library.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_SNMP_BIB_FILE_NAME Macro

File

snmp_config.h

C

```
#define TCPIP_SNMP_BIB_FILE_NAME "snmp.bib"
```

Description

The Microchip mib2bib.jar compiler is used to convert the Microchip MIB script to binary format and it is compatible with the Microchip SNMP agent. which is written in ASCII format. Name of the bib file for SNMP is snmp.bib.

TCPIP_SNMP_COMMUNITY_MAX_LEN Macro

File

snmp_config.h

C

```
#define TCPIP_SNMP_COMMUNITY_MAX_LEN (8u)
```

Description

This is the maximum length for community string. Application must ensure that this length is observed. SNMP module adds one byte extra after TCPIP_SNMP_COMMUNITY_MAX_LEN for adding '0' NULL character.

TCPIP_SNMP_MAX_COMMUNITY_SUPPORT Macro

File

snmp_config.h

C

```
#define TCPIP_SNMP_MAX_COMMUNITY_SUPPORT (3u)
```

Description

Specifying more strings than TCPIP_SNMP_MAX_COMMUNITY_SUPPORT will result in the later strings being ignored (but still wasting program memory). Specifying fewer strings is legal, as long as at least one is present.

TCPIP_SNMP_MAX_MSG_SIZE Macro

File

snmp_config.h

C

```
#define TCPIP_SNMP_MAX_MSG_SIZE 480
```

Description

The maximum length in octets of an SNMP message which this SNMP agent able to process. As per RFC 3411 snmpEngineMaxMessageSize and RFC 1157 (section 4- protocol specification) and implementation supports more than 480 whenever feasible. It should be divisible by 16

TCPIP_SNMP_MAX_NON_REC_ID_OID Macro

File

snmp_config.h

C

```
#define TCPIP_SNMP_MAX_NON_REC_ID_OID 3
```

Description

Update the Non record id OID value which is part of CustomSnmpDemoApp.c file. This is the maximum size for gSnmpNonMibRecInfo[] which is the list of static variable Parent OIDs which are not part of mib.h file. This structure is used to restrict access to static variables of SNMPv3 OIDs from SNMPv2c and SNMPv1 version. With SNMPv3 all the OIDs accessible but when we are using SNMPv2c version , static variables of the SNMPv3 cannot be accessible with SNMP version v2c. SNMP agent supports both SMIv1 and SMIv2 standard and snmp.mib has been updated with respect to SMIV2 standard and it also includes MODULE-IDENTITY (number 1)after ENTERPRISE-ID.

TCPIP_SNMP_NOTIFY_COMMUNITY_LEN Macro

File

snmp_config.h

C

```
#define TCPIP_SNMP_NOTIFY_COMMUNITY_LEN (TCPIP_SNMP_COMMUNITY_MAX_LEN)
```

Description

Maximum length for SNMP Trap community name

TCPIP_SNMP_OID_MAX_LEN Macro

File

snmp_config.h

C

```
#define TCPIP_SNMP_OID_MAX_LEN (18)
```

Description

Maximum length for the OID String. Change this to match your OID string length.

TCPIP_SNMP_TASK_PROCESS_RATE Macro

File

snmp_config.h

C

```
#define TCPIP_SNMP_TASK_PROCESS_RATE (200)
```

Description

SNMP task processing rate, in milli-seconds. The SNMP module will process a timer event with this rate for processing its own state machine, etc. The default value is 200 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

TCPIP_SNMP_TRAP_COMMUNITY_MAX_LEN Macro

File

snmp_config.h

C

```
#define TCPIP_SNMP_TRAP_COMMUNITY_MAX_LEN (TCPIP_SNMP_TRAP_COMMUNITY_MAX_LEN_MEM_USE+1)
```

Description

The maximum size of TRAP community string length

TCPIP_SNMP_TRAP_COMMUNITY_MAX_LEN_MEM_USE Macro

File

snmp_config.h

C

```
#define TCPIP_SNMP_TRAP_COMMUNITY_MAX_LEN_MEM_USE (8)
```

Description

Trap information. This macro will be used to avoid SNMP OID memory buffer corruption

TCPIP_SNMP_TRAP_TABLE_SIZE Macro

File

snmp_config.h

C

```
#define TCPIP_SNMP_TRAP_TABLE_SIZE (2)
```

Description

This table maintains list of interested receivers who should receive notifications when some interesting event occurs.

TCPIP_SNMPV3_AUTH_LOCALIZED_PASSWORD_KEY_LEN Macro

File

snmpv3_config.h

C

```
#define TCPIP_SNMPV3_AUTH_LOCALIZED_PASSWORD_KEY_LEN (20)
```

Description

SNMPv3 Authentication Localized password key length size

TCPIP_SNMPV3_AUTH_LOCALIZED_PASSWORD_KEY_LEN_MEM_USE Macro

File

snmpv3_config.h

C

```
#define TCPIP_SNMPV3_AUTH_LOCALIZED_PASSWORD_KEY_LEN_MEM_USE
(TCPIP_SNMPV3_AUTH_LOCALIZED_PASSWORD_KEY_LEN+1)
```

Description

SNMPv3 authentication localized Key length for memory validation

TCPIP_SNMPV3_PRIV_LOCALIZED_PASSWORD_KEY_LEN Macro

File

snmpv3_config.h

C

```
#define TCPIP_SNMPV3_PRIV_LOCALIZED_PASSWORD_KEY_LEN (20)
```

Description

SNMPv3 Privacy Password key length size

TCPIP_SNMPV3_PRIV_LOCALIZED_PASSWORD_KEY_LEN_MEM_USE Macro

File

snmpv3_config.h

C

```
#define TCPIP_SNMPV3_PRIV_LOCALIZED_PASSWORD_KEY_LEN_MEM_USE
(TCPIP_SNMPV3_PRIV_LOCALIZED_PASSWORD_KEY_LEN+1)
```

Description

SNMPv3 privacy key length size for memory validation

TCPIP_SNMPV3_USER_SECURITY_NAME_LEN Macro

File

snmpv3_config.h

C

```
#define TCPIP_SNMPV3_USER_SECURITY_NAME_LEN (16)
```

Description

Maximum size for SNMPv3 User Security Name length.

TCPIP_SNMPV3_USER_SECURITY_NAME_LEN_MEM_USE Macro

File

snmpv3_config.h

C

```
#define TCPIP_SNMPV3_USER_SECURITY_NAME_LEN_MEM_USE (TCPIP_SNMPV3_USER_SECURITY_NAME_LEN+1)
```

Description

User security name length for memory validation

TCPIP_SNMPV3_USM_MAX_USER Macro

File

snmpv3_config.h

C

```
#define TCPIP_SNMPV3_USM_MAX_USER 3
```

Description

Maximum number of SNMPv3 users. User Security Model should have at least 1 user. Default is 3.

Building the Library

This section lists the files that are available in the SNMP module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/snmp.c`	SNMP implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The SNMP module depends on the following modules:

- TCP/IP Stack Library

- DNS Module
- UDP Module

SNMP Server (Agent)

This section describes the SNMP Server Agent.

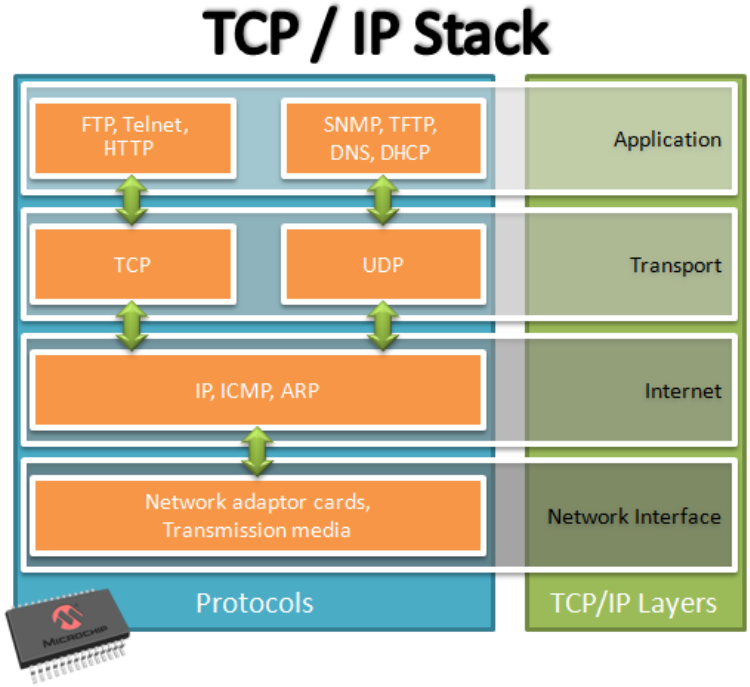
Introduction

The Simple Network Management Protocol (SNMP) is one of the key components of a Network Management System (NMS). SNMP is an application layer protocol that facilitates the exchange of management information among network devices. It is a part of the TCP/IP protocol suite.

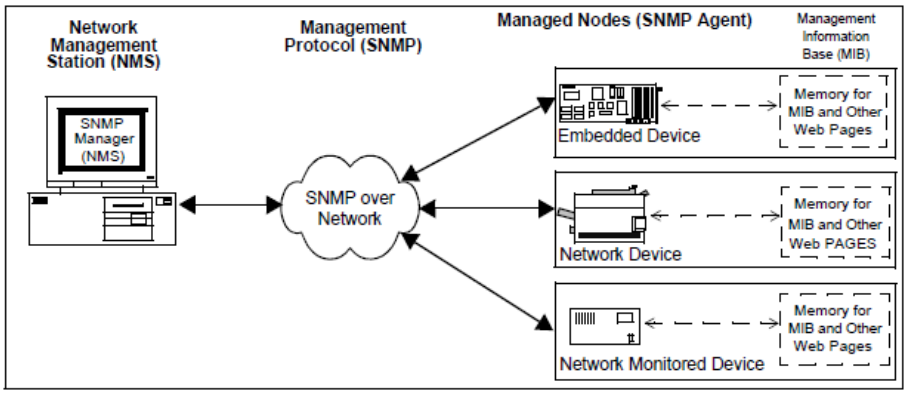
Description

SNMP is an Internet protocol that was originally designed to manage different network devices, such as file servers, hubs, routers, and so on. It can also be used to manage and control an ever increasing number of small embedded systems connected to one another over any IP network. Systems can communicate with each other using SNMP to transfer control and status information, creating a truly distributed system.

Location of the SNMP Stack in the TCP/IP Protocol Stack



Overview of the SNMP Model



The Microchip SNMP Server is a multi-lingual implementation, which supports SNMPv1, V2c, and V3 server features simultaneously. The SNMP Server is implemented to address the requirements of embedded applications and works with both IPv4 and IPv6 addresses. SNMPv1 and V2c are enabled by TCPIP_STACK_USE_SNMP_SERVER. SNMPv3 support is enabled by TCPIP_STACK_USE_SNMPV3_SERVER. Since the SNMPv3 stack requires the support of SNMPv1 and SNMPv2c, TCPIP_STACK_USE_SNMPV3_SERVER should be enabled with TCPIP_STACK_USE_SNMP_SERVER.

Note: Currently, the SNMP agent will be able to communicate with one manager at a time, and it will be connected to either an IPv4 address or an IPv6 address.

V2c

V2c is implemented with support for the configuration of multiple community names and the community names can be configured through the HTTP web interface. An access-restricted web page is provided with the demonstration application to allow dynamic configuration of SNMP communities.

SNMPv3

SNMPv3 RFC specifies different types of access mechanisms, user security model (USM), authentication and privacy protocols. The Microchip SNMPv3 Server is implemented with support for the AES 128 CFB 128 and DES-CBC privacy protocols, and the MD5 and SHA1 message authentication protocols. The demonstration implementation of the server is configured with three types of user names with respective authentication and privacy credentials and authentication types. These credentials and other user information are stored in the global array. The user of the SNMPv3 stack can decide on the number of user names in the User's database to be stored with the SNMPv3 Server. According to the SNMPv3 recommendation, the SNMPv3 Server should not be configured with the authentication and privacy passwords. Instead, it could be configured with the respective localized keys of the password. The Microchip SNMPv3 agent is provided with the password information in the database for "Getting Started" and for understanding purposes only. It is recommended that the SNMPv3 stack be modified to restrict access to the password OIDs declared in the user database.

Note: Even though SNMPv3 also requires SNMPv1 and SNMPv2c, a layer in the SNMP Stack will prevent access to the variables that should be secured by SNMPv3. SNMP variables are structures in a tree in the MIB. Access to parts of this tree is determined by version. For example, SYSTEM-type variables can be accessed regardless of the SNMP version, while SNMPv2c requests can access part of the tree, and authenticated SNMPv3 requests can access the complete tree.

MIB Files

Provides information the Management Information Base (MIB) files.

Description

SNMP describes the hierarchal storage of management objects (referred to with object IDs or OIDs) with MIB files. The Microchip SNMP server demonstration includes two MIB files:

- `mchip.mib` - This is an Abstract Syntax Notation One (ASN.1) formatted MIB file containing information about the variables used in the demonstration
- `snmp.mib` - This is a custom-formatted file that can be parsed to create Web page and header resources that can be accessed with a PIC microcontroller

The TCP/IP Stack includes the mib2bib utility, which will compile the custom Microchip MIB script (`snmp.mib`) to generate two files named snmp.bib and `mib.h`. The snmp.bib file is a compressed record of management objects that will be stored with web pages and the `mib.h` file contains C defines for each OID. These files are included in the appropriate directories for the TCP/IP Demonstration Applications, but for a custom application you must copy snmp.bib to your web page directory, copy `mib.h` to your application directory and include it in your project, rebuild your project, and then rebuild and reupload your web page. This will bundle the BIB file into your web page image, which will allow the SNMP agent to search for the required variable information with the MPFS file system.

MIB Browsers

Provides information the available MIB browsers.

Description

Several SNMP MIB browsers are available. Users can also install a customized MIB browser specific to their application.

This documentation describes how to use the iREASONING Networks MIB Browser to run the TCP/IP SNMP demonstration applications. The MIB Browser can be obtained from: http://www.ireasoning.com/downloadmibbrowserlicense.shtml. The MIB script upload, the MIB tree structure display, and the SNMP query mechanism procedures vary from browser to browser.

Important! The use of a MIB browser or other third-party products may require that users review and agree to the terms of a license. Microchip's reference to the iREASONING Networks MIB Browser is for the users' convenience. It is the user's responsibility to obtain information about, and comply with the terms of, any applicable licenses.

Refer to the Microchip application note, AN870 "SNMP V2c Agent for Microchip TCP/IP Stack" (DS00000870) for more details on the MIB scripts, community names, and demonstration SNMP MIB variable tree structure.

The ASN.1 format `mchip.mib` file is defined with a private variable tree structure for the MIB variables. Also the `mchip.mib` is added with the number of OIDs that could be accessed only with SNMPv3 request. The browser can access every variable in the MIB database provided the community name matches. The access to the MIB variables is restricted to the type of the request. The RFC1213 MIB variables could be accessed with SNMPv2c/v3 request. But the SNMP-FRAMEWORK-MIB.mib variables could only be accessed with a SNMPv3 request if the credentials are matched and the message is authenticated. To modify these MIB variables, corresponding changes must be made to both MIB

scripts (`snmp.mib` and `mchip.mib`).

- For SNMP V2c services , The V2c agent is configured by default with three Read communities ("public", "read", "") and three Write communities ("private","write","public")
- At run-time, the community names can be dynamically configured using the HTTP interface for SNMP community name configuration
- If the V2c agent receives an SNMP request with an unknown community name, the agent will generate an Authentication trap

The V2c agent's multiple community support feature enables the user application to provide limited access to the requesting browser based on the community name used by the browser to access the MIB database variables of the agent.

For SNMPv3 services:

Type	USER 1	USER 2	USER 3
USM User	microchip	SnmpAdmin	root
Security Level	auth, priv	auth, no priv	no auth, no priv
Auth Algorithm	MD5	SHA1	N/A
Auth Password	auth12345	ChandlerUS	N/A
Privacy Algorithm	AES	N/A	N/A
Privacy Password	priv12345	N/A	N/A

If SNMPv3 services are required, SNMPv3 browser is required to be configured with the user name, authentication and privacy password, message authentication hash type, privacy protocol type. The SNMP server would respond only if one of the user credentials and user security parameters in the following table is configured at the manager. The previous table is stored in the global structure with the SNMPv3 server stack. The SNMPv3 server would only respond if the request credentials of the MIB browser matches to that of the stored user data base of the SNMP server.

The Microchip SNMPv3 stack does support only one Context Engine ID with the server. Leave the "Context Name" option in the "Advanced" tab empty. It is ignored on the server.

According to the user and the auth and privacy protocols configured with the SNMP browser, the UDP authenticated and encrypted message would be exchanged between server and the client.

- If the USER 1 values, as shown in the table, are configured in the MIB browser, the data exchange between the client and server is encrypted and authenticated. The PDU could be captured in the Ethernet packet sniffer, such as WireShark, and examined. As the data is encrypted and authenticated, the data integrity and the privacy is achieved.
- If USER 2 values, as shown in the table, are configured in the MIB browser, the data exchange between client and server is authenticated. The data integrity would be checked once the data is received at either end. The message authentication mechanism protects from the possible data sniffing and modification threat, and also guarantees that the data is received from the authenticated and guaranteed source.
- If USER 3 values, as shown in the table, are configured in the MIB browser, the data exchange between client and server is neither authenticated nor encrypted
- Considering the three USER configurations, if the SNMP server is to be accessed over WAN, in the Internet cloud, the data should be encrypted and authenticated to have the highest level of data privacy and integrity

SNMP Traps

Provides information on SNMP traps.

Description

The MPLAB Harmony TCP/IP Stack supports Trap version1 and Trap version2 formatted traps. Traps are notifications from the agent to the manager that are used when a predefined event occurs at the agent.

From `mchip.mib`, the ipv4TrapTable and ipv6TrapTable are the two tabular sections, which are used to configure HOST IPv4 and IPv6 address and this will help the HOST trap receiver to receive the traps.

Several preprocessor macros in the `snmp_config.h` variant header file can be used to enable or disable traps in the agent. Commenting and uncommenting these macros in the file will have different results. The SNMP_TRAP_DISABLED macro will disable traps entirely if it is not commented:

```
#define SNMP_TRAP_DISABLED
```

The user must configure the expected trap format at the SNMP Manager. SNMPv2 entities acting as an agent should be able to generate and transmit SNMP V2 trap PDUs when the manager is configured to receive and process SNMP V2 trap PDUs. To configure the trap format, comment or uncomment the SNMP_STACK_USE_V2_TRAP macro in the `snmp_config.h` header file:

```
#define SNMP_STACK_USE_V2_TRAP
```

If the macro has been commented out, the SNMP agent will send V1 formatted trap PDUs; otherwise, it will send V2 formatted trap PDUs. By default, the SNMP agent is configured to send V2 formatted traps. Note that the SNMP V2c agent should only send V2 formatted traps.

To enable traps in SNMPv3, the `#define SNMP_V1_V2_TRAP_WITH_SNMPv3` macro must be uncommented.

The following table illustrates how to enable/disable traps for different versions of SNMP.

Type	SNMPv1	SNMPv2c	SNMPv3
TRAPv2 (enabled by default)	Comment out the `#define SNMP_TRAP_DISABLED` macro	Comment out the `#define SNMP_TRAP_DISABLED` macro	Comment out the `#define SNMP_TRAP_DISABLED` macro Uncomment the `#define SNMP_V1_V2_TRAP_WITH_SNMPV3` macro
TRAPv2 (disabled by default)	Not supported	Comment out the `#define SNMP_TRAP_DISABLED` macro Uncomment the `#define SNMP_STACK_USE_V2_TRAP` macro	Comment out the `#define SNMP_TRAP_DISABLED` macro Uncomment the `#define SNMP_V1_V2_TRAP_WITH_SNMPV3` macro Uncomment the `#define SNMP_STACK_USE_V2_TRAP` macro

Demonstrations

Two trap demonstrations APIs are included with the TCP/IP Stack. The task functions for these demonstrations are called in the main application function:

- SNMPTrapDemo - This API demonstrates V1 or V2 trap formats (depending of the status of the SNMP_STACK_USE_V2_TRAP macro). The trap PDU will only have one demonstration variable binding on the varbind list.
- SNMPV2TrapDemo - This API provides V2 format notifications with multiple (4) variable bindings. The user should modify or use this routine as a reference for sending V2 trap format notifications with multiple bindings on the varbind list.

Note: The user should only enable one SNMP demonstration API at a time. By default, the SNMPV2TrapDemo API is enabled and SNMPTrapDemo is commented out (disabled).

V1/V2 Formatted Traps with a Single Variable Binding

In the snmp_config.h header file:

- Uncomment `#define SNMP_TRAP_DISABLED`
- Comment `//#define SNMP_STACK_USE_V2_TRAP`

For the Trap demonstration, two events are defined within the V2c agent:

- If the Analog Potentiometer value is greater than 14, the agent will send a Trap every 5 seconds to the configured 'IPv4TrapReceiverIP address'.
- If Button 3 on the demonstration board is pressed, an organization-specific PUSH_BUTTON trap will be sent.

The current implementation of the V2c agent also generates a standard "Authentication Failure Trap":

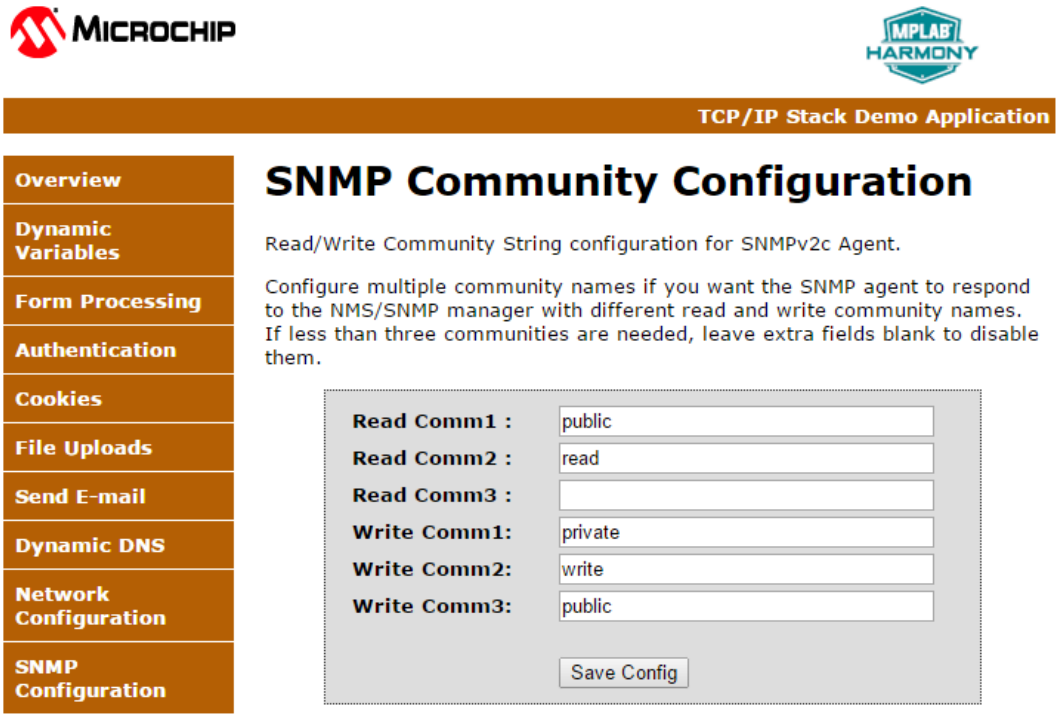
- If a request is received to modify (Set) a private MIB variable, or
- If the value of the variable is requested (Get) by a browser with the wrong community name

HTTP Configuration

Provides information on the SNMP Community Configuration.

Description

If a HTTP2 server is used with the Microchip TCP/IP stack, it is possible to dynamically configure the Read and Write community names through the SNMP Configuration web page. Access the web page using http://mchpboard_e/mpfsupload or http://<Board IP address>(for IPv6 it should be http://<Ipv6 address>:80/index.html), and then access the SNMP Configuration web page through the navigation bar. Use "admin" for the username and "microchip" for the password.



Library Interface

a) SNMP Module Functions

	Name	Description
	TCPIP_SNMP_NotifyIsReady	Resolves given remoteHost IP address into MAC address.
	TCPIP_SNMP_NotifyPrepare	Collects trap notification info and send ARP to remote host.
	TCPIP_SNMP_TrapTimeGet	Gets SNMP Trap UDP client open socket time-out.
	TCPIP_SNMP_ClientGetNet	Get a network interface for SNMP TRAP.
	TCPIP_SNMP_ExactIndexGet	To search for exact index node in case of a Sequence variable.
	TCPIP_SNMP_IsValidCommunity	Validates community name for access control.
	TCPIP_SNMP_IsValidLength	Validates the set variable data length to data type.
	TCPIP_SNMP_MibIDSet	Sets the agent MIB ID for SNP notification.
	TCPIP_SNMP_NextIndexGet	To search for next index node in case of a Sequence variable.
	TCPIP_SNMP_ReadCommunityGet	Gets the readCommunity String with SNMP index.
	TCPIP_SNMP_RecordIDValidation	Used to restrict the access dynamic and non dynamic OID string for a particular SNMP Version.
	TCPIP_SNMP_SendFailureTrap	Prepares and validates the remote node that will receive a trap and send the trap PDU.
	TCPIP_SNMP_TrapInterFaceSet	Sets the TRAP interface for SNMP notification.
	TCPIP_SNMP_TRAPMibIDGet	Gets the agent MIB ID for SNP notification.
	TCPIP_SNMP_TrapSendFlagGet	Gets the status of trap send flag.
	TCPIP_SNMP_TrapSendFlagSet	Sets the status of trap send flag.
	TCPIP_SNMP_TrapSpecificNotificationGet	Gets the specific trap.
	TCPIP_SNMP_TrapSpecificNotificationSet	Sets the specific trap, generic trap, and trap ID.
	TCPIP_SNMP_VarbindGet	Used to get/collect OID variable information.
	TCPIP_SNMP_VarbindSet	Sets the MIB variable with the requested value.
	TCPIP_SNMP_WriteCommunityGet	Gets the writeCommunity String with SNMP index.
	TCPIP_SNMP_AuthTrapFlagGet	Gets the status of authentication trap flag.
	TCPIP_SNMP_AuthTrapFlagSet	Sets the status of authentication trap flag.
	TCPIP_SNMP_IsTrapEnabled	Gets the SNMP Trap status.
	TCPIP_SNMP_TRAPTypeGet	Get SNMP Trap type for version v1 and v2c.
	TCPIP_SNMP_TRAPv1Notify	Creates and Sends TRAPv1 pdu.
	TCPIP_SNMP_TRAPv2Notify	Creates and sends TRAP PDU.

	TCPIP_SNMPV3_TrapTypeGet	Gets SNMP Trap type for version v3.
	TCPIP_SNMP_ValidateTrapIntf	Gets the status of trap interface.
	TCPIP_SNMP_ReadCommunitySet	Sets the readCommunity String with SNMP index.
	TCPIP_SNMP_WriteCommunitySet	Sets the writeCommunity String with SNMP index.
	TCPIP_SNMP_SocketIDGet	Gets the Socket ID for SNMP Server socket.
	TCPIP_SNMP_SocketIDSet	Sets the Socket ID for SNMP Server socket.
	TCPIP_SNMP_Task	Standard TCP/IP stack module task function.

b) SNMPv3 Module Functions

	Name	Description
	TCPIP_SNMPV3_EngineUserDataBaseGet	Get SNMPv3 engine data base details.
	TCPIP_SNMPV3_EngineUserDataBaseSet	Set SNMPv3 engine data base details.
	TCPIP_SNMPv3_TrapConfigDataGet	Gets the SNMPv3 Trap configuration details using the user name index.
	TCPIP_SNMPv3_Notify	Creates and Sends SNMPv3 TRAP PDU.

c) SNMP Data Types and Constants

	Name	Description
	SNMP_END_OF_VAR	This Macro is used for both SNMP SET and GET Variable processing to indicate the end of SNMP variable processing. For multi byte data request, the end byte will be always SNMP_END_OF_VAR.
	SNMP_INDEX_INVALID	This Macro is used for both SNMP SET and GET Sequence Variable processing. SNMP starts processing the start of sequence variable with Invalid index. TCPIP_SNMP_ExactIndexGet and TCPIP_SNMP_NextIndexGet returns a valid index as per SNMP_INDEX_INVALID.
	SNMP_START_OF_VAR	This Macro is used for both SNMP SET and GET Variable processing to indicate the start of SNMP variable processing. For multi byte data request, the first byte will be always SNMP_START_OF_VAR.
	SNMP_V1	This macro is used for SNMP version 1
	SNMP_V2C	This macro is used for SNMP version 2 with community
	SNMP_V3	This macro is used for SNMP version 3 with authentication and privacy
	SNMP_COMMUNITY_TYPE	Definition to represent different type of SNMP communities.
	SNMP_ID	SNMP dynamic variable ID.
	SNMP_INDEX	SNMP sequence variable index.
	SNMP_NON_MIB_RECD_INFO	Restrict access for specific OIDs.
	SNMP_TRAP_IP_ADDRESS_TYPE	Definition of the supported address types for SNMP trap.
	SNMP_VAL	Definition to represent SNMP OID object values.
	SNMP_GENERIC_TRAP_NOTIFICATION_TYPE	Definition to represent different SNMP generic trap types.
	SNMP_VENDOR_SPECIFIC_TRAP_NOTIFICATION_TYPE	Definition to represent different SNMP vendor trap types.

d) SNMPv3 Data Types and Constants

	Name	Description
	SNMPV3_HMAC_HASH_TYPE	Different type of authentication for SNMPv3.
	SNMPV3_PRIV_PROT_TYPE	Different type of encryption and decryption for SNMPv3.
	STD_BASED_SNMP_MESSAGE_PROCESSING_MODEL	Different SNMP Message processing model
	STD_BASED_SNMP_SECURITY_MODEL	Different Security services for SNMPv3 messages.
	STD_BASED_SNMPV3_SECURITY_LEVEL	Different Security Level for SNMPv3 messages.
	TCPIP_SNMPV3_USERDATABASECONFIG_TYPE	Different Configuration parameters of SNMPv3 operation
	TCPIP_SNMP_COMMUNITY_CONFIG	SNMP community configuration.
	TCPIP_SNMP_MODULE_CONFIG	SNMP module configuration.
	TCPIP_SNMPV3_TARGET_ENTRY_CONFIG	SNMP module trap target address configuration.
	TCPIP_SNMPV3_USM_USER_CONFIG	SNMPv3 USM configuration.

Description

This section describes the Application Programming Interface (API) functions of the SNMP module.

Refer to each section for a detailed description.

a) SNMP Module Functions

TCPIP_SNMP_NotifyIsReady Function

Resolves given remoteHost IP address into MAC address.

File

snmp.h

C

```
bool TCPIP_SNMP_NotifyIsReady(IP_MULTI_ADDRESS* remoteHost, SNMP_TRAP_IP_ADDRESS_TYPE
eTrapMultiAddressType);
```

Description

This function resolves given remoteHost IP address into MAC address using ARP module. If remoteHost is not available, this function would never return true. Application must implement time out logic to handle "remoteHost not available" situation.

Remarks

This would fail if there were not UDP socket to open.

Preconditions

TCPIP_SNMP_NotifyPrepare is already called.

Parameters

Parameters	Description
remoteHost	Pointer to remote Host IP address
eTrapMultiAddressType	IPv4 and IPv6 address type

Function

bool TCPIP_SNMP_NotifyIsReady(IP_MULTI_ADDRESS* remoteHost,
SNMP_TRAP_IP_ADDRESS_TYPE eTrapMultiAddressType)

TCPIP_SNMP_NotifyPrepare Function

Collects trap notification info and send ARP to remote host.

File

snmp.h

C

```
void TCPIP_SNMP_NotifyPrepare(IP_MULTI_ADDRESS* remoteHost, char* community, uint8_t communityLen, SNMP_ID
agentIDVar, uint8_t notificationCode, uint32_t timestamp);
```

Returns

None.

Description

This function prepares SNMP module to send SNMP trap notification to remote host. It sends ARP request to remote host to learn remote host MAC address.

Remarks

This is first of series of functions to complete SNMP notification.

Preconditions

TCPIP_SNMP_Initialize() is already called.

Parameters

Parameters	Description
remoteHost	pointer to remote Host IP address

community	Community string to use to notify
communityLen	Community string length
agentIDVar	System ID to use identify this agent
notificaitonCode	Notification Code to use
timestamp	Notification timestamp in 100th of second.

Function

void TCPIP_SNMP_NotifyPrepare(IP_MULTI_ADDRESS* remoteHost,
char* community,
uint8_t communityLen,
SNMP_ID agentIDVar,
uint8_t notificationCode,
uint32_t timestamp)

TCPIP_SNMP_TrapTimeGet Function

Gets SNMP Trap UDP client open socket time-out.

File

snmp.h

C

```
uint32_t TCPIP_SNMP_TrapTimeGet();
```

Returns

uint32_t time

Description

This function returns a uint32_t time(snmpTrapTimer) which is used to time out a SNMP TRAP notification for a HOST. snmpTrapTimer is initialized when there is UDP client socket open either for a HOST IPv4 or IPv6 address.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize() is already called.

Function

uint32_t TCPIP_SNMP_TrapTimeGet(void)

TCPIP_SNMP_ClientGetNet Function

Get a network interface for SNMP TRAP.

File

snmp.h

C

```
TCPIP_NET_HANDLE TCPIP_SNMP_ClientGetNet(int * netIx, TCPIP_NET_HANDLE hNet);
```

Returns

TCPIP_NET_HANDLE

- Success - returns a valid interface
- Failure - no interface

Description

This function is used to get a network interface to transmit SNMP trap.

Remarks

None.

Preconditions

The SNMP module should be initialized.

Parameters

Parameters	Description
netIx	Network index
hNet	Network interface .If hNet is NULL, then a valid interface will returned.

Function

TCPIP_NET_HANDLE TCPIP_SNMP_ClientGetNet(int *netIx,TCPIP_NET_HANDLE hNet);

TCPIP_SNMP_ExactIndexGet Function

To search for exact index node in case of a Sequence variable.

File

snmp.h

C

```
bool TCPIP_SNMP_ExactIndexGet(SNMP_ID var, SNMP_INDEX * index);
```

Returns

-true - If the exact index value exists for a given variable at a given index. -false - If the exact index value does not exist for the given variable

Description

This is a callback function called by SNMP module. This function contents are modified by the application developer with the new MIB Record ID. This function can be called for individual MIB ID with index. This function is used to get the first available index from global or dynamic allocated sequence variable table.

Remarks

Only sequence index needs to be handled in this function and this function is called after TCPIP_SNMP_RecordIDValidation.

Preconditions

TCPIP_SNMP_ProcessVariables() is called.

Parameters

Parameters	Description
var	Variable id as per mib.h (input)
index	Index of variable (input)

Function

bool TCPIP_SNMP_ExactIndexGet(SNMP_ID var,SNMP_INDEX *index)

TCPIP_SNMP_IsValidCommunity Function

Validates community name for access control.

File

snmp.h

C

```
uint8_t TCPIP_SNMP_IsValidCommunity(uint8_t* community);
```

Returns

This function returns the community validation result as READ_COMMUNITY or WRITE_COMMUNITY or INVALID_COMMUNITY.

Description

This function validates the community name for the MIB access to SNMP manager. The SNMP community name received in the request PDU is validated for read and write community names. The agent gives an access to the mib variables only if the community matches with the predefined values. This routine also sets a global flag to send trap if authentication failure occurs.

Remarks

This is a callback function called by module. User application must implement this function and verify that community matches with predefined value. This validation occurs for each SNMP manager request.

Preconditions

TCPIP_SNMP_Initialize is already called.

Parameters

Parameters	Description
community	Pointer to community string as sent by SNMP manager

Function

uint8_t TCPIP_SNMP_IsValidCommunity(uint8_t* community)

TCPIP_SNMP_IsValidLength Function

Validates the set variable data length to data type.

File

snmp.h

C

```
bool TCPIP_SNMP_IsValidLength(SNMP_ID var, uint8_t len, uint8_t index);
```

Returns

- true - if given var can be set to given len
- false - if the given var cannot be set to the given len

Description

This function is used to validate the dynamic variable data length to the variable data type. It is called before the SET request is processed. This is a callback function called by module. User application must implement this function.

Remarks

This function will be called for only dynamic variables that are defined as ASCII_STRING and OCTET_STRING.

Preconditions

TCPIP_SNMP_ProcessSetVar is called.

Parameters

Parameters	Description
var	Variable id whose value is to be set
len	Length value that is to be validated.

Function

bool TCPIP_SNMP_IsValidLength(SNMP_ID var, uint8_t len,uint8_t index)

TCPIP_SNMP_MibIDSet Function

Sets the agent MIB ID for SNP notification.

File

snmp.h

C

```
void TCPIP_SNMP_MibIDSet(uint32_t mibID);
```

Returns

None.

Description

This function is used to Set the MIB ID which is require while transmitting SNMP notification.SNMP user can this function without adding this to the Microchip MIB script.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize is already called.

Parameters

Parameters	Description
mibID	Trap client MIB ID

Function

void TCPIP_SNMP_MibIDSet(uint32_t *mibID)

TCPIP_SNMP_NextIndexGet Function

To search for next index node in case of a Sequence variable.

File

snmp.h

C

```
bool TCPIP_SNMP_NextIndexGet(SNMP_ID var, SNMP_INDEX* index);
```

Returns

- true - If a next index value exists for given variable at given index and index parameter contains next valid index.
- false - If a next index value does not exist for a given variable

Description

This is a callback function called by SNMP module. This function contents are modified by the application developer with the new MIB Record ID. This function can be called for individual MIB ID with index or for a complete MIB table without any instance.

- If the SNMP Sequence MIB variable processing is performed with index or instance value,

it is the responsibility of the agent to send the next available index for that requested variable. This is a only one iteration process. The Manager will not send any further requests for the received index value.

- If SNMP request for a sequence variable starts with only OID without any instance, that is

a complete table is requested without any instance, it is the responsibility of the agent to send the first available index of the table. The Manager will continue the request with the transferred instance until it receives the reply from agent.

This function will only be called for OID variable of type sequence. if the index value starts with SNMP_INDEX_INVALID , then user need to send the response with first available index value.

Remarks

Only sequence index needs to be handled in this function and this function is called after TCPIP_SNMP_RecordIDValidation.

Preconditions

TCPIP_SNMP_ProcessVariables is called.

Parameters

Parameters	Description
var	Variable id whose value is to be returned
index	Next Index of variable that should be transferred

Function

bool TCPIP_SNMP_NextIndexGet(SNMP_ID var,SNMP_INDEX* index)

TCPIP_SNMP_ReadCommunityGet Function

Gets the readCommunity String with SNMP index.

File

snmp.h

C

```
bool TCPIP_SNMP_ReadCommunityGet(int index, int len, uint8_t * dest);
```

Returns

- true - if the community string is collected
- false - if the community string is not collected

Description

This function is used to collect READ community string from the global community table with respect to the index value.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize is already called.

Parameters

Parameters	Description
index	One of the index of community table and it should be less than TCPIP_SNMP_MAX_COMMUNITY_SUPPORT.
len	Length of the community string expected. It should not be more than TCPIP_SNMP_COMMUNITY_MAX_LEN.
dest	Copy the community string to this address and it should have a valid address.

Function

bool TCPIP_SNMP_ReadCommunityGet(int index,int len, uint8_t * dest)

TCPIP_SNMP_RecordIDValidation Function

Used to restrict the access dynamic and non dynamic OID string for a particular SNMP Version.

File

snmp.h

C

```
bool TCPIP_SNMP_RecordIDValidation(uint8_t snmpVersion, bool idPresent, uint16_t varId, uint8_t *
oidValuePtr, uint8_t oidLen);
```

Returns

- true - A record ID exists
- false - A record ID does not exist

Description

This is a callback function called by SNMP module. SNMP user must implement this function as per SNMP version. One need to add the new SNMP MIB IDs here as per SNMP version (e.g., SYS_UP_TIME (250) is common for V1/V2/V3). ENGINE_ID - is the part of V3; therefore, place all of the SNMPv3 var IDs within the macro TCPIP_STACK_USE_SNMPV3_SERVER.

Remarks

This function is specific for record ID validation and this can also be used to restrict OID string.

Preconditions

TCPIP_SNMP_Initialize is already called.

Parameters

Parameters	Description
snmpVersion	different SNMP version
idPresent	true if SNMp record id is present else false
varId	dynamic record ID value as per mib.h

oidValuePtr	OID Value pointer
oidLen	number of OIDs present to be processed

Function

bool TCPIP_SNMP_RecordIDValidation(uint8_t snmpVersion,bool idPresent,
uint16_t varId,uint8_t * oidValuePtr,uint8_t oidLen)

TCPIP_SNMP_SendFailureTrap Function

Prepares and validates the remote node that will receive a trap and send the trap PDU.

File

snmp.h

C

```
void TCPIP_SNMP_SendFailureTrap();
```

Returns

None.

Description

This function is used to send trap notification to previously configured IP address if trap notification is enabled. There are different trap notification code. The current implementation sends trap for authentication failure (4).

Remarks

This is a callback function called by the application on certain predefined events. This routine only implemented to send a authentication failure Notification-type macro with PUSH_BUTTON OID stored in MPFS. If the ARP is not resolved (i.e., if TCPIP_SNMP_NotifyIsReady returns false, this routine times out in 5 seconds). This function should be modified according to event occurred and should update the corresponding OID and notification type to the TRAP PDU.

Preconditions

If the defined application event occurs to send the trap.

Function

void TCPIP_SNMP_SendFailureTrap(void)

TCPIP_SNMP_TrapInterFaceSet Function

Sets the TRAP interface for SNMP notification.

File

snmp.h

C

```
void TCPIP_SNMP_TrapInterFaceSet(TCPIP_NET_HANDLE netIntf);
```

Returns

None.

Description

This function is used to Set the network interface to which the TRAP socket is ready to transmit Notifications to the TRAP receiver address.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize is already called.

Parameters

Parameters	Description
netIntf	Network interface Trap is connected to receiver

Function

void TCPIP_SNMP_TrapInterFaceSet(TCPIP_NET_HANDLE netIntf)

TCPIP_SNMP_TRAPMibIDGet Function

Gets the agent MIB ID for SNP notification.

File

snmp.h

C

```
void TCPIP_SNMP_TRAPMibIDGet(uint32_t * mibID);
```

Returns

None.

Description

This function is used to get the MIB ID which is require while transmitting SNMP notification.This MIB ID is a Agent ID value of the Microchip style MIB script. MIB ID macro value is present in mib.h which is generated by mib2bib.jar.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize is already called.

Parameters

Parameters	Description
mibID	Trap client MIB ID

Function

void TCPIP_SNMP_TRAPMibIDGet(uint32_t *mibID)

TCPIP_SNMP_TrapSendFlagGet Function

Gets the status of trap send flag.

File

snmp.h

C

```
void TCPIP_SNMP_TrapSendFlagGet(bool * trapNotify);
```

Returns

None.

Description

This function is used to get the trap send flag details and this is used only when user is trying to send more than one varbind in a single PDU. That is more than one notification details are required to be part of a single PDU.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize is already called.

Function

void TCPIP_SNMP_TrapSendFlagGet(bool *trapNotify)

TCPIP_SNMP_TrapSendFlagSet Function

Sets the status of trap send flag.

File

snmp.h

C

```
void TCPIP_SNMP_TrapSendFlagSet(bool trapNotify);
```

Returns

None.

Description

This function is used to set the trap send flag details and this is used only when user is trying to send more than one varbind in a single PDU. That is more than one notification details are required to be part of a single PDU. By default TRAP send flag is set to false. If there is only varbind need to be part of Notification PDU, then this function should be called with boolean false. Please find the usage of this flag in this following example.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize is already called.

Example

```
void SNMPv2TrapDemo(void)
{
    //set TRAP send flag to true , it signifies that there are more than one
    // variable need to be the part of SNMP v2 TRAP.
    TCPIP_SNMP_TrapSendFlagSet(true);

    // PUSH button varbind
    TCPIP_SNMP_Notify(PUSH_BUTTON,analogPotVal,0);

    // Before adding the last varbind to the TRAP PDU, TRAP send flag should
    // be set to  false. That it indicates it is the last varbind to the
    // Notification PDU.
    TCPIP_SNMP_TrapSendFlagSet(false);

    // Last varbind LED0_IO
    TCPIP_SNMP_Notify(LED0_IO,analogPotVal,0);

}
```

Function

void TCPIP_SNMP_TrapSendFlagSet(bool trapNotify)

TCPIP_SNMP_TrapSpecificNotificationGet Function

Gets the specific trap.

File

snmp.h

C

```
void TCPIP_SNMP_TrapSpecificNotificationGet(uint8_t * specTrap);
```

Returns

None.

Description

This function is used to get specific trap value. Specific trap values are listed in SNMP_VENDOR_SPECIFIC_TRAP_NOTIFICATION_TYPE.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize is already called.

Parameters

Parameters	Description
specTrap	Vendor specific trap value

Function

void TCPIP_SNMP_TrapSpecificNotificationGet(uint8_t *specTrap)

TCPIP_SNMP_TrapSpecificNotificationSet Function

Sets the specific trap, generic trap, and trap ID.

File

snmp.h

C

```
void TCPIP_SNMP_TrapSpecificNotificationSet(uint8_t specTrap, uint8_t genTrap, SNMP_ID trapID);
```

Returns

None.

Description

The SNMP user needs to call this function before transmitting any traps. This function will set the vendor specific trap, generic trap, and default trap ID value. The SNMPv2 trap will use this trap ID while sending a specific trap.

Remarks

The Trap ID is the NOTIFICATION-TYPE of the ASN.1 MIB format. From the Trap ID, the SNMP agent will be able to obtain the OID string, which will be used while preparing TRAPv2 second varbind.

Preconditions

TCPIP_SNMP_Initialize is already called.

Parameters

Parameters	Description
specTrap	Vendor specific trap value (enumeration value of SNMP_VENDOR_SPECIFIC_TRAP_NOTIFICATION_TYPE)
genTrap	Generic trap (enumeration value of SNMP_GENERIC_TRAP_NOTIFICATION_TYPE)
trapID	Trap ID

Function

void TCPIP_SNMP_TrapSpecificNotificationSet(uint8_t specTrap,uint8_t genTrap,
SNMP_ID trapID)

TCPIP_SNMP_VarbindGet Function

Used to get/collect OID variable information.

File

snmp.h

C

```
bool TCPIP_SNMP_VarbindGet(SNMP_ID var, SNMP_INDEX index, uint8_t* ref, SNMP_VAL* val);
```

Returns

- true - If a value exists for given variable

- false - If a value does not exist for a given variable

Description

This is a callback function called by SNMP module. This function is called only when SNMP GET, GETNEXT and GETBULK request is made. This function content is modified by the application developer. This function contains the implementation of READ enable MIB OID macros.

mib2bib.jar Microchip MIB compiler utility is used to generate mib.h, which lists all the MIB OID ID value.

Remarks

This function may get called more than once depending on number of bytes in a specific get request for given variable. only dynamic read variables needs to be handled.

Preconditions

TCPIP_SNMP_ProcessVariables() is called.

Example

Usage of MIB OID within this function for a ASCII string (multi byte variable)

```
// In the beginning *ref is equal to SNMP_START_OF_VAR
myRef = *ref;
switch(var)
{
// TRAP_COMMUNITY - generated from the Microchip style MIB script using mib2bib.jar,
// is a Sequence variable.
    case TRAP_COMMUNITY:
        if ( index < trapInfo.Size )
        {
        // check if the myRef should not cross the maximum length
             if ( myRef == trapInfo.table[index].communityLen )
             {
             // End of SNMP GET process
                 *ref = SNMP_END_OF_VAR;
                 return true;
             }
            if ( trapInfo.table[index].communityLen == 0u )
                *ref = SNMP_END_OF_VAR; // End of SNMP GET process
            else
            {
                // Start of SNMP GET process byte by byte
                val->byte = trapInfo.table[index].community[myRef];
                myRef++;
                *ref = myRef;
            }
            return true;
        }
        break;
// LED_D5 - generated from the Microchip style MIB script using mib2bib.jar is a scalar variable
    case LED_D5:
        val->byte = LED2_IO;
        return true;
}
```

Parameters

Parameters	Description
var	Variable id whose value is to be returned
index	For a scalar variable , Index value is zero. For sequence variable index value specifies which index value need to be set.
ref	Variable reference used to transfer multi-byte data. It is always SNMP_START_OF_VAR when very first byte is requested. Otherwise, use this as a reference to keep track of multi-byte transfers.

val	Pointer to up to 4 byte buffer: • If var data type is uint8_t, transfer data in val->byte • If var data type is uint16_t, transfer data in val->word • If var data type is uint32_t, transfer data in val->dword • If var data type is IP_ADDRESS, transfer data in val->v[] or val->dword • If var data type is COUNTER32, TIME_TICKS or GAUGE32, transfer data in val->dword • If var data type is ASCII_STRING or OCTET_STRING transfer data in val->byte using multi-byte transfer mechanism.

Function

bool TCPIP_SNMP_VarbindGet(SNMP_ID var, SNMP_INDEX index,uint8_t* ref, SNMP_VAL* val)

TCPIP_SNMP_VarbindSet Function

Sets the MIB variable with the requested value.

File

snmp.h

C

```
bool TCPIP_SNMP_VarbindSet(SNMP_ID var, SNMP_INDEX index, uint8_t ref, SNMP_VAL val);
```

Returns

- true - if it is okay to set more byte(s)
- false - if it is not okay to set more byte(s)

Description

This is a callback function called by module for SNMP SET request. This function content is modified by the application developer. This function contains the implementation of WRITE enable MIB OID macros.

mib2bib.jar Microchip MIB compiler utility is used to generate mib.h, which lists all the MIB OID ID value.

Remarks

This function may get called more than once depending on number of bytes in a specific set request for given variable. only dynamic read/-write variables needs to be handled.

Preconditions

TCPIP_SNMP_ProcessVariables() is called.

Example

```
switch(var)
{
    // LED_D5 - generated from the Microchip style MIB script using mib2bib.jar is a scalar variable
    case LED_D5:
        LED2_IO = val.byte;
        return true;

    // TRAP_COMMUNITY - generated from the Microchip style MIB script using mib2bib.jar,
    // is a Sequence variable.

    case TRAP_COMMUNITY:
        // Since this is a ASCII_STRING data type, SNMP will call with
        // SNMP_END_OF_VAR to indicate no more bytes or end of SNMP SET process
        // Use this information to determine if we just added new row
        // or updated an existing one.
        if ( ref ==  SNMP_END_OF_VAR )
        {
            // Index equal to table size means that we have new row.
            if ( index == trapInfo.Size )
                trapInfo.Size++;

            // Length of string is one more than index.
            trapInfo.table[index].communityLen++;

            return true;
```

```
        }

        // Make sure that index is within our range.
        if ( index < trapInfo.Size )
        {
            // Copy given value into local buffer.
            trapInfo.table[index].community[ref] = val.byte;
            // Keep track of length too.
            // This may not be NULL terminate string.
            trapInfo.table[index].communityLen = (uint8_t)ref;
            return true;
        }
        break;
}
```

Parameters

Parameters	Description
var	Write enable Variable id whose value is to be set
index	For a scalar variable , Index value is zero. For sequence variable index value specifies which index value need to be set.
ref	Variable reference used to transfer multi-byte data 0 if first byte is set otherwise non zero value to indicate corresponding byte being set. SNMP set will performed until ref is not equal to SNMP_END_OF_VAR and SNMP set starts with ref = SNMP_START_OF_VAR.
val	Up to 4 byte data value: • If var data type is uint8_t, variable value is in val->byte • If var data type is uint16_t, variable value is in val->word • If var data type is uint32_t, variable value is in val->dword. • If var data type is IP_ADDRESS, COUNTER32, or GAUGE32, value is in val->dword • If var data type is OCTET_STRING, ASCII_STRING value is in val->byte; multi-byte transfer will be performed to transfer remaining bytes of data.

Function

bool TCPIP_SNMP_VarbindSet(SNMP_ID var, SNMP_INDEX index,
uint8_t ref, SNMP_VAL val)

TCPIP_SNMP_WriteCommunityGet Function

Gets the writeCommunity String with SNMP index.

File

snmp.h

C

```
bool TCPIP_SNMP_WriteCommunityGet(int index, int len, uint8_t * dest);
```

Returns

- true - if the community string is collected
- false - if the community string is not collected

Description

This function is used to collect WRITE community string from the global community table with respect to the index value.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize is already called.

Parameters

Parameters	Description
index	One of the index of community table and it should be less than TCPIP_SNMP_MAX_COMMUNITY_SUPPORT.

len	Length of the community string expected. It should not be more than TCPIP_SNMP_COMMUNITY_MAX_LEN.
dest	Copy the community string to this address and it should have a valid address.

Function

bool TCPIP_SNMP_WriteCommunityGet(int index,int len, uint8_t * dest)

TCPIP_SNMP_AuthTrapFlagGet Function

Gets the status of authentication trap flag.

File

snmp.h

C

```
void TCPIP_SNMP_AuthTrapFlagGet(bool * authTrap);
```

Returns

None.

Description

This function is used to Get the authentication trap send flag and this is used only when the user is trying to send authentication failure trap. For example, sending a trap if community does not match the global community table.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize is already called.

Parameters

Parameters	Description
sendTrap	Trap flag value.

Function

void TCPIP_SNMP_AuthTrapFlagGet(bool *sendTrap)

TCPIP_SNMP_AuthTrapFlagSet Function

Sets the status of authentication trap flag.

File

snmp.h

C

```
void TCPIP_SNMP_AuthTrapFlagSet(bool sendTrap);
```

Returns

None.

Description

This function is used to set the authentication trap send flag and this is used only when user is trying to send authentication failure trap. Ex-sending a trap if community do not match to the global community table.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize is already called.

Function

void TCPIP_SNMP_AuthTrapFlagSet(bool sendTrap)

TCPIP_SNMP_IsTrapEnabled Function

Gets the SNMP Trap status.

File

snmp.h

C

```
bool TCPIP_SNMP_IsTrapEnabled();
```

Returns

- true - SNMP module has trap enabled
- false - SNMP module has trap disabled

Description

This function returns true if SNMP module is enabled to send the trap to to the SNMP manager device.

Remarks

This function is used by the customer function.

Preconditions

TCPIP_SNMP_Initialize is already called.

Function

bool TCPIP_SNMP_IsTrapEnabled(void)

TCPIP_SNMP_TRAPTypeGet Function

Get SNMP Trap type for version v1 and v2c.

File

snmp.h

C

```
bool TCPIP_SNMP_TRAPTypeGet();
```

Returns

- true - trap version is v2
- false - trap version is v1

Description

This function returns true if the trap tye is v2 and the TRAP pdu packet will be a TRAP v2 format.The return value is also used is validated when SNMP module is trying to send a trap for SNMP version v3.

Remarks

This function is used by the customer function.

Preconditions

TCPIP_SNMP_Initialize() is already called.

Function

bool TCPIP_SNMP_TRAPTypeGet(void)

TCPIP_SNMP_TRAPv1Notify Function

Creates and Sends TRAPv1 pdu.

File

snmp.h

C

```
bool TCPIP_SNMP_TRAPv1Notify(SNMP_ID var, SNMP_VAL val, SNMP_INDEX index, SNMP_TRAP_IP_ADDRESS_TYPE
eTrapMultiAddressType);
```

Description

This function creates SNMP trap PDU and sends it to previously specified remoteHost. snmpv1 trap pdu: | PDU-type | enterprise | agent-addr | generic-trap | specific-trap | | time-stamp | varbind-list |

The v1 enterprise is mapped directly to SNMPv2TrapOID.0

Remarks

This would fail if there were not UDP socket to open.

Preconditions

TCPIP_SNMP_NotifyIsReady() is already called and returned true.

Parameters

Parameters	Description
var	SNMP var ID that is to be used in notification
val	Value of var. Only value of uint8_t, uint16_t or uint32_t can be sent.
index	Index of var. If this var is a single,index would be 0, or else if this var Is a sequence, index could be any value from 0 to 127
eTrapMultiAddressType	Trap address type

Function

bool TCPIP_SNMP_TRAPv1Notify(SNMP_ID var, SNMP_VAL val,

SNMP_INDEX index,SNMP_TRAP_IP_ADDRESS_TYPE eTrapMultiAddressType)

TCPIP_SNMP_TRAPv2Notify Function

Creates and sends TRAP PDU.

File

snmp.h

C

```
bool TCPIP_SNMP_TRAPv2Notify(SNMP_ID var, SNMP_VAL val, SNMP_INDEX index, SNMP_TRAP_IP_ADDRESS_TYPE
eTrapMultiAddressType);
```

Description

This function creates SNMP V2 Trap PDU and sends it to previously specified remoteHost.

SNMP V1 trap PDU: | PDU type | enterprise | agent addr | generic trap | specific trap | | time stamp | varbind list |

The v1 enterprise is mapped directly to SNMPv2TrapOID.0

SNMP V2 trap PDU: version (0 or 1) | community | SNMP PDU |PDU type | request id | error status |err index |varbinds

The first two variables (in varbind list) of snmpv2 are: sysUpTime.0 and SNMPv2TrapOID.0

Generic Trap OID is used as the varbind for authentication failure.

Remarks

This would fail if there were not UDP socket to open.

Preconditions

TCPIP_SNMP_NotifyIsReady is already called and returned true.

Parameters

Parameters	Description
var	SNMP var ID that is to be used in notification
val	Value of var. Only value of uint8_t, uint16_t or uint32_t can be sent.
index	Index of var. If this var is a single,index would be 0, or else if this var Is a sequence, index could be any value from 0 to 127
eTrapMultiAddressType	Trap address type

Function

bool TCPIP_SNMP_TRAPv2Notify(SNMP_ID var, SNMP_VAL val, SNMP_INDEX index,
SNMP_TRAP_IP_ADDRESS_TYPE eTrapMultiAddressType)

TCPIP_SNMPV3_TrapTypeGet Function

Gets SNMP Trap type for version v3.

File

snmp.h

C

```
bool TCPIP_SNMPV3_TrapTypeGet();
```

Returns

- true - SNMP3 will use trap version v2
- false - SNMP3 will use trap version v1

Description

This function returns true if SNMP module is trying to send trap version v2 with SNMP version v3.

Remarks

This function is used by the customer function.

Preconditions

TCPIP_SNMP_Initialize() is already called.

Function

bool TCPIP_SNMPV3_TrapTypeGet(void)

TCPIP_SNMP_ValidateTrapIntf Function

Gets the status of trap interface.

File

snmp.h

C

```
bool TCPIP_SNMP_ValidateTrapIntf(TCPIP_NET_HANDLE pIf);
```

Returns

- true - SNMP trap interface is valid
- false - SNMP trap interface is invalid

Description

This function returns true if SNMP module trap interface is a valid interface.

Remarks

This function is used by the customer function.

Preconditions

TCPIP_SNMP_Initialize is already called.

Parameters

Parameters	Description
pif	network interface

Function

bool TCPIP_SNMP_ValidateTrapIntf(TCPIP_NET_HANDLE pIf)

TCPIP_SNMP_ReadCommunitySet Function

Sets the readCommunity String with SNMP index.

File

snmp.h

C

```
bool TCPIP_SNMP_ReadCommunitySet(int index, int len, uint8_t * src);
```

Returns

- true - if the community string is collected
- false - if the community string is not collected

Description

This function is used to configure READ community string from the user and configure the SNMP community table.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize is already called.

Parameters

Parameters	Description
index	One of the index of community table and it should be less than TCPIP_SNMP_MAX_COMMUNITY_SUPPORT.
len	Length of the community string expected. It should not be more than TCPIP_SNMP_COMMUNITY_MAX_LEN.
src	Copy this community string to snmp community table.

Function

bool TCPIP_SNMP_ReadCommunitySet(int index,int len, uint8_t * src)

TCPIP_SNMP_WriteCommunitySet Function

Sets the writeCommunity String with SNMP index.

File

snmp.h

C

```
bool TCPIP_SNMP_WriteCommunitySet(int index, int len, uint8_t * src);
```

Returns

- true - if the community string is collected
- false - if the community string is not collected

Description

This function is used to collect WRITE community string from user and set the community table with respect to the index value.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize is already called.

Parameters

Parameters	Description
index	One of the index of community table and it should be less than TCPIP_SNMP_MAX_COMMUNITY_SUPPORT.

len	Length of the community string expected. It should not be more than TCPIP_SNMP_COMMUNITY_MAX_LEN.
src	Copy this community string to SNMP community table.

Function

bool TCPIP_SNMP_WriteCommunitySet(int index,int len, uint8_t * src)

TCPIP_SNMP_SocketIDGet Function

Gets the Socket ID for SNMP Server socket.

File

snmp.h

C

```
void TCPIP_SNMP_SocketIDGet(UDP_SOCKET * socket);
```

Returns

None.

Description

This function is used to get trap client socket ID for both IPv4 and IPv6 receiver Address.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize is already called.

Parameters

Parameters	Description
socket	Trap client socket ID

Function

void TCPIP_SNMP_SocketIDGet(UDP_SOCKET *socket)

TCPIP_SNMP_SocketIDSet Function

Sets the Socket ID for SNMP Server socket.

File

snmp.h

C

```
void TCPIP_SNMP_SocketIDSet(UDP_SOCKET socket);
```

Returns

None.

Description

This function is used to update socket value of SNMP trap global structure.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize is already called.

Parameters

Parameters	Description
socket	Trap client socket ID

Function

void TCPIP_SNMP_SocketIDSet(UDP_SOCKET socket)

TCPIP_SNMP_Task Function

Standard TCP/IP stack module task function.

File

snmp.h

C

```
void TCPIP_SNMP_Task();
```

Returns

None.

Description

This function performs SNMP module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The SNMP module should have been initialized

Function

void TCPIP_SNMP_Task(void)

b) SNMPv3 Module Functions

TCPIP_SNMPV3_EngineUserDataBaseGet Function

Get SNMPv3 engine data base details.

File

snmpv3.h

C

```
bool TCPIP_SNMPV3_EngineUserDataBaseGet(TCPIP_SNMPV3_USERDATABASECONFIG_TYPE userDataBaseType, uint8_t len,
uint8_t userIndex, void * val);
```

Returns

None.

Description

This function is used to get SNMPv3 Engine data base details using TCPIP_SNMPV3_USERDATABASECONFIG_TYPE enumeration.

Remarks

None

Preconditions

TCPIP_SNMP_Initialize is already called.

Example

```
bool TCPIP_SNMP_VarbindGet(SNMP_ID var, SNMP_INDEX index, uint8_t* ref, SNMP_VAL* val)
{
    switch(var)
    {
        case USER_SECURITY_NAME:
            if(index < TCPIP_SNMPV3_USM_MAX_USER)
            {
```

```
                    if(TCPIP_SNMPV3_EngineUserDataBaseGet(SNMPV3_USERNAME_CONFIG_TYPE,myRef,index,&val->byte)
== false)
                    {
                        *ref = SNMP_END_OF_VAR;
                    }
                    else
                    {
                        myRef++;
                        *ref = myRef;
                    }
                    return true;
                }
                break;
            }
        }
```

Parameters

Parameters	Description
userDataBaseType	SNMPv3 data base configuration type
len	Number of bytes need to be read from data base
userIndex	SNMPv3 user index
val	void pointer to a any data type. Length parameter value is changed according to data type.

Function

void TCPIP_SNMPV3_EngineUserDataBaseGet(TCPIP_SNMPV3_USERDATABASECONFIG_TYPE userDataBaseType,
uint8_t len,uint8_t userIndex,void *val);

TCPIP_SNMPV3_EngineUserDataBaseSet Function

Set SNMPv3 engine data base details.

File

snmpv3.h

C

```
bool TCPIP_SNMPV3_EngineUserDataBaseSet(TCPIP_SNMPV3_USERDATABASECONFIG_TYPE userDataBaseType, uint8_t len,
uint8_t userIndex, void * val);
```

Returns

None.

Description

This function is used to set SNMPv3 Engine data base details using TCPIP_SNMPV3_USERDATABASECONFIG_TYPE enumeration.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize is already called.

Example

```
bool TCPIP_SNMP_VarbindSet(SNMP_ID var, SNMP_INDEX index, uint8_t ref, SNMP_VAL val)
{
  switch(var)
  {
      case USER_SECURITY_NAME:
          if ( ref ==  SNMP_END_OF_VAR )
          {
              if(TCPIP_SNMPV3_EngineUserDataBaseSet(SNMPV3_USERNAME_CONFIG_TYPE,strlen((char*)gSnmpv3UserSec
urityName),
                                                    index,gSnmpv3UserSecurityName) != true)
                  return false;
          }
```

```
            // Make sure that index is within our range.
            if ( index < TCPIP_SNMPV3_USM_MAX_USER )
            {
                // Copy given value into local buffer.
                gSnmpv3UserSecurityName[ref]=val.byte;
                return true;
            }
            break;
    }
}
```

Parameters

Parameters	Description
userDataBaseType	SNMPv3 data base configuration type
len	Number of bytes need to be read from data base
userIndex	SNMPv3 user index
val	void pointer to a any data type. Length parameter value is changed according to data type.

Function

void TCPIP_SNMPV3_EngineUserDataBaseSet(TCPIP_SNMPV3_USERDATABASECONFIG_TYPE userDataBaseType,
uint8_t len,uint8_t userIndex,void *val);

TCPIP_SNMPv3_TrapConfigDataGet Function

Gets the SNMPv3 Trap configuration details using the user name index.

File

snmpv3.h

C

```
void TCPIP_SNMPv3_TrapConfigDataGet(uint8_t userIndex, uint8_t * msgModelType, uint8_t * securityModelType);
```

Returns

None.

Description

This function is used to get SNMPv3 message model type and security model type using user index.

Remarks

None.

Preconditions

TCPIP_SNMP_Initialize is already called.

Parameters

Parameters	Description
userIndex	user name index
msgModelType	message processing type
securityModelType	security model type

Function

void TCPIP_SNMPv3_TrapConfigDataGet(uint8_t userIndex,uint8_t *msgModelType,
uint8_t *securityModelType)

TCPIP_SNMPv3_Notify Function

Creates and Sends SNMPv3 TRAP PDU.

File

snmpv3.h

C

```
bool TCPIP_SNMPv3_Notify(SNMP_ID var, SNMP_VAL val, SNMP_INDEX index, uint8_t targetIndex,
SNMP_TRAP_IP_ADDRESS_TYPE eTrapMultiAddressType);
```

Description

This function creates SNMPv3 trap PDU and sends it to previously specified remoteHost.

Remarks

None.

Preconditions

TRAP event is triggered.

Parameters

Parameters	Description
var	SNMP var ID that is to be used in notification
val	Value of var. Only value of uint8_t, uint16_t or uint32_t can be sent.
index	Index of var. If this var is a single,index would be 0, or else if this var Is a sequence, index could be any value from 0 to 127 targetIndex -index of the 'Snmpv3TrapConfigData' table's security user name for which the TRAP PDU message header to constructed.

Function

bool TCPIP_SNMPv3_Notify(SNMP_ID var, SNMP_VAL val, SNMP_INDEX index,

uint8_t targetIndex)

c) SNMP Data Types and Constants

SNMP_END_OF_VAR Macro

File

snmp.h

C

```
#define SNMP_END_OF_VAR (0xff)
```

Description

This Macro is used for both SNMP SET and GET Variable processing to indicate the end of SNMP variable processing. For multi byte data request, the end byte will be always SNMP_END_OF_VAR.

SNMP_INDEX_INVALID Macro

File

snmp.h

C

```
#define SNMP_INDEX_INVALID (0xff)
```

Description

This Macro is used for both SNMP SET and GET Sequence Variable processing. SNMP starts processing the start of sequence variable with Invalid index. TCPIP_SNMP_ExactIndexGet and TCPIP_SNMP_NextIndexGet returns a valid index as per SNMP_INDEX_INVALID.

SNMP_START_OF_VAR Macro

File

snmp.h

C

```
#define SNMP_START_OF_VAR (0)
```

Description

This Macro is used for both SNMP SET and GET Variable processing to indicate the start of SNMP variable processing. For multi byte data request, the first byte will be always SNMP_START_OF_VAR.

SNMP_V1 Macro

File

snmp.h

C

```
#define SNMP_V1 (0)
```

Description

This macro is used for SNMP version 1

SNMP_V2C Macro

File

snmp.h

C

```
#define SNMP_V2C (1)
```

Description

This macro is used for SNMP version 2 with community

SNMP_V3 Macro

File

snmp.h

C

```
#define SNMP_V3 (3)
```

Description

This macro is used for SNMP version 3 with authentication and privacy

SNMP_COMMUNITY_TYPE Enumeration

Definition to represent different type of SNMP communities.

File

snmp.h

C

```
typedef enum {
  READ_COMMUNITY = 1,
  WRITE_COMMUNITY = 2,
  INVALID_COMMUNITY = 3
} SNMP_COMMUNITY_TYPE;
```

Members

Members	Description
READ_COMMUNITY = 1	Read only community
WRITE_COMMUNITY = 2	Read write community
INVALID_COMMUNITY = 3	Community invalid

Description

Enumeration: SNMP_COMMUNITY_TYPE

List of different SNMP community types.

Remarks

SNMP agent use these community types for both TRAP and SNMP agent request.

SNMP_ID Type

SNMP dynamic variable ID.

File

snmp.h

C

```
typedef uint32_t SNMP_ID;
```

Description

Type: SNMP_ID

Only dynamic and AgentID variables can contain a dyanmic ID. MIB2BIB utility enforces this rule when BIB was generated. All the dynamic IDs are are listed in mib.h. The maximum value of a dynamic ID is 1023.

Remarks

mib2bib.jar utility generates mib.h and snmp.bib from Microchip MIB script. DynamicVar - This command declares defined OID variable as dynamic. Syntax - $DynamicVar(oidName, id).

SNMP_INDEX Type

SNMP sequence variable index.

File

snmp.h

C

```
typedef uint8_t SNMP_INDEX;
```

Description

Type: SNMP_INDEX

The current version limits the size of the index to 7 bits wide, meaning that such arrays can contain up to 127 entries.

Remarks

SequenceVar - This command is part of Microchip MIB script declares a previously defined OID variable as a sequence variable and assigns an index to it. A sequence variable can contain an array of values and any instance of its values can be referenced by an index. More than one sequence variable may share a single index, creating multi dimensional arrays.

More than one index variable is not supported by mib2bib.jar compiler.

SNMP_NON_MIB_RECD_INFO Structure

Restrict access for specific OIDs.

File

snmp.h

C

```
typedef struct {
  uint8_t oidstr[16];
  uint8_t version;
} SNMP_NON_MIB_RECD_INFO;
```

Description

Structure: SNMP_NON_MIB_RECD_INFO

This structure is used to restrict access to static variables of SNMPv3 OIDs from SNMPv2c and SNMPv1 version.OID string length is restricted to 16.

Remarks

None.

SNMP_TRAP_IP_ADDRESS_TYPE Enumeration

Definition of the supported address types for SNMP trap.

File

snmp.h

C

```
typedef enum {
  IPV4_SNMP_TRAP = 1,
  IPV6_SNMP_TRAP
} SNMP_TRAP_IP_ADDRESS_TYPE;
```

Description

Enumeration: SNMP_TRAP_IP_ADDRESS_TYPE

SNMP agent supports both IPv4 and IPv6 trap address type and is able to transmit traps to both IPv4 and IPv6 Host receiver address.

Remarks

None.

SNMP_VAL Union

Definition to represent SNMP OID object values.

File

snmp.h

C

```
typedef union {
  uint32_t dword;
  uint16_t word;
  uint8_t byte;
  uint8_t v[sizeof(uint32_t)];
} SNMP_VAL;
```

Members

Members	Description
uint32_t dword;	double word value
uint16_t word;	word value
uint8_t byte;	byte value
uint8_t v[sizeof(uint32_t)];	byte array

Description

Union: SNMP_VAL

SNMP agent processes different variable types.

Remarks

None.

SNMP_GENERIC_TRAP_NOTIFICATION_TYPE Enumeration

Definition to represent different SNMP generic trap types.

File

snmp.h

C

```
typedef enum {
```

```
  COLD_START = 0x0,
  WARM_START = 0x1,
  LINK_DOWN = 0x2,
  LINK_UP = 0x3,
  AUTH_FAILURE = 0x4,
  EGP_NEIGHBOR_LOSS = 0x5,
  ENTERPRISE_SPECIFIC = 0x6
} SNMP_GENERIC_TRAP_NOTIFICATION_TYPE;
```

Members

Members	Description
COLD_START = 0x0	Controls the sending of SNMP coldstart notifications. A coldStart(0) trap signifies that the sending protocol entity is reinitializing itself such that the configuration of the agent or the protocol entity implementation might be altered.
WARM_START = 0x1	Controls the sending of SNMP warmstart notifications. A warmStart(1) trap signifies that the sending protocol entity is reinitializing itself so that neither the agent configuration nor the protocol entity implementation can be altered.
LINK_DOWN = 0x2	Controls the how SNMP linkdown notifications are sent. A linkDown(2) trap signifies that the sending protocol entity recognizes a failure in one of the communication links represented in the configuration of the agent.
LINK_UP = 0x3	Controls the sending of SNMP linkup notifications. A linkUp(3) trap signifies that the sending protocol entity recognizes that one of the communication links represented in the configuration of the agent has come up.
AUTH_FAILURE = 0x4	Controls the distribution of SNMP authentication failure notifications. An authenticationFailure(4) trap signifies that the sending protocol entity is the addressee of a protocol message that is not properly authenticated. Like Community Name authentication failure
EGP_NEIGHBOR_LOSS = 0x5	Controls the distribution of SNMP egpNeighborLoss notifications.An egpNeighborLoss(5) trap signifies that an EGP neighbor for whom the sending protocol entity was an EGP peer has been marked down and the peer relationship no longer exists.
ENTERPRISE_SPECIFIC = 0x6	Controls the distribution of SNMP enterprise/-specific notifications.An enterpriseSpecific(6) trap signifies that the sending protocol entity recognizes that some enterprise/-specific event has occurred. The specific-trap field identifies the particular trap that occurred.

Description

Enumeration: SNMP_GENERIC_TRAP_NOTIFICATION_TYPE

List of different SNMP specific Notification types.

Remarks

ENTERPRISE_SPECIFIC and AUTH_FAILURE are used while sending specific trap.

SNMP_VENDOR_SPECIFIC_TRAP_NOTIFICATION_TYPE Enumeration

Definition to represent different SNMP vendor trap types.

File

snmp.h

C

```
typedef enum {
  VENDOR_TRAP_DEFAULT = 0x0,
  BUTTON_PUSH_EVENT = 0x1,
  POT_READING_MORE_512 = 0x2
} SNMP_VENDOR_SPECIFIC_TRAP_NOTIFICATION_TYPE;
```

Members

Members	Description
VENDOR_TRAP_DEFAULT = 0x0	Default trap . Agent send use this trap when there is authentication failure.
BUTTON_PUSH_EVENT = 0x1	PUSH button event trap notification
POT_READING_MORE_512 = 0x2	Analog POT meter event trap notification

Description

Enumeration: SNMP_VENDOR_SPECIFIC_TRAP_NOTIFICATION_TYPE

List of different SNMP Vendor Notification types.

Remarks

None.

d) SNMPv3 Data Types and Constants

SNMPV3_HMAC_HASH_TYPE Enumeration

Different type of authentication for SNMPv3.

File

snmpv3.h

C

```
typedef enum {
  SNMPV3_HMAC_MD5 = 0u,
  SNMPV3_HMAC_SHA1,
  SNMPV3_NO_HMAC_AUTH
} SNMPV3_HMAC_HASH_TYPE;
```

Members

Members	Description
SNMPV3_HMAC_MD5 = 0u	MD5 is being calculated HMAC SHA1 authentication protocol
SNMPV3_HMAC_SHA1	SHA-1 is being calculated No authentication is supported

Description

Enumeration: SNMPV3_HMAC_HASH_TYPE

The following authentication types are supported by the SNMPv3 USM model for data confidentiality. SNMPv3 agent supports both MD5 and SHA1 protocol for authentication.

Remarks

None.

SNMPV3_PRIV_PROT_TYPE Enumeration

Different type of encryption and decryption for SNMPv3.

File

snmpv3.h

C

```
typedef enum {
  SNMPV3_DES_PRIV = 0x0,
  SNMPV3_AES_PRIV,
  SNMPV3_NO_PRIV
} SNMPV3_PRIV_PROT_TYPE;
```

Members

Members	Description
SNMPV3_DES_PRIV = 0x0	Data Encryption Standard (DES-CBC) encryption and decryption protocol
SNMPV3_AES_PRIV	Advanced Encryption Standard (AES-CFB) encryption and decryption protocol
SNMPV3_NO_PRIV	No encryption or decryption protocol is supported

Description

Enumeration: SNMPV3_PRIV_PROT_TYPE

These below privacy types are supported by the SNMPv3 USM model for data confidentiality. SNMPv3 agent supports both AES-CFB and DES-CBC encryption and decryption algorithm. For DES-CBC privacy protocol, SNMPv3 agent will use Harmony Crypto Library. For AES-CFB privacy protocol, SNMPv3 agent will use Legacy TCP/IP Crypto Library (For AES, include -aes_pic32mx.a to the project.)

Remarks

128-bit, 192-bit and 256-bit AES are supported.

STD_BASED_SNMP_MESSAGE_PROCESSING_MODEL Enumeration

Different SNMP Message processing model

File

snmpv3.h

C

```
typedef enum {
  SNMPV1_MSG_PROCESSING_MODEL = 0X00,
  SNMPV2C_MSG_PROCESSING_MODEL = 0X01,
  SNMPV2U_V2_MSG_PROCESSING_MODEL = 0X02,
  SNMPV3_MSG_PROCESSING_MODEL = 0X03
} STD_BASED_SNMP_MESSAGE_PROCESSING_MODEL;
```

Members

Members	Description
SNMPV1_MSG_PROCESSING_MODEL = 0X00	SNMP version 1 Message processing model
SNMPV2C_MSG_PROCESSING_MODEL = 0X01	SNMP version 2 Message processing model with community as security feature
SNMPV2U_V2_MSG_PROCESSING_MODEL = 0X02	SNMP version 2 Message processing model
SNMPV3_MSG_PROCESSING_MODEL = 0X03	SNMP version 3 Message processing model with authentication and encryption and decryption

Description

Enumeration: STD_BASED_SNMP_MESSAGE_PROCESSING_MODEL

SNMP Message processing model is responsible for processing an SNMP version specific message and for coordinating the interaction with security sub system. SNMP message processing subsystem is part of an SNMP engine which interacts with the Dispatcher to handle the version specific SNMP messages.

A Message Processing Model describes the version-specific procedures for extracting data from messages, generating messages, calling upon a securityModel to apply its security services to messages.

Remarks

None.

STD_BASED_SNMP_SECURITY_MODEL Enumeration

Different Security services for SNMPv3 messages.

File

snmpv3.h

C

```
typedef enum {
  ANY_SECUTIRY_MODEL = 0x00,
  SNMPV1_SECURITY_MODEL = 0X01,
  SNMPV2C_SECURITY_MODEL = 0X02,
  SNMPV3_USM_SECURITY_MODEL = 0X03
} STD_BASED_SNMP_SECURITY_MODEL;
```

Members

Members	Description
ANY_SECUTIRY_MODEL = 0x00	Security Model Reserved for ANY
SNMPV1_SECURITY_MODEL = 0X01	Security Model reserved fro SNMP version 1
SNMPV2C_SECURITY_MODEL = 0X02	Community Security Model reserved for SNMP version 2
SNMPV3_USM_SECURITY_MODEL = 0X03	User based security model reserved for SNMP version 3

Description

Enumeration: STD_BASED_SNMP_SECURITY_MODEL

SNMP Security subsystem is applied to the transmission and reception of messages and to the processing of the contents of messages.

- The zero value does not identify any particular security model.
- Values between 1 and 255, inclusive, are reserved for standards-track Security Models and are

managed by the Internet Assigned Numbers Authority (IANA).

- Values greater than 255 are allocated to enterprise-specific Security Models. An

enterprise specific securityModel value is defined to be: enterpriseID * 256 + security model within enterprise

Remarks

None.

STD_BASED_SNMPV3_SECURITY_LEVEL Enumeration

Different Security Level for SNMPv3 messages.

File

snmpv3.h

C

```
typedef enum {
  NO_AUTH_NO_PRIV = 1,
  AUTH_NO_PRIV,
  AUTH_PRIV
} STD_BASED_SNMPV3_SECURITY_LEVEL;
```

Members

Members	Description
NO_AUTH_NO_PRIV = 1	without authentication and without privacy
AUTH_NO_PRIV	with authentication but without privacy
AUTH_PRIV	with authentication but with privacy

Description

Enumeration: STD_BASED_SNMPV3_SECURITY_LEVEL

A Level of Security at which SNMPv3 messages can be sent or with which operations are being processed.

Remarks

None.

TCPIP_SNMPV3_USERDATABASECONFIG_TYPE Enumeration

Different Configuration parameters of SNMPv3 operation

File

snmpv3.h

C

```
typedef enum {
  SNMPV3_USERNAME_CONFIG_TYPE = 0,
  SNMPV3_AUTHPASSWD_CONFIG_TYPE,
  SNMPV3_PRIVPASSWD_CONFIG_TYPE,
  SNMPV3_AUTHPASSWDLOCALIZEDKEY_CONFIG_TYPE,
  SNMPV3_PRIVPASSWWDLOCALIZEDKEY_CONFIG_TYPE,
  SNMPV3_HASHTYPE_CONFIG_TYPE,
  SNMPV3_PRIVTYPE_CONFIG_TYPE,
  SNMPV3_TARGET_SECURITY_NAME_TYPE,
  SNMPV3_TARGET_SECURITY_LEVEL_TYPE,
  SNMPV3_TARGET_SECURITY_MODEL_TYPE,
  SNMPV3_TARGET_MP_MODEL_TYPE,
  SNMPV3_ENGINE_ID_TYPE,
  SNMPV3_ENGINE_BOOT_TYPE,
  SNMPV3_ENGINE_TIME_TYPE,
  SNMPV3_ENGINE_MAX_MSG_TYPE
} TCPIP_SNMPV3_USERDATABASECONFIG_TYPE;
```

Members

Members	Description
SNMPV3_USERNAME_CONFIG_TYPE = 0	Snmpv3 user name configuration
SNMPV3_AUTHPASSWD_CONFIG_TYPE	Authentication configuration type
SNMPV3_PRIVPASSWD_CONFIG_TYPE	Encryption and Decryption password configuration
SNMPV3_AUTHPASSWDLOCALIZEDKEY_CONFIG_TYPE	Authorization localized key configuration type
SNMPV3_PRIVPASSWWDLOCALIZEDKEY_CONFIG_TYPE	Encryption and Decryption password localized key configuration type
SNMPV3_HASHTYPE_CONFIG_TYPE	SNMPv3 hash algorithm type
SNMPV3_PRIVTYPE_CONFIG_TYPE	SNMPv3 privacy configuration type
SNMPV3_TARGET_SECURITY_NAME_TYPE	SNMPv3 target address user name . This is for Trap communication
SNMPV3_TARGET_SECURITY_LEVEL_TYPE	SNMPv3 target security type
SNMPV3_TARGET_SECURITY_MODEL_TYPE	SNMPv3 target security model type
SNMPV3_TARGET_MP_MODEL_TYPE	SNMPv3 target security message processing model type
SNMPV3_ENGINE_ID_TYPE	Identifier that uniquely and unambiguously identifies the local SNMPv3 engine
SNMPV3_ENGINE_BOOT_TYPE	Number of times the local SNMPv3 engine has rebooted or reinitialized since the engine ID was last changed
SNMPV3_ENGINE_TIME_TYPE	Number of seconds since the local SNMPv3 engine was last rebooted or reinitialized
SNMPV3_ENGINE_MAX_MSG_TYPE	SNMPv3 Engine Maximum message size the sender can accommodate

Description

Enumeration: TCPIP_SNMPV3_USERDATABASECONFIG_TYPE

These configuration types are used by the SNMP user while doing configuration SNMPv3 parameters. It includes SNMpv3 user name , authentication and encryption configuration parameters.

Remarks

None.

TCPIP_SNMP_COMMUNITY_CONFIG Structure

SNMP community configuration.

File

snmpv3.h

C

```
typedef struct {
  char * communityName;
} TCPIP_SNMP_COMMUNITY_CONFIG;
```

Description

Structure: TCPIP_SNMP_COMMUNITY_CONFIG

This structure is used to configure community details during run-time.

Remarks

None.

TCPIP_SNMP_MODULE_CONFIG Structure

SNMP module configuration.

File

snmpv3.h

C

```
typedef struct {
  bool trapEnable;
  bool snmp_trapv2_use;
  bool snmpv3_trapv1v2_use;
  char* snmp_bib_file;
```

```
  TCPIP_SNMP_COMMUNITY_CONFIG * read_community_config;
  TCPIP_SNMP_COMMUNITY_CONFIG * write_community_config;
  TCPIP_SNMPV3_USM_USER_CONFIG * usm_config;
  TCPIP_SNMPV3_TARGET_ENTRY_CONFIG * trap_target_config;
} TCPIP_SNMP_MODULE_CONFIG;
```

Members

Members	Description
bool trapEnable;	true = agent can send the trap, false = agent shouldn't send the trap
bool snmp_trapv2_use;	true = agent uses Trap version v2 and false = uses Tarp version 1
bool snmpv3_trapv1v2_use;	SNMPv3 trap should be true , only if SNMP version is 3
TCPIP_SNMP_COMMUNITY_CONFIG * read_community_config;	read-only Community configuration
TCPIP_SNMP_COMMUNITY_CONFIG * write_community_config;	write-only Community configuration
TCPIP_SNMPV3_USM_USER_CONFIG * usm_config;	SNMPv3 USM configuration
TCPIP_SNMPV3_TARGET_ENTRY_CONFIG * trap_target_config;	SNMPv3 trap configuration

Description

Structure: TCPIP_SNMP_MODULE_CONFIG

This structure is used to configure SNMP details for runtime configuration.

Remarks

None

TCPIP_SNMPV3_TARGET_ENTRY_CONFIG Structure

SNMP module trap target address configuration.

File

snmpv3.h

C

```
typedef struct {
  char * secname;
  STD_BASED_SNMP_SECURITY_MODEL mp_model;
  STD_BASED_SNMP_SECURITY_MODEL sec_model;
  STD_BASED_SNMPV3_SECURITY_LEVEL sec_level;
} TCPIP_SNMPV3_TARGET_ENTRY_CONFIG;
```

Description

Structure: SNMPV3_TARGET_ENTRY_CONFIG

This structure is used to configure SNMP target details during runtime .

Remarks

None.

TCPIP_SNMPV3_USM_USER_CONFIG Structure

SNMPv3 USM configuration.

File

snmpv3.h

C

```
typedef struct {
  char * username;
  STD_BASED_SNMPV3_SECURITY_LEVEL security_level;
  SNMPV3_HMAC_HASH_TYPE usm_auth_proto;
  char * usm_auth_password;
  SNMPV3_PRIV_PROT_TYPE usm_priv_proto;
  char * usm_priv_password;
```

```
} TCPIP_SNMPV3_USM_USER_CONFIG;
```

Members

Members	Description
char * username;	< user name string
STD_BASED_SNMPV3_SECURITY_LEVEL security_level;	< security level: auth, priv combination
SNMPV3_HMAC_HASH_TYPE usm_auth_proto;	< auth type: md5, sha1
char * usm_auth_password;	< passphrase string for authentication
SNMPV3_PRIV_PROT_TYPE usm_priv_proto;	< priv type: DES
char * usm_priv_password;	< passphrase string for privacy

Description

Structure: SNMPV3_USM_USER_CONFIG

This structure is used to configure predefined SNMPv3 USM details for run-time configuration.

Remarks

None.

Files

Files

Name	Description
snmp.h	Simple Network Management Protocol(SNMP) v1/v2c API header file.
snmpv3.h	Simple Network Management Protocol Version3(SNMPv3) API header file.
snmp_config.h	SNMP configuration file
snmpv3_config.h	SNMPv3 configuration file

Description

This section lists the source and header files used by the library.

snmp.h

Simple Network Management Protocol(SNMP) v1/v2c API header file.

Enumerations

	Name	Description
	SNMP_COMMUNITY_TYPE	Definition to represent different type of SNMP communities.
	SNMP_GENERIC_TRAP_NOTIFICATION_TYPE	Definition to represent different SNMP generic trap types.
	SNMP_TRAP_IP_ADDRESS_TYPE	Definition of the supported address types for SNMP trap.
	SNMP_VENDOR_SPECIFIC_TRAP_NOTIFICATION_TYPE	Definition to represent different SNMP vendor trap types.

Functions

	Name	Description
	TCPIP_SNMP_AuthTrapFlagGet	Gets the status of authentication trap flag.
	TCPIP_SNMP_AuthTrapFlagSet	Sets the status of authentication trap flag.
	TCPIP_SNMP_ClientGetNet	Get a network interface for SNMP TRAP.
	TCPIP_SNMP_ExactIndexGet	To search for exact index node in case of a Sequence variable.
	TCPIP_SNMP_IsTrapEnabled	Gets the SNMP Trap status.
	TCPIP_SNMP_IsValidCommunity	Validates community name for access control.
	TCPIP_SNMP_IsValidLength	Validates the set variable data length to data type.
	TCPIP_SNMP_MibIDSet	Sets the agent MIB ID for SNP notification.
	TCPIP_SNMP_NextIndexGet	To search for next index node in case of a Sequence variable.
	TCPIP_SNMP_NotifyIsReady	Resolves given remoteHost IP address into MAC address.
	TCPIP_SNMP_NotifyPrepare	Collects trap notification info and send ARP to remote host.
	TCPIP_SNMP_ReadCommunityGet	Gets the readCommunity String with SNMP index.
	TCPIP_SNMP_ReadCommunitySet	Sets the readCommunity String with SNMP index.

	TCPIP_SNMP_RecordIDValidation	Used to restrict the access dynamic and non dynamic OID string for a particular SNMP Version.
	TCPIP_SNMP_SendFailureTrap	Prepares and validates the remote node that will receive a trap and send the trap PDU.
	TCPIP_SNMP_SocketIDGet	Gets the Socket ID for SNMP Server socket.
	TCPIP_SNMP_SocketIDSet	Sets the Socket ID for SNMP Server socket.
	TCPIP_SNMP_Task	Standard TCP/IP stack module task function.
	TCPIP_SNMP_TrapInterFaceSet	Sets the TRAP interface for SNMP notification.
	TCPIP_SNMP_TRAPMibIDGet	Gets the agent MIB ID for SNP notification.
	TCPIP_SNMP_TrapSendFlagGet	Gets the status of trap send flag.
	TCPIP_SNMP_TrapSendFlagSet	Sets the status of trap send flag.
	TCPIP_SNMP_TrapSpecificNotificationGet	Gets the specific trap.
	TCPIP_SNMP_TrapSpecificNotificationSet	Sets the specific trap, generic trap, and trap ID.
	TCPIP_SNMP_TrapTimeGet	Gets SNMP Trap UDP client open socket time-out.
	TCPIP_SNMP_TRAPTypeGet	Get SNMP Trap type for version v1 and v2c.
	TCPIP_SNMP_TRAPv1Notify	Creates and Sends TRAPv1 pdu.
	TCPIP_SNMP_TRAPv2Notify	Creates and sends TRAP PDU.
	TCPIP_SNMP_ValidateTrapIntf	Gets the status of trap interface.
	TCPIP_SNMP_VarbindGet	Used to get/collect OID variable information.
	TCPIP_SNMP_VarbindSet	Sets the MIB variable with the requested value.
	TCPIP_SNMP_WriteCommunityGet	Gets the writeCommunity String with SNMP index.
	TCPIP_SNMP_WriteCommunitySet	Sets the writeCommunity String with SNMP index.
	TCPIP_SNMPV3_TrapTypeGet	Gets SNMP Trap type for version v3.

Macros

	Name	Description
	SNMP_END_OF_VAR	This Macro is used for both SNMP SET and GET Variable processing to indicate the end of SNMP variable processing. For multi byte data request, the end byte will be always SNMP_END_OF_VAR.
	SNMP_INDEX_INVALID	This Macro is used for both SNMP SET and GET Sequence Variable processing. SNMP starts processing the start of sequence variable with Invalid index. TCPIP_SNMP_ExactIndexGet and TCPIP_SNMP_NextIndexGet returns a valid index as per SNMP_INDEX_INVALID.
	SNMP_START_OF_VAR	This Macro is used for both SNMP SET and GET Variable processing to indicate the start of SNMP variable processing. For multi byte data request, the first byte will be always SNMP_START_OF_VAR.
	SNMP_V1	This macro is used for SNMP version 1
	SNMP_V2C	This macro is used for SNMP version 2 with community
	SNMP_V3	This macro is used for SNMP version 3 with authentication and privacy

Structures

	Name	Description
	SNMP_NON_MIB_RECD_INFO	Restrict access for specific OIDs.

Types

	Name	Description
	SNMP_ID	SNMP dynamic variable ID.
	SNMP_INDEX	SNMP sequence variable index.

Unions

	Name	Description
	SNMP_VAL	Definition to represent SNMP OID object values.

Description

SNMP Definitions for the Microchip TCP/IP Stack

Simple Network Management Protocol (SNMP) is one of the key components of a Network Management System (NMS). SNMP is an application layer protocol that facilitates the exchange of management information among network devices. It is a part of the TCP/IP protocol suite. The SNMP Manager uses the UDP Port Number 161 to send requests to the agent. The agent uses the UDP Port Number 162 to send Trap(s) or notification events to the manager.

- Supports SNMP Version V1 and V2c over User Datagram Protocol (UDP)
- Supports Get, Get_Bulk, Get_Next, Set and Trap Protocol Data Units (PDUs)
- Supports up to 255 dynamic OIDs and unlimited constant OIDs
- mib2bib.jar utility is Microchip MIB compiler. It accepts Microchip MIB script

in ASCII format and generates two output files: The binary information file, snmp.bib and the C header file , mib.h.

File Name

snmp.h

Company

Microchip Technology Inc.

snmpv3.h

Simple Network Management Protocol Version3(SNMPv3) API header file.

Enumerations

	Name	Description
	SNMPV3_HMAC_HASH_TYPE	Different type of authentication for SNMPv3.
	SNMPV3_PRIV_PROT_TYPE	Different type of encryption and decryption for SNMPv3.
	STD_BASED_SNMP_MESSAGE_PROCESSING_MODEL	Different SNMP Message processing model
	STD_BASED_SNMP_SECURITY_MODEL	Different Security services for SNMPv3 messages.
	STD_BASED_SNMPV3_SECURITY_LEVEL	Different Security Level for SNMPv3 messages.
	TCPIP_SNMPV3_USERDATABASECONFIG_TYPE	Different Configuration parameters of SNMPv3 operation

Functions

	Name	Description
	TCPIP_SNMPV3_EngineUserDataBaseGet	Get SNMPv3 engine data base details.
	TCPIP_SNMPV3_EngineUserDataBaseSet	Set SNMPv3 engine data base details.
	TCPIP_SNMPv3_Notify	Creates and Sends SNMPv3 TRAP PDU.
	TCPIP_SNMPv3_TrapConfigDataGet	Gets the SNMPv3 Trap configuration details using the user name index.

Structures

	Name	Description
	TCPIP_SNMP_COMMUNITY_CONFIG	SNMP community configuration.
	TCPIP_SNMP_MODULE_CONFIG	SNMP module configuration.
	TCPIP_SNMPV3_TARGET_ENTRY_CONFIG	SNMP module trap target address configuration.
	TCPIP_SNMPV3_USM_USER_CONFIG	SNMPv3 USM configuration.

Description

Simple Network Management Protocol (SNMP) v3 API Header File

SNMPv3 provides a secure access to the devices using a combination of authentication and encryption of packets over the network. Comparing with SNMPv1/v2, SNMPv3 ensures that packets can be collected securely from SNMP devices. Microchip SNMPv3 Agent authentication is implemented with MD5 and SHA1 protocols and encryption is implemented with AES protocol. These credentials and other user information are stored in the global array. The user of the SNMPv3 stack can decide on the number of user names in the Userâ€™s data base to be stored with the Server. According to the SNMPv3 recommendation, SNMPv3 server should not be configured with the authentication and privacy passwords. Instead could be configured with the respective localized keys of the password. Microchip SNMPv3 agent is provided with the password information in the database for the â€œGetting Startedâ€• and for understanding purpose only. It is recommended that the SNMPv3 stack should be modified to restrict access to the password OIDs declared in the user data base.

File Name

snmpv3.h

Company

Microchip Technology Inc.

snmp_config.h

SNMP configuration file

Macros

	Name	Description
	TCPIP_SNMP_BIB_FILE_NAME	The Microchip mib2bib.jar compiler is used to convert the Microchip MIB script to binary format and it is compatible with the Microchip SNMP agent. which is written in ASCII format. Name of the bib file for SNMP is snmp.bib.
	TCPIP_SNMP_COMMUNITY_MAX_LEN	This is the maximum length for community string. Application must ensure that this length is observed. SNMP module adds one byte extra after TCPIP_SNMP_COMMUNITY_MAX_LEN for adding '0' NULL character.
	TCPIP_SNMP_MAX_COMMUNITY_SUPPORT	Specifying more strings than TCPIP_SNMP_MAX_COMMUNITY_SUPPORT will result in the later strings being ignored (but still wasting program memory). Specifying fewer strings is legal, as long as at least one is present.
	TCPIP_SNMP_MAX_MSG_SIZE	The maximum length in octets of an SNMP message which this SNMP agent able to process. As per RFC 3411 snmpEngineMaxMessageSize and RFC 1157 (section 4- protocol specification) and implementation supports more than 480 whenever feasible. It should be divisible by 16
	TCPIP_SNMP_MAX_NON_REC_ID_OID	Update the Non record id OID value which is part of CustomSnmpDemoApp.c file. This is the maximum size for gSnmpNonMibRecInfo[] which is the list of static variable Parent OIDs which are not part of mib.h file. This structure is used to restrict access to static variables of SNMPv3 OIDs from SNMPv2c and SNMPv1 version. With SNMPv3 all the OIDs accessible but when we are using SNMPv2c version , static variables of the SNMPv3 cannot be accessible with SNMP version v2c. SNMP agent supports both SMIv1 and SMIv2 standard and snmp.mib has been updated with respect to SMIV2 standard and it... more
	TCPIP_SNMP_NOTIFY_COMMUNITY_LEN	Maximum length for SNMP Trap community name
	TCPIP_SNMP_OID_MAX_LEN	Maximum length for the OID String. Change this to match your OID string length.
	TCPIP_SNMP_TASK_PROCESS_RATE	SNMP task processing rate, in milli-seconds. The SNMP module will process a timer event with this rate for processing its own state machine, etc. The default value is 200 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_SNMP_TRAP_COMMUNITY_MAX_LEN	The maximum size of TRAP community string length
	TCPIP_SNMP_TRAP_COMMUNITY_MAX_LEN_MEM_USE	Trap information. This macro will be used to avoid SNMP OID memory buffer corruption
	TCPIP_SNMP_TRAP_TABLE_SIZE	This table maintains list of interested receivers who should receive notifications when some interesting event occurs.

SNTP Module

This section describes the TCP/IP Stack Library SNTP module.

Introduction

TCP/IP Stack Library Simple Network Time Protocol (SNTP) Module for Microchip Microcontrollers

This library provides the API of the SNTP module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

The SNTP module implements the Simple Network Time Protocol. The module (by default) updates its internal time every 10 minutes using a pool of public global time servers. It then calculates reference times on any call to SNTPGetUTCSeconds using the internal Tick timer module.

The SNTP module is good for providing absolute time stamps. However, it should not be relied upon for measuring time differences (especially small differences). The pool of public time servers is implemented using round-robin DNS, so each update will come from a different server. Differing network delays and the fact that these servers are not verified implies that this time could be non-linear. While it is deemed reliable, it is not guaranteed to be accurate.

The Tick module provides much better accuracy (since it is driven by a hardware clock) and resolution, and should be used for measuring timeouts and other internal requirements.

Developers can change the value of NTP_SERVER if they want to always point to a preferred time server, or to specify a region when accessing time servers. The default is to use the global pool.

Using the Library

This topic describes the basic architecture of the SNTP TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `sntp.h`

The interface to the SNTP TCP/IP Stack library is defined in the `sntp.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the SNTP TCP/IP Stack library should include `tcpip.h`.

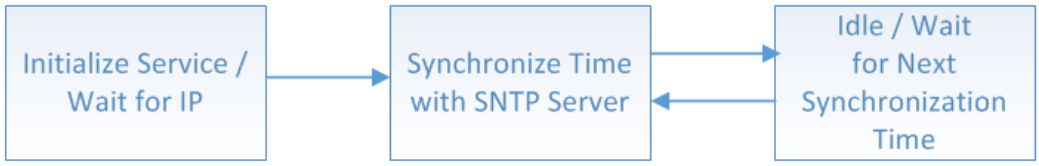
Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

This library provides the API of the SNTP TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

SNTP Software Abstraction Block Diagram



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the SNTP module.

Library Interface Section	Description
Functions	Routines for configuring SNTP
Data Types and Constants	This section provides various definitions describing this API

Configuring the Library

Macros

	Name	Description
	TCPIP_NTP_DEFAULT_CONNECTION_TYPE	The default connection type to use: IPv4/IPv6
	TCPIP_NTP_DEFAULT_IF	for multi-homed hosts, the default SNTP interface
	TCPIP_NTP_EPOCH	Reference Epoch to use. (default: 01-Jan-1970 00:00:00)
	TCPIP_NTP_FAST_QUERY_INTERVAL	Defines how long to wait to retry an update after a failure, seconds. Updates may take up to 6 seconds to fail, so this 14 second delay is actually only an 8-second retry.
	TCPIP_NTP_MAX_STRATUM	The maximum acceptable NTP stratum number Should be less than 16 (unsynchronized server)
	TCPIP_NTP_QUERY_INTERVAL	Defines how frequently to resynchronize the date/time, seconds (default: 10 minutes)
	TCPIP_NTP_REPLY_TIMEOUT	Defines how long to wait before assuming the query has failed, seconds
	TCPIP_NTP_RX_QUEUE_LIMIT	The NTP RX queue limit defines the maximum number of packets that can wait in the NTP queue
	TCPIP_NTP_SERVER	These are normally available network time servers. The actual IP returned from the pool will vary every minute so as to spread the load around stratum 1 timeservers. For best accuracy and network overhead you should locate the pool server closest to your geography, but it will still work if you use the global pool.ntp.org address or choose the wrong one or ship your embedded device to another geography. A direct IP address works too
	TCPIP_NTP_SERVER_MAX_LENGTH	maximum number of characters allowed for the NTP server
	TCPIP_NTP_TASK_TICK_RATE	THE NTP task rate, in milliseconds The default value is 1100 milliseconds. This module contacts an NTP server and a high operation frequency is not required. The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_NTP_TIME_STAMP_TMO	elapsed time that qualifies a time stamp as stale normally it should be correlated with TCPIP_NTP_QUERY_INTERVAL
	TCPIP_NTP_VERSION	The default NTP version to use (3 or 4)

Description

The configuration of the SNTP TCP/IP Stack Library is based on the file `tcpip_config.h`.

This header file contains the configuration selection for the SNTP TCP/IP Stack Library. Based on the selections made, the SNTP TCP/IP Stack Library may support the selected features. These configuration settings will apply to all instances of the SNTP TCP/IP Stack Library.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_NTP_DEFAULT_CONNECTION_TYPE Macro

File

sntp_config.h

C

```
#define TCPIP_NTP_DEFAULT_CONNECTION_TYPE (IP_ADDRESS_TYPE_IPV4)
```

Description

The default connection type to use: IPv4/IPv6

TCPIP_NTP_DEFAULT_IF Macro

File

sntp_config.h

C

```
#define TCPIP_NTP_DEFAULT_IF "PIC32INT"
```

Description

for multi-homed hosts, the default SNTP interface

TCPIP_NTP_EPOCH Macro

File

sntp_config.h

C

```
#define TCPIP_NTP_EPOCH (86400ul * (365ul * 70ul + 17ul))
```

Description

Reference Epoch to use. (default: 01-Jan-1970 00:00:00)

TCPIP_NTP_FAST_QUERY_INTERVAL Macro

File

sntp_config.h

C

```
#define TCPIP_NTP_FAST_QUERY_INTERVAL (14ul)
```

Description

Defines how long to wait to retry an update after a failure, seconds. Updates may take up to 6 seconds to fail, so this 14 second delay is actually only an 8-second retry.

TCPIP_NTP_MAX_STRATUM Macro

File

sntp_config.h

C

```
#define TCPIP_NTP_MAX_STRATUM (15)
```

Description

The maximum acceptable NTP stratum number Should be less than 16 (unsynchronized server)

TCPIP_NTP_QUERY_INTERVAL Macro

File

sntp_config.h

C

```
#define TCPIP_NTP_QUERY_INTERVAL (10ul*60ul)
```

Description

Defines how frequently to resynchronize the date/time, seconds (default: 10 minutes)

TCPIP_NTP_REPLY_TIMEOUT Macro

File

sntp_config.h

C

```
#define TCPIP_NTP_REPLY_TIMEOUT (6ul)
```

Description

Defines how long to wait before assuming the query has failed, seconds

TCPIP_NTP_RX_QUEUE_LIMIT Macro

File

sntp_config.h

C

```
#define TCPIP_NTP_RX_QUEUE_LIMIT (2)
```

Description

The NTP RX queue limit defines the maximum number of packets that can wait in the NTP queue

TCPIP_NTP_SERVER Macro

File

sntp_config.h

C

```
#define TCPIP_NTP_SERVER "pool.ntp.org"
```

Description

These are normally available network time servers. The actual IP returned from the pool will vary every minute so as to spread the load around stratum 1 timeservers. For best accuracy and network overhead you should locate the pool server closest to your geography, but it will still work if you use the global pool.ntp.org address or choose the wrong one or ship your embedded device to another geography. A direct IP address works too

TCPIP_NTP_SERVER_MAX_LENGTH Macro

File

sntp_config.h

C

```
#define TCPIP_NTP_SERVER_MAX_LENGTH 30
```

Description

maximum number of characters allowed for the NTP server

TCPIP_NTP_TASK_TICK_RATE Macro

File

sntp_config.h

C

```
#define TCPIP_NTP_TASK_TICK_RATE (1100)
```

Description

THE NTP task rate, in milliseconds The default value is 1100 milliseconds. This module contacts an NTP server and a high operation frequency is not required. The value cannot be lower than the TCPIP_STACK_TICK_RATE.

TCPIP_NTP_TIME_STAMP_TMO Macro

File

sntp_config.h

C

```
#define TCPIP_NTP_TIME_STAMP_TMO (11 * 60)
```

Description

elapsed time that qualifies a time stamp as stale normally it should be correlated with TCPIP_NTP_QUERY_INTERVAL

TCPIP_NTP_VERSION Macro

File

sntp_config.h

C

```
#define TCPIP_NTP_VERSION (4)
```

Description

The default NTP version to use (3 or 4)

Building the Library

This section lists the files that are available in the SNTP module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/sntp.c`	SNTP implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The SNTP module depends on the following modules:

- TCP/IP Stack Library
- DNS Module
- UDP Module

Library Interface

a) Functions

	Name	Description
	TCPIP_SNTP_ConnectionInitiate	Forces a connection to the NTP server
	TCPIP_SNTP_LastErrorGet	Gets the last error code set in the NTP server.
	TCPIP_SNTP_UTCSecondsGet	Obtains the current time from the SNTP module.
	TCPIP_SNTP_TimeStampGet	Gets the last valid timestamp obtained from an NTP server.
	TCPIP_SNTP_ConnectionParamSet	Sets the current SNTP connection parameters.
	TCPIP_SNTP_Task	Standard TCP/IP stack module task function.

b) Data Types and Constants

	Name	Description
	TCPIP_SNTP_MODULE_CONFIG	Placeholder for SNTP Module Configuration
	TCPIP_SNTP_RESULT	Provides a list of possible results for the SNTP module.

Description

This section describes the Application Programming Interface (API) functions of the SNTP module.
Refer to each section for a detailed description.

a) Functions

TCPIP_SNTP_ConnectionInitiate Function

Forces a connection to the NTP server

File

sntp.h

C

```
TCPIP_SNTP_RESULT TCPIP_SNTP_ConnectionInitiate();
```

Returns

- SNTP_RES_OK - if the call succeeded
- SNTP_RES_PROGRESS - if a connection already in progress another one could not be started

Description

This function will start a connection to the NTP server

Remarks

None.

Preconditions

The TCP/IP Stack should have been initialized.

Function

TCPIP_SNTP_RESULT TCPIP_SNTP_ConnectionInitiate(void);

TCPIP_SNTP_LastErrorGet Function

Gets the last error code set in the NTP server.

File

sntp.h

C

```
TCPIP_SNTP_RESULT TCPIP_SNTP_LastErrorGet();
```

Returns

The last error code encountered by the NTP module.

Description

This function returns the last NTP error code and clears the current error code.

Remarks

None/

Preconditions

The TCP/IP Stack should have been initialized.

Function

TCPIP_SNTP_RESULT TCPIP_SNTP_LastErrorGet(void);

TCPIP_SNTP_UTCSecondsGet Function

Obtains the current time from the SNTP module.

File

sntp.h

C

```
uint32_t TCPIP_SNTP_UTCSecondsGet();
```

Returns

The number of seconds since the Epoch. (Default 01-Jan-1970 00:00:00)

Description

This function obtains the current time as reported by the SNTP module. Use this value for absolute time stamping. The value returned is (by default) the number of seconds since 01-Jan-1970 00:00:00.

Remarks

Do not use this function for time difference measurements. The Tick module is more appropriate for those requirements.

Preconditions

The TCP/IP Stack should have been initialized.

Function

uint32_t TCPIP_SNTP_UTCSecondsGet(void)

TCPIP_SNTP_TimeStampGet Function

Gets the last valid timestamp obtained from an NTP server.

File

sntp.h

C

```
TCPIP_SNTP_RESULT TCPIP_SNTP_TimeStampGet(uint64_t* pTStamp, uint32_t* pLastUpdate);
```

Returns

- SNTP_RES_OK - if the call succeeded
- SNTP_RES_TSTAMP_STALE error code - if there is no recent timestamp

Description

This function gets the last valid timestamp obtained from an NTP server.

Remarks

None.

Preconditions

The TCP/IP Stack should have been initialized.

Parameters

Parameters	Description
pTStamp	pointer to a 64 bit buffer to store the last NTP timestamp could be NULL if the timestamp not needed
pLastUpdate	pointer to store the last time stamp update tick could be NULL if the update time not needed

Function

TCPIP_SNTP_RESULT TCPIP_SNTP_TimeStampGet(uint64_t* pTStamp, uint32_t* pLastUpdate);

TCPIP_SNTP_ConnectionParamSet Function

Sets the current SNTP connection parameters.

File

sntp.h

C

```
TCPIP_SNTP_RESULT TCPIP_SNTP_ConnectionParamSet(TCPIP_NET_HANDLE netH, IP_ADDRESS_TYPE ntpConnType, const char* ntpServer);
```

Returns

- SNTP_RES_OK - if the call succeeded
- TCPIP_SNTP_RESULT error code - if the call did not succeed

Description

This function sets the parameters for the next SNTP connections.

Remarks

None.

Preconditions

The TCP/IP Stack should have been initialized.

Parameters

Parameters	Description
netH	new interface to use as default SNTP interface if 0, the current interface is not changed
ntpConnType	type of connection to make: IPv4 or IPv6 if IP_ADDRESS_TYPE_ANY, the current setting is not changed
ntpServer	the NTP server to be used; name or an IP address can be used if 0, the current NTP server is not changed

Function

TCPIP_SNTP_RESULT TCPIP_SNTP_ConnectionParamSet(TCPIP_NET_HANDLE netH, IP_ADDRESS_TYPE ntpConnType, const char* ntpServer);

TCPIP_SNTP_Task Function

Standard TCP/IP stack module task function.

File

sntp.h

C

```
void TCPIP_SNTP_Task();
```

Returns

None.

Description

This function performs SNTP module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The SNTP module should have been initialized.

Function

void TCPIP_SNTP_Task(void)

b) Data Types and Constants

TCPIP_SNTP_MODULE_CONFIG Structure

File

sntp.h

C

```
typedef struct {
  const char* ntp_server;
  const char* ntp_interface;
  IP_ADDRESS_TYPE ntp_connection_type;
  uint32_t ntp_reply_timeout;
  uint32_t ntp_stamp_timeout;
  uint32_t ntp_success_interval;
  uint32_t ntp_error_interval;
} TCPIP_SNTP_MODULE_CONFIG;
```

Members

Members	Description
const char* ntp_server;	the NTP server to contact; name or IP address
const char* ntp_interface;	the default NTP interface to use
IP_ADDRESS_TYPE ntp_connection_type;	the IPv4/IPv6 connection type
uint32_t ntp_reply_timeout;	timeout for the server reply in seconds
uint32_t ntp_stamp_timeout;	timeout for the time stamp in seconds
uint32_t ntp_success_interval;	server query interval after an successful update, in seconds
uint32_t ntp_error_interval;	server query interval after an error, in seconds

Description

Placeholder for SNTP Module Configuration

TCPIP_SNTP_RESULT Enumeration

Provides a list of possible results for the SNTP module.

File

sntp.h

C

```
typedef enum {
  SNTP_RES_OK,
  SNTP_RES_PROGRESS,
  SNTP_RES_BUSY = -1,
  SNTP_RES_TSTAMP_STALE = -2,
  SNTP_RES_SKT_ERR = -3,
```

```
    SNTP_RES_SKT_BIND_ERR = -4,
    SNTP_RES_NTP_SERVER_TMO = -5,
    SNTP_RES_NTP_VERSION_ERR = -6,
    SNTP_RES_NTP_TSTAMP_ERR = -7,
    SNTP_RES_NTP_SYNC_ERR = -8,
    SNTP_RES_NTP_KOD_ERR = -9,
    SNTP_RES_NTP_DNS_ERR = -10,
    SNTP_RES_NTP_IF_ERR = -11,
    SNTP_RES_NTP_CONN_ERR = -12
} TCPIP_SNTP_RESULT;
```

Members

Members	Description
SNTP_RES_OK	the operation was successful
SNTP_RES_PROGRESS	an NTP operation is in progress
SNTP_RES_BUSY = -1	module is busy
SNTP_RES_TSTAMP_STALE = -2	timestamp is stale, there's no recent timestamp
SNTP_RES_SKT_ERR = -3	NTP socket could not be opened
SNTP_RES_SKT_BIND_ERR = -4	NTP socket bind failed
SNTP_RES_NTP_SERVER_TMO = -5	NTP server could not be accessed
SNTP_RES_NTP_VERSION_ERR = -6	wrong NTP version received
SNTP_RES_NTP_TSTAMP_ERR = -7	wrong NTP time stamp received
SNTP_RES_NTP_SYNC_ERR = -8	NTP time synchronization error
SNTP_RES_NTP_KOD_ERR = -9	an NTP KissOfDeath code has been received
SNTP_RES_NTP_DNS_ERR = -10	an NTP DNS error
SNTP_RES_NTP_IF_ERR = -11	an NTP interface error
SNTP_RES_NTP_CONN_ERR = -12	an NTP connection type error

Description

TCPIP_SNTP_RESULT Enumeration

Provides a list of possible SNTP results.

Remarks

None

TCP Module

This section describes the TCP/IP Stack Library TCP module.

Introduction

TCP/IP Stack Library Transmission Control Protocol (TCP) Module for Microchip Microcontrollers

This library provides the API of the TCP module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

TCP is a standard transport layer protocol described in RFC 793. It provides reliable stream-based connections over unreliable networks, and forms the foundation for HTTP, SMTP, and many other protocol standards.

Using the Library

This topic describes the basic architecture of the TCP TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `tcp.h`

The interface to the TCP TCP/IP Stack library is defined in the `tcp.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the TCP TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

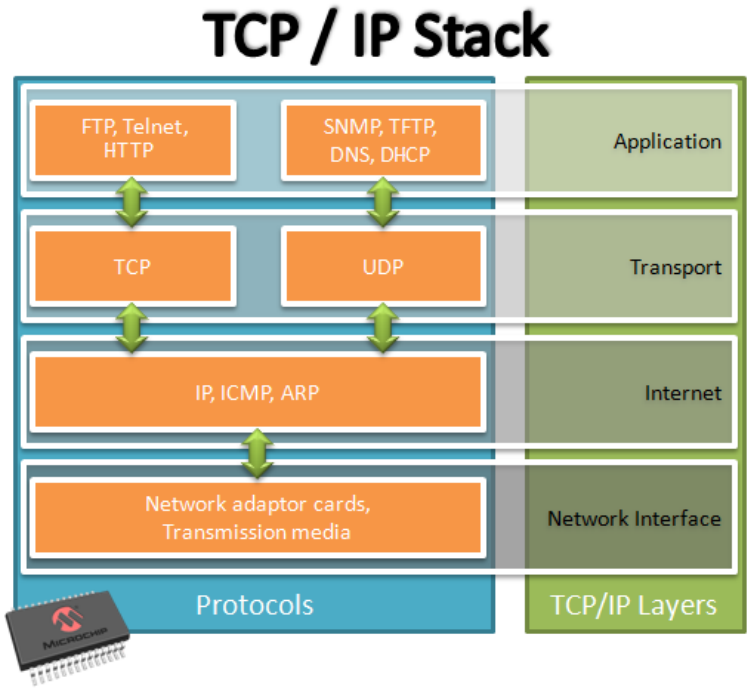
This library provides the API of the TCP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

TCP Software Abstraction Block Diagram

This module provides software abstraction of the TCP module existent in any TCP/IP Stack implementation.

Typical TCP Implementation



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the TCP module.

Library Interface Section	Description
Socket Management Functions	Routines for Managing TCP Sockets
Transmit Data Transfer Functions	Routines for Managing Outgoing Data Transmissions
Receive Data Transfer Functions	Routines for Managing Incoming Data Transmissions
Data Types and Constants	This section provides various definitions describing This API

How the Library Works

This topic describes how the TCP/IP Stack Library TCP module works.

Description

Connections made over TCP guarantee data transfer at the expense of throughput. Connections are made through a three-way handshake process, ensuring a one-to-one connection. Remote nodes advertise how much data they are ready to receive, and all data transmitted must be acknowledged. If a remote node fails to acknowledge the receipt of data, it is automatically retransmitted. This ensures that network errors such as lost, corrupted, or out-of-order packets are automatically corrected.

To accomplish this, TCP must use buffers for both the transmit and receive operations. Once the transmit buffer is full, no more data can be sent until the remote node has acknowledged receipt. For the Microchip TCP/IP Stack, the application must return to the main system loop to allow the other services in the system, including the TCP/IP stack, to advance.. Likewise, the remote node cannot transmit more data until the local device has acknowledged receipt and that space is available in the buffer. When a local application needs to read more data, it must return to the main system/application loop and wait for a new packet to arrive.

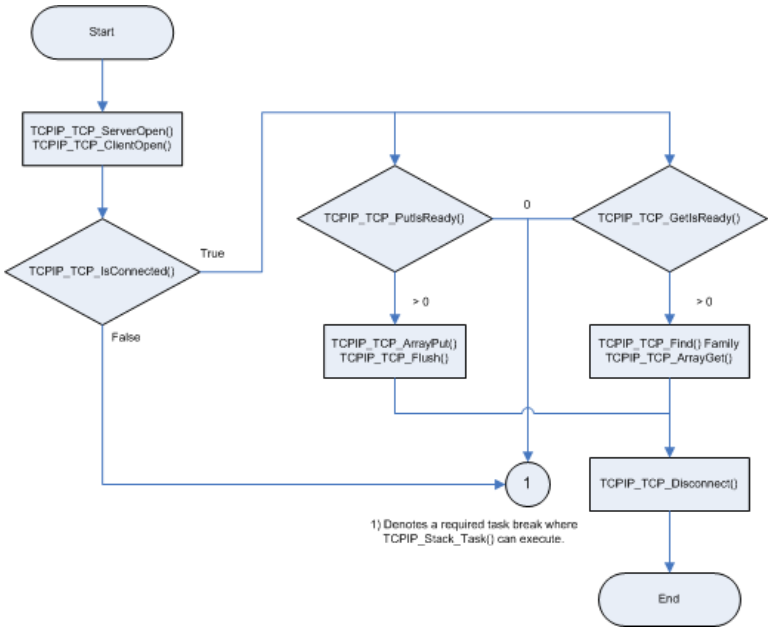
Core Functionality

This topic describes the core functionality of the TCP/IP Stack Library TCP module.

Description

The following diagram provides an overview for the use of the TCP module.

TCP Connection Flow



Server sockets are opened using TCPIP_TCP_ServerOpen. This function will open a listening socket waiting for client connections on the specified TCP port number. A client socket is opened using TCPIP_TCP_ClientOpen. This function will open a socket that connects to a remote host. The remote host is specified using an IP address and a TCP port number.

Once connected, applications can read and write data. On each entry, the application must verify that the socket is still connected. For most applications a call to TCPIP_TCP_IsConnected will be sufficient, but TCPIP_TCP_WasReset may also be used for listening sockets that may turn over quickly.

To write data, call TCPIP_TCP_PutIsReady to check how much space is available. Then, call the TCPIP_TCP_ArrayPut function to write data as space is available. Once complete, call TCPIP_TCP_Flush to transmit data immediately. Alternately, return to the main system/stack loop. Data will be transmitted by the internal TCP state machine as the buffer becomes full or a programmable delay time has passed.

To read data, call TCPIP_TCP_GetIsReady to determine how many bytes are ready to be retrieved. Then use the TCPIP_TCP_ArrayGet function to read data from the socket, and/or the TCPIP_TCP_Find family of functions to locate data in the buffer. When no more data remains, return to the main system/stack loop to wait for more data to arrive.

If the application needs to close the connection, call TCPIP_TCP_Disconnect, and then return to the main system/stack loop and wait for the remote node to acknowledge the disconnection. Client sockets will be closed and associated resources freed, while listening sockets will wait for a new connection. For more information, refer to the examples provided with the MPLAB Harmony distribution examples, or read the associated RFC.

Configuring the Library

Macros

	Name	Description
	TCPIP_TCP_AUTO_TRANSMIT_TIMEOUT_VAL	Timeout before automatically transmitting unflushed data, ms. Default value is 40 ms.
	TCPIP_TCP_CLOSE_WAIT_TIMEOUT	Timeout for the CLOSE_WAIT state, ms If the remote socket closes the connection the TCP/IP stack will automatically close the socket after this timeout. If the value is set to 0 then the socket will wait forever for the application to close the socket (default behavior).
	TCPIP_TCP_DELAYED_ACK_TIMEOUT	Timeout for delayed-acknowledgment algorithm, ms
	TCPIP_TCP_FIN_WAIT_2_TIMEOUT	Timeout for FIN WAIT 2 state, ms
	TCPIP_TCP_KEEP_ALIVE_TIMEOUT	Timeout for keep-alive messages when no traffic is sent, ms
	TCPIP_TCP_MAX_RETRIES	Maximum number of retransmission attempts
	TCPIP_TCP_MAX_SEG_SIZE_RX_LOCAL	TCP Maximum Segment Size for RX (MSS). This value is advertised during TCP connection establishment and the remote node should obey it. The value has to be set in such a way to avoid IP layer fragmentation from causing packet loss. However, raising its value can enhance performance at the (small) risk of introducing incompatibility with certain special remote nodes (ex: ones connected via a slow dial up modem). On Ethernet networks the standard value is 1460. On dial-up links, etc. the default values should be 536. Adjust these values according to your network. Maximum Segment Size for RX (MSS)... more

	TCPIP_TCP_MAX_SEG_SIZE_RX_NON_LOCAL	Maximum Segment Size for RX (MSS) for non local destination networks.
	TCPIP_TCP_MAX_SEG_SIZE_TX	TCP Maximum Segment Size for TX. The TX maximum segment size is actually governed by the remote node's MSS option advertised during connection establishment. However, if the remote node specifies an unmanageably large MSS (ex: > Ethernet MTU), this define sets a hard limit so that TX buffers are not overflowed. If the remote node does not advertise a MSS option, all TX segments are fixed at 536 bytes maximum.
	TCPIP_TCP_MAX_SOCKETS	The maximum number of sockets to create in the stack. When defining TCPIP_TCP_MAX_SOCKETS take into account the number of interfaces the stack is supporting.
	TCPIP_TCP_MAX_SYN_RETRIES	Smaller than all other retries to reduce SYN flood DoS duration
	TCPIP_TCP_MAX_UNACKED_KEEP_ALIVES	Maximum number of keep-alive messages that can be sent without receiving a response before automatically closing the connection
	TCPIP_TCP_SOCKET_DEFAULT_RX_SIZE	Default socket RX buffer size Note that this setting affects all TCP sockets that are created and, together with TCPIP_TCP_MAX_SOCKETS, has a great impact on the heap size that's used by the stack (see TCPIP_STACK_DRAM_SIZE setting). When large RX bufferrs are needed, probably a dynamic, per socket approach, is a better choice (see TCPIP_TCP_OptionsSet function). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput. Note that some modules (like HTTP) use their own settings to... more
	TCPIP_TCP_SOCKET_DEFAULT_TX_SIZE	Default socket TX buffer size Note that this setting affects all TCP sockets that are created and, together with TCPIP_TCP_MAX_SOCKETS, has a great impact on the heap size that's used by the stack (see TCPIP_STACK_DRAM_SIZE setting). When large TX bufferrs are needed, probably a dynamic, per socket approach, is a better choice (see TCPIP_TCP_OptionsSet function). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput. Note that some modules (like HTTP) use their own settings to... more
	TCPIP_TCP_START_TIMEOUT_VAL	Timeout to retransmit unacked data, ms
	TCPIP_TCP_TASK_TICK_RATE	The TCP task processing rate: number of milliseconds to generate an TCP tick. This is the tick that advances the TCP state machine. The default value is 5 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_TCP_WINDOW_UPDATE_TIMEOUT_VAL	Timeout before automatically transmitting a window update due to a TCPIP_TCP_Get() or TCPIP_TCP_ArrayGet() function call, ms.
	TCPIP_TCP_DYNAMIC_OPTIONS	Enable the TCP sockets dynamic options set/get functionality If enabled, the functions: TCPIP_TCP_OptionsSet, TCPIP_TCP_OptionsGet and TCPIP_TCP_FifoSizeAdjust exist and are compiled in If disabled, these functions do not exist and cannot be used/called Note that this setting can affect modules that use TCP sockets
	TCPIP_TCP_MSL_TIMEOUT	Maximum Segment Length (MSL) timeout, seconds This value sets the time a socket will be in the TIME_WAIT/2MSL state after the socket performed an active close. RFC recommended value is 120 sec. Other common values are: 30/60 sec Note that if this symbol is defined to 0, then the TIME_WAIT/2MSL state is skipped! This could lead to duplicate sequence numbers problems if sockets are frequently/rapidly closed and reopened and should be avoided.
	TCPIP_TCP_QUIET_TIME	This value specifies the TCP quiet time: TCP will not send any data for TCPIP_TCP_QUIET_TIME seconds after rebooting! Usualy this value should match the MSL value. Note that if this symbol is defined to 0, then the TCP quiet time state is skipped! During the quiet time there will be no TCP traffic initiated by TCP. So, clients won't be able to connect to remote hosts and servers won't reply to client requests.

Description

The configuration of the TCP/IP Stack Library TCP module is based on the file `system_config.h` (which may include `tcp_config.h`).

This header file contains the configuration selection for the TCP/IP Stack Library TCP module. Based on the selections made, the TCP/IP Stack Library TCP module may support the selected features. These configuration settings will apply to all TCP sockets of the TCP/IP Stack Library.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_TCP_AUTO_TRANSMIT_TIMEOUT_VAL Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_AUTO_TRANSMIT_TIMEOUT_VAL (40ul)
```

Description

Timeout before automatically transmitting unflushed data, ms. Default value is 40 ms.

TCPIP_TCP_CLOSE_WAIT_TIMEOUT Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_CLOSE_WAIT_TIMEOUT (200ul)
```

Description

Timeout for the CLOSE_WAIT state, ms If the remote socket closes the connection the TCP/IP stack will automatically close the socket after this timeout. If the value is set to 0 then the socket will wait forever for the application to close the socket (default behavior).

TCPIP_TCP_DELAYED_ACK_TIMEOUT Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_DELAYED_ACK_TIMEOUT (100ul)
```

Description

Timeout for delayed-acknowledgment algorithm, ms

TCPIP_TCP_FIN_WAIT_2_TIMEOUT Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_FIN_WAIT_2_TIMEOUT (5000ul)
```

Description

Timeout for FIN WAIT 2 state, ms

TCPIP_TCP_KEEP_ALIVE_TIMEOUT Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_KEEP_ALIVE_TIMEOUT (10000ul)
```

Description

Timeout for keep-alive messages when no traffic is sent, ms

TCPIP_TCP_MAX_RETRIES Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_MAX_RETRIES (5u)
```

Description

Maximum number of retransmission attempts

TCPIP_TCP_MAX_SEG_SIZE_RX_LOCAL Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_MAX_SEG_SIZE_RX_LOCAL (1460)
```

Description

TCP Maximum Segment Size for RX (MSS). This value is advertised during TCP connection establishment and the remote node should obey it. The value has to be set in such a way to avoid IP layer fragmentation from causing packet loss. However, raising its value can enhance performance at the (small) risk of introducing incompatibility with certain special remote nodes (ex: ones connected via a slow dial up modem). On Ethernet networks the standard value is 1460. On dial-up links, etc. the default values should be 536. Adjust these values according to your network.

Maximum Segment Size for RX (MSS) for local destination networks.

TCPIP_TCP_MAX_SEG_SIZE_RX_NON_LOCAL Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_MAX_SEG_SIZE_RX_NON_LOCAL (536)
```

Description

Maximum Segment Size for RX (MSS) for non local destination networks.

TCPIP_TCP_MAX_SEG_SIZE_TX Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_MAX_SEG_SIZE_TX (1460u)
```

Description

TCP Maximum Segment Size for TX. The TX maximum segment size is actually governed by the remote node's MSS option advertised during connection establishment. However, if the remote node specifies an unmanageably large MSS (ex: > Ethernet MTU), this define sets a hard limit so that TX buffers are not overflowed. If the remote node does not advertise a MSS option, all TX segments are fixed at 536 bytes maximum.

TCPIP_TCP_MAX_SOCKETS Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_MAX_SOCKETS (10)
```

Description

The maximum number of sockets to create in the stack. When defining TCPIP_TCP_MAX_SOCKETS take into account the number of interfaces the stack is supporting.

TCPIP_TCP_MAX_SYN_RETRIES Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_MAX_SYN_RETRIES (2u)
```

Description

Smaller than all other retries to reduce SYN flood DoS duration

TCPIP_TCP_MAX_UNACKED_KEEP_ALIVES Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_MAX_UNACKED_KEEP_ALIVES (6u)
```

Description

Maximum number of keep-alive messages that can be sent without receiving a response before automatically closing the connection

TCPIP_TCP_SOCKET_DEFAULT_RX_SIZE Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_SOCKET_DEFAULT_RX_SIZE 512
```

Description

Default socket RX buffer size Note that this setting affects all TCP sockets that are created and, together with TCPIP_TCP_MAX_SOCKETS, has a great impact on the heap size that's used by the stack (see TCPIP_STACK_DRAM_SIZE setting). When large RX bufferrs are needed, probably a dynamic, per socket approach, is a better choice (see TCPIP_TCP_OptionsSet function). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput. Note that some modules (like HTTP) use their own settings to specify the buffer size for their TCP sockets.

TCPIP_TCP_SOCKET_DEFAULT_TX_SIZE Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_SOCKET_DEFAULT_TX_SIZE 512
```

Description

Default socket TX buffer size Note that this setting affects all TCP sockets that are created and, together with TCPIP_TCP_MAX_SOCKETS, has a great impact on the heap size that's used by the stack (see TCPIP_STACK_DRAM_SIZE setting). When large TX bufferrs are needed, probably a dynamic, per socket approach, is a better choice (see TCPIP_TCP_OptionsSet function). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput. Note that some modules (like HTTP) use their own settings to specify the buffer size for their TCP sockets.

TCPIP_TCP_START_TIMEOUT_VAL Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_START_TIMEOUT_VAL (1000ul)
```

Description

Timeout to retransmit unacked data, ms

TCPIP_TCP_TASK_TICK_RATE Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_TASK_TICK_RATE (5)
```

Description

The TCP task processing rate: number of milliseconds to generate an TCP tick. This is the tick that advances the TCP state machine. The default value is 5 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

TCPIP_TCP_WINDOW_UPDATE_TIMEOUT_VAL Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_WINDOW_UPDATE_TIMEOUT_VAL (200ul)
```

Description

Timeout before automatically transmitting a window update due to a TCPIP_TCP_Get() or TCPIP_TCP_ArrayGet() function call, ms.

TCPIP_TCP_DYNAMIC_OPTIONS Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_DYNAMIC_OPTIONS 1
```

Description

Enable the TCP sockets dynamic options set/get functionality If enabled, the functions: TCPIP_TCP_OptionsSet, TCPIP_TCP_OptionsGet and TCPIP_TCP_FifoSizeAdjust exist and are compiled in If disabled, these functions do not exist and cannot be used/called Note that this setting can affect modules that use TCP sockets

TCPIP_TCP_MSL_TIMEOUT Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_MSL_TIMEOUT (30)
```

Description

Maximum Segment Length (MSL) timeout, seconds This value sets the time a socket will be in the TIME_WAIT/2MSL state after the socket

performed an active close. RFC recommended value is 120 sec. Other common values are: 30/60 sec Note that if this symbol is defined to 0, then the TIME_WAIT/2MSL state is skipped! This could lead to duplicate sequence numbers problems if sockets are frequently/rapidly closed and reopened and should be avoided.

TCPIP_TCP_QUIET_TIME Macro

File

tcp_config.h

C

```
#define TCPIP_TCP_QUIET_TIME (30)
```

Description

This value specifies the TCP quiet time: TCP will not send any data for TCPIP_TCP_QUIET_TIME seconds after rebooting! Usualy this value should match the MSL value. Note that if this symbol is defined to 0, then the TCP quiet time state is skipped! During the quiet time there will be no TCP traffic initiated by TCP. So, clients won't be able to connect to remote hosts and servers won't reply to client requests.

Building the Library

This section lists the files that are available in the TCP module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/tcp.c`	TCP implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The TCP module depends on the following modules:

- TCP/IP Stack Library
- IPv4 Module

Library Interface

a) Socket Management Functions

	Name	Description
	TCPIP_TCP_ServerOpen	Opens a TCP socket as a server.
	TCPIP_TCP_ClientOpen	Opens a TCP socket as a client.

	TCPIP_TCP_Close	Disconnects an open socket and destroys the socket handle, releasing the associated resources.
	TCPIP_TCP_Connect	Connects a client socket.
	TCPIP_TCP_Bind	Binds a socket to a local address.
	TCPIP_TCP_RemoteBind	Binds a socket to a remote address.
	TCPIP_TCP_IsConnected	Determines if a socket has an established connection.
	TCPIP_TCP_WasReset	Self-clearing semaphore indicating socket reset.
	TCPIP_TCP_Disconnect	Disconnects an open socket.
	TCPIP_TCP_Abort	Aborts a connection.
	TCPIP_TCP_OptionsGet	Allows getting the options for a socket like: current RX/TX buffer size, etc.
	TCPIP_TCP_OptionsSet	Allows setting options to a socket like adjust RX/TX buffer size, etc.
	TCPIP_TCP_SocketInfoGet	Obtains information about a currently open socket.
	TCPIP_TCP_SocketNetGet	Gets the current network interface of an TCP socket.
	TCPIP_TCP_SocketNetSet	Sets the interface for an TCP socket
	TCPIP_TCP_SignalHandlerDeregister	Deregisters a previously registered TCP socket signal handler.
	TCPIP_TCP_SignalHandlerRegister	Registers a TCP socket signal handler.
	TCPIP_TCP_Task	Standard TCP/IP stack module task function.
	TCPIP_TCP_IsReady	Returns the current status of the TCP module
	TCPIP_TCP_SocketsNumberGet	Returns the number of existent TCP sockets.
	TCPIP_TCP_SocketTraceSet	Sets the current socket trace status.

b) Transmit Data Transfer Functions

	Name	Description
	TCPIP_TCP_Put	Writes a single byte to a TCP socket.
	TCPIP_TCP_PutIsReady	Determines how much free space is available in the TCP TX buffer.
	TCPIP_TCP_StringPut	Writes a null-terminated string to a TCP socket.
	TCPIP_TCP_ArrayPut	Writes an array from a buffer to a TCP socket.
	TCPIP_TCP_Flush	Immediately transmits all pending TX data.
	TCPIP_TCP_FifoTxFullGet	Determines how many bytes are pending in the TCP TX FIFO.
	TCPIP_TCP_FifoTxFreeGet	Determines how many bytes are free and could be written in the TCP TX FIFO.

c) Receive Data Transfer Functions

	Name	Description
	TCPIP_TCP_GetIsReady	Determines how many bytes can be read from the TCP RX buffer.
	TCPIP_TCP_ArrayGet	Reads an array of data bytes from a TCP socket's RX buffer/FIFO.
	TCPIP_TCP_ArrayPeek	Reads a specified number of data bytes from the TCP RX buffer/FIFO without removing them from the buffer.
	TCPIP_TCP_ArrayFind	Searches for a string in the TCP RX buffer.
	TCPIP_TCP_Find	Searches for a byte in the TCP RX buffer.
	TCPIP_TCP_Get	Retrieves a single byte to a TCP socket.
	TCPIP_TCP_Peek	Peaks at one byte in the TCP RX buffer/FIFO without removing it from the buffer.
	TCPIP_TCP_Discard	Discards any pending data in the RCP RX FIFO.
	TCPIP_TCP_FifoRxFreeGet	Determines how many bytes are free in the RX buffer/FIFO.
	TCPIP_TCP_FifoSizeAdjust	Adjusts the relative sizes of the RX and TX buffers.
	TCPIP_TCP_FifoRxFullGet	Determines how many bytes are pending in the RX buffer/FIFO.

d) Data Types and Constants

	Name	Description
	TCP_ADJUST_FLAGS	TCP adjust RX and TX buffers flags.
	TCP_OPTION_LINGER_DATA	Socket linger options.
	TCP_PORT	Defines a TCP Port number.
	TCP_SOCKET	Defines a TCP Socket.
	TCP_SOCKET_INFO	TCP socket information.
	TCP_SOCKET_OPTION	TCP Socket run-time options.
	INVALID_SOCKET	Invalid socket indicator macro.
	TCP_OPTION_THRES_FLUSH_TYPE	List of the socket half threshold TX flush types.

	TCPIP_TCP_MODULE_CONFIG	TCP module run-time configuration/initialization data.
	TCP_OPTION_KEEP_ALIVE_DATA	Socket keep alive options
	TCPIP_TCP_SIGNAL_FUNCTION	TCP signal handler.
	TCPIP_TCP_SIGNAL_HANDLE	TCP socket handle.
	TCPIP_TCP_SIGNAL_TYPE	TCP run time signal/event types.
	TCPIP_TCP_STATE	TCP socket state.

Description

This section describes the Application Programming Interface (API) functions of the TCP module.

Refer to each section for a detailed description.

a) Socket Management Functions

TCPIP_TCP_ServerOpen Function

Opens a TCP socket as a server.

File

tcp.h

C

```
TCP_SOCKET TCPIP_TCP_ServerOpen(IP_ADDRESS_TYPE addType, TCP_PORT localPort, IP_MULTI_ADDRESS*
localAddress);
```

Returns

- INVALID_SOCKET - No sockets of the specified type were available to be opened
- TCP_SOCKET handle - Save this handle and use it when calling all other TCP APIs

Description

Provides a unified method for opening TCP server sockets.

Sockets are created at the TCP module initialization, and can be claimed with this function and freed using TCPIP_TCP_Close.

Preconditions

TCP is initialized.

Parameters

Parameters	Description
IP_ADDRESS_TYPE addType	The type of address being used. Example: IP_ADDRESS_TYPE_IPV4.
TCP_PORT localPort	TCP port to listen on for connections.
IP_MULTI_ADDRESS* localAddress	Local address to use. Use 0 if listening on any network interface.

Function

TCP_SOCKET TCPIP_TCP_ServerOpen(IP_ADDRESS_TYPE addType, TCP_PORT localPort,
IP_MULTI_ADDRESS* localAddress)

TCPIP_TCP_ClientOpen Function

Opens a TCP socket as a client.

File

tcp.h

C

```
TCP_SOCKET TCPIP_TCP_ClientOpen(IP_ADDRESS_TYPE addType, TCP_PORT remotePort, IP_MULTI_ADDRESS*
remoteAddress);
```

Returns

- INVALID_SOCKET - No sockets of the specified type were available to be opened
- TCP_SOCKET handle - Save this handle and use it when calling all other TCP APIs

Description

Provides a unified method for opening TCP client sockets.

Sockets are created at the TCP module initialization, and can be claimed with this function and freed using TCPIP_TCP_Abort or TCPIP_TCP_Close.

Remarks

IP_ADDRESS_TYPE_ANY is not supported (not a valid type for client open)!

If the remoteAddress != 0 (and the address pointed by remoteAddress != 0) then the socket will immediately initiate a connection to the remote host

If the remoteAddress is unspecified, no connection is initiated. Client socket parameters can be set using TCPIP_TCP_Bind, TCPIP_TCP_RemoteBind, etc. calls and then connection initiated by calling TCPIP_TCP_Connect.

Preconditions

TCP is initialized.

Parameters

Parameters	Description
IP_ADDRESS_TYPE addType	The type of address being used. Example: IP_ADDRESS_TYPE_IPV4.
TCP_PORT remotePort	TCP port to connect to. The local port for client sockets will be automatically picked by the TCP module.
IP_MULTI_ADDRESS* remoteAddress	The remote address to be used. If 0 then the address is unspecified

Function

TCP_SOCKET TCPIP_TCP_ClientOpen(IP_ADDRESS_TYPE addType, TCP_PORT remotePort,
IP_MULTI_ADDRESS* remoteAddress)

TCPIP_TCP_Close Function

Disconnects an open socket and destroys the socket handle, releasing the associated resources.

File

tcp.h

C

```
bool TCPIP_TCP_Close(TCP_SOCKET hTCP);
```

Returns

- true - If the call succeeded
- false - If the call failed (no such socket)

Description

Graceful Option Set: If the graceful option is set for the socket (default), a TCPIP_TCP_Disconnect will be tried. If the linger option is set (default) the TCPIP_TCP_Disconnect will try to send any queued TX data before issuing FIN. If the FIN send operation fails or the socket is not connected the abort is generated.

Graceful Option Not Set: If the graceful option is not set, or the previous step could not send the FIN,a TCPIP_TCP_Abort is called, sending a RST to the remote node. Communication is closed, the socket is no longer valid and the associated resources are freed.

Preconditions

TCP socket should have been opened with TCPIP_TCP_ServerOpen/TCPIP_TCP_ClientOpen. hTCP - valid socket

Parameters

Parameters	Description
hTCP	Handle to the socket to disconnect and close.

Function

bool TCPIP_TCP_Close(TCP_SOCKET hTCP)

TCPIP_TCP_Connect Function

Connects a client socket.

File

tcp.h

C

```
bool TCPIP_TCP_Connect(TCP_SOCKET hTCP);
```

Returns

- true - If the call succeeded
- false - If the call failed

Description

This function will try to initiate a connection on a client socket that is not connected yet. The client socket should have been created with a call to TCPIP_TCP_ClientOpen having the remoteAddress set to 0.

Remarks

The call will fail if the client socket has no remote host specified. Use TCPIP_TCP_RemoteBind() to specify a remote host address for the client socket.

Preconditions

TCP socket should have been opened with TCPIP_TCP_ClientOpen with an unspecified address. hTCP - valid socket

Parameters

Parameters	Description
hTCP	Handle to the client socket to connect.

Function

bool TCPIP_TCP_Connect(TCP_SOCKET hTCP)

TCPIP_TCP_Bind Function

Binds a socket to a local address.

File

tcp.h

C

```
bool TCPIP_TCP_Bind(TCP_SOCKET hTCP, IP_ADDRESS_TYPE addType, TCP_PORT localPort, IP_MULTI_ADDRESS*
localAddress);
```

Returns

- true - Indicates success
- false - Indicates failure

Description

This function is meant for unconnected server and client sockets. It is similar to TCPIP_TCP_SocketNetSet that assigns a specific source interface for a socket. If localPort is 0 the stack will assign a unique local port. Sockets don't need specific binding, it is done automatically by the stack. However, specific binding can be requested using these functions. Works for both client and server sockets.

Remarks

The call will fail if the socket is already connected (both server and client sockets).

Preconditions

TCP socket should have been opened with TCPIP_TCP_ServerOpen()/TCPIP_TCP_ClientOpen(). hTCP - valid socket

Parameters

Parameters	Description
hTCP	Socket to bind
addType	The type of address being used. Example: IP_ADDRESS_TYPE_IPV4/IP_ADDRESS_TYPE_IPV6.
localPort	Local port to use If 0, the stack will assign a unique local port
localAddress	The local address to bind to. Could be NULL if the local address does not need to be changed

Function

bool TCPIP_TCP_Bind(TCP_SOCKET hTCP, IP_ADDRESS_TYPE addType, TCP_PORT localPort,
IP_MULTI_ADDRESS* localAddress)

TCPIP_TCP_RemoteBind Function

Binds a socket to a remote address.

File

tcp.h

C

```
bool TCPIP_TCP_RemoteBind(TCP_SOCKET hTCP, IP_ADDRESS_TYPE addType, TCP_PORT remotePort, IP_MULTI_ADDRESS*
remoteAddress);
```

Returns

- true - Indicates success
- false - Indicates failure

Description

This function is meant for unconnected server and client sockets. Sockets don't need specific remote binding, they should accept connections on any incoming interface. Thus the binding is done automatically by the stack. However, specific remote binding can be requested using these functions. For a server socket it can be used to restrict accepting connections from a specific remote host. For a client socket it will just change the default binding done when the socket was opened.

Remarks

The socket remote port is changed only if a non-zero remotePort value is passed.

The socket remote host address is changed only if a non-zero remoteAddress value is passed.

The call will fail if the socket is already connected (both server and client sockets).

Preconditions

TCP socket should have been opened with TCPIP_TCP_ServerOpen()/TCPIP_TCP_ClientOpen(). hTCP - valid socket

Parameters

Parameters	Description
hTCP	Socket to bind
addType	The type of address being used. Example: IP_ADDRESS_TYPE_IPV4/IP_ADDRESS_TYPE_IPV6.
remotePort	remote port to use Could be 0 if the remote port does not need to be changed
remoteAddress	The remote address to bind to. Could be NULL if the remote address does not need to be changed

Function

bool TCPIP_TCP_RemoteBind(TCP_SOCKET hTCP, IP_ADDRESS_TYPE addType, TCP_PORT remotePort,
IP_MULTI_ADDRESS* remoteAddress)

TCPIP_TCP_IsConnected Function

Determines if a socket has an established connection.

File

tcp.h

C

```
bool TCPIP_TCP_IsConnected(TCP_SOCKET hTCP);
```

Description

This function determines if a socket has an established connection to a remote node. Call this function after calling TCPIP_TCP_ServerOpen()/TCPIP_TCP_ClientOpen() to determine when the connection is set up and ready for use.

Remarks

A socket is said to be connected only if it is in the TCPIP_TCP_STATE_ESTABLISHED state. Sockets in the process of opening or closing will return false.

Preconditions

TCP socket should have been opened with TCPIP_TCP_ServerOpen()/TCPIP_TCP_ClientOpen(). hTCP - valid socket

Parameters

Parameters	Description
hTCP	The socket to check.

Function

bool TCPIP_TCP_IsConnected(TCP_SOCKET hTCP)

TCPIP_TCP_WasReset Function

Self-clearing semaphore indicating socket reset.

File

tcp.h

C

```
bool TCPIP_TCP_WasReset(TCP_SOCKET hTCP);
```

Description

This function is a self-clearing semaphore indicating whether or not a socket has been disconnected since the previous call. This function works for all possible disconnections: a call to TCPIP_TCP_Disconnect, a FIN from the remote node, or an acknowledgment timeout caused by the loss of a network link. It also returns true after the first call to TCPIP_TCP_Initialize. Applications should use this function to reset their state machines.

Preconditions

TCP is initialized.

Parameters

Parameters	Description
hTCP	The socket to check.

Function

bool TCPIP_TCP_WasReset(TCP_SOCKET hTCP)

TCPIP_TCP_Disconnect Function

Disconnects an open socket.

File

tcp.h

C

```
bool TCPIP_TCP_Disconnect(TCP_SOCKET hTCP);
```

Returns

- true - If the call succeeded
- false - Indicates that the notification could not be sent to the remote host. The call can be reissued at a later time if desired.

Description

This function closes the TX side of a connection by sending a FIN (if currently connected) to the remote node of the connection.

If the socket has the linger option set (default), the queued TX data transmission will be attempted before sending the FIN. If the linger option is off, the queued TX data will be discarded.

Please note that this call may fail in which case it can be re-issued.

Remarks

None.

Preconditions

TCP socket should have been opened with TCPIP_TCP_ServerOpen()/TCPIP_TCP_ClientOpen(). hTCP - valid socket

Parameters

Parameters	Description
hTCP	Handle of the socket to disconnect.

Function

bool TCPIP_TCP_Disconnect(TCP_SOCKET hTCP)

TCPIP_TCP_Abort Function

Aborts a connection.

File

tcp.h

C

```
void TCPIP_TCP_Abort(TCP_SOCKET hTCP, bool killSocket);
```

Returns

None.

Description

This function aborts a connection to a remote node by sending a RST (if currently connected). Any pending TX/RX data is discarded.

A client socket will always be closed and the associated resources released. The socket cannot be used again after this call.

A server socket will abort the current connection:

- if killSocket == false the socket will remain listening
- if killSocket == true the socket will be closed and all associated resources released. The socket cannot be used again after this call.

Preconditions

TCP socket should have been opened with TCPIP_TCP_ServerOpen()/TCPIP_TCP_ClientOpen(). hTCP - valid socket

Parameters

Parameters	Description
hTCP	Handle to the socket to disconnect.
killSocket	if true, it kills a server socket

Function

void TCPIP_TCP_Abort(TCP_SOCKET hTCP, bool killSocket)

TCPIP_TCP_OptionsGet Function

Allows getting the options for a socket like: current RX/TX buffer size, etc.

File

tcp.h

C

```
bool TCPIP_TCP_OptionsGet(TCP_SOCKET hTCP, TCP_SOCKET_OPTION option, void* optParam);
```

Returns

- true - Indicates success
- false - Indicates failure

Description

Various options can be get at the socket level. This function provides compatibility with BSD implementations.

Preconditions

TCP socket should have been opened with TCPIP_TCP_ServerOpen()/TCPIP_TCP_ClientOpen(). hTCP - valid socket

Parameters

Parameters	Description
hTCP	socket to get options for
option	specific option to get
optParam	pointer to an area that will receive the option value; this is option dependent the size of the area has to be large enough to accommodate the specific option • TCP_OPTION_LINGER - pointer to a TCP_OPTION_LINGER_DATA structure • TCP_OPTION_KEEP_ALIVE - pointer to a TCP_OPTION_KEEP_ALIVE_DATA structure • TCP_OPTION_RX_BUFF - size of the new RX buffer • TCP_OPTION_TX_BUFF - size of the new TX buffer • TCP_OPTION_RX_TMO - not supported yet • TCP_OPTION_TX_TMO - not supported yet • TCP_OPTION_NODELAY - pointer to boolean to return current NO DELAY status • TCP_OPTION_EXCLUSIVE_ADDRESS - not supported yet • TCP_OPTION_THRES_FLUSH - a TCP_OPTION_THRES_FLUSH_TYPE • TCP_OPTION_DELAY_SEND_ALL_ACK - pointer to boolean to return current DELAY Send All ACK status

Function

bool TCPIP_TCP_OptionsGet(TCP_SOCKET hTCP, TCP_SOCKET_OPTION option, void* optParam)

TCPIP_TCP_OptionsSet Function

Allows setting options to a socket like adjust RX/TX buffer size, etc.

File

tcp.h

C

```
bool TCPIP_TCP_OptionsSet(TCP_SOCKET hTCP, TCP_SOCKET_OPTION option, void* optParam);
```

Returns

- true - Indicates success
- false - Indicates failure

Description

Various options can be set at the socket level. This function provides compatibility with BSD implementations.

Preconditions

TCP socket should have been opened with TCPIP_TCP_ServerOpen()/TCPIP_TCP_ClientOpen(). hTCP - valid socket

Parameters

Parameters	Description
hTCP	socket to set options for
option	specific option to be set

optParam	the option value; this is option dependent • TCP_OPTION_LINGER - pointer to a TCP_OPTION_LINGER_DATA structure • TCP_OPTION_KEEP_ALIVE - pointer to a TCP_OPTION_KEEP_ALIVE_DATA structure • TCP_OPTION_RX_BUFF - size of the new RX buffer • TCP_OPTION_TX_BUFF - size of the new TX buffer • TCP_OPTION_RX_TMO - not supported yet • TCP_OPTION_TX_TMO - not supported yet • TCP_OPTION_NODELAY - boolean to enable/disable the NO DELAY functionality • TCP_OPTION_EXCLUSIVE_ADDRESS - not supported yet • TCP_OPTION_THRES_FLUSH - a TCP_OPTION_THRES_FLUSH_TYPE • TCP_OPTION_DELAY_SEND_ALL_ACK - boolean to enable/disable the DELAY Send All ACK data functionality

Function

bool TCPIP_TCP_OptionsSet(TCP_SOCKET hTCP, TCP_SOCKET_OPTION option, void* optParam)

TCPIP_TCP_SocketInfoGet Function

Obtains information about a currently open socket.

File

tcp.h

C

```
bool TCPIP_TCP_SocketInfoGet(TCP_SOCKET hTCP, TCP_SOCKET_INFO* pInfo);
```

Returns

- true - if the call succeeded
- false - if no such socket exists or the socket is not open

Description

Fills the provided TCP_SOCKET_INFO structure associated with this socket. This contains the IP addresses and port numbers for both the local and remote endpoints.

Preconditions

TCP is initialized and the socket is connected.

Parameters

Parameters	Description
hTCP	The socket to check.

Function

bool TCPIP_TCP_SocketInfoGet(TCP_SOCKET hTCP, TCP_SOCKET_INFO* remoteInfo)

TCPIP_TCP_SocketNetGet Function

Gets the current network interface of an TCP socket.

File

tcp.h

C

```
TCPIP_NET_HANDLE TCPIP_TCP_SocketNetGet(TCP_SOCKET hTCP);
```

Returns

The handle of the local interface this socket is bound to.

Description

This function returns the interface handle associated to a TCP socket.

Remarks

The returned handle could be NULL if the socket is invalid or the socket is not currently connected.

Preconditions

TCP socket should have been opened with TCPIP_TCP_ClientOpen()/TCPIP_TCP_ServerOpen(). hTCP - valid socket

Parameters

Parameters	Description
hTCP	The TCP socket

Function

TCPIP_NET_HANDLE TCPIP_TCP_SocketNetGet(TCP_SOCKET hTCP);

TCPIP_TCP_SocketNetSet Function

Sets the interface for an TCP socket

File

tcp.h

C

```
bool TCPIP_TCP_SocketNetSet(TCP_SOCKET hTCP, TCPIP_NET_HANDLE hNet);
```

Returns

- true - Indicates success
- false - Indicates failure

Description

This function sets the network interface for an TCP socket

Remarks

An invalid hNet can be passed (0) so that the current network interface selection will be cleared.

Preconditions

TCP socket should have been opened with TCPIP_TCP_ClientOpen()/TCPIP_TCP_ServerOpen(). hTCP - valid socket

Parameters

Parameters	Description
hTCP	The TCP socket
hNet	interface handle.

Function

bool TCPIP_TCP_SocketNetSet(TCP_SOCKET hTCP, TCPIP_NET_HANDLE hNet)

TCPIP_TCP_SignalHandlerDeregister Function

Deregisters a previously registered TCP socket signal handler.

File

tcp.h

C

```
bool TCPIP_TCP_SignalHandlerDeregister(TCP_SOCKET s, TCPIP_TCP_SIGNAL_HANDLE hSig);
```

Returns

- true - if the call succeeds
- false - if no such handler is registered

Description

This function deregisters the TCP socket signal handler.

Preconditions

hSig valid TCP handle.

Parameters

Parameters	Description
s	The TCP socket
hSig	A handle returned by a previous call to TCPIP_TCP_SignalHandlerRegister.

Function

TCPIP_TCP_SignalHandlerDeregister(TCP_SOCKET s, TCPIP_TCP_SIGNAL_HANDLE hSig)

TCPIP_TCP_SignalHandlerRegister Function

Registers a TCP socket signal handler.

File

tcp.h

C

```
TCPIP_TCP_SIGNAL_HANDLE TCPIP_TCP_SignalHandlerRegister(TCP_SOCKET s, TCPIP_TCP_SIGNAL_TYPE sigMask,
TCPIP_TCP_SIGNAL_FUNCTION handler, const void* hParam);
```

Returns

Returns a valid handle if the call succeeds, or a null handle if the call failed (null handler, no such socket, existent handler).

Description

This function registers a TCP socket signal handler. The TCP module will call the registered handler when a TCP signal (TCPIP_TCP_SIGNAL_TYPE) occurs.

Remarks

Only one signal handler per socket is supported. A new handler does not override the existent one. Instead TCPIP_TCP_SignalHandlerDeregister has to be explicitly called.

The handler has to be short and fast. It is meant for setting an event flag, not for lengthy processing!

The hParam is passed by the client but is currently not used and should be 0.

For multi-threaded systems the TCP/IP packet dispatch does not occur on the user thread. The signal handler will be called on a different thread context. It is essential that this handler is non blocking and really fast.

For multi-threaded systems, once set, it is not recommended to change the signal handler at run time. Synchronization between user threads and packet dispatch threads could be difficult. If really need to be changed, make sure that the old handler could still be called and it should be valid until the new one is taken into account. TCPIP_TCP_SignalHandlerDeregister needs to be called before registering another handler.

Preconditions

TCP valid socket.

Parameters

Parameters	Description
s	The TCP socket
sigMask	mask of signals to be reported
handler	signal handler to be called when a TCP event occurs.
hParam	Parameter to be used in the handler call. This is user supplied and is not used by the TCP module. Currently not used and it should be null.

Function

TCPIP_TCP_SignalHandlerRegister(TCP_SOCKET s, TCPIP_TCP_SIGNAL_TYPE sigMask,
TCPIP_TCP_SIGNAL_FUNCTION handler, const void* hParam)

TCPIP_TCP_Task Function

Standard TCP/IP stack module task function.

File

tcp.h

C

```
void TCPIP_TCP_Task();
```

Returns

None.

Description

This function performs TCP module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The TCP module should have been initialized.

Function

void TCPIP_TCP_Task(void)

TCPIP_TCP_IsReady Function

Returns the current status of the TCP module

File

tcp.h

C

```
bool TCPIP_TCP_IsReady();
```

Returns

true - the quiet time has elapsed and the TCP module is ready to transmit data false - the quiet time is still in effect and TCP module is silent

Description

This function returns the current status of the TCP module. If the TCP quiet time has elapsed (or it was not enabled when TCP was built) then the TCP module is ready for operation and TCP sockets can send and receive data. If the TCP quiet time is still in effect, then the TCP module is quiet and it won't transmit any kind of data.

Remarks

The TCP quiet time occurs at the stack start up and can be enabled/disabled using the TCP module configuration parameters.

Preconditions

TCP module properly initialized

Function

bool   TCPIP_TCP_IsReady(void);

TCPIP_TCP_SocketsNumberGet Function

Returns the number of existent TCP sockets.

File

tcp.h

C

```
int TCPIP_TCP_SocketsNumberGet();
```

Returns

The number of TCP sockets

Description

This function returns the number of created TCP sockets. This is the maximum number of sockets that can be opened at any moment as it's been passed as parameter when TCP module was created.

Preconditions

TCP module properly initialized

Function

int TCPIP_TCP_SocketsNumberGet(void)

TCPIP_TCP_SocketTraceSet Function

Sets the current socket trace status.

File

tcp.h

C

```
bool TCPIP_TCP_SocketTraceSet(TCP_SOCKET sktNo, bool enable);
```

Returns

- true if the call succeeded
- false if there was an error (no such socket, tracing not enabled, etc.)

Description

This function enables or disables the trace status of the specified socket. The trace functionality needs to be enabled in the TCP module for this function to succeed. Currently when socket trace is enabled, the current socket state transitions are displayed at the system console.

Preconditions

TCP module properly initialized

Parameters

Parameters	Description
sktNo	socket to enable/disable trace
enable	boolean to enable/disable socket trace

Function

bool TCPIP_TCP_SocketTraceSet(TCP_SOCKET sktNo, bool enable)

b) Transmit Data Transfer Functions

TCPIP_TCP_Put Function

File

tcp.h

C

```
uint16_t TCPIP_TCP_Put(TCP_SOCKET hTCP, uint8_t byte);
```

Description

Writes a single byte to a TCP socket.

Remarks

Note that this function is inefficient and its use is discouraged. A buffered approach (TCPIP_TCP_ArrayPut) is preferred.

Preconditions

TCP socket should have been opened with TCPIP_TCP_ServerOpen()/TCPIP_TCP_ClientOpen(). hTCP - valid socket

Parameters

Parameters	Description
hTCP	The socket to which data is to be written.
byte	The byte to write.

Function

uint16_t TCPIP_TCP_Put(TCP_SOCKET hTCP, uint8_t byte)

TCPIP_TCP_PutIsReady Function

Determines how much free space is available in the TCP TX buffer.

File

tcp.h

C

```
uint16_t TCPIP_TCP_PutIsReady(TCP_SOCKET hTCP);
```

Returns

The number of bytes available to be written in the TCP TX buffer.

Description

Call this function to determine how many bytes can be written to the TCP TX buffer. If this function returns zero, the application must return to the main stack loop before continuing in order to transmit more data.

Preconditions

TCP is initialized.

Parameters

Parameters	Description
hTCP	The socket to check.

Function

uint16_t TCPIP_TCP_PutIsReady(TCP_SOCKET hTCP)

TCPIP_TCP_StringPut Function

Writes a null-terminated string to a TCP socket.

File

tcp.h

C

```
const uint8_t* TCPIP_TCP_StringPut(TCP_SOCKET hTCP, const uint8_t* Data);
```

Returns

Pointer to the byte following the last byte written to the socket. If this pointer does not dereference to a NULL byte, the buffer became full or the socket is not connected.

Description

This function writes a null-terminated string to a TCP socket. The null-terminator is not copied to the socket.

Remarks

The return value of this function differs from that of TCPIP_TCP_ArrayPut. To write long strings in a single state, initialize the *data pointer to the first byte, then call this function repeatedly (breaking to the main stack loop after each call) until the return value dereferences to a NULL byte. Save the return value as the new starting *data pointer otherwise.

Preconditions

TCP is initialized.

Parameters

Parameters	Description
hTCP	The socket to which data is to be written.
data	Pointer to the string to be written.

Function

const uint8_t* TCPIP_TCP_StringPut(TCP_SOCKET hTCP, const uint8_t* data)

TCPIP_TCP_ArrayPut Function

File

tcp.h

C

```
uint16_t TCPIP_TCP_ArrayPut(TCP_SOCKET hTCP, const uint8_t* Data, uint16_t Len);
```

Returns

The number of bytes written to the socket. If less than len, the buffer became full or the socket is not connected.

Description

Writes an array from a buffer to a TCP socket.

Remarks

This operation can cause a TCP packet to be transmitted over the network (i.e., a TCPIP_TCP_Flush operation to be performed) when there is data in the TCP TX buffer that can be sent and any of the following occurs:

- There is no more space available in the TCP buffer.
- The TCP_OPTION_THRES_FLUSH_ON is set and the TX buffer is at least half full
- The amount of data that can be sent is bigger than the remote host MSS or than half of the maximum advertised window size.
- The Nagle algorithm is disabled and there is no unacknowledged data.

If none of these occur and the socket user does not add data to the TX socket buffer, the TCP state machine will automatically flush the buffer when the TCP_AUTO_TRANSMIT_TIMEOUT_VAL time-out elapsed.

The default TCP_AUTO_TRANSMIT_TIMEOUT_VAL is 40 ms.

Preconditions

TCP is initialized.

Parameters

Parameters	Description
hTCP	The socket to which data is to be written.
data	Pointer to the array to be written.
len	Number of bytes to be written.

Function

uint16_t TCPIP_TCP_ArrayPut(TCP_SOCKET hTCP, const uint8_t* data, uint16_t len)

TCPIP_TCP_Flush Function

Immediately transmits all pending TX data.

File

tcp.h

C

```
bool TCPIP_TCP_Flush(TCP_SOCKET hTCP);
```

Returns

None,

Description

This function immediately transmits all pending TX data with a PSH flag. If this function is not called, data will automatically be sent by the TCP state machine (see the TCPIP_TCP_ArrayPut() description/notes).

Remarks

The application should not call this function explicitly because doing this will interfere with the TCP algorithm and degrade performance of the socket data transfer. One exception is when the application knows that it put all the data it needed into the TCP buffer and it makes sense to flush the socket instead of waiting TCP_AUTO_TRANSMIT_TIMEOUT_VAL timeout to elapse.

Preconditions

TCP is initialized and the socket is connected.

Parameters

Parameters	Description
hTCP	The socket whose data is to be transmitted.

Function

bool TCPIP_TCP_Flush(TCP_SOCKET hTCP)

TCPIP_TCP_FifoTxFullGet Function

Determines how many bytes are pending in the TCP TX FIFO.

File

tcp.h

C

```
uint16_t TCPIP_TCP_FifoTxFullGet(TCP_SOCKET hTCP);
```

Returns

Number of bytes pending to be flushed in the TCP TX FIFO.

Description

This function determines how many bytes are pending in the TCP TX FIFO.

Remarks

None.

Preconditions

TCP is initialized.

Parameters

Parameters	Description
hTCP	The socket to check.

Function

uint16_t TCPIP_TCP_FifoTxFullGet(TCP_SOCKET hTCP)

TCPIP_TCP_FifoTxFreeGet Function

Determines how many bytes are free and could be written in the TCP TX FIFO.

File

tcp.h

C

```
uint16_t TCPIP_TCP_FifoTxFreeGet(TCP_SOCKET hTCP);
```

Returns

The number of bytes available to be written in the TCP TX buffer.

Description

Macro: TCPIP_TCP_FifoTxFreeGet(TCP_SOCKET hTCP)

This macro returns the number of bytes that are free in the socket TX buffer.

Remarks

None.

Parameters

Parameters	Description
hTCP	The socket to check.

c) Receive Data Transfer Functions

TCPIP_TCP_GetIsReady Function

Determines how many bytes can be read from the TCP RX buffer.

File

tcp.h

C

```
uint16_t TCPIP_TCP_GetIsReady(TCP_SOCKET hTCP);
```

Returns

The number of bytes available to be read from the TCP RX buffer.

Description

Call this function to determine how many bytes can be read from the TCP RX buffer. If this function returns zero, the application must return to the main stack loop before continuing in order to wait for more data to arrive.

Remarks

None.

Preconditions

TCP is initialized.

Parameters

Parameters	Description
hTCP	The socket to check.

Function

uint16_t TCPIP_TCP_GetIsReady(TCP_SOCKET hTCP)

TCPIP_TCP_ArrayGet Function

Reads an array of data bytes from a TCP socket's RX buffer/FIFO.

File

tcp.h

C

```
uint16_t TCPIP_TCP_ArrayGet(TCP_SOCKET hTCP, uint8_t* buffer, uint16_t count);
```

Returns

The number of bytes read from the socket. If less than len, the RX FIFO buffer became empty or the socket is not connected.

Description

This function reads an array of data bytes from a TCP socket's RX buffer/FIFO. The data is removed from the FIFO in the process.

Remarks

If the supplied buffer is null, the data is simply discarded.

Preconditions

TCP is initialized.

Parameters

Parameters	Description
hTCP	The socket from which data is to be read.
buffer	Pointer to the array to store data that was read.
len	Number of bytes to be read.

Function

uint16_t TCPIP_TCP_ArrayGet(TCP_SOCKET hTCP, uint8_t* buffer, uint16_t len)

TCPIP_TCP_ArrayPeek Function

Reads a specified number of data bytes from the TCP RX buffer/FIFO without removing them from the buffer.

File

tcp.h

C

```
uint16_t TCPIP_TCP_ArrayPeek(TCP_SOCKET hTCP, uint8_t * vBuffer, uint16_t wLen, uint16_t wStart);
```

Description

This function reads a specified number of data bytes from the TCP RX FIFO without removing them from the buffer. No TCP control actions are taken as a result of this function (ex: no window update is sent to the remote node).

Remarks

None.

Preconditions

TCP is initialized.

Parameters

Parameters	Description
hTCP	The socket to peek from (read without removing from stream).
vBuffer	Destination to write the peeked data bytes.
wLen	Length of bytes to peek from the RX FIFO and copy to vBuffer.
wStart	Zero-indexed starting position within the FIFO from which to start peeking.

Function

uint16_t TCPIP_TCP_ArrayPeek(TCP_SOCKET hTCP, uint8_t *vBuffer, uint16_t wLen, uint16_t wStart)

TCPIP_TCP_ArrayFind Function

Searches for a string in the TCP RX buffer.

File

tcp.h

C

```
uint16_t TCPIP_TCP_ArrayFind(TCP_SOCKET hTCP, const uint8_t* cFindArray, uint16_t wLen, uint16_t wStart,
uint16_t wSearchLen, bool bTextCompare);
```

Description

This function finds the first occurrence of an array of bytes in the TCP RX buffer. It can be used by an application to abstract searches out of their own application code. For increased efficiency, the function is capable of limiting the scope of search to a specific range of bytes. It can also perform a case-insensitive search if required.

For example, if the buffer contains "I love PIC MCUs!" and the search array is "love" with a length of 4, a value of 2 will be returned.

Remarks

For better performance of this function, try to search for characters that are expected to exist or limit the scope of the search as much as possible. The HTTP module, for example, uses this function to parse headers. However, it searches for newlines, then the separating colon, then reads the header name to an internal buffer for comparison. This has proven to be significantly faster than searching for full header name strings outright.

Preconditions

TCP is initialized.

Parameters

Parameters	Description
hTCP	The socket to search within.
cFindArray	The array of bytes to find in the buffer.
wLen	Length of cFindArray.
wStart	Zero-indexed starting position within the buffer.
wSearchLen	Length from wStart to search in the buffer.
bTextCompare	true for case-insensitive text search, false for binary search

Function

uint16_t TCPIP_TCP_ArrayFind(TCP_SOCKET hTCP, uint8_t* cFindArray, uint16_t wLen,

uint16_t wStart, uint16_t wSearchLen, bool bTextCompare)

TCPIP_TCP_Find Function

Searches for a byte in the TCP RX buffer.

File

tcp.h

C

```
uint16_t TCPIP_TCP_Find(TCP_SOCKET hTCP, uint8_t cFind, uint16_t wStart, uint16_t wSearchLen, bool bTextCompare);
```

Description

This function finds the first occurrence of a byte in the TCP RX buffer. It can be used by an application to abstract searches out of their own application code. For increased efficiency, the function is capable of limiting the scope of search to a specific range of bytes. It can also perform a case-insensitive search if required.

For example, if the buffer contains "I love PIC MCUs!" and the cFind byte is ' ', a value of 1 will be returned.

Remarks

For better performance of this function, try to search for characters that are expected to exist or limit the scope of the search as much as possible. The HTTP module, for example, uses this function to parse headers. However, it searches for newlines, then the separating colon, then reads the header name to an internal buffer for comparison. This has proven to be significantly faster than searching for full header name strings outright.

Preconditions

TCP is initialized.

Parameters

Parameters	Description
hTCP	The socket to search within.
cFind	The byte to find in the buffer.
wStart	Zero-indexed starting position within the buffer.
wSearchLen	Length from wStart to search in the buffer.
bTextCompare	true for case-insensitive text search, false for binary search

Function

uint16_t TCPIP_TCP_Find(TCP_SOCKET hTCP, uint8_t cFind, uint16_t wStart,

uint16_t wSearchLen, bool bTextCompare)

TCPIP_TCP_Get Function

Retrieves a single byte to a TCP socket.

File

tcp.h

C

```
uint16_t TCPIP_TCP_Get(TCP_SOCKET hTCP, uint8_t* byte);
```

Description

This function retrieves a single byte to a TCP socket.

Remarks

Note that this function is inefficient. A buffered approach (TCPIP_TCP_ArrayGet) is preferred.

Preconditions

TCP socket should have been opened with TCPIP_TCP_ServerOpen()/TCPIP_TCP_ClientOpen(). hTCP - valid socket

Parameters

Parameters	Description
hTCP	The socket from which to read.
byte	Pointer to location in which the read byte should be stored.

Function

uint16_t TCPIP_TCP_Get(TCP_SOCKET hTCP, uint8_t* byte)

TCPIP_TCP_Peek Function

Peaks at one byte in the TCP RX buffer/FIFO without removing it from the buffer.

File

tcp.h

C

```
uint8_t TCPIP_TCP_Peek(TCP_SOCKET hTCP, uint16_t wStart);
```

Description

This function peaks at one byte in the TCP RX buffer/FIFO without removing it from the buffer.

Remarks

Note that this function is inefficient and its use is discouraged. A buffered approach (TCPIP_TCP_ArrayPeek) is preferred.

Preconditions

TCP is initialized.

Parameters

Parameters	Description
hTCP	The socket to peek from (read without removing from stream).
wStart	Zero-indexed starting position within the FIFO to peek from.

Function

uint8_t TCPIP_TCP_Peek(TCP_SOCKET hTCP, uint16_t wStart)

TCPIP_TCP_Discard Function

Discards any pending data in the RCP RX FIFO.

File

tcp.h

C

```
uint16_t TCPIP_TCP_Discard(TCP_SOCKET hTCP);
```

Returns

The number of bytes that have been discarded from the RX buffer.

Description

This function discards any pending data in the TCP RX FIFO.

Preconditions

TCP is initialized.

Parameters

Parameters	Description
hTCP	The socket whose RX buffer/FIFO is to be cleared.

Function

uint16_t TCPIP_TCP_Discard(TCP_SOCKET hTCP)

TCPIP_TCP_FifoRxFreeGet Function

Determines how many bytes are free in the RX buffer/FIFO.

File

tcp.h

C

```
uint16_t TCPIP_TCP_FifoRxFreeGet(TCP_SOCKET hTCP);
```

Returns

The number of bytes free in the TCP RX FIFO. If zero, no additional data can be received until the application removes some data using one of the TCPIP_TCP_Get family functions.

Description

This function determines how many bytes are free in the RX buffer/FIFO.

Preconditions

TCP is initialized.

Parameters

Parameters	Description
hTCP	The socket to check.

Function

uint16_t TCPIP_TCP_FifoRxFreeGet(TCP_SOCKET hTCP)

TCPIP_TCP_FifoSizeAdjust Function

Adjusts the relative sizes of the RX and TX buffers.

File

tcp.h

C

```
bool TCPIP_TCP_FifoSizeAdjust(TCP_SOCKET hTCP, uint16_t wMinRXSize, uint16_t wMinTXSize, TCP_ADJUST_FLAGS vFlags);
```

Description

This function can be used to simultaneously adjust the sizes of the RX and TX FIFOs.

Adjusting the size of the TX/RX FIFO on the fly can allow for optimal transmission speed for one-sided application protocols. For example, HTTP typically begins by receiving large amounts of data from the client, then switches to serving large amounts of data back. Adjusting the FIFO at

these points can increase performance in systems that have limited resources. Once the FIFOs are adjusted, a window update is sent.

Although the TX and RX socket buffers are completely independent, for the purpose of this function they can be considered together if neither TCP_ADJUST_TX_ONLY nor TCP_ADJUST_RX_ONLY flags are set.

In these conditions the TCP_ADJUST_FLAGS control the distribution of the available space between the TX and RX FIFOs. If neither or both of TCP_ADJUST_GIVE_REST_TO_TX and TCP_ADJUST_GIVE_REST_TO_RX are set, the function distributes the remaining space (if any) equally. If the new requested FIFOs space is greater that the old existing FIFOs space the TCP_ADJUST_GIVE_REST_TO_TX and TCP_ADJUST_GIVE_REST_TO_RX are ignored.

TCP_ADJUST_PRESERVE_RX and TCP_ADJUST_PRESERVE_TX request the preserving of the existing data. Existing data can be preserved as long as the old data in the buffer does not exceed the capacity of the new buffer.

Remarks

The function will automatically maintain minimal values for both TX and RX buffers.

To avoid having a socket with no associated buffers, the function first allocates the new buffers and, if succeeded, it frees the old ones.

The TX and RX FIFOs (buffers) associated with a socket are completely separate and independent. However, when TCP_ADJUST_TX_ONLY or TCP_ADJUST_RX_ONLY are not set, for the purpose of this function, the TX and RX FIFOs are considered to be contiguous so that the total FIFO space is divided between the TX and RX FIFOs. This provides backward compatibility with previous versions of this function.

The new flags TCP_ADJUST_TX_ONLY and TCP_ADJUST_RX_ONLY allow changing the size of TX and RX buffers independently. This is the preferred option.

TX or RX associated buffer sizes can be changed too using the socket options. See TCPIP_TCP_OptionsSet.

Preconditions

TCP is initialized.

Parameters

Parameters	Description
hTCP	The socket to be adjusted
wMinRXSize	Minimum number of bytes for the RX FIFO
wMinTXSize	Minimum number of bytes for the TX FIFO
vFlags	If TCP_ADJUST_TX_ONLY or TCP_ADJUST_RX_ONLY are not set, the TX and RX buffers are evaluated together and any
combination of the following flags is valid	TCP_ADJUST_GIVE_REST_TO_RX, TCP_ADJUST_GIVE_REST_TO_TX TCP_ADJUST_PRESERVE_RX, TCP_ADJUST_PRESERVE_TX If TCP_ADJUST_TX_ONLY or TCP_ADJUST_RX_ONLY is set TX and RX buffers are treated individually and TCP_ADJUST_GIVE_REST_TO_TX, TCP_ADJUST_GIVE_REST_TO_RX values are irrelevant. TCP_ADJUST_TX_ONLY and TCP_ADJUST_RX_ONLY both set is invalid.

Function

bool TCPIP_TCP_FifoSizeAdjust(TCP_SOCKET hTCP, uint16_t wMinRXSize, uint16_t wMinTXSize,
TCP_ADJUST_FLAGS vFlags)

TCPIP_TCP_FifoRxFullGet Macro

Determines how many bytes are pending in the RX buffer/FIFO.

File

tcp.h

C

```
#define TCPIP_TCP_FifoRxFullGet(a) TCPIP_TCP_GetIsReady(a)
```

Description

Macro: TCPIP_TCP_FifoRxFullGet

Alias to TCPIP_TCP_GetIsReady provided for API completeness

Remarks

None.

d) Data Types and Constants

TCP_ADJUST_FLAGS Enumeration

TCP adjust RX and TX buffers flags.

File

tcp.h

C

```
typedef enum {
  TCP_ADJUST_GIVE_REST_TO_RX = 0x01,
  TCP_ADJUST_GIVE_REST_TO_TX = 0x02,
  TCP_ADJUST_PRESERVE_RX = 0x04,
  TCP_ADJUST_PRESERVE_TX = 0x08,
  TCP_ADJUST_TX_ONLY = 0x10,
  TCP_ADJUST_RX_ONLY = 0x20
} TCP_ADJUST_FLAGS;
```

Members

Members	Description
TCP_ADJUST_GIVE_REST_TO_RX = 0x01	Resize flag: extra bytes go to RX
TCP_ADJUST_GIVE_REST_TO_TX = 0x02	Resize flag: extra bytes go to TX
TCP_ADJUST_PRESERVE_RX = 0x04	Resize flag: attempt to preserve RX buffer
TCP_ADJUST_PRESERVE_TX = 0x08	Resize flag: attempt to preserve TX buffer
TCP_ADJUST_TX_ONLY = 0x10	Resize flag: adjust the TX buffer only
TCP_ADJUST_RX_ONLY = 0x20	Resize flag: adjust the RX buffer only

Description

Enumeration: TCP_ADJUST_FLAGS

Adjusts socket RX and TX buffer sizes.

TCP_OPTION_LINGER_DATA Structure

Socket linger options.

File

tcp.h

C

```
typedef struct {
  bool lingerEnable;
  bool gracefulEnable;
  uint16_t lingerTmo;
} TCP_OPTION_LINGER_DATA;
```

Members

Members	Description
bool lingerEnable;	Enable/disable linger; enabled by default for any socket.
bool gracefulEnable;	Enable/disable graceful close; enabled by default for any socket.
uint16_t lingerTmo;	Linger timeout in seconds (when enabled). This option is not supported yet.

Description

Structure: TCP_OPTION_LINGER_DATA

This structure defines socket linger options.

TCP_PORT Type

Defines a TCP Port number.

File

tcp.h

C

```
typedef uint16_t TCP_PORT;
```

Description

Type: TCP_PORT

TCP Port Number identifier.

TCP_SOCKET Type

Defines a TCP Socket.

File

tcp.h

C

```
typedef int16_t TCP_SOCKET;
```

Description

Type: TCP_SOCKET

A TCP_SOCKET is stored as a single int16_t number.

TCP_SOCKET_INFO Structure

TCP socket information.

File

tcp.h

C

```
typedef struct {
  IP_ADDRESS_TYPE addressType;
  IP_MULTI_ADDRESS remoteIPaddress;
  IP_MULTI_ADDRESS localIPaddress;
  TCP_PORT remotePort;
  TCP_PORT localPort;
  TCPIP_NET_HANDLE hNet;
  TCPIP_TCP_STATE state;
  uint16_t rxSize;
  uint16_t txSize;
  uint16_t rxPending;
  uint16_t txPending;
} TCP_SOCKET_INFO;
```

Members

Members	Description
IP_ADDRESS_TYPE addressType;	Address type of the socket IPv4 or IPv6
IP_MULTI_ADDRESS remoteIPaddress;	Remote address to which the socket is connected
IP_MULTI_ADDRESS localIPaddress;	Local address socket is bound to
TCP_PORT remotePort;	Port number associated with remote node
TCP_PORT localPort;	Local port number
TCPIP_NET_HANDLE hNet;	Associated interface
TCPIP_TCP_STATE state;	Current socket state
uint16_t rxSize;	size of the RX buffer
uint16_t txSize;	size of the TX buffer
uint16_t rxPending;	bytes pending in RX buffer
uint16_t txPending;	bytes pending in TX buffer

Description

Structure: TCP_SOCKET_INFO

Gets information about a socket.

TCP_SOCKET_OPTION Enumeration

TCP Socket run-time options.

File

tcp.h

C

```
typedef enum {
  TCP_OPTION_LINGER,
  TCP_OPTION_KEEP_ALIVE,
  TCP_OPTION_RX_BUFF,
  TCP_OPTION_TX_BUFF,
  TCP_OPTION_RX_TMO,
  TCP_OPTION_TX_TMO,
  TCP_OPTION_NODELAY,
  TCP_OPTION_EXCLUSIVE_ADDRESS,
  TCP_OPTION_THRES_FLUSH,
  TCP_OPTION_DELAY_SEND_ALL_ACK
} TCP_SOCKET_OPTION;
```

Members

Members	Description
TCP_OPTION_LINGER	The LINGER option controls the action taken when unsent data is queued on a socket and the socket is closed. The linger option can be turned on/off and the timeout can be specified.
TCP_OPTION_KEEP_ALIVE	Enable the use of keep-alive packets on TCP connections. The option can be turned on/off and the timeout can be specified.
TCP_OPTION_RX_BUFF	Request different RX buffer size. Has to call TCPIP_TCP_OptionsGet to see the exact space allocated.
TCP_OPTION_TX_BUFF	Request different TX buffer size. Has to call TCPIP_TCP_OptionsGet to see the exact space allocated.
TCP_OPTION_RX_TMO	Specifies the RX timeout. If no data arrives in the specified timeout the socket is closed.
TCP_OPTION_TX_TMO	Specifies the TX timeout. If no data can be sent in the specified timeout the socket is closed.
TCP_OPTION_NODELAY	Enables the NO DELAY/Nagle algorithm functionality. The default setting is disabled.
TCP_OPTION_EXCLUSIVE_ADDRESS	Enables a socket to be bound for exclusive access. The default setting is disabled - option not supported yet.
TCP_OPTION_THRES_FLUSH	Sets the type of half buffer TX flush for the socket. The default setting is TCP_OPTION_THRES_FLUSH_AUTO
TCP_OPTION_DELAY_SEND_ALL_ACK	Enables/disables the delay of sending the pending data when no unacknowledged data. When this option is disabled, the socket will immediately send any pending data chunk whenever all the previous data is acknowledged by the remote party (there is no unacknowledged data). This holds true for the 1st transmission too, or after a pause of some length. If the option is enabled, the socket will delay sending the data, waiting for more data to accumulate. This could be useful when the application makes multiple calls with small data chunks. The default setting is disabled.

Description

Enumeration: TCP_SOCKET_OPTION

This enumeration defines TCP socket run-time options.

INVALID_SOCKET Macro

Invalid socket indicator macro.

File

tcp.h

C

```
#define INVALID_SOCKET (-1)
```

Description

Macro: INVALID_SOCKET

Indicates that the socket is invalid or could not be opened.

TCP_OPTION_THRES_FLUSH_TYPE Enumeration

List of the socket half threshold TX flush types.

File

tcp.h

C

```
typedef enum {
  TCP_OPTION_THRES_FLUSH_AUTO,
  TCP_OPTION_THRES_FLUSH_OFF,
  TCP_OPTION_THRES_FLUSH_ON
} TCP_OPTION_THRES_FLUSH_TYPE;
```

Members

Members	Description
TCP_OPTION_THRES_FLUSH_AUTO	The socket will set the half buffer flush based on the TX buffer size. This is the default setting. For TX buffers >= 1.5 MSS the half buffer flush will be disabled. This results in higher performance/throughput for the socket.
TCP_OPTION_THRES_FLUSH_OFF	Always disable the socket flush at half buffer threshold. No socket flush is performed when the half TX buffer threshold is passed.
TCP_OPTION_THRES_FLUSH_ON	Always enable the socket flush at half buffer threshold. Socket flush is always performed when the half TX buffer threshold is passed. This is useful for small TX buffers when the remote party implements the delayed ACK algorithm.

Description

Enumeration: TCP_OPTION_THRES_FLUSH_TYPE

Describes the possible types of the socket half threshold TX flush.

TCPIP_TCP_MODULE_CONFIG Structure

TCP module run-time configuration/initialization data.

File

tcp.h

C

```
typedef struct {
  int nSockets;
  uint16_t sktTxBuffSize;
  uint16_t sktRxBuffSize;
} TCPIP_TCP_MODULE_CONFIG;
```

Members

Members	Description
int nSockets;	Number of sockets to be created
uint16_t sktTxBuffSize;	Size of the socket TX buffer
uint16_t sktRxBuffSize;	Size of the socket RX buffer

Description

Structure: TCPIP_TCP_MODULE_CONFIG

This structure defines TCP module run-time configuration/initialization data.

TCP_OPTION_KEEP_ALIVE_DATA Structure

Socket keep alive options

File

tcp.h

C

```
typedef struct {
```

```
  bool keepAliveEnable;
  uint16_t keepAliveTmo;
  uint8_t keepAliveUnackLim;
} TCP_OPTION_KEEP_ALIVE_DATA;
```

Members

Members	Description
bool keepAliveEnable;	Enable/disable keep alive option; disabled by default for any socket.
uint16_t keepAliveTmo;	keep alive timeout in milliseconds ignored when keep alive is disabled if 0, the default build time value is used
uint8_t keepAliveUnackLim;	limit of keep alives to be sent the socket will reset the communication channel if no reply received after so many retries ignored when keep alive is disabled if 0, the default build time value is used

Description

Structure: TCP_OPTION_KEEP_ALIVE_DATA

This structure defines socket keep alive options.

TCPIP_TCP_SIGNAL_FUNCTION Type

TCP signal handler.

File

tcp.h

C

```
typedef void (* TCPIP_TCP_SIGNAL_FUNCTION)(TCP_SOCKET hTCP, TCPIP_NET_HANDLE hNet, TCPIP_TCP_SIGNAL_TYPE
sigType, const void* param);
```

Description

Type: TCPIP_TCP_SIGNAL_FUNCTION

Prototype of a TCP signal handler. Socket user can register a handler for the TCP socket. Once an TCP event occurs the registered handler will be called.

Remarks

The handler has to be short and fast. It is meant for setting an event flag, not for lengthy processing!

Parameters

Parameters	Description
hTCP	TCP socket to be used
hNet	the network interface on which the event has occurred
sigType	type of TCP signal that has occurred
param	additional parameter that can has been specified at the handler registration call is currently not used and will be null

TCPIP_TCP_SIGNAL_HANDLE Type

TCP socket handle.

File

tcp.h

C

```
typedef const void* TCPIP_TCP_SIGNAL_HANDLE;
```

Description

Type: TCPIP_TCP_SIGNAL_HANDLE

A handle that a socket client can use after the signal handler has been registered.

TCPIP_TCP_SIGNAL_TYPE Enumeration

TCP run time signal/event types.

File

tcp.h

C

```
typedef enum {
  TCPIP_TCP_SIGNAL_TX_DONE = 0x0001,
  TCPIP_TCP_SIGNAL_TX_DATA_DONE = 0x0002,
  TCPIP_TCP_SIGNAL_TX_SPACE = 0x0004,
  TCPIP_TCP_SIGNAL_ESTABLISHED = 0x0100,
  TCPIP_TCP_SIGNAL_RX_DATA = 0x0200,
  TCPIP_TCP_SIGNAL_RX_FIN = 0x0400,
  TCPIP_TCP_SIGNAL_RX_RST = 0x0800,
  TCPIP_TCP_SIGNAL_KEEP_ALIVE_TMO = 0x1000
} TCPIP_TCP_SIGNAL_TYPE;
```

Members

Members	Description
TCPIP_TCP_SIGNAL_TX_DONE = 0x0001	A TCP packet was successfully transmitted on the interface. This may indicate or not that new data can be sent with this socket. Note 1: The TCP buffer space is controlled by the TCP state machine; The fact that a packet was transmitted, doesn't necessarily mean that new data can be written into the socket buffer: 2: The packet may be an ACK only packet, retry packet, etc., and does not free any writing space in the socket buffer 3: A new socket writing space may not be available because the other party has not acknowledged the data it was sent so far. Therefore, the information carried by this signal has limited usage. 4: This notification is the result of an user action (explicit call to TCPIP_TCP_Flush) or as a result of the internal TCP state machine
TCPIP_TCP_SIGNAL_TX_DATA_DONE = 0x0002	A TCP data packet carrying valid payload was successfully transmitted on the interface. This may indicate or not that new data can be sent with this socket.
TCPIP_TCP_SIGNAL_TX_SPACE = 0x0004	New TX space is available in the socket TX buffer. This event signals that the remote party has acknowledged some data and, as a result, TX buffer space is available.
TCPIP_TCP_SIGNAL_ESTABLISHED = 0x0100	Socket established a connection (client or server socket)
TCPIP_TCP_SIGNAL_RX_DATA = 0x0200	A data packet was successfully received and there is data available for this socket
TCPIP_TCP_SIGNAL_RX_FIN = 0x0400	Remote host finished it's data and sent a FIN;
TCPIP_TCP_SIGNAL_RX_RST = 0x0800	Remote host reset the connection;
TCPIP_TCP_SIGNAL_KEEP_ALIVE_TMO = 0x1000	Keep alive has timed out; Connection to the remote host has been aborted;

Description

Enumeration: TCPIP_TCP_SIGNAL_TYPE

Description of the signals/events that a TCP socket can generate.

Remarks

These signals are used in the socket event handling notification functions. It is possible that multiple flags are set as part of the same notification.

The signals are 16 bits wide.

TCPIP_TCP_STATE Enumeration

TCP socket state.

File

tcp.h

C

```
typedef enum {
  TCPIP_TCP_STATE_LISTEN,
  TCPIP_TCP_STATE_SYN_SENT,
  TCPIP_TCP_STATE_SYN_RECEIVED,
  TCPIP_TCP_STATE_ESTABLISHED,
  TCPIP_TCP_STATE_FIN_WAIT_1,
  TCPIP_TCP_STATE_FIN_WAIT_2,
```

```
    TCPIP_TCP_STATE_CLOSING,
    TCPIP_TCP_STATE_TIME_WAIT,
    TCPIP_TCP_STATE_CLOSE_WAIT,
    TCPIP_TCP_STATE_LAST_ACK,
    TCPIP_TCP_STATE_CLIENT_WAIT_DISCONNECT,
    TCPIP_TCP_STATE_CLIENT_WAIT_CONNECT,
    TCPIP_TCP_STATE_KILLED
} TCPIP_TCP_STATE;
```

Members

Members	Description
TCPIP_TCP_STATE_LISTEN	Socket is listening for connections
TCPIP_TCP_STATE_SYN_SENT	A SYN has been sent, awaiting an SYN+ACK
TCPIP_TCP_STATE_SYN_RECEIVED	A SYN has been received, awaiting an ACK
TCPIP_TCP_STATE_ESTABLISHED	Socket is connected and connection is established
TCPIP_TCP_STATE_FIN_WAIT_1	FIN WAIT state 1
TCPIP_TCP_STATE_FIN_WAIT_2	FIN WAIT state 2
TCPIP_TCP_STATE_CLOSING	Socket is closing
TCPIP_TCP_STATE_TIME_WAIT	2MSL state
TCPIP_TCP_STATE_CLOSE_WAIT	Waiting to close the socket
TCPIP_TCP_STATE_LAST_ACK	The final ACK has been sent
TCPIP_TCP_STATE_CLIENT_WAIT_DISCONNECT	client socket lost connection, waiting for app close/disconnect
TCPIP_TCP_STATE_CLIENT_WAIT_CONNECT	client socket waiting for connection
TCPIP_TCP_STATE_KILLED	socket is killed; debug reporting state

Description

Enumeration: TCPIP_TCP_STATE

Enumeration describing the possible states of a TCP socket.

Files

Files

Name	Description
tcp.h	Transmission Control Protocol (TCP) Communications Layer API
tcp_config.h	TCP configuration file

Description

This section lists the source and header files used by the library.

tcp.h

Transmission Control Protocol (TCP) Communications Layer API

Enumerations

	Name	Description
	TCP_ADJUST_FLAGS	TCP adjust RX and TX buffers flags.
	TCP_OPTION_THRES_FLUSH_TYPE	List of the socket half threshold TX flush types.
	TCP_SOCKET_OPTION	TCP Socket run-time options.
	TCPIP_TCP_SIGNAL_TYPE	TCP run time signal/event types.
	TCPIP_TCP_STATE	TCP socket state.

Functions

	Name	Description
	TCPIP_TCP_Abort	Aborts a connection.
	TCPIP_TCP_ArrayFind	Searches for a string in the TCP RX buffer.
	TCPIP_TCP_ArrayGet	Reads an array of data bytes from a TCP socket's RX buffer/FIFO.
	TCPIP_TCP_ArrayPeek	Reads a specified number of data bytes from the TCP RX buffer/FIFO without removing them from the buffer.

	TCPIP_TCP_ArrayPut	Writes an array from a buffer to a TCP socket.
	TCPIP_TCP_Bind	Binds a socket to a local address.
	TCPIP_TCP_ClientOpen	Opens a TCP socket as a client.
	TCPIP_TCP_Close	Disconnects an open socket and destroys the socket handle, releasing the associated resources.
	TCPIP_TCP_Connect	Connects a client socket.
	TCPIP_TCP_Discard	Discards any pending data in the RCP RX FIFO.
	TCPIP_TCP_Disconnect	Disconnects an open socket.
	TCPIP_TCP_FifoRxFreeGet	Determines how many bytes are free in the RX buffer/FIFO.
	TCPIP_TCP_FifoSizeAdjust	Adjusts the relative sizes of the RX and TX buffers.
	TCPIP_TCP_FifoTxFreeGet	Determines how many bytes are free and could be written in the TCP TX FIFO.
	TCPIP_TCP_FifoTxFullGet	Determines how many bytes are pending in the TCP TX FIFO.
	TCPIP_TCP_Find	Searches for a byte in the TCP RX buffer.
	TCPIP_TCP_Flush	Immediately transmits all pending TX data.
	TCPIP_TCP_Get	Retrieves a single byte to a TCP socket.
	TCPIP_TCP_GetIsReady	Determines how many bytes can be read from the TCP RX buffer.
	TCPIP_TCP_IsConnected	Determines if a socket has an established connection.
	TCPIP_TCP_IsReady	Returns the current status of the TCP module
	TCPIP_TCP_OptionsGet	Allows getting the options for a socket like: current RX/TX buffer size, etc.
	TCPIP_TCP_OptionsSet	Allows setting options to a socket like adjust RX/TX buffer size, etc.
	TCPIP_TCP_Peek	Peaks at one byte in the TCP RX buffer/FIFO without removing it from the buffer.
	TCPIP_TCP_Put	Writes a single byte to a TCP socket.
	TCPIP_TCP_PutIsReady	Determines how much free space is available in the TCP TX buffer.
	TCPIP_TCP_RemoteBind	Binds a socket to a remote address.
	TCPIP_TCP_ServerOpen	Opens a TCP socket as a server.
	TCPIP_TCP_SignalHandlerDeregister	Deregisters a previously registered TCP socket signal handler.
	TCPIP_TCP_SignalHandlerRegister	Registers a TCP socket signal handler.
	TCPIP_TCP_SocketInfoGet	Obtains information about a currently open socket.
	TCPIP_TCP_SocketNetGet	Gets the current network interface of an TCP socket.
	TCPIP_TCP_SocketNetSet	Sets the interface for an TCP socket
	TCPIP_TCP_SocketsNumberGet	Returns the number of existent TCP sockets.
	TCPIP_TCP_SocketTraceSet	Sets the current socket trace status.
	TCPIP_TCP_StringPut	Writes a null-terminated string to a TCP socket.
	TCPIP_TCP_Task	Standard TCP/IP stack module task function.
	TCPIP_TCP_WasReset	Self-clearing semaphore indicating socket reset.

Macros

	Name	Description
	INVALID_SOCKET	Invalid socket indicator macro.
	TCPIP_TCP_FifoRxFullGet	Determines how many bytes are pending in the RX buffer/FIFO.

Structures

	Name	Description
	TCP_OPTION_KEEP_ALIVE_DATA	Socket keep alive options
	TCP_OPTION_LINGER_DATA	Socket linger options.
	TCP_SOCKET_INFO	TCP socket information.
	TCPIP_TCP_MODULE_CONFIG	TCP module run-time configuration/initialization data.

Types

	Name	Description
	TCP_PORT	Defines a TCP Port number.
	TCP_SOCKET	Defines a TCP Socket.
	TCPIP_TCP_SIGNAL_FUNCTION	TCP signal handler.
	TCPIP_TCP_SIGNAL_HANDLE	TCP socket handle.

Microchip Technology Inc.

tcp_config.h

TCP configuration file

Macros

	Name	Description
	TCPIP_TCP_AUTO_TRANSMIT_TIMEOUT_VAL	Timeout before automatically transmitting unflushed data, ms. Default value is 40 ms.
	TCPIP_TCP_CLOSE_WAIT_TIMEOUT	Timeout for the CLOSE_WAIT state, ms If the remote socket closes the connection the TCP/IP stack will automatically close the socket after this timeout. If the value is set to 0 then the socket will wait forever for the application to close the socket (default behavior).
	TCPIP_TCP_DELAYED_ACK_TIMEOUT	Timeout for delayed-acknowledgment algorithm, ms
	TCPIP_TCP_DYNAMIC_OPTIONS	Enable the TCP sockets dynamic options set/get functionality If enabled, the functions: TCPIP_TCP_OptionsSet, TCPIP_TCP_OptionsGet and TCPIP_TCP_FifoSizeAdjust exist and are compiled in If disabled, these functions do not exist and cannot be used/called Note that this setting can affect modules that use TCP sockets
	TCPIP_TCP_FIN_WAIT_2_TIMEOUT	Timeout for FIN WAIT 2 state, ms
	TCPIP_TCP_KEEP_ALIVE_TIMEOUT	Timeout for keep-alive messages when no traffic is sent, ms
	TCPIP_TCP_MAX_RETRIES	Maximum number of retransmission attempts
	TCPIP_TCP_MAX_SEG_SIZE_RX_LOCAL	TCP Maximum Segment Size for RX (MSS). This value is advertised during TCP connection establishment and the remote node should obey it. The value has to be set in such a way to avoid IP layer fragmentation from causing packet loss. However, raising its value can enhance performance at the (small) risk of introducing incompatibility with certain special remote nodes (ex: ones connected via a slow dial up modem). On Ethernet networks the standard value is 1460. On dial-up links, etc. the default values should be 536. Adjust these values according to your network. Maximum Segment Size for RX (MSS)... more
	TCPIP_TCP_MAX_SEG_SIZE_RX_NON_LOCAL	Maximum Segment Size for RX (MSS) for non local destination networks.
	TCPIP_TCP_MAX_SEG_SIZE_TX	TCP Maximum Segment Size for TX. The TX maximum segment size is actually governed by the remote node's MSS option advertised during connection establishment. However, if the remote node specifies an unmanageably large MSS (ex: > Ethernet MTU), this define sets a hard limit so that TX buffers are not overflowed. If the remote node does not advertise a MSS option, all TX segments are fixed at 536 bytes maximum.
	TCPIP_TCP_MAX_SOCKETS	The maximum number of sockets to create in the stack. When defining TCPIP_TCP_MAX_SOCKETS take into account the number of interfaces the stack is supporting.
	TCPIP_TCP_MAX_SYN_RETRIES	Smaller than all other retries to reduce SYN flood DoS duration
	TCPIP_TCP_MAX_UNACKED_KEEP_ALIVES	Maximum number of keep-alive messages that can be sent without receiving a response before automatically closing the connection
	TCPIP_TCP_MSL_TIMEOUT	Maximum Segment Length (MSL) timeout, seconds This value sets the time a socket will be in the TIME_WAIT/2MSL state after the socket performed an active close. RFC recommended value is 120 sec. Other common values are: 30/60 sec Note that if this symbol is defined to 0, then the TIME_WAIT/2MSL state is skipped! This could lead to duplicate sequence numbers problems if sockets are frequently/rapidly closed and reopened and should be avoided.

	TCPIP_TCP_QUIET_TIME	This value specifies the TCP quiet time: TCP will not send any data for TCPIP_TCP_QUIET_TIME seconds after rebooting! Usualy this value should match the MSL value. Note that if this symbol is defined to 0, then the TCP quiet time state is skipped! During the quiet time there will be no TCP traffic initiated by TCP. So, clients won't be able to connect to remote hosts and servers won't reply to client requests.
	TCPIP_TCP_SOCKET_DEFAULT_RX_SIZE	Default socket RX buffer size Note that this setting affects all TCP sockets that are created and, together with TCPIP_TCP_MAX_SOCKETS, has a great impact on the heap size that's used by the stack (see TCPIP_STACK_DRAM_SIZE setting). When large RX bufferrs are needed, probably a dynamic, per socket approach, is a better choice (see TCPIP_TCP_OptionsSet function). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput. Note that some modules (like HTTP) use their own settings to... more
	TCPIP_TCP_SOCKET_DEFAULT_TX_SIZE	Default socket TX buffer size Note that this setting affects all TCP sockets that are created and, together with TCPIP_TCP_MAX_SOCKETS, has a great impact on the heap size that's used by the stack (see TCPIP_STACK_DRAM_SIZE setting). When large TX bufferrs are needed, probably a dynamic, per socket approach, is a better choice (see TCPIP_TCP_OptionsSet function). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput. Note that some modules (like HTTP) use their own settings to... more
	TCPIP_TCP_START_TIMEOUT_VAL	Timeout to retransmit unacked data, ms
	TCPIP_TCP_TASK_TICK_RATE	The TCP task processing rate: number of milliseconds to generate an TCP tick. This is the tick that advances the TCP state machine. The default value is 5 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_TCP_WINDOW_UPDATE_TIMEOUT_VAL	Timeout before automatically transmitting a window update due to a TCPIP_TCP_Get() or TCPIP_TCP_ArrayGet() function call, ms.

TFTP Module

This section describes the TCP/IP Stack Library TFTP module.

Introduction

This library provides the API of the TFTP module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

TCP/IP Stack Library Trivial File Transfer Protocol (TFTP) module is simple protocol used to transfer files.

The TFTP module only supports client transfers, through the process of reading and writing files (or mail) from/to a remote server. The module cannot list directories, and currently has no provisions for user authentication. In common with other Internet protocols, it passes 8-bit bytes of data.

Using the Library

This topic describes the basic architecture of the TFTP TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `tftpc.h`

The interface to the TFTP TCP/IP Stack library is defined in the `tftpc.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the `tftpc.h` TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the TFTP module.

Library Interface Section	Description
General Functions	This section provides general interface routines to TFTP
Data Types and Constants	This section provides various definitions describing this API

How the Library Works

This topic provides information on how the TFTP module works including write and read requests.

Description

Any transfer begins with a request to read or write a file, which also serves to request a connection. If the server grants the request, the connection is opened and the file is sent in fixed length blocks of 512 bytes. Each data packet contains one block of data, and must be acknowledged by an acknowledgment packet before the next packet can be sent. A data packet of less than 512 bytes, signals termination of a transfer. If a packet gets lost in the network, the intended recipient will time out and may retransmit the last packet (which may be data or an acknowledgment), thus causing the sender of the lost packet to retransmit that lost packet.

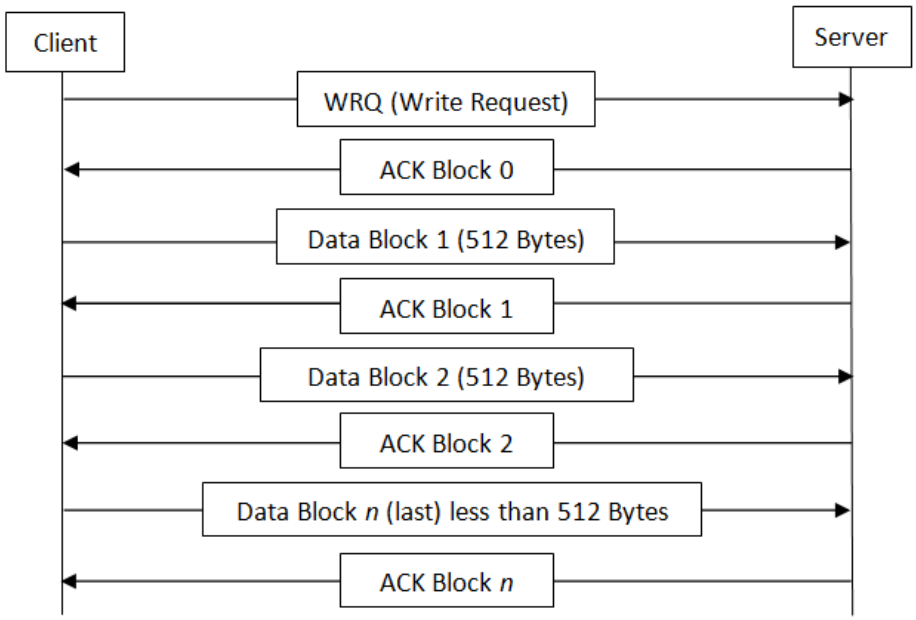
TFTP Client Server Communication

This section provides information on TFTP Write and Read requests.

Description

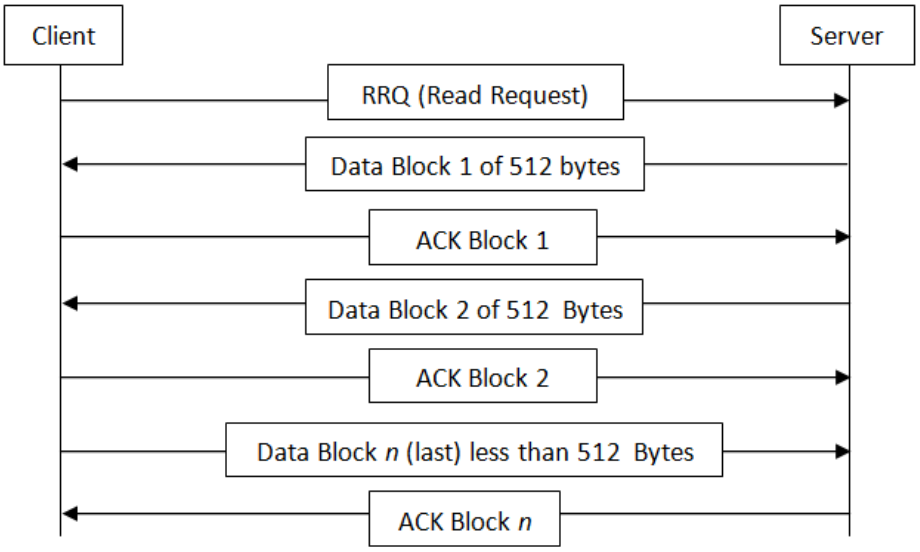
TFTP Write Request (WRQ)

The following diagram illustrates a write request.



TFTP Read Request (RRQ)

The following diagram illustrates a read request.



Configuring the Library

Macros

	Name	Description
	TCPIP_TFTPC_ARP_TIMEOUT	The number of seconds to wait before declaring a TIMEOUT error on PUT.
	TCPIP_TFTPC_CMD_PROCESS_TIMEOUT	The number of seconds to wait before declaring a TIMEOUT error on GET.
	TCPIP_TFTPC_DEFAULT_IF	The default TFTP interface for multi-homed hosts.
	TCPIP_TFTPC_FILENAME_LEN	The maximum value for the file name size.
	TCPIP_TFTPC_HOSTNAME_LEN	The maximum TFTP host name length size.
	TCPIP_TFTPC_MAX_RETRIES	The number of attempts before declaring a TIMEOUT error.
	TCPIP_TFTPC_TASK_TICK_RATE	The TFTP client task rate in milliseconds. The default value is 100 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_TFTPC_USER_NOTIFICATION	allow TFTP client user notification if enabled, the TCPIP_TFTPC_HandlerRegister/TCPIP_TFTPC_HandlerDeRegister functions exist and can be used

Description

The configuration of the TFTP TCP/IP Stack Library is based on the file `tcpip_config.h`.

This header file contains the configuration selection for the TFTP TCP/IP Stack Library. Based on the selections made, the TFTP TCP/IP Stack Library will or will not support selected features. These configuration settings will apply to all instances of the TFTP TCP/IP Stack Library.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_TFTPC_ARP_TIMEOUT Macro

File

tftpc_config.h

C

```
#define TCPIP_TFTPC_ARP_TIMEOUT (3ul)
```

Description

The number of seconds to wait before declaring a TIMEOUT error on PUT.

TCPIP_TFTPC_CMD_PROCESS_TIMEOUT Macro

File

tftpc_config.h

C

```
#define TCPIP_TFTPC_CMD_PROCESS_TIMEOUT (3ul)
```

Description

The number of seconds to wait before declaring a TIMEOUT error on GET.

TCPIP_TFTPC_DEFAULT_IF Macro

File

tftpc_config.h

C

```
#define TCPIP_TFTPC_DEFAULT_IF "PIC32INT"
```

Description

The default TFTP interface for multi-homed hosts.

TCPIP_TFTPC_FILENAME_LEN Macro

File

tftpc_config.h

C

```
#define TCPIP_TFTPC_FILENAME_LEN (32)
```

Description

The maximum value for the file name size.

TCPIP_TFTPC_HOSTNAME_LEN Macro

File

tftpc_config.h

C

```
#define TCPIP_TFTPC_HOSTNAME_LEN (32)
```

Description

The maximum TFTP host name length size.

TCPIP_TFTPC_MAX_RETRIES Macro

File

tftpc_config.h

C

```
#define TCPIP_TFTPC_MAX_RETRIES (3u)
```

Description

The number of attempts before declaring a TIMEOUT error.

TCPIP_TFTPC_TASK_TICK_RATE Macro

File

tftpc_config.h

C

```
#define TCPIP_TFTPC_TASK_TICK_RATE (100)
```

Description

The TFTP client task rate in milliseconds. The default value is 100 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

TCPIP_TFTPC_USER_NOTIFICATION Macro

File

tftpc_config.h

C

```
#define TCPIP_TFTPC_USER_NOTIFICATION false
```

Description

allow TFTP client user notification if enabled, the TCPIP_TFTPC_HandlerRegister/TCPIP_TFTPC_HandlerDeRegister functions exist and can be used

Building the Library

This section lists the files that are available in the TFTP module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (.h) and source (.c) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/tftpc.c`	TFTP implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The TFTP module depends on the following module:

- TCP/IP Stack Library

Library Interface

a) Functions

	Name	Description
	TCPIP_TFTPC_Task	Standard TCP/IP stack module task function.
	TCPIP_TFTPC_GetEventNotification	Get the details of the TFTP client file mode communication event details.
	TCPIP_TFTPC_HandlerDeRegister	Deregisters a previously registered TFTP Client handler.
	TCPIP_TFTPC_HandlerRegister	Registers a TFTPC Handler.
	TCPIP_TFTPC_SetServerAddress	Set the Server IP address for TFTP Client .
	TCPIP_TFTPC_SetCommand	TFTP client command operation configuration.

b) Data Types and Constants

	Name	Description
	_TFTP_CMD_TYPE	File command mode used for TFTP PUT and GET commands.
	TCPIP_TFTP_CMD_TYPE	File command mode used for TFTP PUT and GET commands.
	TCPIP_TFTPC_MODULE_CONFIG	Placeholder for TFTP Client module configuration.
	TCPIP_TFTPC_EVENT_HANDLER	TFTPC event handler prototype.
	TCPIP_TFTPC_EVENT_TYPE	TFTP client Event Type
	TCPIP_TFTPC_HANDLE	TFTPC handle.
	TCPIP_TFTPC_OPERATION_RESULT	Standard error codes for TFTP PUT and GET command operation.

Description

This section describes the Application Programming Interface (API) functions of the TFTP module.
Refer to each section for a detailed description.

a) Functions

TCPIP_TFTPC_Task Function

Standard TCP/IP stack module task function.

File

tftpc.h

C

```
void TCPIP_TFTPC_Task();
```

Returns

None.

Description

This function performs TFTP module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The TFTP module should have been initialized.

Function

void TCPIP_TFTPC_Task(void)

TCPIP_TFTPC_GetEventNotification Function

Get the details of the TFTP client file mode communication event details.

File

tftpc.h

C

```
TCPIP_TFTPC_EVENT_TYPE TCPIP_TFTPC_GetEventNotification();
```

Returns

TCPIP_TFTPC_EVENT_TYPE : It will be OR of different events.

Description

This function returns the event type TCPIP_TFTPC_EVENT_TYPE for different modes of TFTP file communication.

Preconditions

The TFTP Client module must be initialized.

Function

TCPIP_TFTPC_EVENT_TYPE TCPIP_TFTPC_GetEventNotification(void)

TCPIP_TFTPC_HandlerDeRegister Function

Deregisters a previously registered TFTP Client handler.

File

tftpc.h

C

```
bool TCPIP_TFTPC_HandlerDeRegister(TCPIP_TFTPC_HANDLE hDhcp);
```

Returns

- true - if the call succeeds
- false - if no such handler is registered

Description

This function deregisters the TFTP Client event handler.

Preconditions

The TFTP Client module must be initialized.

Parameters

Parameters	Description
htftpc	A handle returned by a previous call to TCPIP_TFTPC_HandlerRegister.

Function

bool TCPIP_TFTPC_HandlerDeRegister(TCPIP_TFTPC_HANDLE htftpc)

TCPIP_TFTPC_HandlerRegister Function

Registers a TFTPC Handler.

File

tftpc.h

C

```
TCPIP_TFTPC_HANDLE TCPIP_TFTPC_HandlerRegister(TCPIP_NET_HANDLE hNet, TCPIP_TFTPC_EVENT_HANDLER handler,
const void* hParam);
```

Returns

Returns a valid handle if the call succeeds, or a null handle if the call failed (out of memory, for example).

Description

This function registers a TFTPC event handler. The TFTP Client module will call the registered handler when a TFTP Client event

(TCPIP_TFTPC_EVENT_TYPE) occurs.

Remarks

The handler has to be short and fast. It is meant for setting an event flag, not for lengthy processing!

The hParam is passed by the client and will be used by the DHCP when the notification is made. It is used for per-thread content or if more modules, for example, share the same handler and need a way to differentiate the callback.

Preconditions

The TFTP Client module must be initialized.

Parameters

Parameters	Description
hNet	Interface handle. Use hNet == 0 to register on all interfaces available.
handler	Handler to be called when a TFTP Client event occurs.
hParam	Parameter to be used in the handler call. This is user supplied and is not used by the DHCP module.

Function

TCPIP_TFTPC_HandlerRegister(TCPIP_NET_HANDLE hNet, TCPIP_TFTPC_EVENT_HANDLER handler,

const void* hParam)

TCPIP_TFTPC_SetServerAddress Function

Set the Server IP address for TFTP Client .

File

tftpc.h

C

```
void TCPIP_TFTPC_SetServerAddress(IP_MULTI_ADDRESS* ipAddr, IP_ADDRESS_TYPE ipType);
```

Returns

None

Description

This function is used to set the TFTP server address(either it will be IPv4 address or IPv6 address). This address will be used for either Get or Put mode of TFTP Client operation.

Preconditions

The TFTP Client module must be initialized.

Parameters

Parameters	Description
ipAddr	pointer to the server address
ipType	type of address: IPv4/IPv6

Function

void TCPIP_TFTPC_SetServerAddress(IP_MULTI_ADDRESS* ipAddr,IP_ADDRESS_TYPE ipType)

TCPIP_TFTPC_SetCommand Function

TFTP client command operation configuration.

File

tftpc.h

C

```
TCPIP_TFTPC_OPERATION_RESULT TCPIP_TFTPC_SetCommand(IP_MULTI_ADDRESS* mAddr, IP_ADDRESS_TYPE ipType,
TCPIP_TFTP_CMD_TYPE cmdType, const char * fileName);
```

Returns

TFTPC_ERROR_BUSY - TFTP client is busy for one file processing and please retry later. when there is a TFTP operation going on, the another operation has to wait till the TFTP operation is completed. TFTPC_ERROR_INVALID_FILE_LENGTH - File Length should not be more than TCPIP_TFTPC_FILENAME_LEN. TFTPC_ERROR_NONE - Successful command operation.

Description

This function is used to set the client mode, server, and file name. The file name is accessed as per the TFTP command mode.

Remarks

None.

Preconditions

The TCP/IP Stack should have been initialized.

Parameters

Parameters	Description
mAddr	Server address
ipType	IP address type either IPv4 or IPv6 type
cmdType	GET or PUT command
fileName	File to be processed

Function

TCPIP_TFTPC_OPERATION_RESULT TCPIP_TFTPC_SetCommand(IP_MULTI_ADDRESS* mAddr,

- IP_ADDRESS_TYPE ipType,TCPIP_TFTP_CMD_TYPE cmdType,
- const char * fileName)

b) Data Types and Constants

TCPIP_TFTP_CMD_TYPE Enumeration

File command mode used for TFTP PUT and GET commands.

File

tftpc.h

C

```
typedef enum _TFTP_CMD_TYPE {
  TFTP_CMD_PUT_TYPE = 0,
  TFTP_CMD_GET_TYPE,
  TFTP_CMD_NONE
} TCPIP_TFTP_CMD_TYPE;
```

Members

Members	Description
TFTP_CMD_PUT_TYPE = 0	TFTP client issues a PUT command to write a file to the server
TFTP_CMD_GET_TYPE	TFTP client issues a GET command to read the file from the server

Description

Enumeration: TCPIP_TFTP_CMD_TYPE

These enum values are issued from the command line.

TCPIP_TFTPC_MODULE_CONFIG Structure

Placeholder for TFTP Client module configuration.

File

tftpc.h

C

```
typedef struct {
  const char* tftpc_interface;
  uint32_t tftpc_reply_timeout;
} TCPIP_TFTPC_MODULE_CONFIG;
```

Members

Members	Description
uint32_t tftpc_reply_timeout;	time-out for the server reply in seconds

Description

Structure: TCPIP_TFTPC_MODULE_CONFIG

This structure is a placeholder for TFTP Client module configuration.

TCPIP_TFTPC_EVENT_HANDLER Type

TFTPC event handler prototype.

File

tftpc.h

C

```
typedef void (* TCPIP_TFTPC_EVENT_HANDLER)(TCPIP_NET_HANDLE hNet, TCPIP_TFTPC_EVENT_TYPE evType,void
*buf,uint32_t bufLen, const void* param);
```

Description

Type: TCPIP_TFTPC_EVENT_HANDLER

Prototype of a TFTPC event handler. Clients can register a handler with the TFTP service. Once an TFTP event occurs the TFTP Client service will be called the registered handler. The handler has to be short and fast. It is meant for setting an event flag, *not* for lengthy processing! buf - Buffer is used to provide the memory Pointer . buf type need to be typecasted to char* while processing bufLen - The number of bytes present in the buffer.

TCPIP_TFTPC_EVENT_TYPE Enumeration

TFTP client Event Type

File

tftpc.h

C

```
typedef enum {
  TFTPC_EVENT_NONE = 0,
  TFTPC_EVENT_PUT_REQUEST = 0x0001,
  TFTPC_EVENT_GET_REQUEST = 0x0002,
  TFTPC_EVENT_ACKED = 0x0004,
  TFTP_EVENT_DATA_RECEIVED = 0x0008,
  TFTPC_EVENT_DECLINE = 0x0010,
  TFTPC_EVENT_TIMEOUT = 0x0020,
  TFTPC_EVENT_COMPLETED = 0x0040,
  TFTPC_EVENT_CONN_LOST = 0x0080,
  TFTPC_EVENT_CONN_ESTABLISHED = 0x0100,
  TFTPC_EVENT_SERVICE_DISABLED = 0x0200,
  TFTPC_EVENT_BUSY = 0x0400
} TCPIP_TFTPC_EVENT_TYPE;
```

Members

Members	Description
TFTPC_EVENT_NONE = 0	TFTP no event
TFTPC_EVENT_PUT_REQUEST = 0x0001	TFTP PUT request sent
TFTPC_EVENT_GET_REQUEST = 0x0002	TFTP GET Request sent
TFTPC_EVENT_ACKED = 0x0004	TFTP request acknowledge was received
TFTP_EVENT_DATA_RECEIVED = 0x0008	TFTP Client received Data for GET request
TFTPC_EVENT_DECLINE = 0x0010	TFTP File Put or Get communication declined due to Bad PDU

TFTPC_EVENT_TIMEOUT = 0x0020	TFTP server timeout
TFTPC_EVENT_COMPLETED = 0x0040	TFTP File Put or Get completed
TFTPC_EVENT_CONN_LOST = 0x0080	connection to the TFTP server lost
TFTPC_EVENT_CONN_ESTABLISHED = 0x0100	connection re-established
TFTPC_EVENT_SERVICE_DISABLED = 0x0200	TFTP service disabled
TFTPC_EVENT_BUSY = 0x0400	TFTP Client communication is going on

Description

Enumeration: TCPIP_TFTPC_EVENT_TYPE

None.

TCPIP_TFTPC_HANDLE Type

TFTPC handle.

File

tftpc.h

C

```
typedef const void* TCPIP_TFTPC_HANDLE;
```

Description

Type: TCPIP_TFTPC_HANDLE

A handle that a client can use after the event handler has been registered.

TCPIP_TFTPC_OPERATION_RESULT Enumeration

Standard error codes for TFTP PUT and GET command operation.

File

tftpc.h

C

```
typedef enum {
  TFTPC_ERROR_NONE = 0,
  TFTPC_ERROR_FILE_NOT_FOUND = -1,
  TFTPC_ERROR_BUSY = -2,
  TFTPC_ERROR_DISK_FULL = -3,
  TFTPC_ERROR_INVALID_OPERATION = -4,
  TFTPC_ERROR_UNKNOWN_TID = -5,
  TFTPC_ERROR_FILE_EXISTS = -6,
  TFTPC_ERROR_NO_SUCH_USE = -7,
  TFTPC_ERROR_DNS_RESOLVE_ERR = -8,
  TFTPC_ERROR_INVALID_INTERFACE = -9,
  TFTPC_ERROR_INVALID_FILE_LENGTH = -10,
  TFTPC_ERROR_INVALID_SERVER_ADDR = -11
} TCPIP_TFTPC_OPERATION_RESULT;
```

Members

Members	Description
TFTPC_ERROR_FILE_NOT_FOUND = -1	TFTP client file not found
TFTPC_ERROR_BUSY = -2	TFTP client is busy when one file put or get transfer is going on.
TFTPC_ERROR_DISK_FULL = -3	TFTP client buffer full
TFTPC_ERROR_INVALID_OPERATION = -4	TFTP client invalid command operation
TFTPC_ERROR_UNKNOWN_TID = -5	TFTP ID error
TFTPC_ERROR_FILE_EXISTS = -6	TFTP client file already exists
TFTPC_ERROR_NO_SUCH_USE = -7	TFTP client not in use
TFTPC_ERROR_DNS_RESOLVE_ERR = -8	TFTP client DNS resolve error
TFTPC_ERROR_INVALID_INTERFACE = -9	TFTP client interface error
TFTPC_ERROR_INVALID_FILE_LENGTH = -10	TFTP client file length is more than the expected size, which should be the size of SYS_FS_MAX_PATH

TFTPC_ERROR_INVALID_SERVER_ADDR = -11	Invalid Server Address

Description

Enumeration: TCPIP_TFTPC_OPERATION_RESULT

This enumeration defines the standard error codes for TFTP PUT and GET command operation.

Files

Files

Name	Description
tftpc.h	The TFTP Client module implements the Trivial File Transfer Protocol (TFTP).
tftpc_config.h	TFTP Client configuration file.

Description

This section lists the source and header files used by the library.

tftpc.h

The TFTP Client module implements the Trivial File Transfer Protocol (TFTP).

Enumerations

	Name	Description
	_TFTP_CMD_TYPE	File command mode used for TFTP PUT and GET commands.
	TCPIP_TFTP_CMD_TYPE	File command mode used for TFTP PUT and GET commands.
	TCPIP_TFTPC_EVENT_TYPE	TFTP client Event Type
	TCPIP_TFTPC_OPERATION_RESULT	Standard error codes for TFTP PUT and GET command operation.

Functions

	Name	Description
	TCPIP_TFTPC_GetEventNotification	Get the details of the TFTP client file mode communication event details.
	TCPIP_TFTPC_HandlerDeRegister	Deregisters a previously registered TFTP Client handler.
	TCPIP_TFTPC_HandlerRegister	Registers a TFTPC Handler.
	TCPIP_TFTPC_SetCommand	TFTP client command operation configuration.
	TCPIP_TFTPC_SetServerAddress	Set the Server IP address for TFTP Client .
	TCPIP_TFTPC_Task	Standard TCP/IP stack module task function.

Structures

	Name	Description
	TCPIP_TFTPC_MODULE_CONFIG	Placeholder for TFTP Client module configuration.

Types

	Name	Description
	TCPIP_TFTPC_EVENT_HANDLER	TFTPC event handler prototype.
	TCPIP_TFTPC_HANDLE	TFTPC handle.

Description

TFTP Client Module API Header File

The TFTP Client module implements the Trivial File Transfer Protocol (TFTP). By default, the module opens a client socket for the default interface configuration. From the command prompt, the TFTP client module mode will be selected. At present only two modes are supported: Read and Write.

- For Read mode - File will be fetched from the Server using the GET command.
- For Write mode - Server will be able to fetch the file from the client using the PUT command.

The TFTP module needs the file system for GET and PUT command operation. When one mode is in operation, access to the other mode or another server is not allowed.

File Name

tftpc.h

Company

Microchip Technology Inc.

tftpc_config.h

TFTP Client configuration file.

Macros

	Name	Description
	TCPIP_TFTPC_ARP_TIMEOUT	The number of seconds to wait before declaring a TIMEOUT error on PUT.
	TCPIP_TFTPC_CMD_PROCESS_TIMEOUT	The number of seconds to wait before declaring a TIMEOUT error on GET.
	TCPIP_TFTPC_DEFAULT_IF	The default TFTP interface for multi-homed hosts.
	TCPIP_TFTPC_FILENAME_LEN	The maximum value for the file name size.
	TCPIP_TFTPC_HOSTNAME_LEN	The maximum TFTP host name length size.
	TCPIP_TFTPC_MAX_RETRIES	The number of attempts before declaring a TIMEOUT error.
	TCPIP_TFTPC_TASK_TICK_RATE	The TFTP client task rate in milliseconds. The default value is 100 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_TFTPC_USER_NOTIFICATION	allow TFTP client user notification if enabled, the TCPIP_TFTPC_HandlerRegister/TCPIP_TFTPC_HandlerDeRegister functions exist and can be used

Telnet Module

This section describes the TCP/IP Stack Library Telnet module.

Introduction

TCP/IP Stack Library Telnet Module for Microchip Microcontrollers

This library provides the API of the Telnet (server) module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

Telnet, which runs over a TCP connection, provides bidirectional, interactive communication between two nodes on the Internet or on a Local Area Network. The Telnet code included with Microchip's TCP/IP stack is a demonstration of the possible utilization of a Telnet server module. The server listens for a Telnet connection. When a client attempts to make one, the demonstration will prompt the client for a username and password, and if the correct one is provided, it will connect the client to a console service running in the system (if this console service is enabled). From this moment on, the Telnet connection can be used for various system and TCP/IP related commands, just as the regular system console is used.

The commands currently implemented and processed by the command processor can be dynamically updated, new commands can be added, etc. See the `tcpip_commands.c` file for the list of TCP/IP-related commands.

Based on this skeleton Telnet code, completely new behavior can be implemented for the Telnet server.

Using the Library

This topic describes the basic architecture of the Telnet TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `telnet.h`

The interface to the Telnet TCP/IP Stack library is defined in the `telnet.h` header file. This file is included by the `tcpip.h` file. Any C language

source (.c) file that uses the Telnet TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

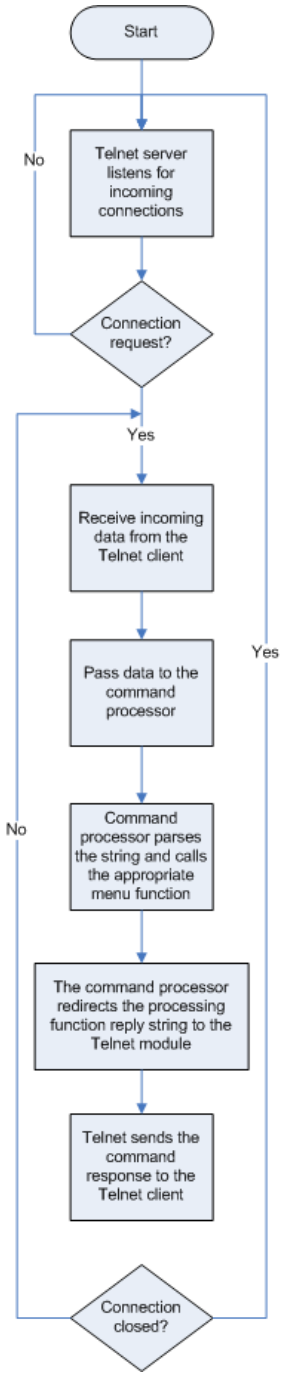
This library provides the API of the Telnet TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

Currently, the Telnet TCP/IP Library runs in the background as a server and does not expose any API functions.

It serves incoming connections by sending the received data string to the command processor, which outputs each command reply to the Telnet channel.

Telnet Software Abstraction Block Diagram



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Telnet module.

Library Interface Section	Description
Functions	This section provides a routine that performs Telnet module tasks in the TCP/IP stack.
Data Types and Constants	This section provides various definitions describing this API

Configuring the Library

Macros

	Name	Description
	TCPIP_TELNET_MAX_CONNECTIONS	Maximum number of Telnet connections
	TCPIP_TELNET_PASSWORD	Default Telnet password
	TCPIP_TELNET_TASK_TICK_RATE	telnet task rate, milliseconds The default value is 100 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_TELNET_USERNAME	Default Telnet user name

Description

The configuration of the Telnet TCP/IP Stack Library is based on the file `tcpip_config.h`.

This header file contains the configuration selection for the Telnet TCP/IP Stack Library. Based on the selections made, the Telnet TCP/IP Stack Library may support the selected features. These configuration settings will apply to all instances of the Telnet TCP/IP Stack Library.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_TELNET_MAX_CONNECTIONS Macro

File

telnet_config.h

C

```
#define TCPIP_TELNET_MAX_CONNECTIONS (2u)
```

Description

Maximum number of Telnet connections

TCPIP_TELNET_PASSWORD Macro

File

telnet_config.h

C

```
#define TCPIP_TELNET_PASSWORD "microchip"
```

Description

Default Telnet password

TCPIP_TELNET_TASK_TICK_RATE Macro

File

telnet_config.h

C

```
#define TCPIP_TELNET_TASK_TICK_RATE 100
```

Description

telnet task rate, milliseconds The default value is 100 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

TCPIP_TELNET_USERNAME Macro

File

telnet_config.h

C

```
#define TCPIP_TELNET_USERNAME "admin"
```

Description

Default Telnet user name

Building the Library

This section lists the files that are available in the Telnet module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/telnet.c`	Telnet implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The Telnet module depends on the following modules:

- TCP/IP Stack Library
- TCP Module

Library Interface

a) Functions

	Name	Description
	TCPIP_TELNET_Task	Standard TCP/IP stack module task function.

b) Data Types and Constants

	Name	Description
	TCPIP_TELNET_MODULE_CONFIG	Telnet Configuration structure placeholder

Description

This section describes the Application Programming Interface (API) functions of the Telnet module.

Refer to each section for a detailed description.

a) Functions

TCPIP_TELNET_Task Function

Standard TCP/IP stack module task function.

File

telnet.h

C

```
void TCPIP_TELNET_Task();
```

Returns

None.

Description

This function performs Telnet module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The Telnet module should have been initialized.

Function

void TCPIP_TELNET_Task(void)

b) Data Types and Constants

TCPIP_TELNET_MODULE_CONFIG Structure

File

telnet.h

C

```
typedef struct {
} TCPIP_TELNET_MODULE_CONFIG;
```

Description

Telnet Configuration structure placeholder

Configuration file

Macros

	Name	Description
	TCPIP_TELNET_MAX_CONNECTIONS	Maximum number of Telnet connections
	TCPIP_TELNET_PASSWORD	Default Telnet password
	TCPIP_TELNET_TASK_TICK_RATE	telnet task rate, milliseconds The default value is 100 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_TELNET_USERNAME	Default Telnet user name

Description

Telnet Configuration file

This file contains the Telnet module configuration options

File Name

telnet_config.h

Company

Microchip Technology Inc.

UDP Module

This section describes the TCP/IP Stack Library UDP module.

Introduction

TCP/IP Stack Library UDP Module for Microchip Microcontrollers

This library provides the API of the UDP module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

UDP is a standard transport layer protocol described in RFC 768. It provides fast but unreliable data-gram based transfers over networks, and

forms the foundation SNTP, SNMP, DNS, and many other protocol standards.

Using the Library

This topic describes the basic architecture of the UDP TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `udp.h`

The interface to the UDP TCP/IP Stack library is defined in the `udp.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the UDP TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

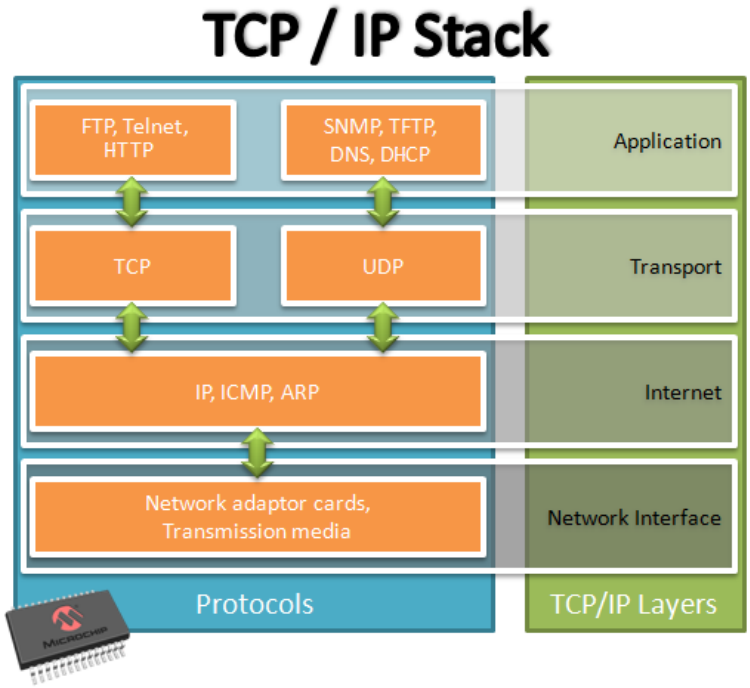
This library provides the API of the UDP TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

UDP Software Abstraction Block Diagram

This module provides software abstraction of the UDP module existent in any TCP/IP Stack implementation. It allows a user to UDP network traffic by opening and using UDP sockets.

Typical UDP Implementation



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the UDP module.

Library Interface Section	Description
Socket Management Functions	Routines for Managing UDP Sockets
Transmit Data Transfer Functions	Routines for Managing Outgoing Data Transmissions
Receive Data Transfer Functions	Routines for Managing Incoming Data Transmissions
Data Types and Constants	This section provides various definitions describing This API

How the Library Works

This topic describes how the UDP TCP/IP Stack Library works.

Description

Connections over UDP should be thought of as data-gram based transfers. Each packet is a separate entity, the application should expect some packets to arrive out-of-order or even fail to reach the destination node. This is in contrast to TCP, in which the connection is thought of as a stream and network errors are automatically corrected. These tradeoffs in reliability are made for an increase in throughput. In general, UDP transfers operate two to three times faster than those made over TCP.

UDP sockets have their own TX buffers. Once the transmit buffer has valid data it is the socket user's responsibility to send the data over the network , calling the corresponding TCPIP_UDP_Flush function.

There is no state machine within the UDP module to automatically take care of the data transmission.

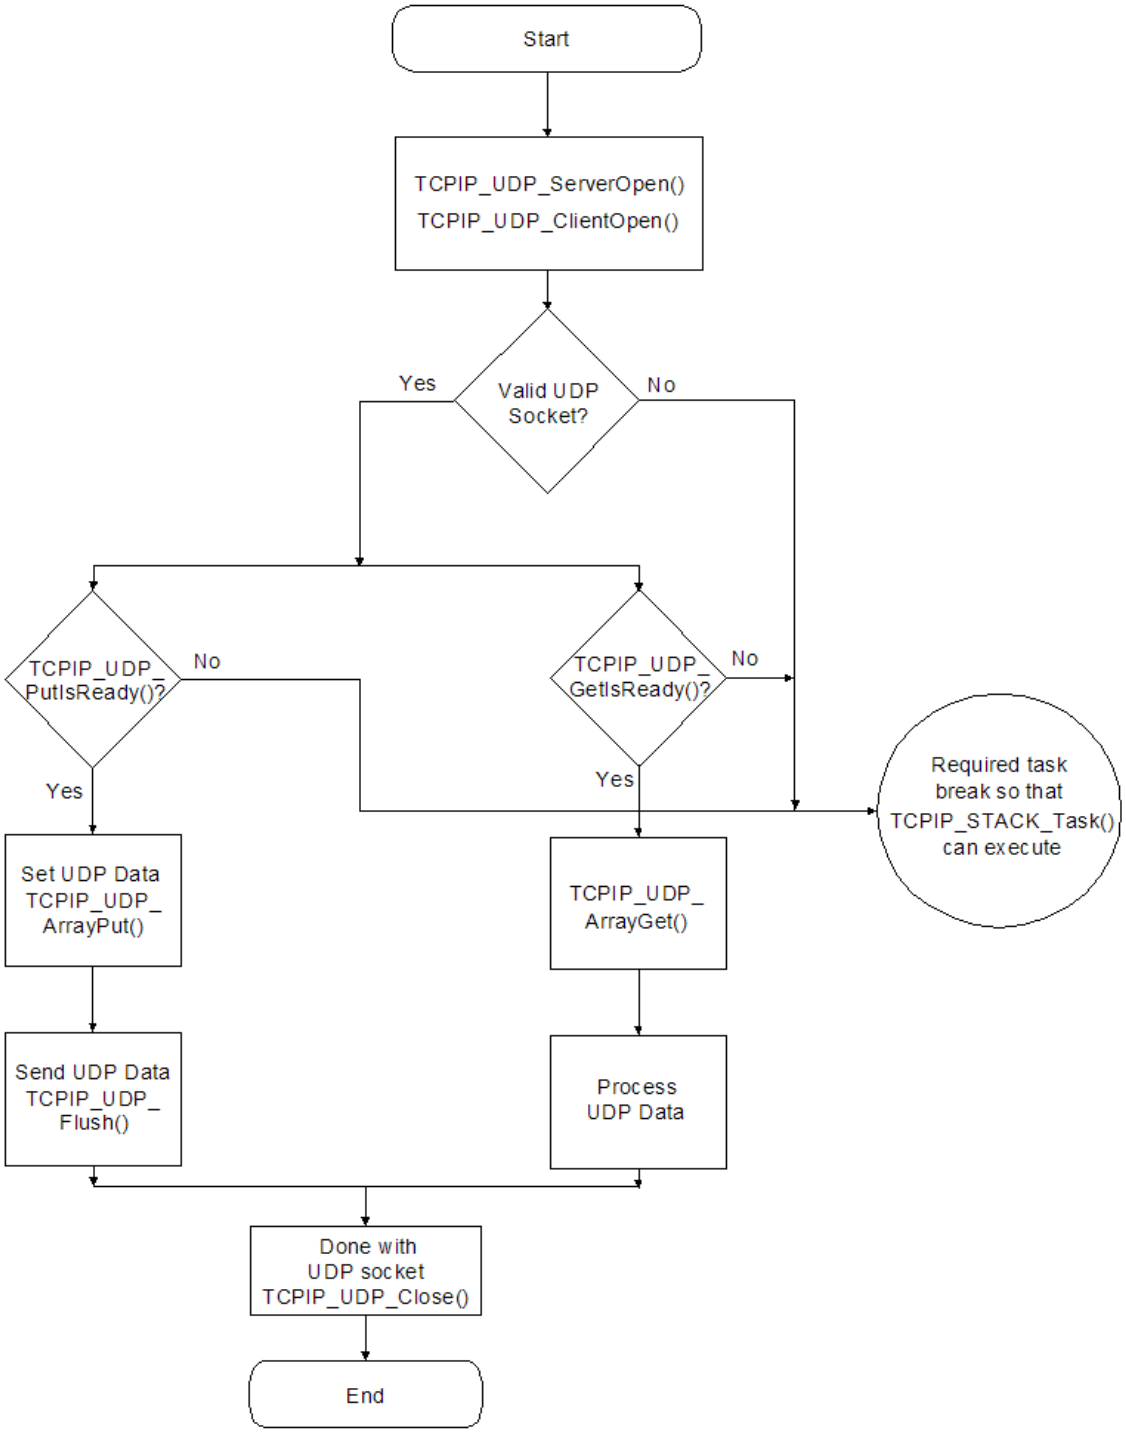
On the receive side, a UDP socket does not have its own RX buffer; however, it will use the RX buffer that was allocated by the corresponding MAC driver for receiving a network packet. What this means is that the user of the UDP socket will have to consume that pending RX data (or discard it), because eventually, the stack will run out of memory for other incoming traffic.

Core Functionality

This topic describes the core functionality of the UDP TCP/IP Stack Library.

Description

The following flow diagram provides an overview for the use of the UDP module:



Server/listening sockets are opened using TCPIP_UDP_ServerOpen. Client sockets are opened using TCPIP_UDP_ClientOpen. A client socket needs to have a remote address specified before it can transmit data.

Once the socket is opened, you can immediately begin transmitting data. To transmit a segment, call TCPIP_UDP_PutIsReady to determine how many bytes can be written. Then, use any of the TCPIP_UDP_ArrayPut family of functions to write data to the socket. Once all data has been written, call TCPIP_UDP_Flush to build and transmit the packet. Since each UDP socket has its own TX buffer, the sequence previously described can be executed in multiple steps. That data that is written in the socket is persistent and it will be stored until TCPIP_UDP_Flush is called.

Configuring the Library

Macros

	Name	Description
	TCPIP_UDP_MAX_SOCKETS	Maximum number of UDP sockets that can be opened simultaneously These sockets will be created when the module is initialized.
	TCPIP_UDP_SOCKET_DEFAULT_RX_QUEUE_LIMIT	The maximum number of RX packets that can be queued by an UDP socket at a certain time. Note that UDP sockets do not use their own RX buffers but instead use the network driver supplied packets and a timely processing is critical to avoid packet memory starvation for the whole stack. This symbol sets the maximum number of UDP buffers/packets that can be queued for a UDP socket at a certain time. Once this limit is reached further incoming packets are silently discarded. Adjust depending on the number of RX buffers that are available for the stack and the... more
	TCPIP_UDP_SOCKET_DEFAULT_TX_QUEUE_LIMIT	The maximum number of TX packets that can be queued by an UDP socket at a certain time. For sockets that need to transfer a lot of data (Iperf, for example), especially on slow connections this limit prevents running out of memory because the MAC/PHY transfer cannot keep up with the UDP packet allocation rate imposed by the application. Adjust depending on the TCPIP_UDP_SOCKET_DEFAULT_TX_SIZE, the connection speed and the amount of memory available to the stack.
	TCPIP_UDP_SOCKET_DEFAULT_TX_SIZE	Default socket TX buffer size. Note that this setting affects all UDP sockets that are created and, together with TCPIP_UDP_MAX_SOCKETS, has a great impact on the heap size that's used by the stack (see TCPIP_STACK_DRAM_SIZE setting). When large TX bufferrs are needed, probably a dynamic, per socket approach, is a better choice (see TCPIP_UDP_OptionsSet function).
	TCPIP_UDP_SOCKET_POOL_BUFFER_SIZE	Size of the buffers in the UDP pool. Any UDP socket that is enabled to use the pool and has the TX size <= than this size can use a buffer from the pool. Note that this setting, together with TCPIP_UDP_SOCKET_POOL_BUFFERS, has impact on the heap size that's used by the stack (see TCPIP_STACK_DRAM_SIZE setting).
	TCPIP_UDP_SOCKET_POOL_BUFFERS	Number of buffers in the private UDP pool. These are preallocated buffers that are to be used by UDP sockets only. This improves the UDP socket throughput and is meant only for UDP sockets that have to sustain high TX traffic rate. However, this memory is not returned to the stack heap, it always belongs to UDP. A socket needs to have an option set in order to use the buffers pool (see the UDPSetOptions()). Use 0 to disable the feature.
	TCPIP_UDP_USE_RX_CHECKSUM	Check incoming packets to have proper checksum.
	TCPIP_UDP_USE_TX_CHECKSUM	Calculate and transmit a checksum when sending data. Checksum is not mandatory for UDP packets but is highly recommended. This will affect the UDP TX performance.
	TCPIP_UDP_USE_POOL_BUFFERS	enable the build of the pre-allocated pool buffers option

Description

The configuration of the UDP TCP/IP Stack Library is based on the file `system_config.h`. (which may include `udp_config.h`).

This header file contains the configuration selection for the UDP TCP/IP Stack Library. Based on the selections made, the UDP TCP/IP Stack Library may support the selected features. These configuration settings will apply to the single instance of the UDP TCP/IP Stack Library for all sockets.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_UDP_MAX_SOCKETS Macro

File

udp_config.h

C

```
#define TCPIP_UDP_MAX_SOCKETS (10)
```

Description

Maximum number of UDP sockets that can be opened simultaneously These sockets will be created when the module is initialized.

TCPIP_UDP_SOCKET_DEFAULT_RX_QUEUE_LIMIT Macro

File

udp_config.h

C

```
#define TCPIP_UDP_SOCKET_DEFAULT_RX_QUEUE_LIMIT 3
```

Description

The maximum number of RX packets that can be queued by an UDP socket at a certain time. Note that UDP sockets do not use their own RX buffers but instead use the network driver supplied packets and a timely processing is critical to avoid packet memory starvation for the whole stack. This symbol sets the maximum number of UDP buffers/packets that can be queued for a UDP socket at a certain time. Once this limit is reached further incoming packets are silently discarded. Adjust depending on the number of RX buffers that are available for the stack and the amount of memory available to the stack.

TCPIP_UDP_SOCKET_DEFAULT_TX_QUEUE_LIMIT Macro

File

udp_config.h

C

```
#define TCPIP_UDP_SOCKET_DEFAULT_TX_QUEUE_LIMIT 3
```

Description

The maximum number of TX packets that can be queued by an UDP socket at a certain time. For sockets that need to transfer a lot of data (Iperf, for example), especially on slow connections this limit prevents running out of memory because the MAC/PHY transfer cannot keep up with the UDP packet allocation rate imposed by the application. Adjust depending on the TCPIP_UDP_SOCKET_DEFAULT_TX_SIZE, the connection speed and the amount of memory available to the stack.

TCPIP_UDP_SOCKET_DEFAULT_TX_SIZE Macro

File

udp_config.h

C

```
#define TCPIP_UDP_SOCKET_DEFAULT_TX_SIZE 512
```

Description

Default socket TX buffer size. Note that this setting affects all UDP sockets that are created and, together with TCPIP_UDP_MAX_SOCKETS, has a great impact on the heap size that's used by the stack (see TCPIP_STACK_DRAM_SIZE setting). When large TX bufferrs are needed, probably a dynamic, per socket approach, is a better choice (see TCPIP_UDP_OptionsSet function).

TCPIP_UDP_SOCKET_POOL_BUFFER_SIZE Macro

File

udp_config.h

C

```
#define TCPIP_UDP_SOCKET_POOL_BUFFER_SIZE 512
```

Description

Size of the buffers in the UDP pool. Any UDP socket that is enabled to use the pool and has the TX size <= than this size can use a buffer from the pool. Note that this setting, together with TCPIP_UDP_SOCKET_POOL_BUFFERS, has impact on the heap size that's used by the stack (see TCPIP_STACK_DRAM_SIZE setting).

TCPIP_UDP_SOCKET_POOL_BUFFERS Macro

File

udp_config.h

C

```
#define TCPIP_UDP_SOCKET_POOL_BUFFERS 4
```

Description

Number of buffers in the private UDP pool. These are preallocated buffers that are to be used by UDP sockets only. This improves the UDP socket throughput and is meant only for UDP sockets that have to sustain high TX traffic rate. However, this memory is not returned to the stack heap, it always belongs to UDP. A socket needs to have an option set in order to use the buffers pool (see the UDPSetOptions()). Use 0 to disable the feature.

TCPIP_UDP_USE_RX_CHECKSUM Macro

File

udp_config.h

C

```
#define TCPIP_UDP_USE_RX_CHECKSUM
```

Description

Check incoming packets to have proper checksum.

TCPIP_UDP_USE_TX_CHECKSUM Macro

File

udp_config.h

C

```
#define TCPIP_UDP_USE_TX_CHECKSUM
```

Description

Calculate and transmit a checksum when sending data. Checksum is not mandatory for UDP packets but is highly recommended. This will affect the UDP TX performance.

TCPIP_UDP_USE_POOL_BUFFERS Macro

File

udp_config.h

C

```
#define TCPIP_UDP_USE_POOL_BUFFERS false
```

Description

enable the build of the pre-allocated pool buffers option

Building the Library

This section lists the files that are available in the UDP module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/udp.c	UDP implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The UDP module depends on the following modules:

- TCP/IP Stack Library
- IPv4 Module

Library Interface

a) Socket Management Functions

	Name	Description
	TCPIP_UDP_ServerOpen	Opens a UDP socket as a server.
	TCPIP_UDP_ClientOpen	Opens a UDP socket as a client.
	TCPIP_UDP_IsOpened	Determines if a socket was opened.
	TCPIP_UDP_IsConnected	Determines if a socket has an established connection.
	TCPIP_UDP_Bind	Bind a socket to an address type, local port and address. This function is meant primarily for client sockets.
	TCPIP_UDP_RemoteBind	Bind a socket to an address type, remote port and address. This function is meant primarily for server sockets.
	TCPIP_UDP_Close	Closes a UDP socket and frees the handle.
	TCPIP_UDP_OptionsGet	Allows getting the options for a socket such as current RX/TX buffer size, etc.
	TCPIP_UDP_OptionsSet	Allows setting options to a socket like adjust RX/TX buffer size, etc
	TCPIP_UDP_SocketInfoGet	Returns information about a selected UDP socket.
	TCPIP_UDP_SocketNetGet	Gets the network interface of an UDP socket
	TCPIP_UDP_SocketNetSet	Sets the network interface for an UDP socket
	TCPIP_UDP_TxOffsetSet	Moves the pointer within the TX buffer.
	TCPIP_UDP_SourceIPAddressSet	Sets the source IP address of a socket
	TCPIP_UDP_BcastIPV4AddressSet	Sets the broadcast IP address of a socket Allows an UDP socket to send broadcasts.
	TCPIP_UDP_DestinationIPAddressSet	Sets the destination IP address of a socket
	TCPIP_UDP_DestinationPortSet	Sets the destination port of a socket
	TCPIP_UDP_Disconnect	Disconnects a UDP socket and re-initializes it.
	TCPIP_UDP_SignalHandlerDeregister	Deregisters a previously registered UDP socket signal handler.
	TCPIP_UDP_SignalHandlerRegister	Registers a UDP socket signal handler.
	TCPIP_UDP_Task	Standard TCP/IP stack module task function.
	TCPIP_UDP_SocketsNumberGet	Returns the number of existent UDP sockets.

b) Transmit Data Transfer Functions

	Name	Description
	TCPIP_UDP_PutIsReady	Determines how many bytes can be written to the UDP socket.
	TCPIP_UDP_TxPutIsReady	Determines how many bytes can be written to the UDP socket.
	TCPIP_UDP_ArrayPut	Writes an array of bytes to the UDP socket.

	TCPIP_UDP_StringPut	Writes a null-terminated string to the UDP socket.
	TCPIP_UDP_Put	Writes a byte to the UDP socket.
	TCPIP_UDP_TxCountGet	Returns the amount of bytes written into the UDP socket.
	TCPIP_UDP_Flush	Transmits all pending data in a UDP socket.

c) Receive Data Transfer Functions

	Name	Description
	TCPIP_UDP_GetIsReady	Determines how many bytes can be read from the UDP socket.
	TCPIP_UDP_ArrayGet	Reads an array of bytes from the UDP socket.
	TCPIP_UDP_Get	Reads a byte from the UDP socket.
	TCPIP_UDP_RxOffsetSet	Moves the read pointer within the socket RX buffer.
	TCPIP_UDP_Discard	Discards any remaining RX data from a UDP socket.

d) Data Types and Constants

	Name	Description
	INVALID_UDP_SOCKET	Indicates a UDP socket that is not valid
	UDP_PORT	Defines a UDP Port Number
	UDP_SOCKET	Provides a handle to a UDP Socket
	UDP_SOCKET_BCAST_TYPE	This is type UDP_SOCKET_BCAST_TYPE.
	UDP_SOCKET_INFO	Information about a socket
	UDP_SOCKET_OPTION	UDP socket options
	TCPIP_UDP_MODULE_CONFIG	UDP module run time configuration/initialization data.
	TCPIP_UDP_SIGNAL_FUNCTION	UDP Signal Handler.
	TCPIP_UDP_SIGNAL_HANDLE	UDP socket handle.
	TCPIP_UDP_SIGNAL_TYPE	UDP run-time signal types.

Description

This section describes the Application Programming Interface (API) functions of the UDP module.

Refer to each section for a detailed description.

a) Socket Management Functions

TCPIP_UDP_ServerOpen Function

Opens a UDP socket as a server.

File

udp.h

C

```
UDP_SOCKET TCPIP_UDP_ServerOpen(IP_ADDRESS_TYPE addType, UDP_PORT localPort, IP_MULTI_ADDRESS*
localAddress);
```

Returns

- INVALID_SOCKET - No sockets of the specified type were available to be opened.
- A UDP_SOCKET handle - Save this handle and use it when calling all other UDP APIs.

Description

Provides a unified method for opening UDP server sockets.

Preconditions

UDP is initialized.

Example

IP_ADDRESS_TYPE_IPV4 or IP_ADDRESS_TYPE_IPV6. It can be IP_ADDRESS_TYPE_ANY and the server socket will accept any incoming type of connection.

UDP_PORT localPort - UDP port on which to listen for connections

IP_MULTI_ADDRESS* localAddress - Local address to use. Can be NULL if any incoming interface will do.

Parameters

Parameters	Description
IP_ADDRESS_TYPE addType	The type of address being used.

Function

UDP_SOCKET TCPIP_UDP_ServerOpen(IP_ADDRESS_TYPE addType, UDP_PORT localPort,
IP_MULTI_ADDRESS* localAddress)

TCPIP_UDP_ClientOpen Function

Opens a UDP socket as a client.

File

udp.h

C

```
UDP_SOCKET TCPIP_UDP_ClientOpen(IP_ADDRESS_TYPE addType, UDP_PORT remotePort, IP_MULTI_ADDRESS*
remoteAddress);
```

Returns

- INVALID_SOCKET - No sockets of the specified type were available to be opened.
- A UDP_SOCKET handle - Save this handle and use it when calling all other UDP APIs.

Description

Provides a unified method for opening UDP client sockets.

Remarks

None.

Preconditions

UDP is initialized.

Parameters

Parameters	Description
IP_ADDRESS_TYPE addType	The type of address being used. Example: IP_ADDRESS_TYPE_IPV4 or IP_ADDRESS_TYPE_IPV6. It can also be IP_ADDRESS_TYPE_ANY if the type of the socket will be specified later (using TCPIP_UDP_Bind, TCPIP_UDP_RemoteBind).
UDP_PORT remotePort	The remote UDP port to which a connection should be made. The local port for client sockets will be automatically picked by the UDP module.
IP_MULTI_ADDRESS* remoteAddress	The remote address to connect to. Not used if addType == IP_ADDRESS_TYPE_ANY. Can be NULL if later set by a call to TCPIP_UDP_RemoteBind.

Function

TCPIP_UDP_ClientOpen(IP_ADDRESS_TYPE addType, UDP_PORT remotePort,
IP_MULTI_ADDRESS* remoteAddress)

TCPIP_UDP_IsOpened Macro

Determines if a socket was opened.

File

udp.h

C

```
#define TCPIP_UDP_IsOpened(hUDP) TCPIP_UDP_IsConnected(hUDP)
```

Description

This function determines if a socket was opened.

Remarks

This is a backward compatibility call.

Preconditions

None.

Parameters

Parameters	Description
hUDP	The socket to check.

Function

bool TCPIP_UDP_IsOpened(UDP_SOCKET hUDP)

TCPIP_UDP_IsConnected Function

Determines if a socket has an established connection.

File

udp.h

C

```
bool TCPIP_UDP_IsConnected(UDP_SOCKET hUDP);
```

Description

This function determines if a socket has an established connection to a remote node. Call this function after calling TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen to determine when the connection is set up and ready for use.

Remarks

An UDP server or client socket can always send data, as long as it has a valid destination address, even if there's no remote socket connected to it. This function will return true if the socket is opened and currently has a valid destination. Note that this is true if a client socket was opened with a remote host address, a socket received data from a remote host, or a explicit remote bind was done.

Preconditions

None.

Parameters

Parameters	Description
hUDP	The socket to check.

Function

bool TCPIP_UDP_IsConnected(UDP_SOCKET hUDP)

TCPIP_UDP_Bind Function

Bind a socket to an address type, local port and address. This function is meant primarily for client sockets.

File

udp.h

C

```
bool TCPIP_UDP_Bind(UDP_SOCKET hUDP, IP_ADDRESS_TYPE addType, UDP_PORT localPort, IP_MULTI_ADDRESS*
localAddress);
```

Returns

- true - Indicates success
- false - Indicates failure

Description

Sockets don't need specific binding, it is done automatically by the stack However, specific binding can be requested using this function. Works for

both client and server sockets. For a server socket it will restrict accepting connections of a specific type on a specific interface only. For a client socket it will force a specific address type and a local port and interface.

Remarks

If address type IP_ADDRESS_TYPE_ANY is used, the localAddress parameter won't be used and the socket won't change the local address. However, for the call to succeed, socket must have been created with IP_ADDRESS_TYPE_ANY type and must not be currently bound to a IP_ADDRESS_TYPE_IPV4/IP_ADDRESS_TYPE_IPV6 type.

If address type IP_ADDRESS_TYPE_IPV4/IP_ADDRESS_TYPE_IPV6 is used, then the socket type will be changed accordingly, and the localAddress will be used, if provided. The socket will be bound to this type of address. For the call to succeed the socket must currently have the type IP_ADDRESS_TYPE_ANY or to match the addType parameter.

If localAddress is the valid address of a network interface, and addType != IP_ADDRESS_TYPE_ANY, then the call will enforce UDP_OPTION_STRICT_NET on the socket.

If localPort is 0, the stack will assign a unique local port (if the socket doesn't already have a unique local port)

In order to change dynamically the type of address, the socket must have been created with a IP_ADDRESS_TYPE_ANY type and not currently bound to a different address type. TCPIP_UDP_Disconnect could be issued to remove a previous IP type binding.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen()/TCPIP_UDP_ClientOpen()(). hUDP - valid socket

Parameters

Parameters	Description
hUDP	The socket to bind.
addType	The type of address being used. Valid values are IP_ADDRESS_TYPE_ANY/IP_ADDRESS_TYPE_IPV4/IP_ADDRESS_TYPE_IPV6.
localPort	The local port to bind to.
localAddress	Local address to use.

Function

bool TCPIP_UDP_Bind(UDP_SOCKET hUDP, IP_ADDRESS_TYPE addType, UDP_PORT localPort,
IP_MULTI_ADDRESS* localAddress);

TCPIP_UDP_RemoteBind Function

Bind a socket to an address type, remote port and address. This function is meant primarily for server sockets.

File

udp.h

C

```
bool TCPIP_UDP_RemoteBind(UDP_SOCKET hUDP, IP_ADDRESS_TYPE addType, UDP_PORT remotePort, IP_MULTI_ADDRESS*
remoteAddress);
```

Returns

- true - Indicates success
- false - Indicates failure

Description

Sockets don't need specific remote binding, they should accept connections on any incoming interface. Therefore, the binding is done automatically by the stack. However, specific remote binding can be requested using this function. For a server socket it can be used to restrict accepting connections from a specific remote host. For a client socket it will just change the default binding done when the socket was opened.

Remarks

If address type IP_ADDRESS_TYPE_ANY is used, the remoteAddress parameter won't be used and the socket won't change the remote destination address. However, for the call to succeed, socket must have been created with IP_ADDRESS_TYPE_ANY type and must not be currently bound to a IP_ADDRESS_TYPE_IPV4/IP_ADDRESS_TYPE_IPV6 type.

If address type IP_ADDRESS_TYPE_IPV4/IP_ADDRESS_TYPE_IPV6 is used, then the socket type will be changed accordingly, and the remoteAddress will be used, if provided. The socket will be bound to this type of address. For the call to succeed the socket must currently have the type IP_ADDRESS_TYPE_ANY or to match the addType parameter.

If the remoteAddress != 0 and addType != IP_ADDRESS_TYPE_ANY, the call will enforce UDP_OPTION_STRICT_ADDRESS on the socket.

The remote port is always changed, even if remotePort == 0. It will enforce UDP_OPTION_STRICT_PORT on the socket.

In order to change dynamically the type of address, the socket must have been created with a IP_ADDRESS_TYPE_ANY type and not currently bound to a different address type. TCPIP_UDP_Disconnect could be issued to remove a previous IP type binding.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket

Parameters

Parameters	Description
hUDP	The socket to bind.
addType	The type of address being used. Valid values are IP_ADDRESS_TYPE_ANY/IP_ADDRESS_TYPE_IPV4/IP_ADDRESS_TYPE_IPV6.
remotePort	The remote port to bind to.
remoteAddress	Remote address to use.

Function

bool TCPIP_UDP_RemoteBind(UDP_SOCKET hUDP, IP_ADDRESS_TYPE addType,
UDP_PORT remotePort, IP_MULTI_ADDRESS* remoteAddress);

TCPIP_UDP_Close Function

Closes a UDP socket and frees the handle.

File

udp.h

C

```
bool TCPIP_UDP_Close(UDP_SOCKET hUDP);
```

Returns

- true - If the call succeeded
- false - If the call failed (no such socket)

Description

Closes a UDP socket and frees the handle. Call this function to release a socket and return it to the pool for use by future communications.

Remarks

Always close the socket when no longer in use. This will free the allocated resources, including the TX buffers.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket

Parameters

Parameters	Description
hUDP	The socket handle to be released.

Function

bool TCPIP_UDP_Close(UDP_SOCKET hUDP)

TCPIP_UDP_OptionsGet Function

Allows getting the options for a socket such as current RX/TX buffer size, etc.

File

udp.h

C

```
bool TCPIP_UDP_OptionsGet(UDP_SOCKET hUDP, UDP_SOCKET_OPTION option, void* optParam);
```

Returns

- true - Indicates success
- false - Indicates failure

Description

Various options can be retrieved at the socket level. This function provides compatibility with BSD implementations.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen()/TCPIP_UDP_ClientOpen()(). hUDP - valid socket

Parameters

Parameters	Description
hUDP	socket to get options for
option	specific option to get
optParam	pointer to an area that will receive the option value; this is option dependent
the size of the area has to be large enough to accommodate the specific option	• UDP_OPTION_STRICT_PORT - pointer to boolean • UDP_OPTION_STRICT_NET - pointer to boolean • UDP_OPTION_STRICT_ADDRESS - pointer to boolean • UDP_OPTION_BROADCAST - pointer to UDP_SOCKET_BCAST_TYPE • UDP_OPTION_BUFFER_POOL - pointer to boolean • UDP_OPTION_TX_BUFF - pointer to a 16 bit value to receive bytes of the TX buffer • UDP_OPTION_TX_QUEUE_LIMIT - pointer to an 8 bit value to receive the TX queue limit • UDP_OPTION_RX_QUEUE_LIMIT - pointer to an 8 bit value to receive the RX queue limit • UDP_OPTION_RX_AUTO_ADVANCE - pointer to boolean

Function

bool TCPIP_UDP_OptionsGet(UDP_SOCKET hUDP, UDP_SOCKET_OPTION option, void* optParam);

TCPIP_UDP_OptionsSet Function

Allows setting options to a socket like adjust RX/TX buffer size, etc

File

udp.h

C

```
bool TCPIP_UDP_OptionsSet(UDP_SOCKET hUDP, UDP_SOCKET_OPTION option, void* optParam);
```

Returns

- true - Indicates success
- false - Indicates failure

Description

Various options can be set at the socket level. This function provides compatibility with BSD implementations.

Remarks

Changing the UDP_OPTION_BUFFER_POOL will discard the data in the current socket buffer

- UDP_OPTION_TX_BUFF - 16-bit value in bytes of the TX buffer

the UDP_OPTION_TX_BUFF will discard the data in the current socket buffer

- UDP_OPTION_TX_QUEUE_LIMIT - 8-bit value of the TX queue limit
- UDP_OPTION_RX_QUEUE_LIMIT - 8-bit value of the RX queue limit
- UDP_OPTION_RX_AUTO_ADVANCE - boolean enable/disable

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen()/TCPIP_UDP_ClientOpen()(). hUDP - valid socket

Parameters

Parameters	Description
hUDP	socket to set options for
option	specific option to be set

optParam	the option value; this is option dependent: • UDP_OPTION_STRICT_PORT - boolean enable/disable • UDP_OPTION_STRICT_NET - boolean enable/disable • UDP_OPTION_STRICT_ADDRESS - boolean enable/disable • UDP_OPTION_BROADCAST - UDP_SOCKET_BCAST_TYPE • UDP_OPTION_BUFFER_POOL - boolean enable/disable

Function

bool TCPIP_UDP_OptionsSet(UDP_SOCKET hUDP, UDP_SOCKET_OPTION option, void* optParam);

TCPIP_UDP_SocketInfoGet Function

Returns information about a selected UDP socket.

File

udp.h

C

```
bool TCPIP_UDP_SocketInfoGet(UDP_SOCKET hUDP, UDP_SOCKET_INFO* pInfo);
```

Returns

- true - if the call succeeded
- false - if no such socket or invalid pInfo

Description

This function will fill a user passed UDP_SOCKET_INFO structure with status of the selected socket.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen()/TCPIP_UDP_ClientOpen()(). hUDP - valid socket pInfo - valid address of a UDP_SOCKET_INFO structure

Parameters

Parameters	Description
UDP_SOCKET hUDP	Socket for which information is to be obtained
UDP_SOCKET_INFO* pInfo	pointer to UDP_SOCKET_INFO to receive socket information

Function

bool TCPIP_UDP_SocketInfoGet(UDP_SOCKET hUDP, UDP_SOCKET_INFO* pInfo)

TCPIP_UDP_SocketNetGet Function

Gets the network interface of an UDP socket

File

udp.h

C

```
TCPIP_NET_HANDLE TCPIP_UDP_SocketNetGet(UDP_SOCKET hUDP);
```

Returns

Handle of the interface that socket currently uses.

Description

This function returns the interface handle of an UDP socket

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket

Parameters

Parameters	Description
hUDP	The UDP socket

Function

TCPIP_NET_HANDLE TCPIP_UDP_SocketNetGet(UDP_SOCKET hUDP)

TCPIP_UDP_SocketNetSet Function

Sets the network interface for an UDP socket

File

udp.h

C

```
bool TCPIP_UDP_SocketNetSet(UDP_SOCKET hUDP, TCPIP_NET_HANDLE hNet);
```

Returns

- true - Indicates success
- false - Indicates failure

Description

This function sets the network interface for an UDP socket

Remarks

A NULL hNet can be passed (0) so that the current socket network interface selection will be cleared

If the hNet != 0, it will enforce UDP_OPTION_STRICT_NET on the socket.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket

Parameters

Parameters	Description
hUDP	The UDP socket
hNet	interface handle

Function

bool TCPIP_UDP_SocketNetSet(UDP_SOCKET hUDP, TCPIP_NET_HANDLE hNet)

TCPIP_UDP_TxOffsetSet Function

Moves the pointer within the TX buffer.

File

udp.h

C

```
bool TCPIP_UDP_TxOffsetSet(UDP_SOCKET hUDP, uint16_t wOffset, bool relative);
```

Returns

- true - if the offset was valid and the write pointer has been moved
- false - if the offset was not valid

Description

This function allows the write location within the TX buffer to be specified. Future calls to TCPIP_UDP_Put, TCPIP_UDP_ArrayPut, TCPIP_UDP_StringPut, etc will write data from the indicated location.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket

Parameters

Parameters	Description
hUDP	UDP socket handle
wOffset	Offset in the UDP packet data payload to move the write pointer.
relative	if true, the wOffset is added to the current write pointer. else the wOffset is from the beginning of the UDP buffer

Function

bool TCPIP_UDP_TxOffsetSet(UDP_SOCKET hUDP, uint16_t wOffset, bool relative)

TCPIP_UDP_SourceIPAddressSet Function

Sets the source IP address of a socket

File

udp.h

C

```
bool TCPIP_UDP_SourceIPAddressSet(UDP_SOCKET hUDP, IP_ADDRESS_TYPE addType, IP_MULTI_ADDRESS* localAddress);
```

Returns

- true - Indicates success
- false - Indicates failure:
- invalid socket
- invalid socket address type
- unspecified localAddress

Description

This function sets the IP source address, which allows changing the source P address dynamically.

Remarks

The call will fail if localAddress is 0. The source IP address will not be changed.

Preconditions

UDP initialized UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket localAddress - valid address pointer

Parameters

Parameters	Description
hUDP	the UDP socket
addType	Type of address: IPv4/IPv6
localAddress	pointer to an address to use

Function

bool TCPIP_UDP_SourceIPAddressSet(UDP_SOCKET hUDP, IP_ADDRESS_TYPE addType,
IP_MULTI_ADDRESS* localAddress)

TCPIP_UDP_BcastIPV4AddressSet Function

Sets the broadcast IP address of a socket Allows an UDP socket to send broadcasts.

File

udp.h

C

```
bool TCPIP_UDP_BcastIPV4AddressSet(UDP_SOCKET hUDP, UDP_SOCKET_BCAST_TYPE bcastType, TCPIP_NET_HANDLE hNet);
```

Returns

- true - Indicates success
- false - Indicates failure:

- invalid socket
- invalid socket address type
- a broadcast for the specified interface could not be obtained
- invalid broadcast type specified

Description

It sets the broadcast address for the socket

Remarks

This function allows changing of the destination IPv4 address dynamically.

However, the call will fail if the socket was previously set to broadcast using the TCPIP_UDP_OptionsSet call. TCPIP_UDP_OptionsSet takes precedence.

Preconditions

UDP initialized UDP socket should have been opened with TCPIP_UDP_ServerOpen()/TCPIP_UDP_ClientOpen()(). hUDP - valid socket

Parameters

Parameters	Description
hUDP	the UDP socket
bcastType	Type of broadcast
hNet	handle of an interface to use for the network directed broadcast Not used for network limited broadcast

Function

bool TCPIP_UDP_BcastIPV4AddressSet(UDP_SOCKET hUDP, UDP_SOCKET_BCAST_TYPE bcastType,
TCPIP_NET_HANDLE hNet)

TCPIP_UDP_DestinationIPAddressSet Function

Sets the destination IP address of a socket

File

udp.h

C

```
bool TCPIP_UDP_DestinationIPAddressSet(UDP_SOCKET hUDP, IP_ADDRESS_TYPE addType, IP_MULTI_ADDRESS*
remoteAddress);
```

Returns

- true - Indicates success
- false - Indicates failure:
- invalid socket
- invalid socket address type
- socket is of broadcast type

Description

- It sets the IP destination address This allows changing the IP destination address dynamically.

Remarks

The call will fail if the socket was previously set to broadcast using the TCPIP_UDP_OptionsSet call. TCPIP_UDP_OptionsSet takes precedence.

The call will fail if remoteAddress is 0. The destination IP address will not be changed.

Preconditions

UDP initialized UDP socket should have been opened with TCPIP_UDP_ServerOpen()/TCPIP_UDP_ClientOpen()(). hUDP - valid socket
remoteAddress - valid address pointer

Parameters

Parameters	Description
hUDP	the UDP socket
addType	Type of address: IPv4/IPv6
remoteAddress	pointer to an address to use

Function

bool TCPIP_UDP_DestinationIPAddressSet(UDP_SOCKET hUDP, IP_ADDRESS_TYPE addType,
IP_MULTI_ADDRESS* remoteAddress)

TCPIP_UDP_DestinationPortSet Function

Sets the destination port of a socket

File

udp.h

C

```
bool TCPIP_UDP_DestinationPortSet(UDP_SOCKET s, UDP_PORT remotePort);
```

Returns

- true - Indicates success
- false - Indicates an invalid socket

Description

This function sets the destination port, which allows changing the destination port dynamically.

Remarks

The destination remote port will always be changed, even if remotePort == 0.

It will not change the UDP_OPTION_STRICT_PORT on the socket.

Preconditions

UDP initialized UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket

Parameters

Parameters	Description
hUDP	the UDP socket
remotePort	destination port to use

Function

bool TCPIP_UDP_DestinationPortSet(UDP_SOCKET s, UDP_PORT remotePort)

TCPIP_UDP_Disconnect Function

Disconnects a UDP socket and re-initializes it.

File

udp.h

C

```
bool TCPIP_UDP_Disconnect(UDP_SOCKET hUDP, bool flushRxQueue);
```

Returns

- true - Indicates success
- false - Indicates failure

Description

Disconnects a UDP socket and re-initializes it. Call this function to return the socket to its initial open state and to use it for future communication.

This function is meant especially for server sockets that could listen on multiple interfaces and on both IPv4 and IPv6 networks.

When a server socket received an inbound IPv4 connection it will be bound to IPv4 connections until it's closed or disconnected. Same is true for IPv6 connections.

Remarks

The call will try to maintain as much as possible from the socket state.

This will free the allocated TX buffers if the socket was opened with IP_ADDRESS_TYPE_ANY.

All the pending RX packets will be cleared when flushRxQueue is set. Otherwise the packets will be kept and will be available for next read

operations.

Note that if the RX pending packets exist and are not flushed, the socket will be bound immediately to the connection corresponding to the pending packet in the queue.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen()/TCPIP_UDP_ClientOpen()(). hUDP - valid socket

Parameters

Parameters	Description
hUDP	The socket handle to be disconnected.
flushRxQueue	boolean to flush the pending RX queue

Function

bool TCPIP_UDP_Disconnect(UDP_SOCKET hUDP, bool flushRxQueue)

TCPIP_UDP_SignalHandlerDeregister Function

Deregisters a previously registered UDP socket signal handler.

File

udp.h

C

```
bool TCPIP_UDP_SignalHandlerDeregister(UDP_SOCKET s, TCPIP_UDP_SIGNAL_HANDLE hSig);
```

Returns

- true - if the call succeeds
- false - if no such handler is registered

Description

Deregisters the UDP socket signal handler.

Preconditions

hSig valid UDP signal handle.

Parameters

Parameters	Description
s	The UDP socket
hSig	A handle returned by a previous call to TCPIP_UDP_SignalHandlerRegister.

Function

TCPIP_UDP_SignalHandlerDeregister(UDP_SOCKET s, TCPIP_UDP_SIGNAL_HANDLE hSig)

TCPIP_UDP_SignalHandlerRegister Function

Registers a UDP socket signal handler.

File

udp.h

C

```
TCPIP_UDP_SIGNAL_HANDLE TCPIP_UDP_SignalHandlerRegister(UDP_SOCKET s, TCPIP_UDP_SIGNAL_TYPE sigMask,
TCPIP_UDP_SIGNAL_FUNCTION handler, const void* hParam);
```

Returns

Returns a valid handle if the call succeeds, or a null handle if the call failed (null handler, no such socket, existent handler).

Description

This function registers a UDP socket signal handler. The UDP module will call the registered handler when a UDP signal (TCPIP_UDP_SIGNAL_TYPE) occurs.

Remarks

Only one signal handler per socket is supported. A new handler does not override the existent one. Instead TCPIP_UDP_SignalHandlerDeregister has to be explicitly called.

The handler has to be short and fast. It is meant for setting an event flag, not for lengthy processing!

The hParam is passed by the client but is currently not used and should be 0.

For multi-threaded systems the TCP/IP packet dispatch does not occur on the user thread. The signal handler will be called on a different thread context. It is essential that this handler is non blocking and really fast.

For multi-threaded systems, once set, it is not recommended to change the signal handler at run time. Synchronization between user threads and packet dispatch threads could be difficult. If really need to be changed, make sure that the old handler could still be called and it should be valid until the new one is taken into account. TCPIP_UDP_SignalHandlerDeregister needs to be called before registering another handler.

Preconditions

UDP valid socket.

Parameters

Parameters	Description
s	The UDP socket
sigMask	mask of signals to be reported
handler	signal handler to be called when a UDP signal occurs.
hParam	Parameter to be used in the handler call. This is user supplied and is not used by the UDP module. Currently not used and it should be null.

Function

TCPIP_UDP_SignalHandlerRegister(UDP_SOCKET s, TCPIP_UDP_SIGNAL_TYPE sigMask,
TCPIP_UDP_SIGNAL_FUNCTION handler, const void* hParam)

TCPIP_UDP_Task Function

Standard TCP/IP stack module task function.

File

udp.h

C

```
void TCPIP_UDP_Task();
```

Returns

None.

Description

This function performs UDP module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The UDP module should have been initialized.

Function

void TCPIP_UDP_Task(void)

TCPIP_UDP_SocketsNumberGet Function

Returns the number of existent UDP sockets.

File

udp.h

C

```
int TCPIP_UDP_SocketsNumberGet();
```

Returns

The number of UDP sockets

Description

This function returns the number of created UDP sockets. This is the maximum number of sockets that can be opened at any moment as it's been passed as parameter when UDP module was created.

Preconditions

UDP module properly initialized

Function

int TCPIP_UDP_SocketsNumberGet(void)

b) Transmit Data Transfer Functions

TCPIP_UDP_PutIsReady Function

Determines how many bytes can be written to the UDP socket.

File

udp.h

C

```
uint16_t TCPIP_UDP_PutIsReady(UDP_SOCKET hUDP);
```

Returns

The number of bytes that can be written to this socket.

Description

This function determines how many bytes can be written to the specified UDP socket.

Remarks

If the current socket TX buffer is in use (in traffic), this function will allocate a new TX buffer. Otherwise the current TX buffer will be used.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket

Parameters

Parameters	Description
hUDP	UDP socket handle

Function

uint16_t TCPIP_UDP_PutIsReady(UDP_SOCKET hUDP)

TCPIP_UDP_TxPutIsReady Function

Determines how many bytes can be written to the UDP socket.

File

udp.h

C

```
uint16_t TCPIP_UDP_TxPutIsReady(UDP_SOCKET hUDP, unsigned short count);
```

Returns

The number of bytes that can be written to this socket.

Description

This function returns the number of bytes that can be written to the specified UDP socket.

Remarks

The function won't increase the size of the UDP TX buffer. If this is needed use TCPIP_UDP_OptionsSet. The count variable is not used.

The function is similar to the TCPIP_UDP_PutIsReady and maintained for backward compatibility.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket

Parameters

Parameters	Description
hUDP	UDP socket handle
count	Number of bytes requested

Function

uint16_t TCPIP_UDP_TxPutIsReady(UDP_SOCKET hUDP, unsigned short count)

TCPIP_UDP_ArrayPut Function

Writes an array of bytes to the UDP socket.

File

udp.h

C

```
uint16_t TCPIP_UDP_ArrayPut(UDP_SOCKET hUDP, const uint8_t * cData, uint16_t wDataLen);
```

Returns

The number of bytes successfully placed in the UDP transmit buffer. If this value is less than wDataLen, then the buffer became full and the input was truncated.

Description

This function writes an array of bytes to the UDP socket, while incrementing the socket write pointer. TCPIP_UDP_PutIsReady could be used before calling this function to verify that there is room in the socket buffer.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket cData - valid pointer

Parameters

Parameters	Description
hUDP	UDP socket handle
cData	The array to write to the socket.
wDataLen	Number of bytes from cData to be written.

Function

uint16_t TCPIP_UDP_ArrayPut(UDP_SOCKET hUDP, const uint8_t *cData, uint16_t wDataLen)

TCPIP_UDP_StringPut Function

Writes a null-terminated string to the UDP socket.

File

udp.h

C

```
const uint8_t* TCPIP_UDP_StringPut(UDP_SOCKET hUDP, const uint8_t * strData);
```

Returns

A pointer to the byte following the last byte written. Note that this is different than the TCPIP_UDP_ArrayPut functions. If this pointer does not dereference to a NULL byte, then the buffer became full and the input data was truncated.

Description

This function writes a null-terminated string to the UDP socket while incrementing the socket write pointer. TCPIP_UDP_PutIsReady could be used before calling this function to verify that there is room in the socket buffer.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket strData - valid pointer

Parameters

Parameters	Description
hUDP	UDP socket handle
strData	Pointer to the string to be written to the socket.

Function

uint8_t* TCPIP_UDP_StringPut(UDP_SOCKET hUDP, const uint8_t *strData)

TCPIP_UDP_Put Function

Writes a byte to the UDP socket.

File

udp.h

C

```
uint16_t TCPIP_UDP_Put(UDP_SOCKET hUDP, uint8_t v);
```

Description

This function writes a single byte to the UDP socket, while incrementing the socket write pointer. TCPIP_UDP_PutIsReady could be used before calling this function to verify that there is room in the socket buffer.

Remarks

This function is very inefficient and its use is discouraged. A buffered approach (TCPIP_UDP_ArrayPut) is preferred.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket

Parameters

Parameters	Description
hUDP	UDP socket handle
v	The byte to be loaded into the transmit buffer.

Function

uint16_t TCPIP_UDP_Put(UDP_SOCKET hUDP, uint8_t v)

TCPIP_UDP_TxCountGet Function

Returns the amount of bytes written into the UDP socket.

File

udp.h

C

```
uint16_t TCPIP_UDP_TxCountGet(UDP_SOCKET hUDP);
```

Description

This function returns the amount of bytes written into the UDP socket, i.e. the current position of the write pointer.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket

Parameters

Parameters	Description
hUDP	UDP socket handle

Function

uint16_t TCPIP_UDP_TxCountGet(UDP_SOCKET hUDP)

TCPIP_UDP_Flush Function

Transmits all pending data in a UDP socket.

File

udp.h

C

```
uint16_t TCPIP_UDP_Flush(UDP_SOCKET hUDP);
```

Returns

The number of bytes that currently were in the socket TX buffer and have been flushed. Otherwise, 0 if the packet could not be transmitted:

- invalid socket
- invalid remote address
- no route to the remote host could be found

Description

This function builds a UDP packet with the pending TX data and marks it for transmission over the network interface. There is no UDP state machine to send the socket data automatically. The UDP socket client must call this function to actually send the data over the network.

Remarks

Note that a UDP socket must be flushed to send data over the network. There is no UDP state machine (auto transmit) for UDP sockets.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket

Parameters

Parameters	Description
hUDP	UDP socket handle

Function

uint16_t TCPIP_UDP_Flush(UDP_SOCKET hUDP)

c) Receive Data Transfer Functions

TCPIP_UDP_GetIsReady Function

Determines how many bytes can be read from the UDP socket.

File

udp.h

C

```
uint16_t TCPIP_UDP_GetIsReady(UDP_SOCKET hUDP);
```

Returns

The number of bytes that can be read from this socket.

Description

This function will return the number of bytes that are available in the specified UDP socket RX buffer.

Remarks

The UDP socket queues incoming RX packets in an internal queue.

If currently there is no RX packet processed (as a result of retrieving all available bytes with TCPIP_UDP_ArrayGet, for example), this call will advance the RX packet to be processed to the next queued packet.

If a RX packet is currently processed, the call will return the number of bytes left to be read from this packet.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket

Parameters

Parameters	Description
hUDP	UDP socket handle

Function

uint16_t TCPIP_UDP_GetIsReady(UDP_SOCKET hUDP)

TCPIP_UDP_ArrayGet Function

Reads an array of bytes from the UDP socket.

File

udp.h

C

```
uint16_t TCPIP_UDP_ArrayGet(UDP_SOCKET hUDP, uint8_t * cData, uint16_t wDataLen);
```

Returns

The number of bytes successfully read from the UDP buffer. If this value is less than wDataLen, then the buffer was emptied and no more data is available.

Description

This function reads an array of bytes from the UDP socket, while adjusting the current read pointer and decrementing the remaining bytes available. TCPIP_UDP_GetIsReady should be used before calling this function to get the number of the available bytes in the socket.

Remarks

For discarding a number of bytes in the RX buffer the TCPIP_UDP_RxOffsetSet() can also be used.

The UDP socket queues incoming RX packets in an internal queue. This call will try to retrieve the bytes from the current processing packet but it won't advance the processed packet. TCPIP_UDP_GetIsReady should be called to advance the processed RX packet.

TCPIP_UDP_Discard should be called when done processing the current RX packet.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket

Parameters

Parameters	Description
hUDP	UDP socket handle
cData	The buffer to receive the bytes being read. If NULL, the bytes are simply discarded
wDataLen	Number of bytes to be read from the socket.

Function

uint16_t TCPIP_UDP_ArrayGet(UDP_SOCKET hUDP, uint8_t *cData, uint16_t wDataLen)

TCPIP_UDP_Get Function

Reads a byte from the UDP socket.

File

udp.h

C

```
uint16_t TCPIP_UDP_Get(UDP_SOCKET hUDP, uint8_t * v);
```

Description

This function reads a single byte from the UDP socket, while decrementing the remaining RX buffer length. TCPIP_UDP_GetIsReady should be used before calling this function to get the number of bytes available in the socket.

Remarks

This function is very inefficient and its usage is discouraged. A buffered approach (TCPIP_UDP_ArrayGet) is preferred.

See the previous notes for TCPIP_UDP_ArrayGet function.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket

Parameters

Parameters	Description
hUDP	socket handle
v	The buffer to receive the data being read.

Function

uint16_t TCPIP_UDP_Get(UDP_SOCKET hUDP, uint8_t *v)

TCPIP_UDP_RxOffsetSet Function

Moves the read pointer within the socket RX buffer.

File

udp.h

C

```
void TCPIP_UDP_RxOffsetSet(UDP_SOCKET hUDP, uint16_t rOffset);
```

Returns

None.

Description

This function allows the user to specify the read location within the socket RX buffer. Future calls to TCPIP_UDP_Get and TCPIP_UDP_ArrayGet will read data from the indicated location forward.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket

Parameters

Parameters	Description
hUDP	UDP socket handle
wOffset	Offset from beginning of UDP packet data payload to place the read pointer.

Function

void TCPIP_UDP_RxOffsetSet(UDP_SOCKET hUDP, uint16_t wOffset)

TCPIP_UDP_Discard Function

Discards any remaining RX data from a UDP socket.

File

udp.h

C

```
uint16_t TCPIP_UDP_Discard(UDP_SOCKET hUDP);
```

Returns

Number of discarded bytes, if any.

Description

This function discards any remaining received data in the UDP socket.

Remarks

The UDP socket queues incoming RX packets in an internal queue.

This call will discard the remaining bytes (if any) in the current RX packet and will advance the RX packet to be processed to the next queued packet.

This function should be normally called after retrieving the available bytes with TCPIP_UDP_ArrayGet.

When data available, calling it repeatedly will discard one pending RX packet at a time.

Note that a call to TCPIP_UDP_Discard is not needed if all bytes are retrieved with TCPIP_UDP_ArrayGet and then TCPIP_UDP_GetIsReady is called.

Preconditions

UDP socket should have been opened with TCPIP_UDP_ServerOpen/TCPIP_UDP_ClientOpen. hUDP - valid socket

Parameters

Parameters	Description
hUDP	socket handle

Function

uint16_t TCPIP_UDP_Discard(UDP_SOCKET hUDP)

d) Data Types and Constants

INVALID_UDP_SOCKET Macro

File

udp.h

C

```
#define INVALID_UDP_SOCKET (-1)        // Indicates a UDP socket that is not valid
```

Description

Indicates a UDP socket that is not valid

UDP_PORT Type

File

udp.h

C

```
typedef uint16_t UDP_PORT;
```

Description

Defines a UDP Port Number

UDP_SOCKET Type

File

udp.h

C

```
typedef int16_t UDP_SOCKET;
```

Description

Provides a handle to a UDP Socket

UDP_SOCKET_BCAST_TYPE Enumeration

File

udp.h

C

```
typedef enum {
  UDP_BCAST_NONE,
  UDP_BCAST_NETWORK_LIMITED,
  UDP_BCAST_NETWORK_DIRECTED
} UDP_SOCKET_BCAST_TYPE;
```

Members

Members	Description
UDP_BCAST_NONE	no broadcast
UDP_BCAST_NETWORK_LIMITED	network limited broadcast
UDP_BCAST_NETWORK_DIRECTED	network directed broadcast

Description

This is type UDP_SOCKET_BCAST_TYPE.

UDP_SOCKET_INFO Structure

File

udp.h

C

```
typedef struct {
  IP_ADDRESS_TYPE addressType;
  IP_MULTI_ADDRESS remoteIPaddress;
  IP_MULTI_ADDRESS localIPaddress;
  IP_MULTI_ADDRESS sourceIPaddress;
  IP_MULTI_ADDRESS destIPaddress;
  UDP_PORT remotePort;
  UDP_PORT localPort;
  TCPIP_NET_HANDLE hNet;
  uint16_t rxQueueSize;
  uint16_t txSize;
} UDP_SOCKET_INFO;
```

Members

Members	Description
IP_ADDRESS_TYPE addressType;	address type of the socket
IP_MULTI_ADDRESS remoteIPaddress;	current socket destination address
IP_MULTI_ADDRESS localIPaddress;	current socket source address
IP_MULTI_ADDRESS sourceIPaddress;	source address of the last packet
IP_MULTI_ADDRESS destIPaddress;	destination address of the last packet
UDP_PORT remotePort;	Port number associated with remote node
UDP_PORT localPort;	local port number
TCPIP_NET_HANDLE hNet;	associated interface
uint16_t rxQueueSize;	packets waiting in the rx queue
uint16_t txSize;	tx buffer size

Description

Information about a socket

UDP_SOCKET_OPTION Enumeration

File

udp.h

C

```
typedef enum {
  UDP_OPTION_STRICT_PORT,
  UDP_OPTION_STRICT_NET,
  UDP_OPTION_STRICT_ADDRESS,
  UDP_OPTION_BROADCAST,
  UDP_OPTION_BUFFER_POOL,
  UDP_OPTION_TX_BUFF,
  UDP_OPTION_TX_QUEUE_LIMIT,
  UDP_OPTION_RX_QUEUE_LIMIT,
  UDP_OPTION_RX_AUTO_ADVANCE
} UDP_SOCKET_OPTION;
```

Members

Members	Description
UDP_OPTION_STRICT_PORT	When connection is done the socket stores the remote host local port. If option is enabled the remote host local port is always checked to match the initial one. If disabled the remote host local port is not checked. Disabled by default on a socket server. Enabled by default on a client socket.
UDP_OPTION_STRICT_NET	When connection is done the socket stores the network interface the connection occurred on. If option is enabled the socket accepts data only from the interface that matches the initial connection. If disabled the socket receives data from any remote host regardless of the interface on which the packet arrived. Disabled by default on a socket server. Enabled by default on a client socket.
UDP_OPTION_STRICT_ADDRESS	When connection is done the socket stores the address of the remote host. If option is enabled the socket accepts data only from the host with address that matches the initial connection. If disabled the socket receives data from any remote host regardless of the address of that host. Disabled by default on a socket server. Enabled by default on a client socket.
UDP_OPTION_BROADCAST	Enables the Broadcast transmission by the socket
UDP_OPTION_BUFFER_POOL	Enables the socket to use the private UDP buffers pool. The size of the TX buffer has to be less than the size of the buffers in the pool.
UDP_OPTION_TX_BUFF	Request different TX buffer size. Has to call TCPIP_UDP_OptionsGet to see the exact space allocated.
UDP_OPTION_TX_QUEUE_LIMIT	Sets the maximum number of packets that can be queued/allocated by an UDP socket at a certain time. For sockets that need to transmit a lot of data (Iperf client, for example), especially on slow connections this limit prevents running out of memory because the MAC transfer cannot keep up with the UDP packet allocation rate imposed by the application. Adjust depending on the size of the UDP TX buffer, the connection speed and the amount of memory available to the stack.
UDP_OPTION_RX_QUEUE_LIMIT	Sets the maximum number of RX packets that can be queued by an UDP socket at a certain time. Setting this value to 0 will disable the socket receive functionality
UDP_OPTION_RX_AUTO_ADVANCE	Sets the RX auto advance option for a socket. The option is off by default If set, the option will automatically advance the socket to the next awaiting RX packet when a call to TCPIP_UDP_ArrayGet is made and no more data is available from the current packet. Setting this option forces the socket user to correctly monitor the number of bytes available and issue a TCPIP_UDP_Discard only when there's bytes left in the current packet. However sequential calls to TCPIP_UDP_ArrayGet can be made without the need to insert calls to TCPIP_UDP_Discard If cleared (default case) the socket user can safely issue a TCPIP_UDP_Discard even after calling TCPIP_UDP_ArrayGet to read all the bytes from the current RX packet Note that TCPIP_UDP_GetIsReady will always advance the current RX packet when no more data is available in the current packet. Even when the option is cleared a call to TCPIP_UDP_Discard is still not needed if all bytes are retrieved with TCPIP_UDP_ArrayGet and then TCPIP_UDP_GetIsReady is called.

Description

UDP socket options

TCPIP_UDP_MODULE_CONFIG Structure

UDP module run time configuration/initialization data.

File

udp.h

C

```
typedef struct {
  uint16_t nSockets;
  uint16_t sktTxBuffSize;
  uint16_t poolBuffers;
  uint16_t poolBufferSize;
} TCPIP_UDP_MODULE_CONFIG;
```

Members

Members	Description
uint16_t nSockets;	number of sockets to be created
uint16_t sktTxBuffSize;	default size of the socket TX buffer
uint16_t poolBuffers;	number of buffers in the pool; 0 if none
uint16_t poolBufferSize;	size of the buffers in the pool; all equal

Description

Structure: TCPIP_UDP_MODULE_CONFIG

UDP module configuration/initialization

TCPIP_UDP_SIGNAL_FUNCTION Type

UDP Signal Handler.

File

udp.h

C

```
typedef void (* TCPIP_UDP_SIGNAL_FUNCTION)(UDP_SOCKET hUDP, TCPIP_NET_HANDLE hNet, TCPIP_UDP_SIGNAL_TYPE
sigType, const void* param);
```

Description

Type: TCPIP_UDP_SIGNAL_FUNCTION

Prototype of a UDP signal handler. Socket user can register a handler for the UDP socket. Once an UDP signals occurs the registered handler will be called.

Remarks

The handler has to be short and fast. It is meant for setting an event flag, not for lengthy processing!

Parameters

Parameters	Description
hUDP	UDP socket to be used
hNet	the network interface on which the event has occurred
sigType	type of UDP signal that has occurred
param	additional parameter that can has been specified at the handler registration call Currently not used and it will be null.

TCPIP_UDP_SIGNAL_HANDLE Type

UDP socket handle.

File

udp.h

C

```
typedef const void* TCPIP_UDP_SIGNAL_HANDLE;
```

Description

Type: TCPIP_UDP_SIGNAL_HANDLE

A handle that a socket client can use after the signal handler has been registered.

TCPIP_UDP_SIGNAL_TYPE Enumeration

UDP run-time signal types.

File

udp.h

C

```
typedef enum {
  TCPIP_UDP_SIGNAL_TX_DONE = 0x0001,
  TCPIP_UDP_SIGNAL_RX_DATA = 0x0100
} TCPIP_UDP_SIGNAL_TYPE;
```

Members

Members	Description
TCPIP_UDP_SIGNAL_TX_DONE = 0x0001	A data packet was successfully transmitted on the interface There may be available buffer space to send new data
TCPIP_UDP_SIGNAL_RX_DATA = 0x0100	A data packet was successfully received and there is data available for this socket

Description

Enumeration: TCPIP_UDP_SIGNAL_TYPE

Description of the signals/events that a UDP socket can generate.

Remarks

These signals are used in the socket event handling notification functions. Currently a UDP notification doesn't set multiple flags as the TX and RX events are handled separately.

The signals are 16 bits wide.

Files

Name	Description
udp.h	UDP is a standard transport layer protocol described in RFC 768. It provides fast but unreliable data-gram based transfers over networks, and forms the foundation SNTP, SNMP, DNS, and many other protocol standards
udp_config.h	UDP Configuration file

Description

This section lists the source and header files used by the library.

udp.h

UDP is a standard transport layer protocol described in RFC 768. It provides fast but unreliable data-gram based transfers over networks, and forms the foundation SNTP, SNMP, DNS, and many other protocol standards

Enumerations

	Name	Description
	TCPIP_UDP_SIGNAL_TYPE	UDP run-time signal types.
	UDP_SOCKET_BCAST_TYPE	This is type UDP_SOCKET_BCAST_TYPE.
	UDP_SOCKET_OPTION	UDP socket options

Functions

	Name	Description
	TCPIP_UDP_ArrayGet	Reads an array of bytes from the UDP socket.
	TCPIP_UDP_ArrayPut	Writes an array of bytes to the UDP socket.
	TCPIP_UDP_BcastIPV4AddressSet	Sets the broadcast IP address of a socket Allows an UDP socket to send broadcasts.
	TCPIP_UDP_Bind	Bind a socket to an address type, local port and address. This function is meant primarily for client sockets.
	TCPIP_UDP_ClientOpen	Opens a UDP socket as a client.
	TCPIP_UDP_Close	Closes a UDP socket and frees the handle.
	TCPIP_UDP_DestinationIPAddressSet	Sets the destination IP address of a socket
	TCPIP_UDP_DestinationPortSet	Sets the destination port of a socket
	TCPIP_UDP_Discard	Discards any remaining RX data from a UDP socket.
	TCPIP_UDP_Disconnect	Disconnects a UDP socket and re-initializes it.
	TCPIP_UDP_Flush	Transmits all pending data in a UDP socket.
	TCPIP_UDP_Get	Reads a byte from the UDP socket.
	TCPIP_UDP_GetIsReady	Determines how many bytes can be read from the UDP socket.
	TCPIP_UDP_IsConnected	Determines if a socket has an established connection.
	TCPIP_UDP_OptionsGet	Allows getting the options for a socket such as current RX/TX buffer size, etc.
	TCPIP_UDP_OptionsSet	Allows setting options to a socket like adjust RX/TX buffer size, etc
	TCPIP_UDP_Put	Writes a byte to the UDP socket.
	TCPIP_UDP_PutIsReady	Determines how many bytes can be written to the UDP socket.
	TCPIP_UDP_RemoteBind	Bind a socket to an address type, remote port and address. This function is meant primarily for server sockets.
	TCPIP_UDP_RxOffsetSet	Moves the read pointer within the socket RX buffer.
	TCPIP_UDP_ServerOpen	Opens a UDP socket as a server.
	TCPIP_UDP_SignalHandlerDeregister	Deregisters a previously registered UDP socket signal handler.
	TCPIP_UDP_SignalHandlerRegister	Registers a UDP socket signal handler.
	TCPIP_UDP_SocketInfoGet	Returns information about a selected UDP socket.
	TCPIP_UDP_SocketNetGet	Gets the network interface of an UDP socket
	TCPIP_UDP_SocketNetSet	Sets the network interface for an UDP socket
	TCPIP_UDP_SocketsNumberGet	Returns the number of existent UDP sockets.
	TCPIP_UDP_SourceIPAddressSet	Sets the source IP address of a socket
	TCPIP_UDP_StringPut	Writes a null-terminated string to the UDP socket.
	TCPIP_UDP_Task	Standard TCP/IP stack module task function.
	TCPIP_UDP_TxCountGet	Returns the amount of bytes written into the UDP socket.
	TCPIP_UDP_TxOffsetSet	Moves the pointer within the TX buffer.
	TCPIP_UDP_TxPutIsReady	Determines how many bytes can be written to the UDP socket.

Macros

	Name	Description
	INVALID_UDP_SOCKET	Indicates a UDP socket that is not valid
	TCPIP_UDP_IsOpened	Determines if a socket was opened.

Structures

	Name	Description
	TCPIP_UDP_MODULE_CONFIG	UDP module run time configuration/initialization data.
	UDP_SOCKET_INFO	Information about a socket

Types

	Name	Description
	TCPIP_UDP_SIGNAL_FUNCTION	UDP Signal Handler.
	TCPIP_UDP_SIGNAL_HANDLE	UDP socket handle.
	UDP_PORT	Defines a UDP Port Number
	UDP_SOCKET	Provides a handle to a UDP Socket

Description

UDP Module Definitions for the Microchip TCP/IP Stack

UDP is a standard transport layer protocol described in RFC 768.

File Name

udp.h

Company

Microchip Technology Inc.

udp_config.h

UDP Configuration file

Macros

	Name	Description
	TCPIP_UDP_MAX_SOCKETS	Maximum number of UDP sockets that can be opened simultaneously These sockets will be created when the module is initialized.
	TCPIP_UDP_SOCKET_DEFAULT_RX_QUEUE_LIMIT	The maximum number of RX packets that can be queued by an UDP socket at a certain time. Note that UDP sockets do not use their own RX buffers but instead use the network driver supplied packets and a timely processing is critical to avoid packet memory starvation for the whole stack. This symbol sets the maximum number of UDP buffers/packets that can be queued for a UDP socket at a certain time. Once this limit is reached further incoming packets are silently discarded. Adjust depending on the number of RX buffers that are available for the stack and the... more
	TCPIP_UDP_SOCKET_DEFAULT_TX_QUEUE_LIMIT	The maximum number of TX packets that can be queued by an UDP socket at a certain time. For sockets that need to transfer a lot of data (Iperf, for example), especially on slow connections this limit prevents running out of memory because the MAC/PHY transfer cannot keep up with the UDP packet allocation rate imposed by the application. Adjust depending on the TCPIP_UDP_SOCKET_DEFAULT_TX_SIZE, the connection speed and the amount of memory available to the stack.
	TCPIP_UDP_SOCKET_DEFAULT_TX_SIZE	Default socket TX buffer size. Note that this setting affects all UDP sockets that are created and, together with TCPIP_UDP_MAX_SOCKETS, has a great impact on the heap size that's used by the stack (see TCPIP_STACK_DRAM_SIZE setting). When large TX bufferrs are needed, probably a dynamic, per socket approach, is a better choice (see TCPIP_UDP_OptionsSet function).
	TCPIP_UDP_SOCKET_POOL_BUFFER_SIZE	Size of the buffers in the UDP pool. Any UDP socket that is enabled to use the pool and has the TX size <= than this size can use a buffer from the pool. Note that this setting, together with TCPIP_UDP_SOCKET_POOL_BUFFERS, has impact on the heap size that's used by the stack (see TCPIP_STACK_DRAM_SIZE setting).
	TCPIP_UDP_SOCKET_POOL_BUFFERS	Number of buffers in the private UDP pool. These are preallocated buffers that are to be used by UDP sockets only. This improves the UDP socket throughput and is meant only for UDP sockets that have to sustain high TX traffic rate. However, this memory is not returned to the stack heap, it always belongs to UDP. A socket needs to have an option set in order to use the buffers pool (see the UDPSetOptions()). Use 0 to disable the feature.
	TCPIP_UDP_USE_POOL_BUFFERS	enable the build of the pre-allocated pool buffers option
	TCPIP_UDP_USE_RX_CHECKSUM	Check incoming packets to have proper checksum.
	TCPIP_UDP_USE_TX_CHECKSUM	Calculate and transmit a checksum when sending data. Checksum is not mandatory for UDP packets but is highly recommended. This will affect the UDP TX performance.

Description

User Datagram Protocol (UDP) Configuration file

Zeroconf Module

This section describes the TCP/IP Stack Library Zeroconf module.

Introduction

TCP/IP Stack Library Zero Configuration (Zeroconf) Module for Microchip Microcontrollers

This library provides the API of the Zeroconf module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

Zero configuration (Zeroconf), provides a mechanism to ease the configuration of a device on a network. It also provides for a more human-like naming convention, instead of relying on IP addresses alone. Zeroconf also goes by the names Bonjour (Apple) and Avahi (Linux), and is an IETF standard.

Using the Library

This topic describes the basic architecture of the Zeroconf TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header Files: `tcpip_helper.h`, `zero_conf_link_local.h`, and `zero_conf_multicast_dns.h`

The interface to the Zeroconf TCP/IP Stack library is defined in the `tcpip_helper.h`, `zero_conf_link_local.h`, and `zero_conf_multicast_dns.h` header files. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the Zeroconf TCP/IP Stack library should include `tcpip.h`.

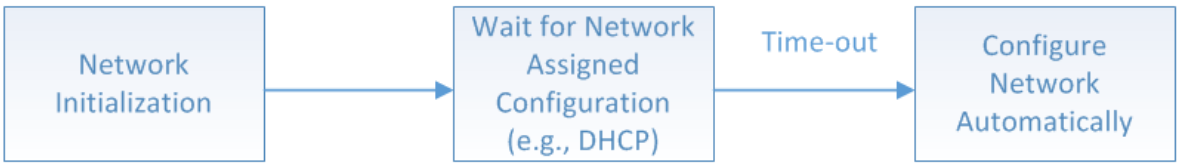
Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

This library provides the API of the Zeroconf TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

Zeroconf Software Abstraction Model



Bonjour Service Model

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Zeroconf module.

Library Interface Section	Description
Multicast DNS Functions	This section provides multicast DNS interface routines to Zeroconf
Link Local Functions	This section provides Link Local interface routines to Zeroconf
Data Types and Constants	This section provides various definitions describing this API

Core Functionality

This section provides information on core functionality.

Enabling

Zeroconf can be enabled in the MPLAB Harmony Configurator, or by setting the following two defines in `system_config.h` file:

- TCPIP_STACK_USE_ZEROCONF_LINK_LOCAL
- TCPIP_STACK_USE_ZEROCONF_MDNS_SD

Link Local (Zeroconf)

The first component of Zeroconf is the ability to self-assign an IP address to each member of a network. Normally, a DHCP server would handle such situations. However, in cases where no DHCP server exists, Zeroconf enabled devices negotiate unique IP addresses amongst themselves.

mDNS

The second component of Zeroconf is the ability to self-assign human-readable hostnames for themselves. Multicast DNS provides a local network the ability to have the features of a DNS server. Users can use easily remembered hostnames to accesses the devices on the network. In the event that devices elect to use the same hostname, as in the IP address resolution, each of the devices will auto-negotiate new names for themselves (usually by appending a number to the end of the name).

Service Discovery

The last component of Zeroconf is service discovery. All Zeroconf devices can broadcast what services they provide. For instance, a printer can broadcast that it has printing services available. A thermostat can broadcast that it has an HVAC control service. Other interested parties on the network who are looking for certain services can then see a list of devices that have the capability of providing the service, and connect directly to it. This further eliminates the need to know whether something exists on a network (and what its IP or hostname is). As an end-user, all you would need to do is query the network if a certain service exists, and easily connect to it.

Demonstration

The demonstration, when enabled, shows all three items working together. Each development kit in the network assumes the hostname of MCHPBOARD-x.local, where 'x' is an number incrementing from 1 (only in the case where multiple kits are programmed for the network). Each board will broadcast its service, which is the DemoWebServer.

Zeroconf Enabled Environments

All Apple products have Zeroconf enabled by default. On Windows, you'll need to download the Safari web browser, and during the install, enable support for Bonjour. Note that in the Safari browser, you can browse and see a list of all Bonjour enabled devices, and click through to them automatically.

Configuring the Library

The configuration of the Zeroconf TCP/IP Stack Library is based on the file `tcpip_config.h`.

This header file contains the configuration selection for the Zeroconf TCP/IP Stack Library. Based on the selections made, the Zeroconf TCP/IP Stack Library may support the selected features. These configuration settings will apply to all instances of the Zeroconf TCP/IP Stack Library.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

Building the Library

This section lists the files that are available in the Zeroconf module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/zero_conf_helper.c`	Zeroconf helper function implementation file.
`/src/zero_conf_link_local.c`	Zeroconf local link configuration implementation file.
`/src/zero_conf_multicast_dns.c`	Service advertisement and Multicast DNS implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The Zeroconf module depends on the following modules:

- TCP/IP Stack Library
- ARP Module
- UDP Module

Library Interface

a) Multicast DNS Functions

	Name	Description
	TCPIP_MDNS_ServiceDeregister	DNS Service Discovery function for end-user to deregister a service advertisement, which was previously registered with the TCPIP_MDNS_ServiceRegister function.
	TCPIP_MDNS_ServiceRegister	DNS Service Discovery function for end-users to register a service advertisement. The service is associated with all interfaces.
	TCPIP_MDNS_ServiceUpdate	DNS-Service Discovery function for end-user to update the service advertisement, which was previously registered with TCPIP_MDNS_ServiceRegister.
	TCPIP_MDNS_Task	Standard TCP/IP stack module task function.

b) Link Local Functions

	Name	Description
	TCPIP_ZCLL_Disable	Disables Zero Configuration on the specified interface.
	TCPIP_ZCLL_Enable	Enables Zero Configuration on the specified interface.
	TCPIP_ZCLL_IsEnabled	Returns whether or not an interface is enabled for zero configuration
	TCPIP_ZCLL_Task	Standard TCP/IP stack module task function.

c) Data Types and Constants

	Name	Description
	MDNSD_ERR_CODE	void DisplayHostName(uint8_t *HostName);

	ZCLL_MODULE_CONFIG	Placeholder for Zero Configuration Link Layer module configuration.

Description

This section describes the Application Programming Interface (API) functions of the Zeroconf module.

Refer to each section for a detailed description.

a) Multicast DNS Functions

TCPIP_MDNS_ServiceDeregister Function

DNS Service Discovery function for end-user to deregister a service advertisement, which was previously registered with the TCPIP_MDNS_ServiceRegister function.

File

zero_conf_multicast_dns.h

C

```
MDNSD_ERR_CODE TCPIP_MDNS_ServiceDeregister(TCPIP_NET_HANDLE netH);
```

Returns

MDNSD_ERR_CODE - Returns an error code to indicate whether or not registration is successful:

- MDNSD_SUCCESS - Returns on success of call
- MDNSD_ERR_INVAL - When the input parameters are invalid or if the function is invoked in an invalid state

Description

This function is used by end-user application to deregister DNS Service Discovery on a local network. When this gets invoked by end-user DNS SD stack sends out Good-Bye packets to update all peer machines that service will no longer be present. All peer machines remove the corresponding entry from the Browser list.

This is the last functions that needs to be invoked by the end-user application to free the DNS SD stack for some other application.

Preconditions

TCPIP_MDNS_ServiceRegister must be invoked before this call.

Parameters

Parameters	Description
netH	handle of the network to be deregistered

Function

MDNSD_ERR_CODE TCPIP_MDNS_ServiceDeregister()

TCPIP_MDNS_ServiceRegister Function

DNS Service Discovery function for end-users to register a service advertisement. The service is associated with all interfaces.

File

zero_conf_multicast_dns.h

C

```
MDNSD_ERR_CODE TCPIP_MDNS_ServiceRegister(TCPIP_NET_HANDLE netH, const char * srv_name, const char *
srv_type, uint16_t port, const uint8_t * txt_record, uint8_t auto_rename, void (*call_back)(char *name,
MDNSD_ERR_CODE err, void *context), void * context);
```

Returns

MDNSD_ERR_CODE - Returns Error-code to indicate whether or not registration is successful:

- MDNSD_SUCCESS - returns on success of call
- MDNSD_ERR_BUSY - When already some other service is being advertised using this DNS SD stack
- MDNSD_ERR_INVAL - Invalid parameter

Description

This function is used by end-user application to announce its service on local network. All peer machines that are compliant with Multicast DNS

and DNS Service Discovery protocol can detect the announcement and lists out an entry in the Service Browser list. The end-user selects an entry to connect to this service. So ultimately this is an aid to end-user to discover any service of interest on a local network.

This is the first function that needs to be invoked by end-user application. Presently Multicast-DNS and Service discovery stack supports only single service advertisement. Once the application wants to terminate the service it has to invoke TCPIP_MDNS_ServiceDeregister function to free the DNS SD stack for some other application.

Preconditions

None.

Parameters

Parameters	Description
netH	handle of the network to be registered
srv_name	Service Name, which is being advertised
srv_type	For a HTTP-Service its "_http._tcp.local"
_http	is application protocol proceeded with an underscore
_tcp	is lower-layer protocol on which service runs
local	is to represent service is on local-network For a iTunes Music Sharing "_daap._tcp.local" For a Printing Service "_ipp._tcp.local" Refer to http://www.dns-sd.org/ServiceTypes.html for more service types.
port	Port number on which service is running
txt_len	For additional information about service like default page (e.g., "index.htm") for HTTP-service. Length of such additional information
txt_record	String of additional information (e.g., "index.htm") for HTTP service.
auto_rename	A flag to indicate DNS-SD stack, whether to rename the service automatically or not. If this is set to '0' Callback parameter will be used to indicate the conflict error and user has to select different name and re-register with this function. If this is set to '1' service-name will be automatically renamed with numerical suffix.
callback	Callback function, which is user-application defined. This callback gets invoked on completion of service advertisement. If an service name-conflict error is detected and auto_rename is set to '0' callback gets invoked with MDNSD_ERR_CONFLICT as error-code.
context	Opaque context (pointer to opaque data), which needs to be used in callback function.

Function

MDNSD_ERR_CODE TCPIP_MDNS_ServiceRegister(...)

TCPIP_MDNS_ServiceUpdate Function

DNS-Service Discovery function for end-user to update the service advertisement, which was previously registered with TCPIP_MDNS_ServiceRegister.

File

zero_conf_multicast_dns.h

C

```
MDNSD_ERR_CODE TCPIP_MDNS_ServiceUpdate(TCPIP_NET_HANDLE netH, uint16_t port, const uint8_t * txt_record);
```

Returns

MDNSD_ERR_CODE - Returns an error code to indicate whether or not registration is successful:

- MDNSD_SUCCESS - returns on success of call
- MDNSD_ERR_INVAL - When the input parameters are invalid or if the function is invoked in invalid state

Description

This function is used by the end-user application to update its service, which was previously registered. With this function, the end-user application updates the port number on which the service is running. It can also update the additional information of service. For example, the default page can be updated to new page and corresponding page name can be input to this function to update all peer machines. The modified service will be announced with new contents on local network.

This is an optional function and should be invoked only if it is necessary.

Preconditions

TCPIP_MDNS_ServiceRegister must be invoked before this call.

Parameters

Parameters	Description
netH	Handle of the network to perform the service update
port	Port number on which service is running
txt_record	String of additional information (e.g., "index.htm") for HTTP-service.

Function

MDNSD_ERR_CODE TCPIP_MDNS_ServiceUpdate(
TCPIP_NET_HANDLE netH,
uint16_t port,
const uint8_t *txt_record)

TCPIP_MDNS_Task Function

Standard TCP/IP stack module task function.

File

zero_conf_multicast_dns.h

C

```
void TCPIP_MDNS_Task();
```

Returns

None.

Description

This function performs MDNS module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

MDNS module should have been initialized.

Function

void TCPIP_MDNS_Task(void)

b) Link Local Functions

TCPIP_ZCLL_Disable Function

Disables Zero Configuration on the specified interface.

File

zero_conf_link_local.h

C

```
bool TCPIP_ZCLL_Disable(TCPIP_NET_HANDLE hNet);
```

Returns

- true - Indicates success
- false - Indicates failure

Description

This API is used by end-user application to disable Zero Configuration on a specific interface.

Remarks

None.

Preconditions

The TCP/IP stack must be initialized before calling this function.

Parameters

Parameters	Description
hNet	handle of the network to be disabled

Function

bool TCPIP_ZCLL_Disable(TCPIP_NET_HANDLE hNet)

TCPIP_ZCLL_Enable Function

Enables Zero Configuration on the specified interface.

File

zero_conf_link_local.h

C

```
bool TCPIP_ZCLL_Enable(TCPIP_NET_HANDLE hNet);
```

Returns

- true - Indicates success
- false - Indicates failure

Description

This API is used by end-user application to enable Zero Configuration on a specific interface.

Remarks

None.

Preconditions

TCP/IP stack must be initialized before calling this function.

Parameters

Parameters	Description
hNet	handle of the network to be enabled

Function

bool TCPIP_ZCLL_Enable(TCPIP_NET_HANDLE hNet)

TCPIP_ZCLL_IsEnabled Function

Returns whether or not an interface is enabled for zero configuration

File

zero_conf_link_local.h

C

```
bool TCPIP_ZCLL_IsEnabled(TCPIP_NET_HANDLE hNet);
```

Returns

- true - interface is enabled for zero configuration
- false - interface is not enabled for zero configuration

Description

This API is used by end-user application check whether or not that an interface is enabled for zero configuration.

Preconditions

The TCP/IP stack must be initialized before calling this function.

Parameters

Parameters	Description
hNet	handle of the network to be examined

Function

bool TCPIP_ZCLL_IsEnabled(TCPIP_NET_HANDLE hNet)

TCPIP_ZCLL_Task Function

Standard TCP/IP stack module task function.

File

zero_conf_link_local.h

C

```
void TCPIP_ZCLL_Task();
```

Returns

None.

Description

This function performs ZCLL module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The ZCLL module should have been initialized.

Function

void TCPIP_ZCLL_Task(void)

c) Data Types and Constants

MDNSD_ERR_CODE Enumeration

File

zero_conf_multicast_dns.h

C

```
typedef enum {
  MDNSD_SUCCESS = 0,
  MDNSD_ERR_BUSY = 1,
  MDNSD_ERR_CONFLICT = 2,
  MDNSD_ERR_INVAL = 3
} MDNSD_ERR_CODE;
```

Members

Members	Description
MDNSD_ERR_BUSY = 1	Already Being used for another Service
MDNSD_ERR_CONFLICT = 2	Name Conflict
MDNSD_ERR_INVAL = 3	Invalid Parameter

Description

void DisplayHostName(uint8_t *HostName);

ZCLL_MODULE_CONFIG Structure

File

zero_conf_link_local.h

C

```
typedef struct {
} ZCLL_MODULE_CONFIG;
```

Description

Placeholder for Zero Configuration Link Layer module configuration.

Files

Files

Name	Description

Test Libraries Help

This section provides descriptions of the Test Libraries that are available in MPLAB Harmony.

Test Harness Library

This section describes the Test Harness Library that is available in MPLAB Harmony.

Description

There are two types of test libraries included in the MPLAB Harmony installation. The first type is a single Test Harness Library. This library implements a state machine that runs and manages specially developed tests that are used to validate the behavior of MPLAB Harmony-compatible libraries in the different execution environments supported. The second type of test library implements the tests that are run by the Test Harness Library. These libraries are predefined and implemented by Microchip to validate existing MPLAB Harmony drivers, middleware, and other libraries. This type of library may be used in conjunction with the test harness library to verify the behavior of different implementations of existing MPLAB Harmony libraries.

Introduction

This library runs and manages specially developed tests used to validate the behavior of MPLAB Harmony-compatible libraries in the different execution environments supported.

Description

This Test Harness Library help and usage documentation defines the library's interface and expected behavior. To utilize the Test Harness Library, a test application must be developed that initializes and runs the Test Harness Library. Additionally, tests must be written that fulfill the requirements of the Test Harness Library. These tests need to call the interface functions of a Library Under Test (LUT) and verify its expected behavior. Refer to the MPLAB Test Harness User's Guide for additional details on developing tests and test applications.

The Test Harness Library can execute a number of tests, each of which validates some aspect of the interface and behavior of a MPLAB Harmony-compatible library. Each test can have a number of sub-tests. If all sub-tests pass, the test passes. If any sub-test fails, the test fails. If all tests in a given configuration pass, the harness reports an overall passing result. If any test fails, the harness reports an overall failure result. Error messages, individual test results, and other messages are output as they occur, provided that a SYS_DEBUG output method is available and has been configured. Otherwise, a debugger must be used to check the results stored in an internal data structure of the Test Harness.

Library Overview

This section provides an overview of the Test Harness Library.

Description

The library interface routines are divided into various sub-sections, which address one of the blocks of the overall operation of the Test Harness Library.

Library Interface Section	Description
System Interface Functions	Functions used by the MPLAB Harmony system to initialize and maintain the Test Harness Library and libraries under test.
Platform Initialization Functions	Functions used to perform hardware or test platform-specific initialization.
Test Results Functions	Functions used by tests to report results to the harness.
Test Time-out Functions	Function used to maintain the test time out timer.
Test Harness Initialization Data Types	These structures provide the list of tests that the harness executes.
Test Interface Function Pointer Types	These pointers define the functions that the Test Harness requires each test must implement.

State Machine

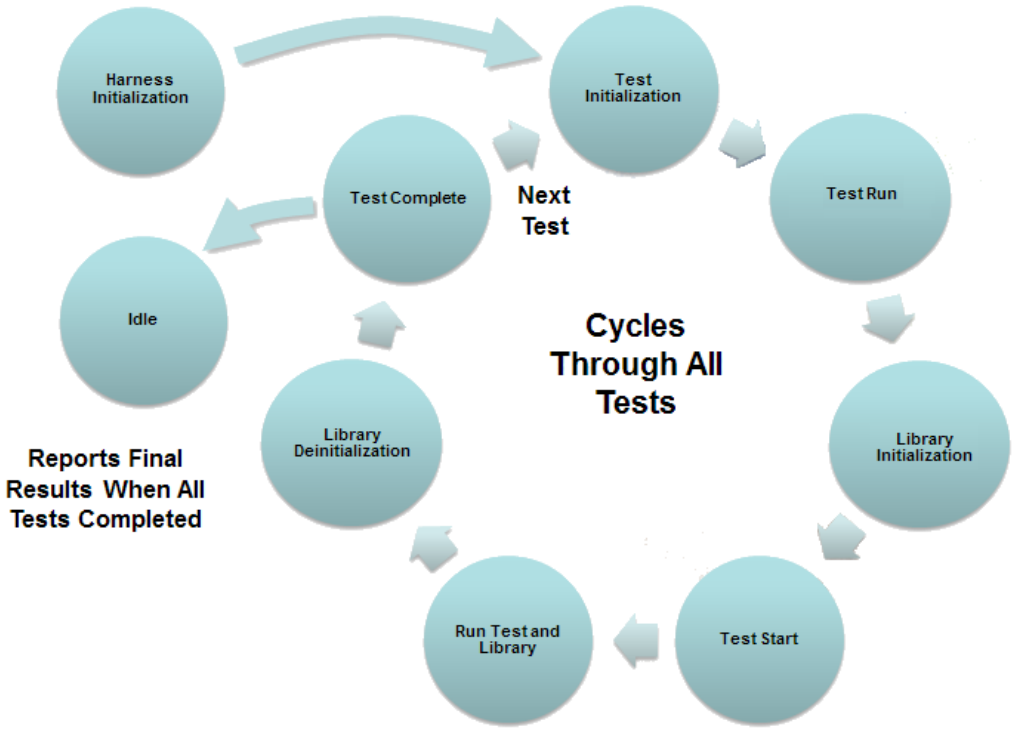
This topic describes the State Machine for the MPLAB Harmony Test Harness Library.

Description

The Test Harness State Machine (see **Figure 1**) runs in a cycle that executes all tests in the test list that was provided to it when it was initialized. This state machine first performs any required configuration-specific initialization by calling the TEST_PlatformInitialize function. Then, it initializes and prepares the first test to be run. When the test indicates that it is ready, the harness initializes the library and runs both the test and the LUT. As the test runs, it reports intermediate "sub-test" results back to the harness, which accumulates them for later reporting. The tests and harness

use debug message output to print results and information, if so configured. Intermediate debug messages can be "printed" at any time, but they may affect test timing. When the test is completed, the test harness deinitializes the LUT, reports results for that test, and advances to the next test library to start the process over again. When the last test finishes, the harness reports the final results and goes idle or hits a breakpoint (in Debug mode).

Figure 1: Test Harness State Machine



Refer to the MPLAB Harmony Test Harness User's Guide for information on using the Test Harness Library to develop test applications and for information on developing tests that meet the requirements of the test harness.

Using the Library

This topic describes the basic architecture of the Test Harness Library and provides information and examples on its use.

Description

The interface to the Test Harness Library is defined in the `test_harness.h` header file.

Any C language source (`.c`) file that uses the Test Harness Library must include `test_harness.h`.

How the Library Works

This section provides information on how the Test Harness Library works.

Core Functionality

Refer to the MPLAB Harmony Test Harness User's Guide for information on the core functionality of the Test Harness Library.

Configuring the Library

Macros

	Name	Description
	TEST_HARNESS_MAX_NUM_TASKS_PER_LIBRARY	Defines the maximum number of "Tasks" routines implemented by a single library under test.
	TEST_HARNESS_MAX_NUM_INSTANCES_PER_LIBRARY	Defines the maximum number of instances of a single library under test.
	TEST_IDLE_SLEEP_MS	Defines the number of milliseconds the test harness will sleep when the test reports that it is idle.
	TEST_IDLE_SLEEP_MS_LIBRARY	Defines the number of milliseconds the library tasks function will sleep when the library is idle.

	TEST_TIMER_CLOCK_PRESCALER	Defines the selected clock prescaler value for the timeout timer.
	TEST_TIMER_CLOCK_SOURCE	Defines the selected clock source for the timer used for the timeout timer.
	TEST_TIMER_ID	Defines the timer peripheral used for the test timeout timer.
	TEST_TIMER_INCREMENT_PERIOD	Defines the number of timer counts that make up a single timer period.
	TEST_TIMER_INTERRUPT_PRIORITY	Defines the interrupt priority for the selected test timer.
	TEST_TIMER_INTERRUPT_SOURCE	Defines the interrupt source ID of the timer used for the timeout timer.
	TEST_TIMER_INTERRUPT_SUBPRIORITY	Defines the interrupt subpriority for the selected test timer.
	TEST_TIMER_INTERRUPT_VECTOR	Defines the interrupt vector for the selected test timer.
	TEST_TIMER_MS_PER_INCREMENT	Defines the number of milliseconds per timer increment period.
	TEST_TIMER_MS_TIMEOUT	Defines the number of milliseconds that must expire before a test will time out.

Description

The configuration of the Test Harness Library is based on the file `system_config.h`.

This header file contains the configuration selections for the Test Harness Library. Based on the selections made, the library may support the support selected features.

The path to this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TEST_HARNESS_MAX_NUM_TASKS_PER_LIBRARY Macro

Defines the maximum number of "Tasks" routines implemented by a single library under test.

File

test_config_template.h

C

```
#define TEST_HARNESS_MAX_NUM_TASKS_PER_LIBRARY 5
```

Description

Maximum Number of Tasks for a Library Under Test

This configuration parameter defines the maximum number of "Tasks" routines are allowed for a single library under test.

Remarks

This parameter has a default value defined in test_harness.h that will generate a warning when used. To eliminate the warning, define a value in system_config.h.

TEST_HARNESS_MAX_NUM_INSTANCES_PER_LIBRARY Macro

Defines the maximum number of instances of a single library under test.

File

test_harness.h

C

```
#define TEST_HARNESS_MAX_NUM_INSTANCES_PER_LIBRARY 3
```

Description

Maximum Number of Instances of a Library Under Test

Remarks

Refer to config/test_config_template.h for additional information.

TEST_IDLE_SLEEP_MS Macro

Defines the number of milliseconds the test harness will sleep when the test reports that it is idle.

File

test_config_template.h

C

```
#define TEST_IDLE_SLEEP_MS 50
```

Description

Test Idle Sleep Time

This configuration option defines the number of milliseconds that the test harness will sleep before calling the tasks function of the test when the it reports it is idle.

Remarks

This capability is only supported in an RTOS configuration, but this value must be defined in all configurations.

TEST_IDLE_SLEEP_MS_LIBRARY Macro

Defines the number of milliseconds the library tasks function will sleep when the library is idle.

File

test_config_template.h

C

```
#define TEST_IDLE_SLEEP_MS_LIBRARY 5
```

Description

Library under Test Idle Sleep Time

This configuration option defines the number of milliseconds that the test harness will sleep before calling the tasks function of the library under test when the library status reports it is idle.

Remarks

This capability is only supported in an RTOS configuration, but this value must be defined in all configurations.

TEST_TIMER_CLOCK_PRESCALER Macro

Defines the selected clock prescaler value for the timeout timer.

File

test_config_template.h

C

```
#define TEST_TIMER_CLOCK_PRESCALER TMR_PRESCALE_VALUE_256
```

Description

Timeout Timer Clock Prescaler

This configuration option defines the selected clock prescaler value for the timeout timer.

Remarks

The frequency of the clock source selected by the TEST_TIMER_CLOCK_SOURCE is divided by the value identified by this option.

The test harness takes direct ownership of this timer, utilizing the timer peripheral library to control it. The selected prescaler value must be valid for the selected timer, as defined by the timer peripheral library.

TEST_TIMER_CLOCK_SOURCE Macro

Defines the selected clock source for the timer used for the timeout timer.

File

test_config_template.h

C

```
#define TEST_TIMER_CLOCK_SOURCE TMR_CLOCK_SOURCE_PERIPHERAL_CLOCK
```

Description

Timeout Timer Clock Source

This configuration option defines the selected clock source for the timer used for the timeout timer.

Remarks

The test harness takes direct ownership of this timer, utilizing the timer peripheral library to control it. The selected clock source must be valid for the selected timer, as defined by the timer peripheral library.

TEST_TIMER_ID Macro

Defines the timer peripheral used for the test timeout timer.

File

test_config_template.h

C

```
#define TEST_TIMER_ID TMR_ID_1
```

Description

Timeout Timer

This configuration option defines the timer peripheral used for the test timeout timer. It must be defined as the timer peripheral library instance ID of the desired timer instance.

Remarks

This parameter has a default value defined in test_harness.c that will generate a warning when used. To eliminate the warning, define a value in system_config.h.

The test harness takes direct ownership of this timer, utilizing the timer peripheral library to control it. The selected timer ID must be valid, as defined by the timer peripheral library.

TEST_TIMER_INCREMENT_PERIOD Macro

Defines the number of timer counts that make up a single timer period.

File

test_config_template.h

C

```
#define TEST_TIMER_INCREMENT_PERIOD 31250
```

Description

Test Timer Increment Period

This configuration option defines the number of timer counts of the selected timer clock source that will be counted before a single timer period expires.

Remarks

The test harness takes direct ownership of this timer, operating it in 16-bit mode. The selected period value must be valid for the selected timer, as defined by the timer peripheral library.

TEST_TIMER_INTERRUPT_PRIORITY Macro

Defines the interrupt priority for the selected test timer.

File

test_config_template.h

C

```
#define TEST_TIMER_INTERRUPT_PRIORITY INT_PRIORITY_LEVEL1
```

Description

Test Timer Interrupt Priority

This configuration option defines the interrupt priority for the selected test timer.

Remarks

None.

TEST_TIMER_INTERRUPT_SOURCE Macro

Defines the interrupt source ID of the timer used for the timeout timer.

File

test_config_template.h

C

```
#define TEST_TIMER_INTERRUPT_SOURCE INT_SOURCE_TIMER_1
```

Description

Timeout Timer Interrupt Source

This configuration option defines the interrupt source ID of the timer used for the timeout timer.

Remarks

The test harness utilizes the interrupt system service to control this interrupt. The selected interrupt source must be valid for the selected timer, as defined by the interrupt system service.

TEST_TIMER_INTERRUPT_SUBPRIORITY Macro

Defines the interrupt subpriority for the selected test timer.

File

test_config_template.h

C

```
#define TEST_TIMER_INTERRUPT_SUBPRIORITY INT_SUBPRIORITY_LEVEL0
```

Description

Test Timer Interrupt Subpriority

This configuration option defines the interrupt subpriority for the selected test timer.

Remarks

None.

TEST_TIMER_INTERRUPT_VECTOR Macro

Defines the interrupt vector for the selected test timer.

File

test_config_template.h

C

```
#define TEST_TIMER_INTERRUPT_VECTOR INT_VECTOR_T1
```

Description

Test Timer Interrupt Vector

This configuration option defines the interrupt vector for the selected test timer.

Remarks

None.

TEST_TIMER_MS_PER_INCREMENT Macro

Defines the number of milliseconds per timer increment period.

File

test_config_template.h

C

```
#define TEST_TIMER_MS_PER_INCREMENT 100
```

Description

Test Timer Milliseconds Per Increment

This configuration option defines the number of milliseconds that expire per timer period. The internal timeout timer is incremented by this many milliseconds every time the timer period defined by the TEST_TIMER_INCREMENT_PERIOD configuration option expires.

Remarks

This configuration option effectively translates the timer period from scaled clock cycles to milliseconds.

TEST_TIMER_MS_TIMEOUT Macro

Defines the number of milliseconds that must expire before a test will time out.

File

test_config_template.h

C

```
#define TEST_TIMER_MS_TIMEOUT 2000
```

Description

Test Timer Timeout Value

This configuration option defines the number of milliseconds that must expire before a test will time out and be considered as a failure.

Remarks

None.

Building the Library

This section lists the files that are available in the Test Harness Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/test`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/test_harness.h`	This file provides the interface definitions of the Test Harness Library.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/test_harness.c`	Test Harness Library implementation.

Optional File(s)

There are no optional files for the Test Harness Library.

Module Dependencies

The Test Harness Library is dependent upon the following libraries and header files.

- Interrupt System Service Library
- Operating System Abstraction Layer (OSAL)
- Debug System Service Library (or an implementation of the SYS_DEBUG_PRINT and SYS_DEBUG_MESSAGE macros)
- sys_common.h
- sys_module.h

Library Interface

a) System Interface Functions

	Name	Description
	TEST_Initialize	MPLAB Harmony test harness initialization routine.
	TEST_Tasks	Runs the current test's tasks functions.
	TEST_HarnessTasks	MPLAB Harmony test harness' tasks function.
	TEST_LibraryTasksPolled	Calls the a tasks function of a library under test when the test harness is ready to run the library.
	TEST_LibraryTasksISR	Calls an ISR-based tasks function of the library under test.

b) Platform Initialization Functions

	Name	Description
	TEST_PlatformInitialize	Called by the test harness to initialize configuration-specific test support.
	TEST_PlatformReady	Indicates that the test configuration is ready and testing can begin.

c) Test Results Functions

	Name	Description
	TEST_HasCompleted	Allows a test to indicate that it has completed.
	TEST_HasPassedSubtest	Allows a test module to indicate that an individual subtest has completed and identifies if it has passed or failed.
	TEST_LibraryInitialize	Indicates that the test is ready for the harness to initialize the library under test.

d) Test Time-out Functions

	Name	Description
	TEST_TimerIncrement	Increments test timeout timer.

e) Test Harness Initialization Data Types

	Name	Description
	LIBRARY_UNDER_TEST	This is type LIBRARY_UNDER_TEST.
	_library_under_test	This is type LIBRARY_UNDER_TEST.
	_test_data	Holds data necessary to initialize and run a single test.
	_test_init_data	Holds the test harness's initialization data.
	TEST_DATA	Holds data necessary to initialize and run a single test.
	TEST_INIT_DATA	Holds the test harness's initialization data.

f) Test Interface Function Pointer Types

	Name	Description
	TEST_MODULE_INITIALIZE_ROUTINE	Pointer to a routine that initializes a test module.
	TEST_MODULE_START_FUNCTION	Pointer to a routine that starts the test module.
	TEST_MODULE_STATUS_ROUTINE	Pointer to a routine that gets the current status of a test module.
	TEST_MODULE_TASKS_ROUTINE	Pointer to a routine that performs the tasks necessary to maintain the state machine of a test module system module.

Description

This section describes the APIs of the Test Harness Library.

a) System Interface Functions

TEST_Initialize Function

MPLAB Harmony test harness initialization routine.

File

test_harness.h

C

```
void TEST_Initialize(const TEST_INIT_DATA * init);
```

Returns

None.

Description

This function initializes the MPLAB Harmony test harness. It places the harness in its initial state and prepares it to run so that the TEST_HarnessTasks function can be called.

Remarks

This routine must be called from the SYS_Initialize function.

The test harness will initialize tests and libraries under test later, under control of its state machine.

Preconditions

All other system required initialization routines should be called before calling this routine (in "SYS_Initialize"). This function should be called before or in place of the application's in initialization function.

Example

```
TEST_Initialize();
```

Parameters

Parameters	Description
init	Pointer to test initialization data.

Function

void TEST_Initialize (const APP_TH_INIT_DATA *init)

TEST_Tasks Function

Runs the current test's tasks functions.

File

test_harness.h

C

```
void TEST_Tasks(unsigned int number);
```

Returns

None.

Description

This function runs the current test's tasks functions, once the harness determines that the test should run.

Remarks

This function uses the following configuration parameters.

- TEST_IDLE_SLEEP_MS - Number of milliseconds that the test will sleep waiting for the module when it is busy.

Preconditions

The system and test harness must have all been initialized.

Example

None.

Parameters

Parameters	Description
number	Test's tasks function number. (Tests can have more than one tasks function.

Function

void TEST_Tasks(unsigned int number)

TEST_HarnessTasks Function

MPLAB Harmony test harness' tasks function.

File

test_harness.h

C

```
void TEST_HarnessTasks();
```

Returns

None.

Description

This routine is the tasks function of the MPLAB Harmony test harness and defines the state machine and core logic of the test harness.

Remarks

This routine must be called from SYS_Tasks() routine or from an RTOS thread loop.

Preconditions

Any required system initialization functions must have been called and the "TEST_Initialize" function must have been called.

Example

```
TEST_HarnessTasks();
```

Function

void TEST_HarnessTasks (void)

TEST_LibraryTasksPolled Function

Calls the a tasks function of a library under test when the test harness is ready to run the library.

File

test_harness.h

C

```
void TEST_LibraryTasksPolled(unsigned int testIndex, SYS_MODULE_INDEX libraryIndex,
SYS_MODULE_TASKS_ROUTINE libraryTasks);
```

Returns

None.

Description

This routine calls a tasks function of a library under test, indirectly under control of the test harness once the test is ready to verify the library.

Remarks

This routine must be called from the SYS_Tasks function or the appropriate RTOS thread loop when the library under test is configured for polled mode.

This routine will prevent the library's tasks function from being called before the library has been initialized.

Preconditions

The system, harness, and test must have been initialized.

Example

```
TEST_LibraryTasksPolled();
```

Parameters

Parameters	Description
testIndex	Index in test list to the test for this library.
libraryIndex	Index in test list for this instance of the library.
libraryTasks	Pointer to the library's Tasks function.

Function

void TEST_LibraryTasksPolled (unsigned int testIndex,
SYS_MODULE_INDEX libraryIndex,
SYS_MODULE_TASKS_ROUTINE libraryTasks)

TEST_LibraryTasksISR Function

Calls an ISR-based tasks function of the library under test.

File

test_harness.h

C

```
void TEST_LibraryTasksISR(unsigned int testIndex, SYS_MODULE_INDEX moduleIndex, SYS_MODULE_TASKS_ROUTINE
libraryTasks, INT_SOURCE source);
```

Returns

None.

Description

This routine calls an ISR-based tasks function of a library under test, indirectly under control of the test harness once the test is ready to verify the library.

Remarks

This routine must be called from the appropriate ISR vector function when the module under test is configured for interrupt mode.

Preconditions

The system, harness, and test must have been initialized.

Example

```
void __ISR(_TIMER_2_VECTOR, ipl2) _IntHandlerDrvTmrInstance1(void)
{
    TEST_LibraryTasksISR(2, 0, SAMPLE_Tasks, INT_SOURCE_TIMER_2);
}
```

Parameters

Parameters	Description
testIndex	Index to the APP_TH_TEST_DATA data structure passed to the test harness's "TEST_HarnessTasks" routine during system initialization.
moduleIndex	Index to the appropriate module instance.
libraryTasks	Pointer to the appropriate "Tasks" function for the library under test.
source	Interrupt source ID.

Function

void TEST_LibraryTasksISR (unsigned int testIndex,
SYS_MODULE_INDEX libraryTasks,
SYS_MODULE_TASKS_ROUTINE mutTasks,
INT_SOURCE source)

b) Platform Initialization Functions

TEST_PlatformInitialize Function

Called by the test harness to initialize configuration-specific test support.

File

test_harness.h

C

```
bool TEST_PlatformInitialize();
```

Returns

- true - If successfully able to initialize the configuration-specific test support.
- false - If not able to successfully initialize the configuration-specific test support.

Description

This function is called by the test harness to initialize configuration- specific test support.

Remarks

A weak implementation of this function is provided in the test harness library. If no external implementation is defined, then the internal weak implementation (which simply returns "true") will be used.

Preconditions

The system must have been initialized.

Example

None.

Function

bool TEST_PlatformInitialize (void)

TEST_PlatformReady Function

Indicates that the test configuration is ready and testing can begin.

File

test_harness.h

C

```
void TEST_PlatformReady();
```

Returns

None.

Description

This function indicates that the test configuration is ready and testing can begin. The purpose of this function is to allow the call to the TEST_PlatformInitialize function to return false when the configuration requires some time to complete its initialization.

Remarks

If TEST_PlatformInitialize returns "true", then it is not necessary to call this function.

Preconditions

The system, and test harness must have been initialized.

Example

TEST_PlatformReady();

Function

void TEST_PlatformReady (void)

c) Test Results Functions

TEST_HasCompleted Function

Allows a test to indicate that it has completed.

File

test_harness.h

C

```
void TEST_HasCompleted();
```

Returns

None.

Description

This function allows a test to indicate that it has completed. It is used to prematurely end the test.

Remarks

The harness will automatically end the test when the test's "Status" function indicates it has completed.

The test harness will accumulate and report subtest results using SYS_PRINT and/or SYS_MESSAGE macros. The test does not need to report results. Test only need to report debug info using SYS_DEBUG_* macros to help identify the reason for any failure.

A test is considered to have passed if all sub-tests pass. If any sub-tests fail, the test is considered to have failed. If no subtest results are reported, the test is considered to have failed.

Preconditions

The test harness must have been initialized.

Example

```
// Indicate that a test with one subtest has passed.
TEST_HasPassedSubtest(true);
TEST_HasCompleted();
```

Function

void TEST_HasCompleted (void)

TEST_HasPassedSubtest Function

Allows a test module to indicate that an individual subtest has completed and identifies if it has passed or failed.

File

test_harness.h

C

```
void TEST_HasPassedSubtest(bool passed);
```

Returns

None.

Description

This function allows a test module to indicate that an individual subtest has completed and identifies if it has passed or failed.

Remarks

The test harness will accumulate and report subtest results using SYS_PRINT and/or SYS_MESSAGE macros. The test module does not need to report results. Tests only need to report debug info using SYS_DEBUG_* macros to help identify the reason for any failure.

A test is considered to have passed if all sub-tests pass. If any sub-tests fail, the test is considered to have failed. If no subtest results are reported, the test is considered to have failed.

Preconditions

The application must have been initialized.

Example

```
// Indicate that the subtest has passed.
```

```
TEST_HasPassedSubtest(true);
```

Function

void TEST_HasPassedSubtest (bool passed)

TEST_LibraryInitialize Function

Indicates that the test is ready for the harness to initialize the library under test.

File

test_harness.h

C

```
bool TEST_LibraryInitialize();
```

Returns

- true If initialization of the library under test completed.
- false If initialization of the library under test has not yet completed.

Description

This function indicates that the test is ready for the harness to initialize the library under test.

Remarks

None.

Preconditions

The system, test harness, and test must have been initialized.

Example

if (TEST_LibraryInitialize()) { // begin testing }

Function

bool TEST_LibraryInitialize (void)

d) Test Time-out Functions

TEST_TimerIncrement Function

Increments test timeout timer.

File

test_harness.h

C

```
void TEST_TimerIncrement();
```

Returns

None.

Description

This function increments the test timeout counter by a number of milliseconds defined by TEST_TIMER_MS_PER_INCREMENT.

Remarks

This function should be called by the interrupt or alarm callback from the timer used by the test harness.

Preconditions

The system, test harness, test and timer must have been initialized.

Example

```
void __ISR(_TIMER_1_VECTOR, IPL1AUTO) _IntHandlerDrvTmrInstance0(void)
{
```

```
    TEST_TimerIncrement();
    PLIB_INT_SourceFlagClear(INT_ID_0, INT_SOURCE_TIMER_1);
}
```

Function

void TEST_TimerIncrement (void)

e) Test Harness Initialization Data Types

LIBRARY_UNDER_TEST Structure

File

test_harness.h

C

```
typedef struct _library_under_test {
  SYS_MODULE_INITIALIZE_ROUTINE initialize;
  SYS_MODULE_REINITIALIZE_ROUTINE reinitialize;
  SYS_MODULE_DEINITIALIZE_ROUTINE deinitialize;
  SYS_MODULE_STATUS_ROUTINE status;
  unsigned int numberOfInstances;
  unsigned int numberOfTasks;
  SYS_MODULE_TASKS_ROUTINE tasks[TEST_HARNESS_MAX_NUM_TASKS_PER_LIBRARY];
  SYS_MODULE_INIT * initData[TEST_HARNESS_MAX_NUM_INSTANCES_PER_LIBRARY];
} LIBRARY_UNDER_TEST;
```

Members

Members	Description
SYS_MODULE_INITIALIZE_ROUTINE initialize;	Pointer to the library's initialization routine.
SYS_MODULE_REINITIALIZE_ROUTINE reinitialize;	Pointer to the library's reinitialization routine.
SYS_MODULE_DEINITIALIZE_ROUTINE deinitialize;	Pointer to the library's deinitialization routine.
SYS_MODULE_STATUS_ROUTINE status;	Pointer to the library's status routine.
unsigned int numberOfInstances;	Number of instances of the library under test.
unsigned int numberOfTasks;	Number of tasks routines required by each instance of the library under test.
SYS_MODULE_TASKS_ROUTINE tasks[TEST_HARNESS_MAX_NUM_TASKS_PER_LIBRARY];	Array of pointers to the library's "Tasks" routine(s).
SYS_MODULE_INIT * initData[TEST_HARNESS_MAX_NUM_INSTANCES_PER_LIBRARY];	Array of pointers to the library's init data structures.

Description

This is type LIBRARY_UNDER_TEST.

TEST_DATA Structure

Holds data necessary to initialize and run a single test.

File

test_harness.h

C

```
typedef struct _test_data {
  char * name;
  TEST_MODULE_INITIALIZE_ROUTINE initialize;
  TEST_MODULE_TASKS_ROUTINE tasks[TEST_HARNESS_MAX_NUM_TASKS];
  TEST_MODULE_START_FUNCTION start;
  TEST_MODULE_STATUS_ROUTINE status;
  SYS_MODULE_INDEX index;
  SYS_MODULE_INIT * initData;
  LIBRARY_UNDER_TEST * library;
  SYS_MODULE_OBJ testObj;
```

```
  unsigned int passed;
  unsigned int count;
  bool completed;
} TEST_DATA;
```

Members

Members	Description
char * name;	Pointer to test name string.
TEST_MODULE_INITIALIZE_ROUTINE initialize;	Pointer to test's initialize routine.
TEST_MODULE_TASKS_ROUTINE tasks[TEST_HARNESS_MAX_NUM_TASKS];	Pointer to test's tasks routine.
TEST_MODULE_START_FUNCTION start;	Pointer to test's start routine.
TEST_MODULE_STATUS_ROUTINE status;	Pointer to test's status routine.
SYS_MODULE_INDEX index;	Test module's index.
SYS_MODULE_INIT * initData;	Initial data for test module.
LIBRARY_UNDER_TEST * library;	Pointer to library under test data structure.
SYS_MODULE_OBJ testObj;	Test module's object handle.
unsigned int passed;	Count of sub-tests that have passed.
unsigned int count;	Count of sub-tests that have been run.
bool completed;	Flag indicating all sub-tests completed (module is idle).

Description

Test Data

This structure holds the data necessary to initialize and run a single test.

TEST_INIT_DATA Structure

Holds the test harness's initialization data.

File

test_harness.h

C

```
typedef struct _test_init_data {
  unsigned int numberOfTests;
  TEST_DATA * tests;
} TEST_INIT_DATA;
```

Members

Members	Description
unsigned int numberOfTests;	Number of tests.
TEST_DATA * tests;	Pointer to test data array.

Description

Test Harness Initialization Data

This structure holds the test harness's initialization data.

f) Test Interface Function Pointer Types

TEST_MODULE_INITIALIZE_ROUTINE Type

Pointer to a routine that initializes a test module.

File

test_harness.h

C

```
typedef SYS_MODULE_INITIALIZE_ROUTINE TEST_MODULE_INITIALIZE_ROUTINE;
```

Returns

A handle to the instance of the test module that was initialized. This handle is a necessary parameter to all of the other harness level routines for this test.

Description

This data type is a pointer to a routine that initializes a test module.

Remarks

This function will only be called once per test instance when the harness is ready to initialize the test instance.

Preconditions

The system and harness initialization must have been completed before the harness state machine will call the initialization routine for any tests.

Parameters

Parameters	Description
index	Identifier for the test instance to be initialized
init	Pointer to the data structure containing any data necessary to initialize the test. This pointer may be null if no data is required and default initialization is to be used.

Function

SYS_MODULE_OBJ TEST__Initialize) (
const SYS_MODULE_INDEX index,
const SYS_MODULE_INIT * const init)

TEST_MODULE_START_FUNCTION Type

Pointer to a routine that starts the test module.

File

test_harness.h

C

```
typedef bool (* TEST_MODULE_START_FUNCTION)(SYS_MODULE_OBJ object);
```

Returns

- true - If the test module is successfully able to start testing.
- false - If the test module is unable to start testing.

Description

This is a pointer to a routine that starts the test application.

Remarks

Each test module's "Start" function is called via a pointer to begin running the test contained in that module.

Preconditions

The test harness application and the test application must have been initialized and "running" (i.e., the test applications tasks function must be called from the test harness's state machine).

Example

None.

Parameters

Parameters	Description
object	Object handle to the module instance

Function

bool TEST__Start (SYS_MODULE_INDEX index)

TEST_MODULE_STATUS_ROUTINE Type

Pointer to a routine that gets the current status of a test module.

File

test_harness.h

C

```
typedef SYS_MODULE_STATUS_ROUTINE TEST_MODULE_STATUS_ROUTINE;
```

Returns

One of the possible status codes from SYS_STATUS, extended to include:

SYS_STATUS_TEST_COMPLETED - Indicates the test has completed.

Description

This data type is a pointer to a routine that gets the current status of a test module.

Remarks

A test's status operation can be used to determine when the test is busy or has completed as well as to obtain general status of the test.

If the status operation returns SYS_STATUS_BUSY, the previous operation has not yet completed. Once the status operation returns SYS_STATUS_READY, any previous operations have completed.

The value of SYS_STATUS_ERROR is negative (-1). A module may define module-specific error values of less or equal SYS_STATUS_ERROR_EXTENDED (-10).

The status function must NEVER block.

If the status operation returns an error value the test has failed.

Preconditions

The system and harness initialization must have (and will be) completed and the test module's initialization routine will have been called before the harness will call the status routine for a test.

Example

None.

Parameters

Parameters	Description
object	Handle to the module instance

Function

SYS_STATUS TEST__Status (SYS_MODULE_OBJ object)

TEST_MODULE_TASKS_ROUTINE Type

Pointer to a routine that performs the tasks necessary to maintain the state machine of a test module system module.

File

test_harness.h

C

```
typedef void (* TEST_MODULE_TASKS_ROUTINE)(SYS_MODULE_OBJ object, unsigned int index);
```

Returns

None.

Description

This data type is a pointer to a routine that performs the tasks necessary to maintain the state machine of a test module module.

Remarks

A test module can have one or more (up to TEST_HARNESS_MAX_NUM_TASKS) tasks functions.

Preconditions

The system and harness initialization must have been completed and the test's initialization routine called before the harness will call any of the test's tasks routines.

Example

None.

Parameters

Parameters	Description
object	Handle to the test instance object
index	Index identifying which tasks function is being called. This index can be used to identify if a single task function is called from a different tasks context.

Function

void TEST__Tasks (SYS_MODULE_OBJ object, unsigned int index)

Files

Files

Name	Description
test_harness.h	This header file provides prototypes and definitions for the MPLAB Harmony test harness.
test_config_template.h	Test harness configuration template file.

Description

This section lists the source and header files used by the TEST HARNESS LIB Library.

test_harness.h

This header file provides prototypes and definitions for the MPLAB Harmony test harness.

Functions

	Name	Description
	TEST_HarnessTasks	MPLAB Harmony test harness' tasks function.
	TEST_HasCompleted	Allows a test to indicate that it has completed.
	TEST_HasPassedSubtest	Allows a test module to indicate that an individual subtest has completed and identifies if it has passed or failed.
	TEST_Initialize	MPLAB Harmony test harness initialization routine.
	TEST_LibraryInitialize	Indicates that the test is ready for the harness to initialize the library under test.
	TEST_LibraryTasksISR	Calls an ISR-based tasks function of the library under test.
	TEST_LibraryTasksPolled	Calls the a tasks function of a library under test when the test harness is ready to run the library.
	TEST_PlatformInitialize	Called by the test harness to initialize configuration-specific test support.
	TEST_PlatformReady	Indicates that the test configuration is ready and testing can begin.
	TEST_Tasks	Runs the current test's tasks functions.
	TEST_TimerIncrement	Increments test timeout timer.

Macros

	Name	Description
	TEST_HARNESS_MAX_NUM_INSTANCES_PER_LIBRARY	Defines the maximum number of instances of a single library under test.

Structures

	Name	Description
	_library_under_test	This is type LIBRARY_UNDER_TEST.
	_test_data	Holds data necessary to initialize and run a single test.
	_test_init_data	Holds the test harness's initialization data.
	LIBRARY_UNDER_TEST	This is type LIBRARY_UNDER_TEST.

	TEST_DATA	Holds data necessary to initialize and run a single test.
	TEST_INIT_DATA	Holds the test harness's initialization data.

Types

	Name	Description
	TEST_MODULE_INITIALIZE_ROUTINE	Pointer to a routine that initializes a test module.
	TEST_MODULE_START_FUNCTION	Pointer to a routine that starts the test module.
	TEST_MODULE_STATUS_ROUTINE	Pointer to a routine that gets the current status of a test module.
	TEST_MODULE_TASKS_ROUTINE	Pointer to a routine that performs the tasks necessary to maintain the state machine of a test module system module.

Description

MPLAB Harmony Test Harness Header File

This header file provides function prototypes and data type definitions for the test harness interface.

File Name

test_harness.h

Company

Microchip Technology Inc.

test_config_template.h

Test harness configuration template file.

Macros

	Name	Description
	TEST_HARNESS_MAX_NUM_TASKS_PER_LIBRARY	Defines the maximum number of "Tasks" routines implemented by a single library under test.
	TEST_IDLE_SLEEP_MS	Defines the number of milliseconds the test harness will sleep when the test reports that it is idle.
	TEST_IDLE_SLEEP_MS_LIBRARY	Defines the number of milliseconds the library tasks function will sleep when the library is idle.
	TEST_TIMER_CLOCK_PRESCALER	Defines the selected clock prescaler value for the timeout timer.
	TEST_TIMER_CLOCK_SOURCE	Defines the selected clock source for the timer used for the timeout timer.
	TEST_TIMER_ID	Defines the timer peripheral used for the test timeout timer.
	TEST_TIMER_INCREMENT_PERIOD	Defines the number of timer counts that make up a single timer period.
	TEST_TIMER_INTERRUPT_PRIORITY	Defines the interrupt priority for the selected test timer.
	TEST_TIMER_INTERRUPT_SOURCE	Defines the interrupt source ID of the timer used for the timeout timer.
	TEST_TIMER_INTERRUPT_SUBPRIORITY	Defines the interrupt subpriority for the selected test timer.
	TEST_TIMER_INTERRUPT_VECTOR	Defines the interrupt vector for the selected test timer.
	TEST_TIMER_MS_PER_INCREMENT	Defines the number of milliseconds per timer increment period.
	TEST_TIMER_MS_TIMEOUT	Defines the number of milliseconds that must expire before a test will time out.

Description

Test Harness Configuration Template

This file provides the list of all the configurations that can be used with the test harness. This file should not be included by any source files. It is strictly for documentation.

USB Libraries Help

This section provides descriptions of the USB libraries that are available in MPLAB Harmony.

USB Device Library

This section provides information on the USB Device libraries that are available in MPLAB Harmony.

USB Device Library - Getting Started

This section provides information for getting started with the USB Device Library.

Introduction

Provides an introduction to the MPLAB Harmony USB Device Library

Description

The MPLAB Harmony USB Device Library (referred to as the USB Device Library) provides embedded application developers with a framework to design and develop a wide variety of USB Devices. A choice of Full Speed only or Full Speed and Hi-Speed USB operations are available, depending on the selected PIC32 microcontroller. The USB Device Library facilitates development of standard USB devices through function drivers that implement standard USB Device class specification. Vendor USB devices can be implemented via USB Device Layer Endpoint functions. The USB Device Library is modular, thus allowing application developers to readily design composite USB devices. The USB Device Library is a part of the MPLAB Harmony installation and is accompanied by demonstration applications that highlight library usage. These demonstrations can also be modified or updated to build custom applications. The USB Device Library also features the following:

- Support for different USB device classes (CDC, Audio, HID, MSD, and Vendor)
- Supports multiple instance of the same class in a composite device
- Supports multiple configurations at different speeds
- Supports Full-Speed and High-Speed operation
- Supports multiple USB peripherals (allows multiple device stacks)
- Modular and Layered architecture
- Supports deferred control transfer responses
- Completely non-blocking
- Supports both polled and interrupt operation
- Works readily in an RTOS application

This document serves as a getting started guide and provides information on the following:

- USB Device Library architecture
- USB Device Library - application interaction
- Creating your own USB device

Note: It is assumed that the reader is familiar with the USB 2.0 specification (available at www.usbif.org). While the document, for the sake completeness, does cover certain aspects of the USB 2.0 protocol, it is recommended that the reader refer to the specification for a complete description of USB operation.

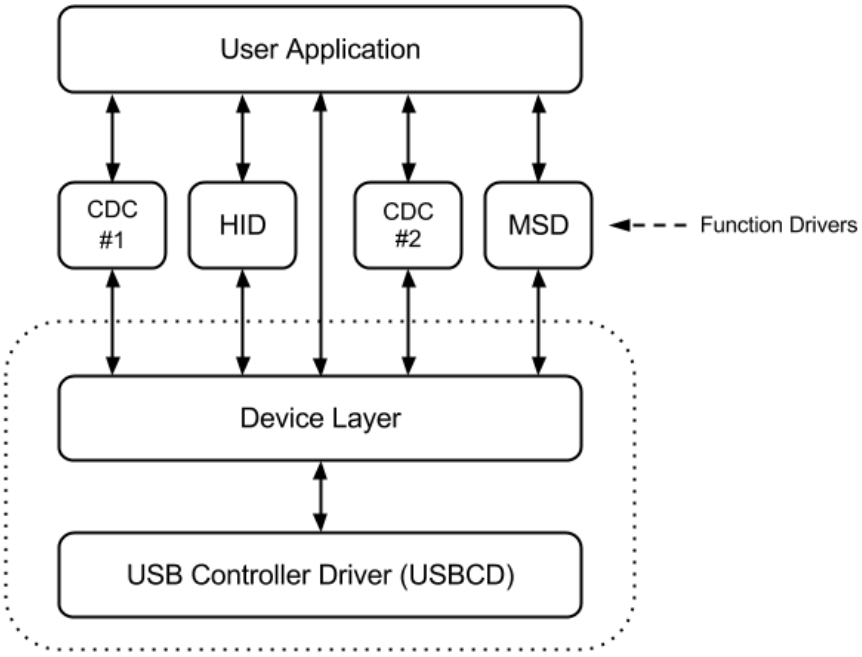
USB Device Library Architecture

Describes the USB Device Library Architecture.

Description

The USB Device Library features a modular and layered architecture, as illustrated in the following figure.

USB Device Library Architecture



As seen in the figure, the USB Device Library consists of the following three major components.

USB Controller Driver (USBCD)

The USBCD manages the state of the USB peripheral and provides the Device Layer with structured data access methods to the USB. It also provides the Device layer with USB events. The USBCD is a MPLAB Harmony driver and uses the MPLAB Harmony framework components (the USB peripheral Library, the Interrupt System Service) for its operation. It supports only one client per instance of the USB Peripheral. This client would typically be the Device Layer. In case of multiple USB peripherals, the USBCD can manage multiple USB peripherals, each being accessed by one client. The driver is accessed exclusively by the Device Layer in the USB Device Layer Architecture. It is initialized by the Device Layer (when the Device Layer is initialized) and in case of polling operation, its Tasks routine is called by the Device Layer. The USBCD provides functions to:

- Enable, disable and stall endpoints
- Schedule USB transfers
- Attach or detach the device
- Control resume signalling

The USB Controller Driver can be configured for Polled or Interrupt mode. Configuring the driver for Interrupt mode configures the Device Stack for Device mode operation. Configuring the driver for Polled mode configures the USB Device Stack for Polled mode operation. An USB device can be designed using either the polled or interrupt mode. However, it is recommended that the USB Controller Driver (and therefore the USB Device Stack) be configured for Interrupt mode. This reduces the impact of other application components on the operation of the Device Stack. Configuring for Interrupt mode also ensure timely stack event generation and stack response to bus events on the USB.

Device Layer

The Device Layer responds to the enumeration requests issued by the USB Host. It has exclusive access to an instance of the USBCD and the control endpoint (Endpoint 0). When the Host issues a class specific control transfer request, the Device Layer will analyze the setup packet of the control transfer and will route the control transfer to the appropriate function driver. The Device Layer must be initialized with the following data:

- Master Descriptor Table - This is a table of all the configuration descriptors and string descriptors.
- Function Driver Registration Table - This table contains information about the function drivers in the application
- USBCD initialization information - This specifies the USB peripheral interrupt, the USB Peripheral instance and Sleep mode operation options

The Device Layer initializes all function drivers that are registered with it when it receives a Set Configuration (for a supported configuration) from the Host. It deinitializes the function drivers when a USB reset event occurs. It initializes the USBCD, opens it and registers a event handler to receive USB events. The Device Layer can also be opened by the application (the application becomes a client to the Device Layer). The application can then receive bus and device events and respond to control transfer requests. The Device Layer provides events to the application such as device configured or device reset. Some of these events are notification-only events, while other events require the application to take action.

Function Drivers

The Function Drivers implements various USB device classes as per the class specification. The USB Device Library architecture can support multiple instances of a function driver. An example would be a USB CDC device that emulates two serial ports. Function drivers provide an abstracted and an easy to use interface to the application. The application must register an event handler with the function driver to receive function driver events and must respond to some of these events with control transfer read/write functions. Function drivers access the bus through the Device Layer.

USB Device Library - Application Interaction

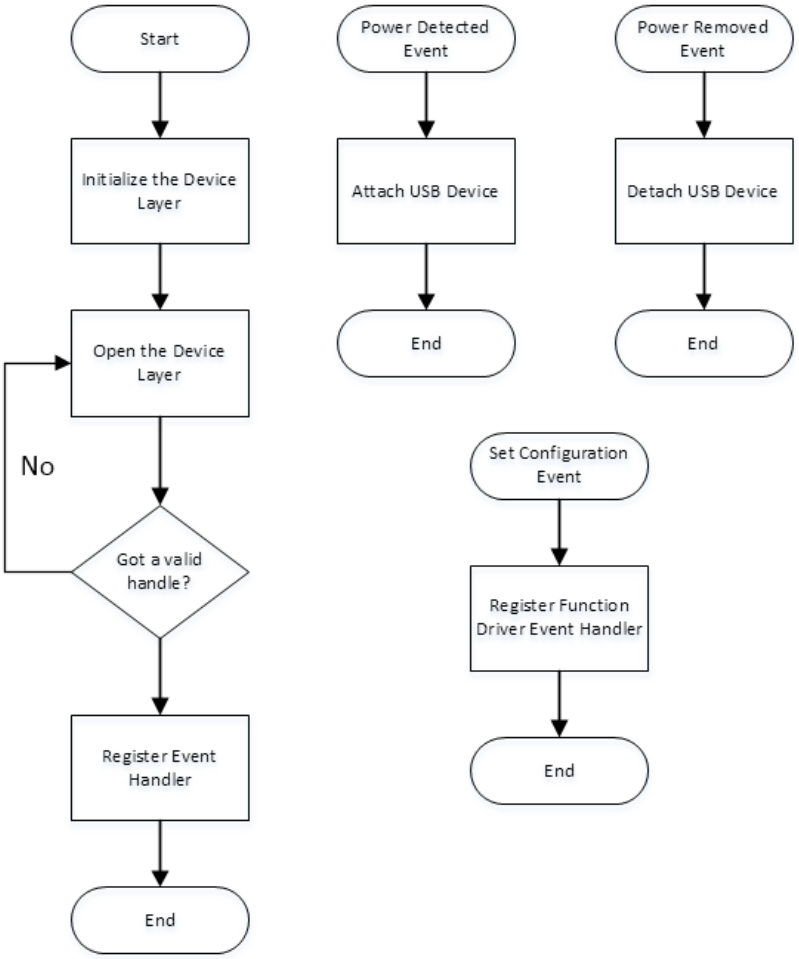
Describes how the application must interact with the USB Device Stack.

Description

Note: Additional information on program, data, and stack memory requirements, and a list of USB application configurations is available in the USB Demonstrations section.

The following figure highlights the steps that the application must follow to use the USB Device Library.

Application Interaction with Device Layer

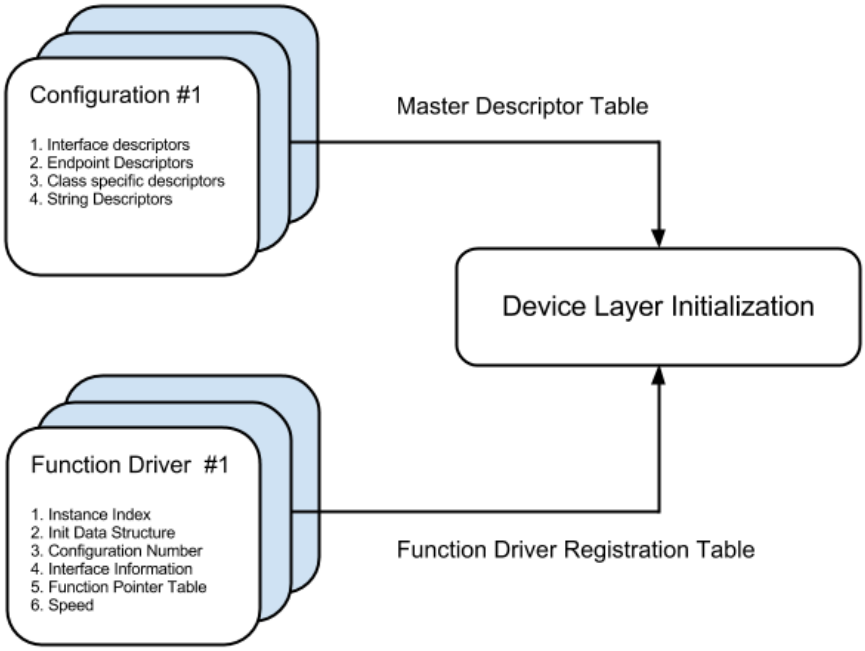


The application must first initialize the Device Layer. As a part of the Device Layer initialization process, the Device Layer initialization structure must be defined which in turn requires the following data structures to be designed

- The master descriptor table
- The function driver registration table

The following figure shows a pictorial representation of the data that forms the Device Layer initialization structure. Additional information on Device Layer initialization is available in the Device Layer Help File.

Device Layer Initialization



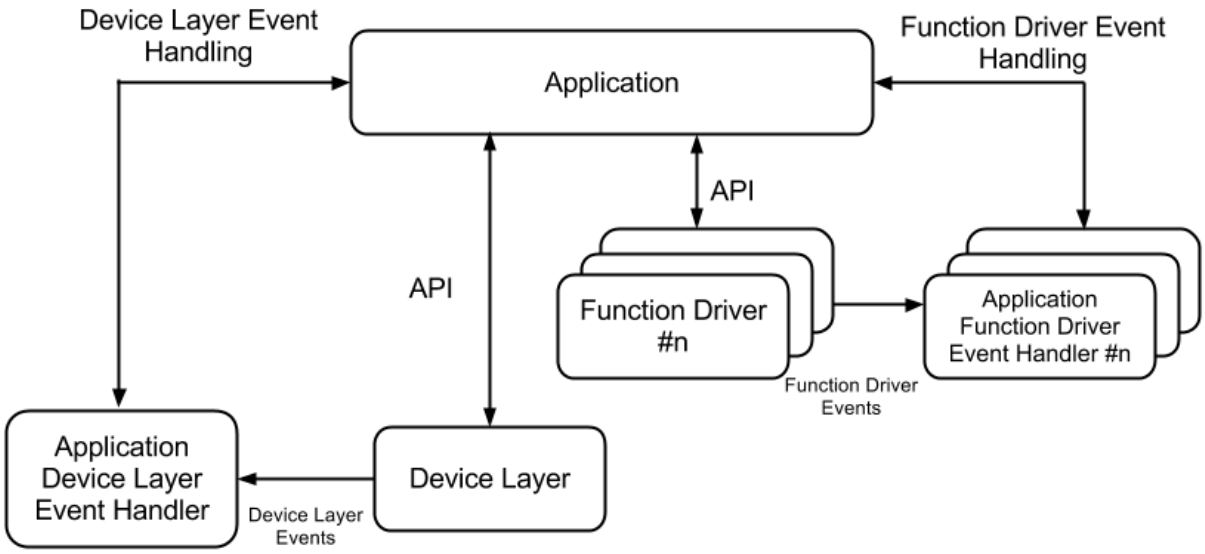
After successful initialization of the Device layer, the application can open the Device layer and register a Device layer event handler. The Device layer event handler receives device level events such as device configured, device deconfigured, device reset and device suspended. The device configured event and deconfigured event are important. The application can use the device deconfigured event to reinitialize its internal state machine. When the application receives a device configured event, it must register event handlers for each function driver that is relevant to the configuration that was set. The function driver event handler registration must be done in the device configured event context because the Device layer acknowledges the set configuration request from the host when it exits the device configured event handler context. The application at this point should be ready to respond to function driver events.

Note: Not registering the function driver event handler in the Device layer configured event could cause the device to not respond to the host requests and therefore, be non-compliant.

Once configured, the device is now ready to serve its intended function on the USB. The application interacts with the Device layer and function drivers through API function and event handlers. The application must be aware of function driver events which require application response. For example, the USB_DEVICE_CDC_EVENT_SET_LINE_CODING event from the USB CDC Function Driver requires the application to respond with a USB_DEVICE_ControlRead function. This function provides the buffer to receive the line coding parameters that the Host sends in the data stage of the Set Line Coding control transfer.

The following figure shows the application interaction with Device layer and function driver after the device has been configured.

Application - Device Layer Interaction after device configuration



In the previous figure, the application should have registered the Device layer event handler before attaching the device on the bus. It should have registered the function driver event handler before exiting the device configured - Device layer event. The application will then receive function

driver instance specific events via the function driver event handlers.

Deferring Control Transfer Responses

Class-specific control transfer related function driver events require the application to complete the data stage and/or the status of the control transfer. The application does this by using the Device Layer Control Transfer API to complete the Control Read/Write transfers. The application may typically be able the complete required data processing, and to continue (or end) the control transfer within the function driver event handler context. However, there could be cases where the required control transfer data processing may require hardware access or extended computation. Performing extended processing or waiting for external hardware within the function driver event handler context is not recommended as the USB 2.0 Specification places restrictions on the control transfer response time.

In cases where the application is not ready to respond to control transfer requests within the function driver event handler context, the USB Device Library provides the option of deferring the response to the control transfer event. The application can respond to the control transfer request after exiting the handler function. The application must still observe the USB 2.0 Specification control transfer timing requirements while responding to the control transfer. Deferring the response in such a manner provides the application with flexibility to analyze the control transfer without degrading the performance of the device on the USB.

Creating Your Own USB Device

Describes how to create a USB device with the MPLAB Harmony USB Device Library.

Description

The first step in creating a USB device is identifying whether the desired device function fits into any of the standard USB device class functions. Using standard USB classes may be advantageous as major operating systems feature Host driver support for standard USB devices. However, the application may not want to tolerate the overhead associated with standard USB device class protocols, in which case, a Vendor USB device can be implemented. A Vendor USB device can be implemented by using the USB Device Layer Endpoint functions; however, these devices will require custom USB host drivers for their operation. Having identified the device class to be used, the following approaches are available for developing a USB device by using the USB Device Library.

Use the Available Library Demonstration Applications

The USB Device Library release package contains a set of demonstration applications that are representative of common USB devices. These can be modified easily to include application specific initialization and application logic. The application logic must be non-blocking and could be implemented as a state machine. Note that the function names and file names referred to in the following section are the those used in the USB Device Library demonstration applications.

- The application specific initialization can be called in the APP_Initialize function (in the `app.c` file). The APP_Initialize function is called from the SYS_Initialize function, which in turn is called when the device comes out of Power-on Reset (POR).
- The application logic is implemented as a state machine in the APP_Tasks function (in the `app.c` file). The application logic can interact with the function driver and the Device layer by using available API calls.
- The application logic can track device events by processing the events in the application USB device event handler function (APP_USBDeviceEventHandler function in `app.c`).

Build a USB Device Library Application Using the MPLAB Harmony Configurator (MHC)

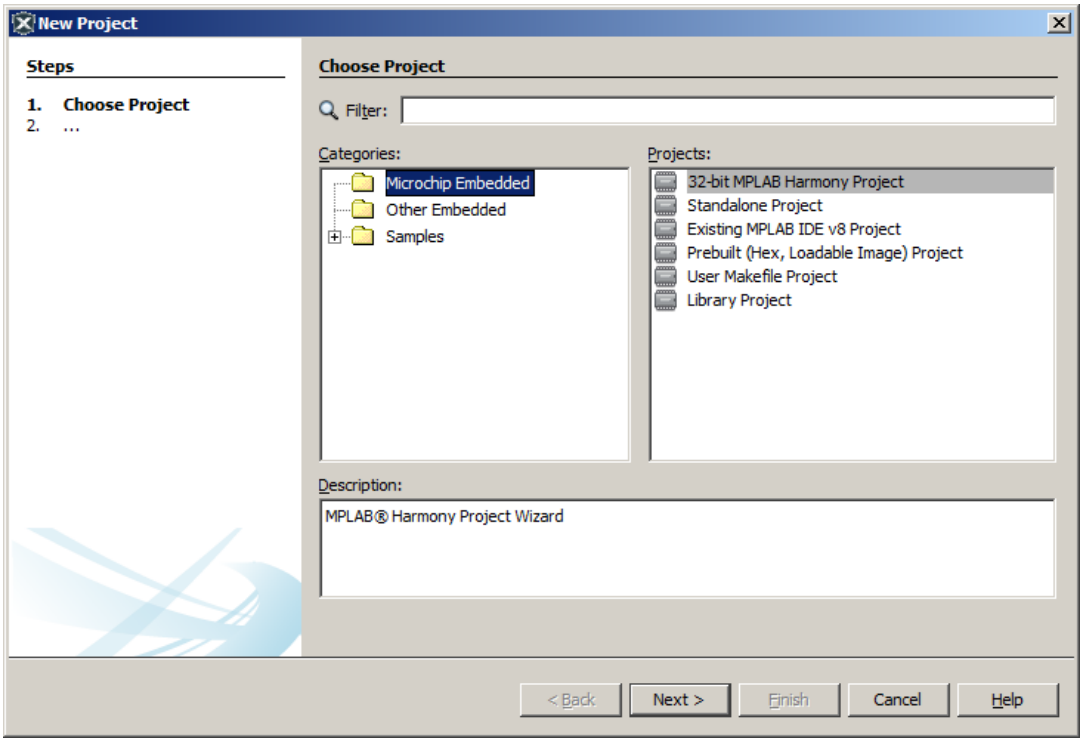
In a case where the available demonstration applications do not meet the end application requirements, a USB device can be created by building a USB Device Library application from scratch. It is recommended to use the Microchip Harmony Configurator (MHC) to generate a USB Device project. Using the MHC ensures that the correct and required MPLAB Harmony framework files are included in the project. The following section outlines the steps to follow to generate the project using the MHC.

Before You Begin

The following process assumes that the MHC plug-in, `com-microchip-mplab-module-mhc.nbm`, which is located in `<install-dir>/utilities/mhc`, is installed in MPLAB X IDE. If the MHC plug-in is not already installed, refer to Installing a Plug-in Module for information.

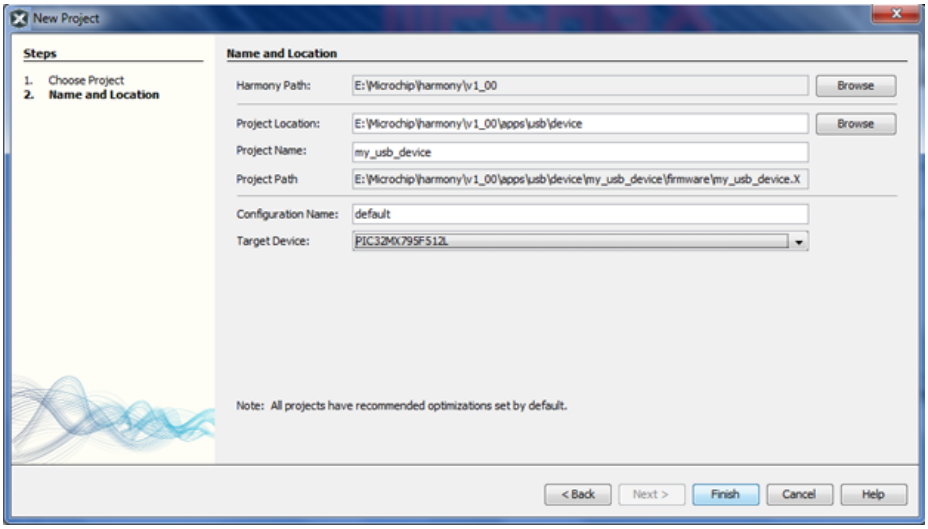
Step 1: Create a New MPLAB X IDE Project

In MPLAB X IDE, select *File* > *New Project* to open the New Project dialog and in Categories: select **Microchip Embedded** and in Projects: select **MPLAB Harmony Project**, and then click **Next**.



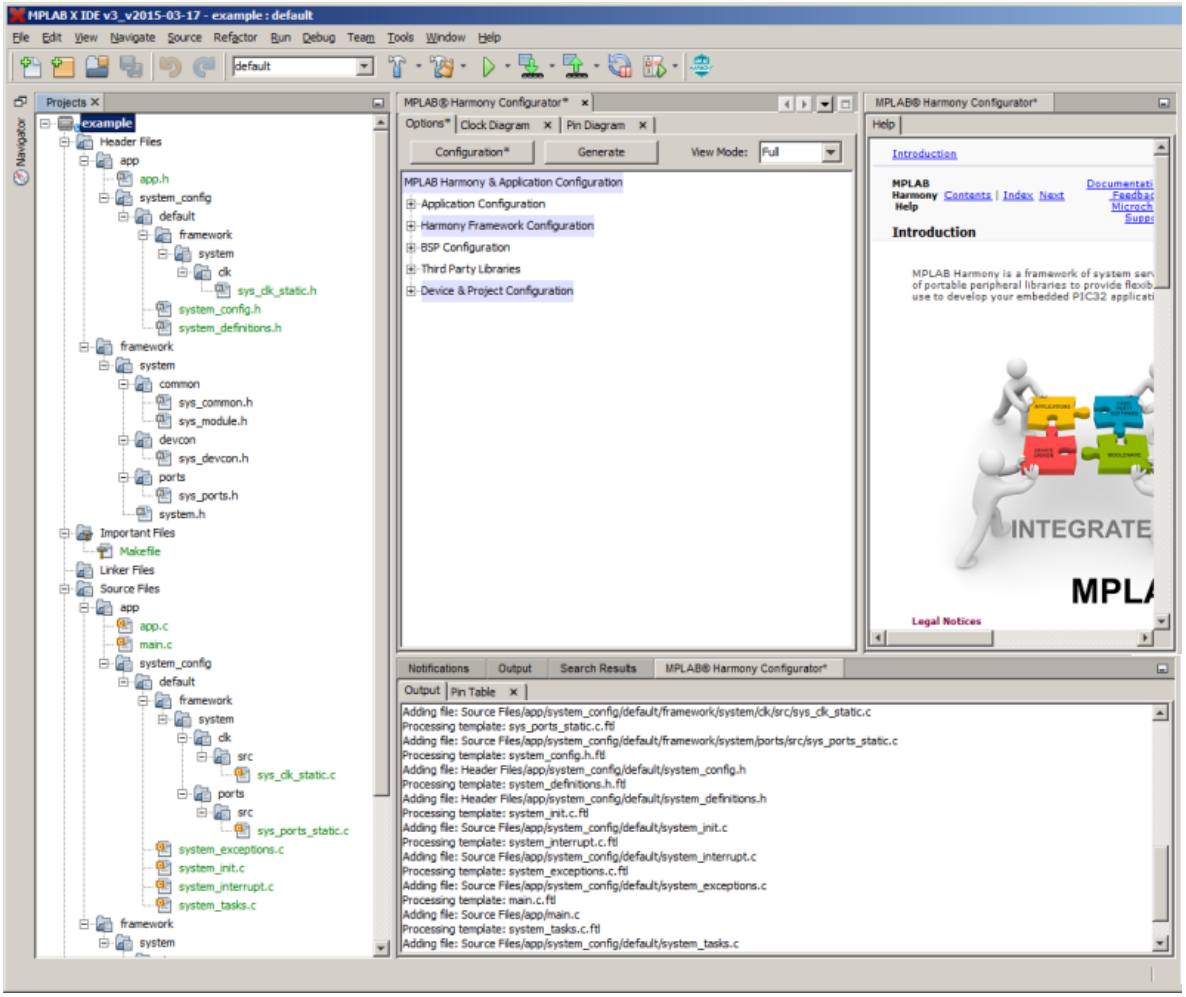
Step 2: Specify Project Name, Location and PIC32 Device Type

In the New Project dialog, specify the Project Location, Project Name, and the Target Device, and then click **Finish**.

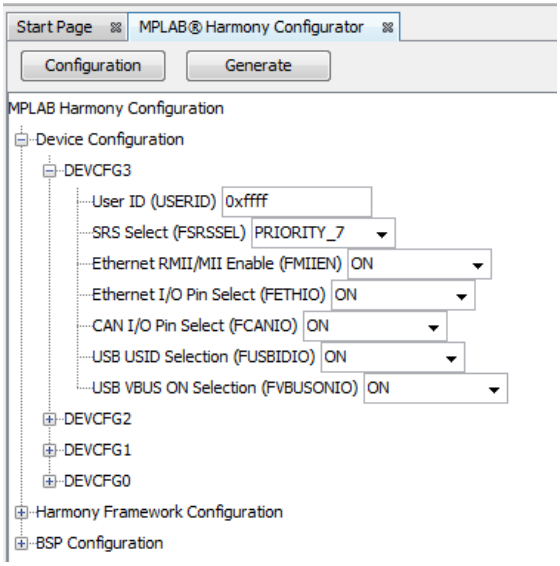


Step 3: Start the MPLAB Harmony Configurator

Open the MHC by selecting *Tools* > *Embedded* > *MPLAB Harmony Configurator*. The initial view is shown in the following figure.

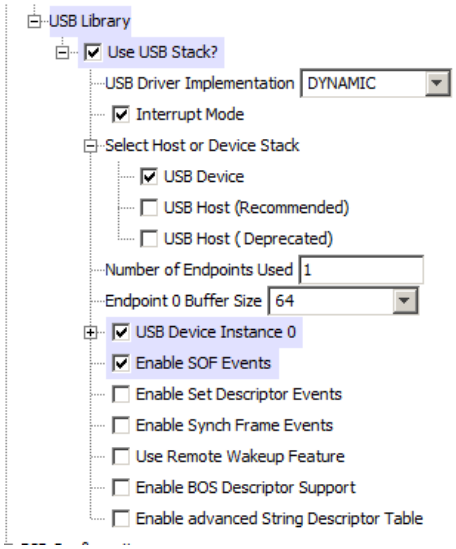


Step 4: Select Device Configuration and configure the fields as required



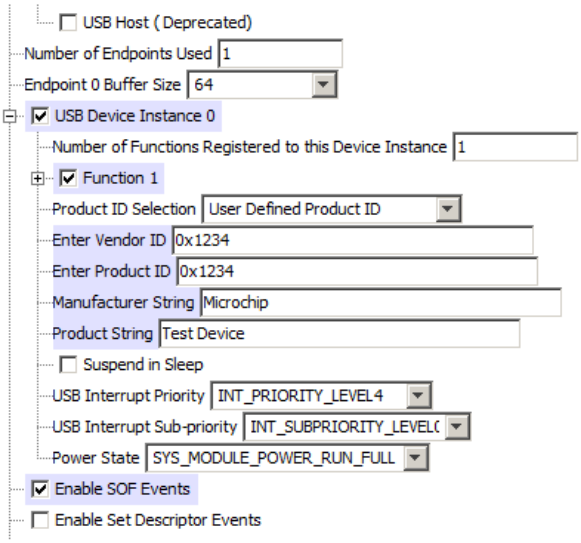
Step 5: MPLAB Harmony Framework Configuration

Expand the MPLAB Harmony Framework Configuration and select **USB Library**, and then select **Use USB Stack**. Doing this will also automatically include other MPLAB Harmony Framework components, that are required by the USB Stack into the project. Select **USB Device** and configure the different parameters as desired.



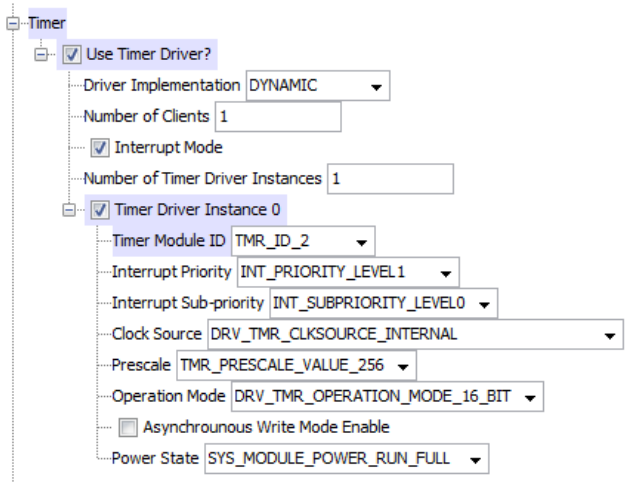
Step 6: MPLAB Harmony Framework Configuration

Expand USB Device Instance 0 and configure parameters as desired.



Step 7: MPLAB Harmony Framework Configuration

For a PIC32MZ device, expand *MPLAB Harmony Framework Configuration >Drivers >Timer* and select the Timer Module ID as TMR_ID_2.



Step 8: Configure Interrupt Priorities

The interrupt priorities of the following modules should be configured as per application needs.

For PIC32MX devices:

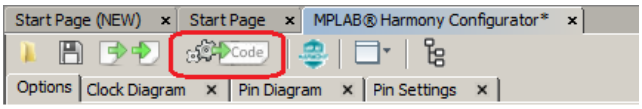
- USB Device Layer

For PIC32MZ devices:

- USB Device Layer
- Timer Driver

Step 9: Generate code

Click **Generate** to generate the code for this configuration.



Step 10: Add application specific information

The following components should be manually added to the generated code:

- USB Descriptors, Function Driver Registration table, USB Device Layer Master Descriptor Table. These data structures should be placed in `system_init.c`. Refer to the USB Device Layer Library section for more information.
- Application initialization steps should be implemented in APP_Initialize function in `app.c`
- Application Tasks routine should be implemented in APP_Tasks function in `app.c`

Step 11: Create a USB Device Layer Event Handler

The application should create a Device Layer Event Handler which will handle all the events generated by the Device Layer. The following code shows a list of all possible events that are generated by the Device Layer. The code can be used in the application and updated to meet the application requirements. Refer to the USB Device Layer Library section for more details on the Device Layer Event Handling. The USB_DEVICE_Attach function can be called to attach the device on the USB when the USB_DEVICE_EVENT_POWER_DETECTED event occurs.

This code example shows how the application can set a Device Layer Event Handler.

```
// Application states
typedef enum
{
    //Application's state machine's initial state.
    APP_STATE_INIT=0,
    APP_STATE_SERVICE_TASKS,
    APP_STATE_WAIT_FOR_CONFIGURATION,
} APP_STATES;

USB_DEVICE_HANDLE usbDeviceHandle;
APP_STATES appState;

// This is the application device layer event handler function.

USB_DEVICE_EVENT_RESPONSE APP_USBDeviceEventHandler
(
    USB_DEVICE_EVENT event,
    void * pData,
    uintptr_t context
)
{
    USB_SETUP_PACKET * setupPacket;
    switch(event)
    {
        case USB_DEVICE_EVENT_POWER_DETECTED:
            // This event in generated when VBUS is detected. Attach the device
            USB_DEVICE_Attach(usbDeviceHandle);
            break;

        case USB_DEVICE_EVENT_POWER_REMOVED:
            // This event is generated when VBUS is removed. Detach the device
            USB_DEVICE_Detach (usbDeviceHandle);
            break;

        case USB_DEVICE_EVENT_CONFIGURED:
            // This event indicates that Host has set Configuration in the Device.
            break;

        case USB_DEVICE_EVENT_CONTROL_TRANSFER_SETUP_REQUEST:
            // This event indicates a Control transfer setup stage has been completed.
            setupPacket = (USB_SETUP_PACKET *)pData;

            // Parse the setup packet and respond with a USB_DEVICE_ControlSend(),
            // USB_DEVICE_ControlReceive or USB_DEVICE_ControlStatus().
```

```
                break;

            case USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_SENT:
                // This event indicates that a Control transfer Data has been sent to Host.
                break;

            case USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_RECEIVED:
                // This event indicates that a Control transfer Data has been received from Host.
                break;

            case USB_DEVICE_EVENT_CONTROL_TRANSFER_ABORTED:
                // This event indicates a control transfer was aborted.
                break;

            case USB_DEVICE_EVENT_SUSPENDED:
                break;

            case USB_DEVICE_EVENT_RESUMED:
                break;

            case USB_DEVICE_EVENT_ERROR:
                break;

            case USB_DEVICE_EVENT_RESET:
                break;

            case USB_DEVICE_EVENT_SOF:
                // This event indicates an SOF is detected on the bus. The     USB_DEVICE_SOF_EVENT_ENABLE
                // macro should be defined to get this event.
                break;
            default:
                break;
        }
    }
```

Step 12: Function Driver Event Handling

The application should create a Function Driver Event Handler which will handle all the events generated by the Function Driver. Refer to the **Event Handling** topic in the applicable function driver documentation for more details on the Function Driver Event Handling.

Step 13: Opening the Device Layer

The application should open the Device Layer in the Application tasks routine and register an event handler with the Device Layer. The Device Layer will generate events when the event handler is registered.

The following code shows an example for how to the open the Device Layer.

```
void APP_Tasks ( void )
    {
        // Check the application's current state.
        switch ( appState )
        {
            // Application's initial state.
            case APP_STATE_INIT:
                // Open the device layer
                usbDeviceHandle = USB_DEVICE_Open( USB_DEVICE_INDEX_0,
                    DRV_IO_INTENT_READWRITE );

                if(usbDeviceHandle != USB_DEVICE_HANDLE_INVALID)
                {
                    // Register a callback with device layer to get event notification
                    USB_DEVICE_EventHandlerSet(usbDeviceHandle,
                        APP_USBDeviceEventHandler, 0);
                    appState = APP_STATE_WAIT_FOR_CONFIGURATION;
                }
                else
                {
                    // The Device Layer is not ready to be opened. We should try
                    // gain later.
                }
                break;

            case APP_STATE_SERVICE_TASKS:
```

```
                break;

                // The default state should never be executed.
            default:
                break;
        }
    }
```

USB Device Stack Porting Guide

This section provides information for porting a MLA USB Device to MPLAB Harmony.

Introduction

This topic provides information for porting a MLA USB Device to MPLAB Harmony.

Source Files to Include

This topic provides information on the source files to be included when porting a MLA USB device project to MPLAB Harmony.

Description

The following table lists the source files that must be included for MLA based and MPLAB Harmony based USB device projects. In MLA there is no separate controller driver implementation. Both enumeration functionality and controller driver is implemented in the `usb_device.c` file. In the MPLAB Harmony USB Device Stack, the controller driver is implemented in the `drv_usb.c` and `drv_usb_device.c` files, and enumeration functionality is implemented in the `usb_device.c` file.

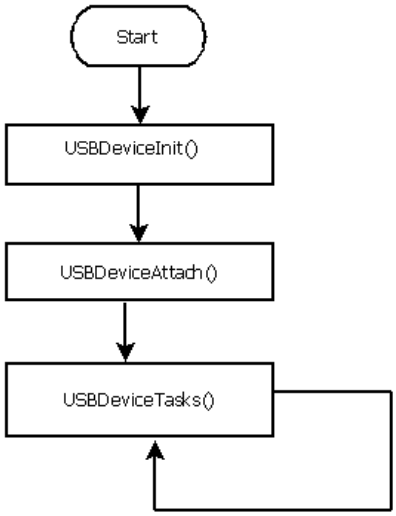
MLA	MPLAB Harmony	Description
`usb_device.c`	`usb_device.c`	In MLA, this file contains enumeration functionality and controller driver implementations. In MPLAB Harmony, this file implements enumeration functionality only.
`usb_function_xxx.c` (Where `xxx` stands for function driver name such as hid, msd, etc.)	`usb_device_xxx.c` (Where `xxx` stands for function driver name such as hid, msd, etc.)	Contains all function driver implementations.
`usb_descriptors.c`	`system_init.c`	Contains USB stack configurations.
N/A	`drv_usb.c` and `drv_usb_device.c`	USB peripheral driver implementation.

Initializing the USB Device Stack

This topic provides initialization information when porting a MLA USB device project to MPLAB Harmony.

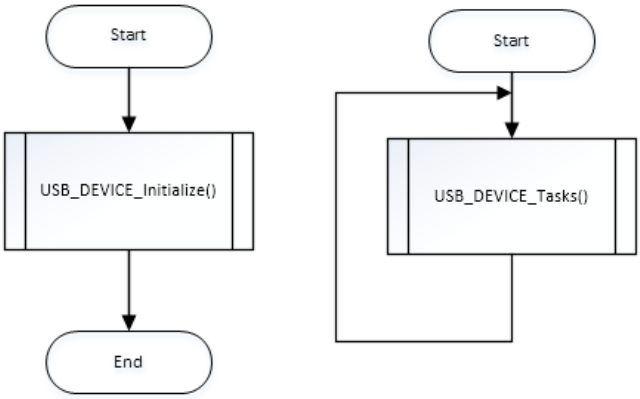
Description

In MLA, initializing the USB device stack consists of calling USB functions in the sequence shown in the following flow chart.



The USBDeviceInit function will initialize the USB Device stack. USBDeviceAttach function will attach the device to bus. USBDeviceTasks function will run the stack task routine.

In the MPLAB Harmony USB Device Stack, initializing the USB device stack consists of calling USB functions in the sequence shown in the following chart.



The USB_DEVICE_Initialize function will initialize the USB device stack. On successful initialization, this function returns a valid system object. This system object is passed to the USB_DEVICE_Tasks function. This function is called periodically in the MPLAB Harmony SYS_Tasks function to maintain the state of the USB Device.

Configuring the Stack

This topic provides stack configuration information when porting a MLA USB device project to MPLAB Harmony.

Description

To configure the stack in MLA, USB descriptors have to be defined in the `usb_descriptors.c` file. The configuration is done in `usb_config.h`. Whereas in MPLAB Harmony, USB descriptors are defined in `system_init.c`. The MPLAB Harmony USB Device Stack configuration is done in `system_config.h`. Aside from descriptors, users must also define a function registration table and a master descriptor table in `system_init.c`. Refer to the specific USB Device section for more information on the function registration table and the master descriptor table.

Calling the Device Layer API

Provides information on calling the Device Layer API functions.

Description

In the Microchip Library of Applications (MLA), the application does not have to explicitly open the Device Layer to invoke the Device Layer API. The Device Layer APIs do not require a client handle.

The MPLAB Harmony USB Device Stack supports multiple instances and therefore requires a client handle. The USB_DEVICE_Open function opens a Device Layer instance and returns a application client handle to the instance of the Device Layer that was opened. This handle is then passed to Device Layer API to specify the instance of Device Layer to be accessed.

Event Handling

This topic provides event handling information when porting a MLA USB device project to MPLAB Harmony.

Description

In MLA, users handle events inside the USER_USB_CALLBACK_EVENT_HANDLER function. Whereas in MPLAB Harmony, the user application client will have to register an event handler with the USB device stack using the USB_DEVICE_EventHandlerSet function. All USB bus events are then forwarded to this user registered event handler function.

The following code shows an example of registering the event handler for the MPAB Harmony stack using the USB_DEVICE_EventHandlerSet function. In the example, the USB_DEVICE_EventHandlerSet function is the application event handler.

```
/* Open the Device Layer */

USB_DEVICE_HANDLE usbDeviceHandle;

usbDeviceHandle = USB_DEVICE_Open(USB_DEVICE_INDEX_0, DRV_IO_INTENT_READWRITE);

/* Register an event handler */

USB_DEVICE_EventHandlerSet(usbDeviceHandle, APP_USBDeviceEventHandler, 0);
```

The following code shows the implementation of the APP_USBDeviceEventHandler function.

```
void APP_USBDeviceEventHandler ( USB_DEVICE_EVENT event, void * eventData, uintptr_t context )
{
    switch ( event )
    {
        case USB_DEVICE_EVENT_SOF:

            break;

        case USB_DEVICE_EVENT_RESET:

            break;

        case USB_DEVICE_EVENT_CONFIGURED:

            break;

        case USB_DEVICE_EVENT_POWER_DETECTED:

            /* VBUS was detected. We can attach the device */
            USB_DEVICE_Attach(appData.deviceHandle);
            break;

        case USB_DEVICE_EVENT_POWER_REMOVED:

            /* VBUS is not available any more. Detach the device. */
            USB_DEVICE_Detach(appData.deviceHandle);
            break;

        case USB_DEVICE_EVENT_SUSPENDED:

            break;

        case USB_DEVICE_EVENT_RESUMED:

    break;

        case USB_DEVICE_EVENT_ERROR:

    break;

        default:
            break;
    }
}
```

Initializing and Communicating with the Endpoint

This topic provides endpoint initialization and communication information when porting a MLA USB device project to MPLAB Harmony.

Description

In MLA, user applications explicitly initialize the required endpoints and can directly read and write to the endpoints. The following code shows how MLA initializes the endpoints in an event handler when the device is configured.

```
 ********************************************************************/
BOOL USER_USB_CALLBACK_EVENT_HANDLER(int event, void *pdata, WORD size)
{
    switch(event)
    {
        case EVENT_CONFIGURED:
             //enable the HID endpoint
            USBEnableEndpoint(HID_EP,
              USB_IN_ENABLED|USB_OUT_ENABLED|USB_HANDSHAKE_ENABLED|USB_DISALLOW_SETUP);
            //Re-arm the OUT endpoint for the next packet
            USBOutHandle = HIDRxPacket(HID_EP,(BYTE*)&ReceivedDataBuffer,64);
            break;

        case EVENT_TRANSFER:
            //Add application specific callback task or callback function here if desired.
            break;
        case EVENT_SOF:
            USBCB_SOF_Handler();
            break;
        case EVENT_SUSPEND:
            USBCBSuspend();
```

Endpoint configured in MLA

For MPLAB Harmony, the user application only manages endpoints directly for Generic USB device implementations. For standard USB devices, the USB device layer initializes the endpoint and any communication to an endpoint must occur through function driver APIs. The USB device layer initializes the endpoint based on the information provided by the user in the configurations descriptor. The USB device layer does this by parsing the descriptors table at run time. So the user does not have to explicitly enable or disable the endpoint.

Handling Endpoint 0 (EP0) Packets

This topic provides information for handling Endpoint 0 packets when porting a MLA USB device project to MPLAB Harmony.

Description

Standard device requests are handled by device stack in both MLA and MPLAB Harmony. The difference lies in handling class specific requests. In MLA, the class specific requests are forwarded to the application as EP0 events and application forwards them to appropriate function driver. The following code shows how the application forwards them to appropriate function driver in the event handler.

```
 ********************************************************************/
BOOL USER_USB_CALLBACK_EVENT_HANDLER(int event, void *pdata, WORD size)
{
    switch(event)
    {
        case EVENT_EP0_REQUEST:
            USBCheckHIDRequest();
            break;

        case EVENT_TRANSFER:
            //Add application specific callback task or callback function here if desi
            break;

        case EVENT_CONFIGURED:
             //enable the HID endpoint
            USBEnableEndpoint(HID_EP,
              USB_IN_ENABLED|USB_OUT_ENABLED|USB_HANDSHAKE_ENABLED|USB_DISALLOW_SETUP)
```

EP0 request is forwarded to HID

For the MPLAB Harmony USB Device Stack, EP0 events are generated from the appropriate function driver as meaningful events. For example, the HID function driver in MPLAB Harmony parses the EP0 packet to generate events like USB_DEVICE_HID_EVENT_GET_IDLE, USB_DEVICE_HID_EVENT_SET_REPORT, and USB_DEVICE_HID_EVENT_SET_IDLE, etc.

The following code shows how the event handler callback is registered with the HID function driver using the USB_DEVICE_HID_EventHandlerSet function. This is done in the Device Layer USB_DEVICE_EVENT_CONFIGURED event.

```
case USB_DEVICE_EVENT_CONFIGURED:
     /* Set the flag indicating device is configured. */
     appData.deviceConfigured = true;

     /* Save the other details for later use. */
```

```
    appData.configurationValue = ((USB_DEVICE_EVENT_DATA_CONFIGURED*)
                                  eventData)->configurationValue;

    /* Register application HID event handler */
    USB_DEVICE_HID_EventHandlerSet(USB_DEVICE_HID_INDEX_0, APP_USBDeviceHIDEventHandler,
                                   (uintptr_t)&appData);
```

The following code shows the implementation of the HID event handler function in the application. Note how the HID function driver converts EP0 requests to a HID class-specific control transfer event.

```
USB_DEVICE_HID_EVENT_RESPONSE APP_USBDeviceHIDEventHandler
(
    USB_DEVICE_HID_INDEX iHID,
    USB_DEVICE_HID_EVENT event,
    void * eventData,
    uintptr_t userData
)
{
    USB_DEVICE_HID_EVENT_DATA_REPORT_SENT * reportSent;
    USB_DEVICE_HID_EVENT_DATA_REPORT_RECEIVED * reportReceived;

    /* Check type of event */
    switch (event)
    {

        case USB_DEVICE_HID_EVENT_SET_IDLE:

            /* For now we just accept this request as is. We acknowledge
             * this request using the USB_DEVICE_HID_ControlStatus()
             * function with a USB_DEVICE_CONTROL_STATUS_OK flag */

            USB_DEVICE_ControlStatus(appData.usbDevHandle, USB_DEVICE_CONTROL_STATUS_OK);

            /* Save Idle rate received from Host */
            appData.idleRate = ((USB_DEVICE_HID_EVENT_DATA_SET_IDLE*)eventData)->duration;
            break;
```

USB Device Stack Porting Example

Provides information on porting a MLA Device Stack demonstration application to the MPLAB Harmony USB Device Stack.

Description

With the introduction of MPLAB Harmony, PIC32MX USB device applications can now be developed using either the USB Device Stack available in Microchip Application Libraries (MLA) v2013-06-15 or the USB Device Stack in the latest version of MPLAB Harmony

In a case where an existing or a partially developed MLA-based USB Device application needs to be migrated to use the MPLAB Harmony USB Device Stack, the migration process is not a one-to-one process, as there are API level differences between the MLA and MPLAB Harmony USB Device Stack. This guide provides a detailed step-by-step comparison between a MLA USB Device and a MPLAB Harmony USB Device application, with an objective to enable the application migration process.

An existing v2013-06-15 MLA USB Device Stack example, the “Device – CDC – Basic Demo” will be compared with the MPLAB Harmony USB Device cdc_com_port_single demonstration application. The outline of the comparative analysis is as follows:

- Highlight framework level similarities and differences between the MLA and MPLAB Harmony USB Device Stack
- Analyze and compare the files included in the MLA “Device – CDC – Basic Demo” demonstration application project to the files included in the MPLAB Harmony USB Device Stack cdc_com_port_single demonstration application
- Analyze and compare the PIC32 Device Fuse Configuration macros, USB Device Stack Configuration, USB Device Stack API and application API in the MLA “Device – CDC – Basic Demo” demonstration application source code with their equivalents in the MPLAB Harmony USB Device cdc_com_port_single demonstration application project

The projects to be compared are available in the MLA USB Device and MPLAB Harmony USB Device demonstration applications folders.

Prerequisites

Describes the prerequisites for using this porting example.

Description

Ensure that the following software is installed:

- Microchip Libraries for Applications v2013-06-15
- The latest version of MPLAB Harmony (available by visiting: www.microchip.com/harmony)

In addition, knowledge of common project-related operations and settings in MPLAB X IDE, as well as familiarity with the MLA USB Solutions and

the USB protocol is assumed.

USB Device Stack in MLA and MPLAB Harmony

In this section, the key similarities and differences between the USB Device Stack in MLA and MPLAB Harmony are discussed.

Description

Similarities

The key similarities between the USB Device Stack in MLA and MPLAB Harmony are:

- Both solutions support Interrupt and Polled mode operation
- Both solutions require configuration macros to control/define functional aspects of the device stack
- Both solutions contain module Tasks routines that need to be invoked either in a `while(1)` application superloop and/or in the USB Interrupt Service Routine (ISR)
- In both solutions, the function drivers and Device Layer are implemented as separate modules

Differences

The key differences between the USB Device Stack in MLA and MPLAB Harmony are listed in the following table.

MPLAB Harmony	MLA
In MPLAB Harmony, the complete user application is factored into System and Application code sections. The code sections are implemented in separate source code files. This represents the MPLAB Harmony Application paradigm.	There is no such factoring in MLA.
In MPLAB Harmony, the USB peripheral management is performed by a USB Controller Driver. This is implemented separately.	The MLA USB Device stack combines the implementation of Device Layer and controller driver into one file.
In MPLAB Harmony, the USB Device Layer is a MPLAB Harmony module and requires the application to open it to access the Device Layer functions.	This is not required in MLA.
In MPLAB Harmony, Device Layer API is factored into System and Client functions. The application calls the client functions along with the Device Layer Handle.	There is no such factoring in the MLA Device Layer implementation.
In MPLAB Harmony, function driver API require the specification of an instance index.	This is typically not required in MLA.
In MPLAB Harmony, the USB Device Stack uses System Services to access shared system resources.	The MLA does not contain a formal implementation of such system services.
In MPLAB Harmony, the Device Layer initializes the function driver based on the configuration set by the host. This process does not require application intervention.	In MLA, the application must add code for the Set Configuration Event handling routine to invoke the initialize routine of the required function driver.

MLA and MPLAB Harmony USB Device Stack Files

This section analyzes the files included in the MLA "Device – CDC – Basic Demo" demonstration application MPLAB X IDE project and identifies the equivalent MPLAB Harmony USB Device Stack and Framework files in the MPLAB Harmony USB Device cdc_com_port_single demonstration MPLAB X IDE project.

The MLA "Device – CDC – Basic Demo" demonstration application MPLAB X IDE project is located in the following MLA installation path: `microchip_solutions_v2013-06-15/USB/Device - CDC - Basic Demo/Firmware/MPLAB.X`.

The MPLAB Harmony cdc_com_port_single project is located in the `<install-dir>/apps/usb/device/cdc_com_port_single/firmware/cdc_com_port_single.X`.

Description

The following table lists the source (`.c`) files and header (`.h`) configuration files in the MLA "Device – CDC – Basic Demo" demonstration application project and their MPLAB Harmony counterparts (along with their paths). The parent folder for MPLAB Harmony framework files, unless otherwise specified, is `<install-dir>/framework`. The table also contains files which are exclusively required by the MPLAB Harmony project.

Classification	MLA USB Device Stack Application	MPLAB Harmony USB Device Stack Application
USB Device Layer Implementation	`usb_device.c`	`/usb/usb_device.c`
USB Device CDC Function Driver	`usb_function_cdc.c`	`/usb/src/dynamic/usb_device_cdc.c` `/usb/src/dynamic/usb_device_cdc_acm.c`

Application main file	`main.c`	`main.c`
		`app.c`
		`app.h` (see **Note**)

USB Device Descriptors	`usb_descriptors.c`	`system_init.c` (See System Configuration in this table.)
USB Device Stack Configuration	`usb_config.h`	`system_config.h` (See System Configuration in this table.)
Hardware Specification	`HardwareProfile.h` `HardwareProfile – PIC32 USB Starter Kit.h`	(See Board Support Package in this table.)
Board Support Package	N/A	`bsp/pic32mx_usb_sk2/bsp_sys_init.c` `bsp/pic32mx_usb_sk2/bsp_config.h`

System Services	N/A	`system/int/src/sys_int_pic32.c`
		`system/devcon/src/sys_devcon.c`
		`system/devcon/src/pic32mx/sys_devcon_pic32mx.c`

PIC32MX USB Driver	N/A	`driver/usb/usbfs/src/dynamic/drv_usb.c` `driver/usb/usbfs/src/dynamic/drv_usb_device.c`

System Configuration (see **Note**)	N/A	`system_config.h`
		`system_init.c`
		`system_interrupt.c`
		`system_tasks.c`
		`system_definitions.h`

Peripheral Library	N/A	`<install-dir>/bin/framework/peripheral/PIC32MX795F512L_peripherals.a`

Note: These files, which are not a part of the MPLAB Harmony Framework, are application-specific and must be coded to meet the needs of the application.

Source Code Analysis

Provides code comparison information.

Description

In this section, the MLA "Device – CDC – Basic Demo" demonstration application source code will be compared to the MPLAB Harmony cdc_com_port_single demonstration application source code. The MLA "Device – CDC – Basic Demo" demonstration application logic implementation can be classified into the following components

- Fuse configuration and Initialization
- Demonstration Application Logic
- Event Handling
- Invoking the Task Routine
- USB Descriptors
- Device Stack Configuration

The following sections discuss the comparison of these components with the MPLAB Harmony USB Device Stack and MPLAB Harmony application paradigm.

Fuse Configuration and Initialization

Provides information on fuse configuration and initialization.

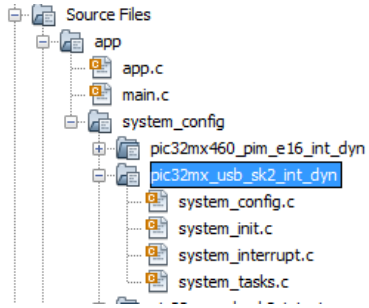
Description

The microcontroller fuse configuration in the MLA “Device – CDC – Basic Demo” demonstration application is implemented in the project `main.c` file.

Open the MLA “Device – CDC – Basic Demo” project in MPLAB X IDE and open the `main.c` file. Browse to line 277 of the file. This code region defines the fuse configuration macros while using the PIC32 USB Starter Kit II. The following screen capture shows this code.

```
277 #elif defined(PIC32_USB_STARTER_KIT)
278     #pragma config UPLLEN   = ON        // USB PLL Enabled
279     #pragma config FPLLMUL  = MUL_15        // PLL Multiplier
280     #pragma config UPLLIDIV = DIV_2         // USB PLL Input Divider
281     #pragma config FPLLIDIV = DIV_2         // PLL Input Divider
282     #pragma config FPLLODIV = DIV_1         // PLL Output Divider
283     #pragma config FPBDIV   = DIV_1         // Peripheral Clock divisor
284     #pragma config FWDTEN   = OFF           // Watchdog Timer
285     #pragma config WDTPS    = PS1           // Watchdog Timer Postscale
286     #pragma config FCKSM    = CSDCMD        // Clock Switching & Fail Safe Clock Monitor
287     #pragma config OSCIOFNC = OFF           // CLKO Enable
288     #pragma config POSCMOD  = HS            // Primary Oscillator
289     #pragma config IESO     = OFF           // Internal/External Switch-over
290     #pragma config FSOSCEN  = OFF           // Secondary Oscillator Enable (KLO was off)
291     #pragma config FNOSC    = PRIPLL        // Oscillator Selection
292     #pragma config CP       = OFF           // Code Protect
293     #pragma config BWP      = OFF           // Boot Flash Write Protect
294     #pragma config PWP      = OFF           // Program Flash Write Protect
295     #pragma config ICESEL   = ICS_PGx2      // ICE/ICD Comm Channel Select
```

In the MPLAB Harmony cdc_com_port_single project, locate the system configuration files. These files are located in the `<install-dir>/app/system_config` logical project folder. Within this folder, expand the `pic32mx_usb_sk2_int_dyn` configuration folder, as shown in the following figure.



Open `system_init.c` and review the fuse configurations. In MPLAB Harmony projects, the device fuse configuration macros are implemented in the `system_init.c` file. This file is a MPLAB Harmony system configuration file and is configuration-specific.

Continue with analysis of the MLA USB Demo `main.c` file. Navigate to line 488 of this file. This code region contains the application main function. The InitializeSystem function call at line 491 initializes the system. Further analysis of the InitializeSystem function indicates that this function (see line 648 of the file) configures the PIC32MX Cache and Flash Wait state for maximum performance for 60 MHz operating frequency, calls application specific user initialization function UserInit (see line 763) and then initializes the device stack by calling USBDeviceInit function (see line 765).

The following table lists the initialization related functions of the MLA USB Demonstration Application and their respective functional equivalent functions in the MPLAB Harmony USB Demonstration Application.

MLA USB Demonstration Application Function	Equivalent MPLAB Harmony USB Demonstration Application Function
InitializeSystem	SYS_Initialize
SYSTEMConfigPerformance	SYS_DEVCON_PerformanceConfig
UserInit	APP_Initialize
mInitAllLEDs mInitAllSwitches	BSP_Initialize
USBDeviceInit	USB_DEVICE_Initialize

The usbDevInitData and sysDevconInit data structures in MPLAB Harmony `system_init.c` are initialization data structures for the MPLAB Harmony USB Device Layer and the Device Control System Service, respectively. Please note that unlike the MLA USB Device Layer, the MPLAB Harmony USB Device Layer requires the specification of an endpoint table (see the endpointTable array declaration in `system_init.c`). The size of this table should be USB_DEVICE_ENDPOINT_TABLE_SIZE. This table (actually a byte array) should be aligned at 512 bytes address boundary.

The MPLAB Harmony Interrupt System Service functions, SYS_INT_VectorPrioritySet and SYS_INT_Enable,set the USB Interrupt Vector Priority and enable the global interrupts respectively. The USB_DEVICE_Initialize function initializes the USB Device Layer. The APP_Initialize function initializes the application data structure.

Demonstration Application Logic

Provides information on the demonstration application logic.

Description

The application logic in the MLA "Device – CDC – Basic Demo" demonstration application is implemented in the ProcessIO function (see line 819 of the project `main.c` file). This function is called periodically via the application `while(1)` loop (see line 521 of `main.c`). The ProcessIO function

calls the getsUSBUSART, putrsUSBUSART, and putUSBUSART functions to transfer data over the CDC Device Interface. The USBUSARTIsTxTrfReady function checks if the CDC function driver is ready to accept data for transmission. The CDCTxService function maintains the CDC function driver transmit state machine and is called periodically through the ProcessIO function (see line 870 of `main.c`).

In the MPLAB Harmony project, the appData object defined in the `app.h` file serves as a container for all application global data. The APP_StateReset function in the `app.c` file is called by the application and returns true if the device is not configured. This then causes the application state machine to reset.

The MPLAB Harmony application logic state machine (the APP_Tasks function) is implemented in `app.c`. The MPLAB Harmony USB Device Stack requires the application logic to be coded as a state machine that yields to the system periodically. In this state machine, the MPLAB Harmony USB Device Stack application must first open the USB Device Layer to access the functionality of the Device Layer. This is done through the USB_DEVICE_Open function. This step is not required in the MLA USB Device Stack application. The MPLAB Harmony USB Device Stack application can then wait for the device to be configured.

In the MPLAB Harmony USB Device application, the device is attached to the bus when VBUS power is detected. This is done by calling the USB_DEVICE_Attach function in the USB_DEVICE_EVENT_POWER_DETECTED function in APP_USBDeviceEventHandler function. The equivalent MLA USB Device Stack function is the USBDeviceAttach function. The USB_DEVICE_CDC_Read and USB_DEVICE_CDC_Write functions are called to transfer data over the CDC interface. The following table lists some of the MLA USB CDC function driver routines and their equivalents in the MPLAB Harmony CDC Function Driver API.

MLA USB CDC Function Driver Routine	MPLAB Harmony CDC Function Driver Routine
getsUSBUSART	USB_DEVICE_CDC_Read
putUSBUSART	USB_DEVICE_CDC_Write
putrsUSBUSART	USB_DEVICE_CDC_Write
CDCTxService	No equivalent routine. In the MPLAB Harmony USB Device Stack Framework, function driver state machine is updated by the Device Layer.
USBUSARTIsTxTrfReady	No equivalent routine. In the MPLAB Harmony USB Device Stack Framework, all data transfers are scheduled in a queue. The application does not need to check if the transmit state machine is ready. The application must use function driver events to check when a transfer is complete.

In the MLA USB CDC Function Driver, the getsUSBUSART function returns zero if no data has been received. In MPLAB Harmony CDC Function driver, the application must schedule a read with the USB_DEVICE_CDC_Read function, and then wait for the read complete event.

In the MLA USB CDC Function Driver, the application uses the USBUSARTIsTxTrfReady function to check if the CDC function is ready to transmit data. In the MPLAB Harmony CDC Function driver, the application does not need to check for transmit status. It schedules a write transfer request through the USB_DEVICE_CDC_Write function. If the request is added successfully to the queue, the application receives a valid transfer handle. The completion the transfer is indicated by an event. The MPLAB Harmony USB_DEVICE_CDC_Read and the USB_DEVICE_CDC_Write functions add transfer requests to a queue. The size of the queue is configurable. The MLA USB CDC Function driver does not support queuing.

Event Handling

Provides information on handling Device Layer events.

Description

The MLA USB Device Layer provides events to the application. In the MLA "Device – CDC – Basic Demo" demonstration application, the USB Device Layer application event handle, USER_USB_CALLBACK_EVENT_HANDLER, is implemented at line 1427 of the project `main.c` file. The MLA USB CDC function driver does not provide events to the application.

The MPLAB Harmony USB Device Layer Event handler is implemented in the APP_USBDeviceEventHandler function. The following table lists the MLA USB Device Layer Event and the equivalent MPLAB Harmony USB Device Layer Events. The MPLAB Harmony USB Device Layer features additional events that facilitate application device state management. Refer to the USB Device Layer Library documentation for more details.

MLA USB Device Layer Events	MPLAB Harmony USB Device Layer Events
EVENT_CONFIGURED	USB_DEVICE_EVENT_CONFIGURED
EVENT_SET_DESCRIPTOR	The USB Device Layer implementation in the MPLAB Harmony v0.80.xx installs Set Descriptor requests from the Host. The USB Device Layer implementation in the MPLAB Harmony v1.0 will provide this event to the application as USB_DEVICE_EVENT_SET_DESCRIPTOR event.
EVENT_EP0_REQUEST	USB_DEVICE_EVENT_CONTROL_TRANSFER_SETUP_REQUEST
EVENT_ATTACH	USB_DEVICE_EVENT_POWER_DETECTED
EVENT_TRANSFER_TERMINATED	USB_DEVICE_EVENT_CONTROL_TRANSFER_ABORTED
EVENT_TRANSFER	Not Applicable for standard device types. The USB Device Layer implementation in the MPLAB Harmony v1.0 will provide a USB_DEVICE_EVENT_ENDPOINT_READ_COMPLETE and a USB_DEVICE_ENDPOINT_WRITE_COMPLETE event for Generic device implementations.

EVENT_SOF	USB_DEVICE_EVENT_SOF
EVENT_RESUME	USB_DEVICE_EVENT_RESUMED
EVENT_SUSPEND	USB_DEVICE_EVENT_SUSPENDED
EVENT_BUS_ERROR	USB_DEVICE_EVENT_ERROR
EVENT_TRANSFER_TERMINATED	The USB Device Layer implementation in the MPLAB Harmony does not provide this event.

- The MLA USB Device Layer Event Handler function is fixed and needs to be specified for the code to compile. The MPLAB Harmony USB Device Layer Event Handler is Device Layer instance specific and is set through the USB_DEVICE_EventHandlerSet function. This function is called after the device layer is opened successfully in the APP_Tasks function.
- The MLA USB Device Layer Event Handler implementation must invoke the required function driver initialization routine in the EVENT_CONFIGURED event. This is not required in the MPLAB Harmony USB Device Layer Event Handler. The MPLAB Harmony USB Device Layer internally initializes all the function drivers associated with the configuration that the USB Host has set. The application should instead register event handlers with all the initialized function drivers.
- The MLA USB Device Layer Event Handler implementation must handle class specific control requests in the EVENT_EP0_REQUEST event response. The MPLAB Harmony USB Device Layer internally routes class specific requests directly to the function drivers. This process does not require application intervention. The MPLAB Harmony USB_DEVICE_EVENT_CONTROL_TRANSFER_SETUP_REQUEST event is generated when device layer receives a control transfer that is cannot be handled by the Device Layer or the Function Driver.

The MLA CDC Function Driver Interface is not event based and hence does not require an event handler. The MPLAB CDC Function Driver Interface is event based and requires a function driver instance specific event handler to be registered. This event handler is registered through the USB_DEVICE_CDC_EventHandlerSet function. The event handler should be registered in the Device Layer Set Configuration Event

Invoking the Tasks Routine

Provides information on how to invoke the Task Routine.

Description

Refer to line 502 of MLA "Device – CDC – Basic Demo" demonstration application file, `main.c`. This section of the code invokes the MLA USB Device Layer Task Routine, the USBDeviceTasks function, in the application `while(1)` superloop if the Device Stack is configured for Polled mode. If the Device Stack is configured for Interrupt mode operation, the USBDeviceTasks function is called (see line 664 of the `usb_device.c` file) in the USB Interrupt Service Routine. The MLA USB Device Stack features only one Task routine function.

The USB Device Layer Tasks routine in the MPLAB Harmony USB Device Stack is implemented by the USB_DEVICE_Tasks function. This function must be always be called in the SYS_Tasks function, regardless of whether the USB Device Stack is configured for Polled or Interrupt mode of operation. The MPLAB Harmony USB Device Stack defines an additional Interrupt mode specific task routine, the USB_DEVICE_Tasks_ISR function, that must be called from the USB Peripheral Interrupt Service Routine (ISR). This function should only be called in the USB Peripheral ISR. The USB Peripheral ISR is implemented in the `system_interrupt.c` file.

USB Device Descriptors

The USB Device Descriptors in the MLA "Device – CDC – Basic Demo" demonstration application are defined in the `usb_descriptors.c` file. This file contains the USB Device, Configuration, and String Descriptors.

Description

The USB Device Descriptors in the MLA “Device – CDC – Basic Demo” demonstration application are defined in the `usb_descriptors.c` file. This file contains the USB Device, Configuration and String Descriptors.

The USB Device, Configuration, and String Descriptors. USB Descriptors in a MPLAB Harmony USB Device Stack Demonstration Application are specified in the `system_init.c` file. Some of the macros (those that define endpoint and direction) used in the "Device – CDC – Basic Demo" demonstration application USB descriptors are not used in the MPLAB Harmony cdc_com_port_single USB Descriptors.

The `system_init.c` file also contains additional data structures needed by the MPLAB Harmony USB Device Stack. These are:

- Function Driver registration table (funcRegistrationTable), which provisions functions drivers to be included in this USB device
- Master Descriptor table (usbMasterDescriptor), which provides information configuration and the string descriptors to the USB Device Layer
- Table of speed specific configuration descriptors (fullSpeedConfigDescSet)
- CDC function driver initialization data structure (cdcInit). This structure contains the size of the CDC read and write, and the serial state notification send queues.

Note: The MLA USB Device layer does not require the specification of the data structures.

Device Stack Configuration

The USB Device Stack configuration in the MLA "Device – CDC – Basic Demo" demonstration application is defined in the project-specific `usb_config.h` file, located in the Project firmware folder.

Description

The USB Device Stack configuration in the MPLAB Harmony cdc_com_port_single demonstration application needs to be specified in the `system_config.h` file. This includes the configuration for the USB Controller Driver, Device Layer, and CDC Function Driver. The following table shows the MLA USB Device Stack Configuration macros and their equivalent MPLAB Harmony USB Device Stack Configuration Macros.

MLA USB Device Stack Configuration Macros	MPLAB Harmony USB Device Stack Configuration Macros
USB_EP0_BUFF_SIZE	USB_DEVICE_EP0_BUFFER_SIZE
USB_MAX_NUM_INT	The number of the interface used by a function driver instance is specified via an entry in the Function Driver Registration Table (in `system_init.c`).
USB_USER_DEVICE_DESCRIPTOR	This USB Device Descriptor is specified via the Master Descriptor Table (in `system_init.c`).
USB_PING_PONG_MODE	Not applicable. The USB Controller is always configured for maximum performance (full ping pong).
USB_POLLING USB_INTERRUPT	DRV_USB_INTERRUPT_MODE. Should be set to true for Interrupt mode and false for Polled mode.
USB_PULLUP_OPTION	Not applicable.
USB_TRANSCEIVER_OPTION	Not applicable.
USB_SPEED_OPTION	This is defined via the USB_DEVICE_INIT data structure at Device Layer Initialization in `system_init.c`.
USB_ENABLE_STATUS_STAGE_TIMEOUTS	Not applicable.
USB_SUPPORT_DEVICE	Specified via DRV_USB_DEVICE_SUPPORT and DRV_USB_HOST_SUPPORT. These can be set to true to enable the required feature.
USB_ENABLE_ALL_HANDLERS	Not applicable. All Device Layer events are provided via one event handler registered dynamically.
USB_USE_CDC	Not applicable. Function Drivers are provisioned via an entry in the Function Driver Registration Table (in `system_init.c`).
CDC_COMM_INTF_ID CDC_COMM_EP CDC_COMM_IN_EP_SIZE CDC_DATA_INTF_ID CDC_DATA_EP CDC_DATA_OUT_EP_SIZE CDC_DATA_IN_EP_SIZE	Not applicable. The number of the interface used by a function driver instance is specified via an entry in the Function Driver Registration Table (in `system_init.c`). The Device Layer obtains endpoint information for a specific instance of the CDC driver from the USB Configuration Descriptor.
USB_CDC_SUPPORT_ABSTRACT_CONTROL_MANAGEMENT_CAPABILITIES_D1	Not applicable. Features are defined by the CDC Class specific descriptors.

The MPLAB Harmony USB Device Stack requires specification of other configuration macros. Refer to the USB Device Library and the USB Driver Libraries sections for additional information.

USB Audio 1.0 Device Library

This section describes the USB Audio 1.0 Device Library.

Introduction

This section provides information on library design, configuration, usage and the library interface for the USB Audio 1.0 Device Library.

Description

The MPLAB Harmony USB Audio 1.0 Device Library (also referred to as the Audio 1.0 Function Driver or library) features routines to implement a USB Audio 1.0 Device. Examples of Audio USB Devices include USB Speakers, microphones, and voice telephony. The library provides a convenient abstraction of the USB Audio 1.0 Device specification and simplifies the implementation of USB Audio 1.0 Devices.

Using the Library

This topic describes the basic architecture of the Audio 1.0 Function Driver and provides information and examples on its use.

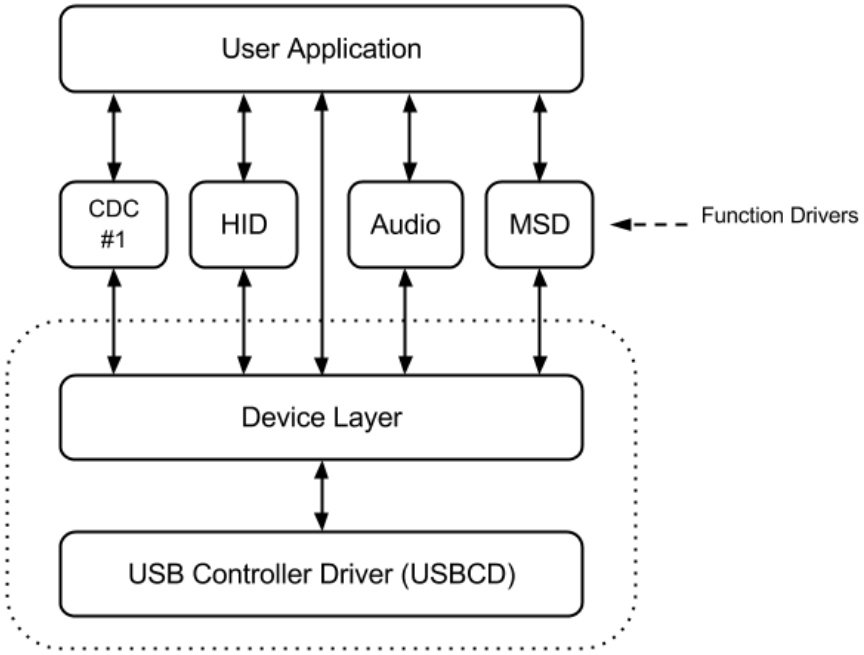
Abstraction Model

Describes the Abstraction Model of the USB Audio 1.0 Device Library.

Description

The Audio 1.0 Function Driver offers various services to the USB Audio 1.0 device to communicate with the host by abstracting USB specification details. It must be used along with the USB Device layer and USB controller to communicate with the USB host. Figure 1 shows a block diagram of the MPLAB Harmony USB Device Stack Architecture and where the Audio 1.0 Function Driver is placed.

Figure 1: USB Device 1.0 Audio Device Driver



The USB controller driver takes the responsibility of managing the USB peripheral on the device. The USB 1.0 Device Layer handles the device enumeration, etc. The USB Device 1.0 Layer forwards all Audio-specific control transfers to the Audio 1.0 Function Driver. The Audio 1.0 Function Driver interprets the control transfers and requests application's intervention through event handlers and a well-defined set of functions. The application must respond to the Audio events either in or out of the event handler. Some of these events are related to Audio 1.0 Device Class specific control transfers. The application must complete these control transfers within the timing constraints defined by USB.

Library Overview

The USB Audio 1.0 Device Library mainly interacts with the system, its clients and function drivers, as shown in the Abstraction Model.

The library interface routines are divided into sub-sections, which address one of the blocks or the overall operation of the USB Audio 1.0 Device Library.

Library Interface Section	Description
Functions	Provides event handler, read/write, and transfer cancellation functions.

How the Library Works

Initializing the Library

Describes how the USB Audio 1.0 Device driver is initialized.

Description

The Audio 1.0 Function Driver instance for a USB device configuration is initialized by the Device Layer when the configuration is set by the host. This process does not require application intervention. Each instance of the Audio 1.0 Function Driver should be registered with the Device layer through the Device Layer Function Driver Registration Table. The Audio 1.0 Function Driver requires a initialization data structure to be specified. This is a USB_DEVICE_AUDIO_INIT data type that specifies the size of the read and write queues. The funcDriverInit member of the function driver registration table entry of the Audio 1.0 Function Driver instance should point to this initialization data structure. The USB_DEVICE_AUDIO_FUNCTION_DRIVER object is a global object provided by the Audio 1.0 Function Driver and provides the Device Layer with an entry point into the Audio 1.0 Function Driver. The following code shows an example of how the Audio 1.0 Function Driver can be registered with the Device Layer.

```
/* This code shows an example of how an Audio 1.0 Function Driver instances
 * can be registered with the Device Layer via the Device Layer Function Driver
 * Registration Table.  In this case Device Configuration 1 consists of one
 * Audio 1.0 Function Driver instance. */

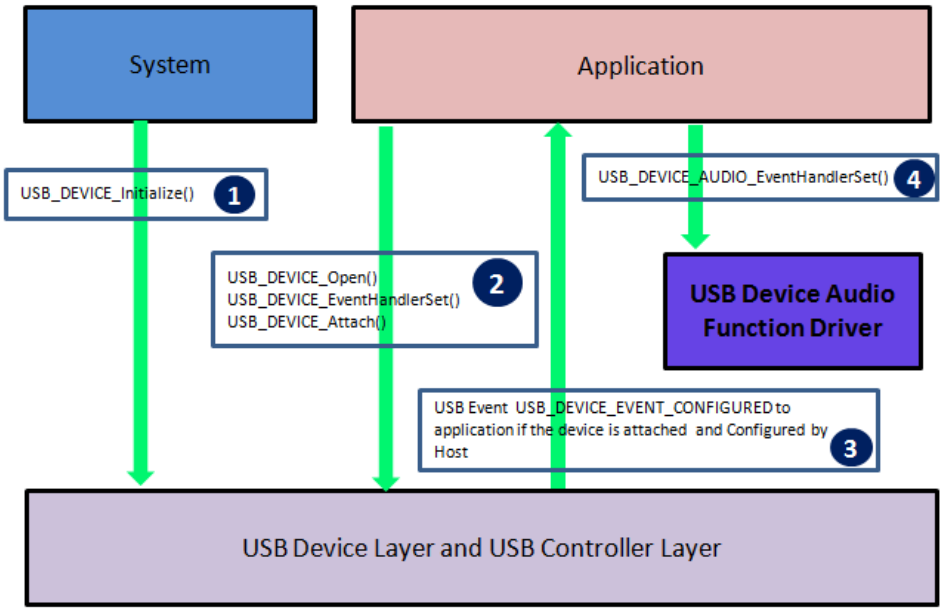
/* The Audio 1.0 Function Driver requires an initialization data structure that
 * specifies the read and write buffer queue sizes. Note that these settings are
 * also affected by the USB_DEVICE_AUDIO_QUEUE_DEPTH_COMBINED configuration
 * macro. */

const USB_DEVICE_AUDIO_INIT audioDeviceInit =
{
    .queueSizeRead = 1,
    .queueSizeWrite = 1
};

const USB_DEVICE_FUNC_REGISTRATION_TABLE funcRegistrationTable[1] =
{
    {
        .speed = USB_SPEED_FULL,                    // Supported speed
        .configurationValue = 1,                    // To be initialized for Configuration 1
        .interfaceNumber = 0,                       // Starting interface number.
        .numberOfInterfaces = 2,                    // Number of interfaces in this instance
        .funcDriverIndex = 0,                       // Function Driver instance index is 0
        .funcDriverInit = &audioDeviceInit,         // Function Driver does not need initialization data
structure
        .driver = USB_DEVICE_AUDIO_FUNCTION_DRIVER  // Pointer to Function Driver - Device Layer interface
functions
    },
};
```

The following figure illustrates the typical sequence that is followed in the application when using the Audio 1.0 Function Driver.

Typical USB Audio 1.0 Device Sequence



1. Call set of APIs to initialize USB Device Layer (refer to the USB Device Layer Library section for details about these APIs).
2. The Device Layer provides a callback to the application for any USB Device events like attached, powered, configured, etc. The application should receive a callback with an event USB_DEVICE_EVENT_CONFIGURED to proceed.
3. Once the Device Layer is configured, the application needs to register a callback function with the Audio 1.0 Function Driver to receive Audio Control transfers, and also other Audio 1.0 Function Driver events. Now the application can use Audio 1.0 Function Driver APIs to communicate with the USB Host.

Event Handling

Describes Audio 1.0 Function Driver event handler registration and event handling.

Description

Registering a Audio 1.0 Function Driver Callback Function

While creating a USB Audio 1.0 Device application, an event handler must be registered with the Device Layer (the Device Layer Event Handler) and every Audio 1.0 Function Driver instance (Audio 1.0 Function Driver Event Handler). The application needs to register the event handler with the Audio 1.0 Function Driver:

- For receiving Audio Control Requests from Host like Volume Control, Mute Control, etc.
- For handling other events from USB Audio 1.0 Device Driver (e.g., Data Write Complete or Data Read Complete)

The event handler should be registered before the USB device layer acknowledges the SET CONFIGURATION request from the USB Host. To ensure this, the callback function should be set in the USB_DEVICE_EVENT_CONFIGURED event that is generated by the device layer. The following code example shows how this can be done.

```
/* This a sample Application Device Layer Event Handler
 * Note how the USB Audio 1.0 Device Driver callback function
 * USB_DEVICE_AUDIO_EventHandlerSet()
 * is registered in the USB_DEVICE_EVENT_CONFIGURED event.  */

void APP_USBDeviceEventHandler( USB_DEVICE_EVENT event,
                                void * pEventData, uintptr_t context )
{
    switch ( event )
    {
        case USB_DEVICE_EVENT_RESET:
        case USB_DEVICE_EVENT_DECONFIGURED:

            // USB device is reset or device is deconfigured.
            // This means that USB device layer is about to deinitialize
            // all function drivers.

            break;

        case USB_DEVICE_EVENT_CONFIGURED:
```

```
            /* check the configuration */
            if ( ((USB_DEVICE_EVENT_DATA_CONFIGURED *)
                  (eventData))->configurationValue == 1)
            {

                USB_DEVICE_AUDIO_EventHandlerSet
                     ( USB_DEVICE_AUDIO_INDEX_0,
                       APP_USBDeviceAudioEventHandler ,
                       (uintptr_t)NULL);

                /* mark that set configuration is complete */
                appData.isConfigured = true;

            }
            break;

        case USB_DEVICE_EVENT_SUSPENDED:

            break;

        case USB_DEVICE_EVENT_RESUMED:
        case USB_DEVICE_EVENT_POWER_DETECTED:
        /* VBUS has been detected */
        USB_DEVICE_Attach(appData.usbDeviceHandle);
    break;
        case USB_DEVICE_EVENT_POWER_REMOVED:
        /*VBUS is not available anymore. */
        USB_DEVICE_Detach(appData.usbDeviceHandle);
    break;
        case USB_DEVICE_EVENT_ERROR:
        default:
            break;
    }
}
```

Event Handling

The Audio 1.0 Function Driver provides events to the application through the event handler function registered by the application. These events indicate:

- Completion of a read or a write data transfer
- Audio Control Interface requests
- Completion of data and the status stages of Audio Control Interface related control transfer

The Audio Control Interface Request events and the related control transfer events typically require the application to respond with the Device Layer Control Transfer routines to complete the control transfer. Based on the generated event, the application may be required to:

- Respond with a USB_DEVICE_ControlSend function, which is completes the data stage of a Control Read Transfer
- Respond with a USB_DEVICE_ControlReceive function, which provisions the data stage of a Control Write Transfer
- Respond with a USB_DEVICE_ControlStatus function, which completes the handshake stage of the Control Transfer. The application can either STALL or Acknowledge the handshake stage through the USB_DEVICE_ControlStatus function.

The following table shows the CDC Function Driver Control Transfer related events and the required application control transfer actions.

Audio 1.0 Function Driver Control Transfer Event	Required Application Action
USB_DEVICE_AUDIO_EVENT_CONTROL_SET_CUR USB_DEVICE_AUDIO_EVENT_CONTROL_SET_MIN USB_DEVICE_AUDIO_EVENT_CONTROL_SET_MAX USB_DEVICE_AUDIO_EVENT_CONTROL_SET_RES USB_DEVICE_AUDIO_EVENT_CONTROL_SET_MEM	Identify the control type using the associated event data. If a data stage is expected, use the USB_DEVICE_ControlReceive function to receive expected data. If a data stage is not required or if the request is not supported, use the USB_DEVICE_ControlStatus function to Acknowledge or Stall the request.
USB_DEVICE_AUDIO_EVENT_CONTROL_GET_CUR USB_DEVICE_AUDIO_EVENT_CONTROL_GET_MIN USB_DEVICE_AUDIO_EVENT_CONTROL_GET_MAX USB_DEVICE_AUDIO_EVENT_CONTROL_GET_RES USB_DEVICE_AUDIO_EVENT_CONTROL_GET_MEM	Identify the control type using the associated event data. Use the USB_DEVICE_ControlSend function to send the expected data. If the request is not supported, use the USB_DEVICE_ControlStatus function to Stall the request.
USB_DEVICE_AUDIO_EVENT_ENTITY_GET_STAT	Identify the entity type using the associated event data. Use the USB_DEVICE_ControlSend function to send the expected data. If the request is not supported, use the USB_DEVICE_ControlStatus function to Stall the request.

USB_DEVICE_AUDIO_CONTROL_TRANSFER_DATA_RECEIVED	Acknowledge or stall using the USB_DEVICE_ControlStatus function.
USB_DEVICE_AUDIO_CONTROL_TRANSFER_DATA_SENT	Action not required.
USB_DEVICE_AUDIO_EVENT_CONTROL_TRANSFER_UNKNOWN	Interpret the setup packet and use the Device layer Control transfer functions to complete the transfer.

The application must analyze the wIndex field of the event data (received with the control transfer event) to identify the entity that is being addressed. The application must be aware of all entities included in the application and their IDs. Once identified, the application can then type cast the event data to entity type the specific control request type. For example, if the Host sends a control request to set the volume of the Audio device, the following occurs in this order:

1. The Audio 1.0 Function Driver will generate a USB_DEVICE_AUDIO_EVENT_CONTROL_SET_CUR event.
2. The application must type cast the event data to a USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_CUR type and check the entityID field.
3. The entityID field will be identified by the application as a Feature Unit.
4. The application must now type cast the event data type as a USB_AUDIO_FEATURE_UNIT_CONTROL_REQUEST data type and check the controlSelector field.
5. If the controlSelector field is a USB_AUDIO_VOLUME_CONTROL, the application can then call the USB_DEVICE_AUDIO_ControlReceive function to receive the new volume settings.

Based on the type of event, the application should analyze the event data parameter of the event handler. This data member should be type cast to an event specific data type. The following table shows the event and the data type to use while type casting. Note that the event data member is not required for all events

Audio 1.0 Function Driver Event	Related Event Data Type
USB_DEVICE_AUDIO_EVENT_CONTROL_SET_CUR	USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_CUR *
USB_DEVICE_AUDIO_EVENT_CONTROL_SET_MIN	USB_DEVICE_AUDIO_EVENT_ DATA_CONTROL_SET_MIN *

Handling Audio Control Requests:

When the Audio 1.0 Function Driver receives an Audio Class Specific Control Transfer Request, it passes this control transfer to the application as a Audio 1.0 Function Driver event. The following code example shows how to handle an Audio Control request.

```
// This code example shows handling Audio Control requests. The following code
// handles a Mute request (both SET and GET) received from a USB Host.

void APP_USBDeviceAudioEventHandler
(
    USB_DEVICE_AUDIO_INDEX iAudio ,
    USB_DEVICE_AUDIO_EVENT event ,
    void * pData,
    uintptr_t context
)
{
    USB_DEVICE_AUDIO_EVENT_DATA_INTERFACE_SETTING_CHANGED *interfaceInfo;
    USB_DEVICE_AUDIO_EVENT_DATA_READ_COMPLETE *readEventData;
```

```
uint8_t entityID;
uint8_t controlSelector;
if ( iAudio == 0 )
{
    switch (event)
    {
        case USB_DEVICE_AUDIO_EVENT_INTERFACE_SETTING_CHANGED:

            /* We have received a request from USB host to change the
             * Interface-Alternate setting. The application should be aware
             * of the association between alternate settings and the device
             * features to be enabled.*/

            interfaceInfo = (USB_DEVICE_AUDIO_EVENT_DATA_INTERFACE_SETTING_CHANGED *)pData;
            appData.activeInterfaceAlternateSetting = interfaceInfo->interfaceAlternateSetting;
            appData.state = APP_USB_INTERFACE_ALTERNATE_SETTING_RCVD;
            break;

        case USB_DEVICE_AUDIO_EVENT_READ_COMPLETE:
            /* We have received an audio frame from the Host.
               Now send this audio frame to Audio Codec for Playback. */
            break;

        case USB_DEVICE_AUDIO_EVENT_WRITE_COMPLETE:
            break;

        case USB_DEVICE_AUDIO_EVENT_CONTROL_SET_CUR:

            /* This is an example of handling Audio control request. In this
             * case the control request is targeted to the Mute Control in
             * a feature unit entity. This event indicates that the current
             * value needs to be set. */

            entityID = ((USB_AUDIO_CONTROL_INTERFACE_REQUEST*)pData)->entityID;
            if (entityID == APP_ID_FEATURE_UNIT)
            {
                controlSelector = ((USB_AUDIO_FEATURE_UNIT_CONTROL_REQUEST*)pData)->controlSelector;
                if (controlSelector == USB_AUDIO_MUTE_CONTROL)
                {
                    /* It is confirmed that this request is targeted to the
                     * mute control. We schedule a control transfer receive
                     * to get data from the host. */

                    USB_DEVICE_ControlReceive(appData.usbDevHandle, (void *) &(appData.dacMute), 1 );
                    appData.currentAudioControl = APP_USB_AUDIO_MUTE_CONTROL;
                }
            }
            break;

        case USB_DEVICE_AUDIO_EVENT_CONTROL_GET_CUR:

            /* This event occurs when the host is requesting a current
             * status of control */

            entityID = ((USB_AUDIO_CONTROL_INTERFACE_REQUEST*)pData)->entityID;
            if (entityID == APP_ID_FEATURE_UNIT)
            {
                controlSelector = ((USB_AUDIO_FEATURE_UNIT_CONTROL_REQUEST*)pData)->controlSelector;
                if (controlSelector == USB_AUDIO_MUTE_CONTROL)
                {
                    /* Use the control send function to send the status of
                     * the control to the host */
                    USB_DEVICE_ControlSend(appData.usbDevHandle, (void *)&(appData.dacMute), 1 );
                }
            }
            break;

        case USB_DEVICE_AUDIO_EVENT_CONTROL_SET_MIN:
        case USB_DEVICE_AUDIO_EVENT_CONTROL_GET_MIN:
```

```
            case USB_DEVICE_AUDIO_EVENT_CONTROL_SET_MAX:
            case USB_DEVICE_AUDIO_EVENT_CONTROL_GET_MAX:
            case USB_DEVICE_AUDIO_EVENT_CONTROL_SET_RES:
            case USB_DEVICE_AUDIO_EVENT_CONTROL_GET_RES:
            case USB_DEVICE_AUDIO_EVENT_ENTITY_GET_MEM:

                /* In this example, all of these control requests are not
                 * supported. So these are stalled. */
                USB_DEVICE_ControlStatus (appData.usbDevHandle, USB_DEVICE_CONTROL_STATUS_ERROR);
                break;

            case USB_DEVICE_AUDIO_EVENT_CONTROL_TRANSFER_DATA_RECEIVED:

                /* This event occurs when data has been received in a control
                 * transfer */

                USB_DEVICE_ControlStatus(appData.usbDevHandle, USB_DEVICE_CONTROL_STATUS_OK );
                if (appData.currentAudioControl == APP_USB_AUDIO_MUTE_CONTROL)
                {
                    appData.state = APP_MUTE_AUDIO_PLAYBACK;
                    appData.currentAudioControl = APP_USB_CONTROL_NONE;
                }
                break;

            case  USB_DEVICE_AUDIO_EVENT_CONTROL_TRANSFER_DATA_SENT:
                break;
            default:
                break;
        }
    }
}
```

Transferring Data

Describes how to send/receive data to/from USB Host using this USB Audio 1.0 Device Driver.

Description

The USB Audio 1.0 Device Driver provides functions to send and receive data.

Receiving Data

The USB_DEVICE_AUDIO_Read function schedules a data read. When the host transfers data to the device, the Audio 1.0 Function Driver receives the data and invokes the USB_DEVICE_AUDIO_EVENT_READ_COMPLETE event. This event indicates that audio data is now available in the application specified buffer.

The Audio 1.0 Function Driver supports buffer queuing. The application can schedule multiple read requests. Each request is assigned a unique buffer handle, which is returned with the USB_DEVICE_AUDIO_EVENT_READ_COMPLETE event. The application can use the buffer handle to track completion to queued requests. Using this feature allows the application to implement audio buffering schemes such as ping-pong buffering.

Sending Data

The USB_DEVICE_AUDIO_Write schedules a data write. When the host sends a request for the data, the Audio 1.0 Function Driver transfers the data and invokes the USB_DEVICE_AUDIO_EVENT_WRITE_COMPLETE event.

The Audio 1.0 Function Driver supports buffer queuing. The application can schedule multiple write requests. Each request is assigned a unique buffer handle, which is returned with the USB_DEVICE_AUDIO_EVENT_WRITE_COMPLETE event. The application can use the buffer handle to track completion to queued requests. Using this feature allows the application to implement audio buffering schemes such as ping-pong buffering.

Configuring the Library

Describes how to configure the USB Audio 1.0 Device Driver.

Macros

	Name	Description
	USB_DEVICE_AUDIO_INSTANCES_NUMBER	Specifies the number of Audio Function Driver instances.
	USB_DEVICE_AUDIO_MAX_ALTERNATE_SETTING	Specifies the maximum number of Alternate Settings per streaming interface.

	USB_DEVICE_AUDIO_MAX_STREAMING_INTERFACES	Specifies the maximum number of Audio Streaming interfaces in an Audio Function Driver instance.
	USB_DEVICE_AUDIO_QUEUE_DEPTH_COMBINED	Specifies the combined queue size of all Audio function driver instances.

Description

The application designer must specify the following configuration parameters while using the USB Audio 1.0 Device Driver. The configuration macros that implement these parameters must be located in the `system_config.h` file in the application project and a compiler include path (to point to the folder that contains this file) should be specified.

USB_DEVICE_AUDIO_INSTANCES_NUMBER Macro

Specifies the number of Audio Function Driver instances.

File

usb_device_audio_v1_0_config_template.h

C

```
#define USB_DEVICE_AUDIO_INSTANCES_NUMBER
```

Description

USB device Audio Maximum Number of instances

This macro defines the number of instances of the Audio Function Driver. For example, if the application needs to implement two instances of the Audio Function Driver (to create two composite Audio Device) on one USB Device, the macro should be set to 2. Note that implementing a USB Device that features multiple Audio interfaces requires appropriate USB configuration descriptors.

Remarks

None.

USB_DEVICE_AUDIO_MAX_ALTERNATE_SETTING Macro

Specifies the maximum number of Alternate Settings per streaming interface.

File

usb_device_audio_v1_0_config_template.h

C

```
#define USB_DEVICE_AUDIO_MAX_ALTERNATE_SETTING
```

Description

Maximum number of Alternate Settings

This macro defines the maximum number of Alternate Settings per streaming interface. If the Audio Device features multiple streaming interfaces, this configuration constant should be equal to the the maximum number of alternate required amongst the streaming interfaces.

Remarks

None.

USB_DEVICE_AUDIO_MAX_STREAMING_INTERFACES Macro

Specifies the maximum number of Audio Streaming interfaces in an Audio Function Driver instance.

File

usb_device_audio_v1_0_config_template.h

C

```
#define USB_DEVICE_AUDIO_MAX_STREAMING_INTERFACES
```

Description

Maximum Audio Streaming Interfaces

This macro defines the maximum number of streaming interfaces in an Audio Function Driver instance. In case of multiple Audio Function Driver instances, this constant should be equal to the maximum number of interfaces amongst the Audio Function Driver instances.

Remarks

None.

USB_DEVICE_AUDIO_QUEUE_DEPTH_COMBINED Macro

Specifies the combined queue size of all Audio function driver instances.

File

usb_device_audio_v1_0_config_template.h

C

```
#define USB_DEVICE_AUDIO_QUEUE_DEPTH_COMBINED
```

Description

USB device Audio Combined Queue Size

This macro defines the number of entries in all queues in all instances of the Audio function driver. This value can be obtained by adding up the read and write queue sizes of each Audio Function driver instance. In a simple single instance USB Audio device application, that does not require buffer queuing, the USB_DEVICE_AUDIO_QUEUE_DEPTH_COMBINED macro can be set to 2. Consider a case of a Audio function driver instances, with has a read queue size of 2 and write queue size of 3, this macro should be set to 5 (2 + 3).

Remarks

None.

Building the Library

This section lists the files that are available in the USB Audio 1.0 Device Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/usb`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
usb_device_audio_v1_0.h	This header file must be included in every source file that needs to invoke USB Audio 1.0 Device Driver APIs.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/dynamic/usb_device_audio_v1_0.c	This file contains all of functions, macros, definitions, variables, datatypes, etc., that are specific to the USB Audio Specification v1.0 implementation of the Audio 1.0 Function Driver.
/src/dynamic/usb_device_audio_read_write.c	Contains implementation of the Audio 1.0 Function Driver read and write functions.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The USB Audio 1.0 Device Library depends on the following modules:

- USB Device Library

Library Interface

a) Functions

	Name	Description
	USB_DEVICE_AUDIO_EventHandlerSet	This function registers an event handler for the specified Audio function driver instance.
	USB_DEVICE_AUDIO_Read	This function requests a data read from the USB Device Audio Function Driver Layer.
	USB_DEVICE_AUDIO_TransferCancel	This function cancels a scheduled Audio Device data transfer.
	USB_DEVICE_AUDIO_Write	This function requests a data write to the USB Device Audio Function Driver Layer.

b) Data Types and Constants

	Name	Description
	USB_DEVICE_AUDIO_EVENT_RESPONSE_NONE	USB Device Audio Function Driver event handler response type none.
	USB_DEVICE_AUDIO_TRANSFER_HANDLE_INVALID	USB Device Audio Function Driver invalid transfer handle definition.
	USB_DEVICE_AUDIO_EVENT	USB Device Audio Function Driver events.
	USB_DEVICE_AUDIO_EVENT_DATA_READ_COMPLETE	USB Device Audio Function Driver audio read and write complete event data.
	USB_DEVICE_AUDIO_EVENT_DATA_WRITE_COMPLETE	USB Device Audio Function Driver audio read and write complete event data.
	USB_DEVICE_AUDIO_EVENT_HANDLER	USB Device Audio event handler function pointer type.
	USB_DEVICE_AUDIO_EVENT_RESPONSE	USB Device Audio Function Driver event callback response type.
	USB_DEVICE_AUDIO_INDEX	USB Device Audio function driver index.
	USB_DEVICE_AUDIO_RESULT	USB Device Audio Function Driver USB Device Audio result enumeration.
	USB_DEVICE_AUDIO_TRANSFER_HANDLE	USB Device Audio Function Driver transfer handle definition.
	USB_DEVICE_AUDIO_FUNCTION_DRIVER	USB Device Audio Function Driver function pointer.
	USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_CUR	This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_CUR.
	USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MAX	This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MAX.
	USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MEM	This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MEM.
	USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MIN	This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MIN.
	USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_RES	This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_RES.
	USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_CUR	USB Device Audio Function Driver set and get request data.
	USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MAX	This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MAX.
	USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MEM	This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MEM.
	USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MIN	This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MIN.
	USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_RES	This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_RES.

	USB_DEVICE_AUDIO_EVENT_DATA_INTERFACE_SETTING_CHANGED	USB Device Audio Function Driver alternate interface setting event data.
	USB_DEVICE_AUDIO_INIT	USB Device Audio Function Driver initialization data structure.
	USB_DEVICE_AUDIO_EVENT_DATA_ENTITY_GET_STAT	This is type USB_DEVICE_AUDIO_EVENT_DATA_ENTITY_GET_STAT.
	USB_DEVICE_AUDIO_TRANSFER_ABORT_NOTIFY	USB Audio Transfer abort notification enable

Description

This section describes the Application Programming Interface (API) functions of the USB Device Audio 1.0 Library.

Refer to each section for a detailed description.

a) Functions

USB_DEVICE_AUDIO_EventHandlerSet Function

This function registers an event handler for the specified Audio function driver instance.

File

usb_device_audio_v1_0.h

C

```
USB_DEVICE_AUDIO_RESULT USB_DEVICE_AUDIO_EventHandlerSet(USB_DEVICE_AUDIO_INDEX instanceIndex,
USB_DEVICE_AUDIO_EVENT_HANDLER eventHandler, uintptr_t context);
```

Returns

- USB_DEVICE_AUDIO_RESULT_OK - The operation was successful
- USB_DEVICE_AUDIO_RESULT_ERROR_INSTANCE_INVALID - The specified instance does not exist.
- USB_DEVICE_AUDIO_RESULT_ERROR_PARAMETER_INVALID - The eventHandler parameter is NULL

Description

This function registers a event handler for the specified Audio function driver instance. This function should be called by the application when it receives a SET CONFIGURATION event from the device layer. The application must register an event handler with the function driver in order to receive and respond to function driver specific events and control transfers. If the event handler is not registered, the device layer will stall function driver specific commands and the USB device may not function.

Remarks

None.

Preconditions

This function should be called when the function driver has been initialized as a result of a set configuration.

Example

```
// The following code shows an example for registering an event handler. The
// application specifies the context parameter as a pointer to an
// application object (appObject) that should be associated with this
// instance of the Audio function driver.

USB_DEVICE_AUDIO_RESULT result;

USB_DEVICE_AUDIO_EVENT_RESPONSE APP_USBDeviceAUDIOEventHandler
(
    USB_DEVICE_AUDIO_INDEX instanceIndex ,
    USB_DEVICE_AUDIO_EVENT event ,
    void* pData,
    uintptr_t context
)
{
    // Event Handling comes here

    switch(event)
    {
```

```
            ...
        }

        return(USB_DEVICE_AUDIO_EVENT_RESPONSE_NONE);
    }

    result = USB_DEVICE_AUDIO_EventHandlerSet ( USB_DEVICE_AUDIO_INSTANCE_0 ,
                &APP_USBDeviceAUDIOEventHandler, (uintptr_t) &appObject);

    if(USB_DEVICE_AUDIO_RESULT_OK != result)
    {
        // Do error handling here
    }
```

Parameters

Parameters	Description
instance	Instance of the Audio Function Driver.
eventHandler	A pointer to event handler function.
context	Application specific context that is returned in the event handler.

Function

USB_DEVICE_AUDIO_RESULT USB_DEVICE_AUDIO_EventHandlerSet
(
USB_DEVICE_AUDIO_INDEX instance ,
USB_DEVICE_AUDIO_EVENT_HANDLER eventHandler ,
uintptr_t context
);

USB_DEVICE_AUDIO_Read Function

This function requests a data read from the USB Device Audio Function Driver Layer.

File

usb_device_audio_v1_0.h

C

```
USB_DEVICE_AUDIO_RESULT USB_DEVICE_AUDIO_Read(USB_DEVICE_AUDIO_INDEX instanceIndex,
USB_DEVICE_AUDIO_TRANSFER_HANDLE* transferHandle, uint8_t interfaceNumber, void * data, size_t size);
```

Returns

- USB_DEVICE_AUDIO_RESULT_OK - The read request was successful. transferHandle contains a valid transfer handle.
- USB_DEVICE_AUDIO_RESULT_ERROR_TRANSFER_QUEUE_FULL - internal request queue is full. The read request could not be added.
- USB_DEVICE_AUDIO_RESULT_ERROR_INSTANCE_NOT_CONFIGURED - The specified instance is not configured yet.
- USB_DEVICE_AUDIO_RESULT_ERROR_INSTANCE_INVALID - The specified instance was not provisioned in the application and is invalid.

Description

This function requests a data read from the USB Device Audio Function Driver Layer. The function places a requests with driver, the request will get serviced as data is made available by the USB Host. A handle to the request is returned in the transferHandle parameter. The termination of the request is indicated by the USB_DEVICE_AUDIO_EVENT_READ_COMPLETE event. The amount of data read and the transfer handle associated with the request is returned along with the event. The transfer handle expires when event handler for the USB_DEVICE_AUDIO_EVENT_READ_COMPLETE exits. If the read request could not be accepted, the function returns an error code and transferHandle will contain the value USB_DEVICE_AUDIO_TRANSFER_HANDLE_INVALID.

Remarks

While the using the Audio Function Driver with PIC32MZ USB module, the audio buffer provided to the USB_DEVICE_AUDIO_Read function should be placed in coherent memory and aligned at a 16 byte boundary. This can be done by declaring the buffer using the __attribute__((coherent, aligned(16))) attribute. An example is shown here

```
uint8_t data[256] __attribute__((coherent, aligned(16)));
```

Preconditions

The function driver should have been configured.

Example

```
// Shows an example of how to read. This assumes that
// device had been configured. The example attempts to read
// data from interface 1.

USB_DEVICE_AUDIO_INDEX instanceIndex;
USB_DEVICE_AUDIO_TRANSFER_HANDLE transferHandle;
unit8_t interfaceNumber;
unit8_t rxBuffer[192]; // Use this attribute for PIC32MZ __attribute__((coherent, aligned(16)))
USB_DEVICE_AUDIO_RESULT readRequestResult;

instanceIndex = 0; //specify the Audio Function driver instance number.
interfaceNumber = 1; //Specify the Audio Streaming interface number.

readRequestResult = USB_DEVICE_AUDIO_Read ( instanceIndex, &transferHandle,
                        interfaceNumber, &rxBuffer, 192);

if(USB_DEVICE_AUDIO_RESULT_OK != readRequestResult)
{
    //Do Error handling here
}

// The completion of the read request will be indicated by the
// USB_DEVICE_AUDIO_EVENT_READ_COMPLETE event. The transfer handle
// and the amount of data read will be returned along with the
// event.
```

Parameters

Parameters	Description
instance	USB Device Audio Function Driver instance.
transferHandle	Pointer to a USB_DEVICE_AUDIO_TRANSFER_HANDLE type of variable. This variable will contain the transfer handle in case the read request was successful.
interfaceNum	The USB Audio streaming interface number on which read request is to placed.
data	pointer to the data buffer where read data will be stored. In case of PIC32MZ device, this buffer should be located in coherent memory and should be aligned a 16 byte boundary.
size	Size of the data buffer. Refer to the description section for more details on how the size affects the transfer.

Function

```
 USB_DEVICE_AUDIO_RESULT USB_DEVICE_AUDIO_Read
(
    USB_DEVICE_AUDIO_INDEX instanceIndex ,
    USB_DEVICE_AUDIO_TRANSFER_HANDLE* transferHandle,
uint8_t interfaceNum ,
void * data ,
size_t size
);
```

USB_DEVICE_AUDIO_TransferCancel Function

This function cancels a scheduled Audio Device data transfer.

File

usb_device_audio_v1_0.h

C

```
USB_DEVICE_AUDIO_RESULT USB_DEVICE_AUDIO_TransferCancel(USB_DEVICE_AUDIO_INDEX instanceIndex,
```

```
USB_DEVICE_AUDIO_TRANSFER_HANDLE transferHandle);
```

Returns

- USB_DEVICE_AUDIO_RESULT_OK - The transfer will be canceled completely or partially.
- USB_DEVICE_AUDIO_RESULT_ERROR - The transfer could not be canceled because it has either completed, the transfer handle is invalid or the last transaction is in progress.

Description

This function cancels a scheduled Audio Device data transfer. The transfer could have been scheduled using the USB_DEVICE_AUDIO_Read, USB_DEVICE_AUDIO_Write, or the USB_DEVICE_AUDIO_SerialStateNotificationSend functions. If a transfer is still in the queue and its processing has not started, the transfer is canceled completely. A transfer that is in progress may or may not get canceled depending on the transaction that is presently in progress. If the last transaction of the transfer is in progress, the transfer will not be canceled. If it is not the last transaction in progress, the in-progress will be allowed to complete. Pending transactions will be canceled. The first transaction of an in progress transfer cannot be canceled.

Remarks

None.

Preconditions

The USB Device should be in a configured state.

Example

```
// The following code snippet cancels a AUDIO transfer.

USB_DEVICE_AUDIO_TRANSFER_HANDLE transferHandle;
USB_DEVICE_AUDIO_RESULT result;

result = USB_DEVICE_AUDIO_TransferCancel(instanceIndex, transferHandle);

if(USB_DEVICE_AUDIO_RESULT_OK == result)
{
    // The transfer cancellation was either completely or
    // partially successful.
}
```

Parameters

Parameters	Description
instanceIndex	AUDIO Function Driver instance index.
transferHandle	Transfer handle of the transfer to be canceled.

Function

```
USB_DEVICE_AUDIO_RESULT USB_DEVICE_AUDIO_TransferCancel
(
    USB_DEVICE_AUDIO_INDEX instanceIndex,
    USB_DEVICE_AUDIO_TRANSFER_HANDLE transferHandle
);
```

USB_DEVICE_AUDIO_Write Function

This function requests a data write to the USB Device Audio Function Driver Layer.

File

usb_device_audio_v1_0.h

C

```
USB_DEVICE_AUDIO_RESULT USB_DEVICE_AUDIO_Write(USB_DEVICE_AUDIO_INDEX instanceIndex,
USB_DEVICE_AUDIO_TRANSFER_HANDLE * transferHandle, uint8_t interfaceNumber, void * data, size_t size);
```

Returns

- USB_DEVICE_AUDIO_RESULT_OK - The read request was successful. transferHandle contains a valid transfer handle.
- USB_DEVICE_AUDIO_RESULT_ERROR_TRANSFER_QUEUE_FULL - internal request queue is full. The write request could not be added.

- USB_DEVICE_AUDIO_RESULT_ERROR_INSTANCE_NOT_CONFIGURED - The specified instance is not configured yet.
- USB_DEVICE_AUDIO_RESULT_ERROR_INSTANCE_INVALID - The specified instance was not provisioned in the application and is invalid.

Description

This function requests a data write to the USB Device Audio Function Driver Layer. The function places a requests with driver, the request will get serviced as data is requested by the USB Host. A handle to the request is returned in the transferHandle parameter. The termination of the request is indicated by the USB_DEVICE_AUDIO_EVENT_WRITE_COMPLETE event. The amount of data written and the transfer handle associated with the request is returned along with the event in writeCompleteData member of the pData parameter in the event handler.

The transfer handle expires when event handler for the USB_DEVICE_AUDIO_EVENT_WRITE_COMPLETE exits. If the write request could not be accepted, the function returns an error code and transferHandle will contain the value USB_DEVICE_AUDIO_TRANSFER_HANDLE_INVALID.

Remarks

While the using the Audio Function Driver with the PIC32MZ USB module, the audio buffer provided to the USB_DEVICE_AUDIO_Write function should be placed in coherent memory and aligned at a 16 byte boundary. This can be done by declaring the buffer using the __attribute__((coherent, aligned(16))) attribute. An example is shown here

```
uint8_t data[256] __attribute__((coherent, aligned(16)));
```

Preconditions

The function driver should have been configured.

Example

```
// Shows an example of how to write audio data to the audio streaming
// interface . This assumes that device is configured and the audio
// streaming interface is 1.

USB_DEVICE_AUDIO_INDEX instanceIndex;
USB_DEVICE_AUDIO_TRANSFER_HANDLE transferHandle;
unit8_t interfaceNumber;
unit8_t txBuffer[192]; // Use this attribute for PIC32MZ __attribute__((coherent, aligned(16)))
USB_DEVICE_AUDIO_RESULT writeRequestResult;

instanceIndex = 0; //specify the Audio Function driver instance number.
interfaceNumber = 1; //Specify the Audio Streaming interface number.

writeRequestResult = USB_DEVICE_AUDIO_Write ( instanceIndex, &transferHandle,
                            interfaceNumber, &txBuffer, 192);

if(USB_DEVICE_AUDIO_RESULT_OK != writeRequestResult)
{
    //Do Error handling here
}

// The completion of the write request will be indicated by the
// USB_DEVICE_AUDIO_EVENT_WRITE_COMPLETE event. The transfer handle
// and transfer size is provided along with this event.
```

Parameters

Parameters	Description
instance	USB Device Audio Function Driver instance.
transferHandle	Pointer to a USB_DEVICE_AUDIO_TRANSFER_HANDLE type of variable. This variable will contain the transfer handle in case the write request was successful.
interfaceNum	The USB Audio streaming interface number on which the write request is to placed.
data	pointer to the data buffer contains the data to be written. In case of PIC32MZ device, this buffer should be located in coherent memory and should be aligned a 16 byte boundary.
size	Size of the data buffer.

Function

```
USB_DEVICE_AUDIO_RESULT USB_DEVICE_AUDIO_Write
(
    USB_DEVICE_AUDIO_INDEX instance ,
    USB_DEVICE_AUDIO_TRANSFER_HANDLE* transferHandle,
uint8_t interfaceNum ,
```

```
void * data ,
size_t size
);
```

b) Data Types and Constants

USB_DEVICE_AUDIO_EVENT_RESPONSE_NONE Macro

USB Device Audio Function Driver event handler response type none.

File

usb_device_audio_v1_0.h

C

```
#define USB_DEVICE_AUDIO_EVENT_RESPONSE_NONE
```

Description

USB Device Audio Function Driver Event Handler Response None

This is the definition of the Audio Function Driver event handler response type none.

Remarks

Intentionally defined to be empty.

USB_DEVICE_AUDIO_TRANSFER_HANDLE_INVALID Macro

USB Device Audio Function Driver invalid transfer handle definition.

File

usb_device_audio_v1_0.h

C

```
#define USB_DEVICE_AUDIO_TRANSFER_HANDLE_INVALID
```

Description

USB Device Audio Function Driver Invalid Transfer Handle Definition

This definition defines a Invalid USB Device Audio Function Driver Transfer Handle. A Invalid Transfer Handle is returned by the USB_DEVICE_Audio_Write , USB_DEVICE_Audio_Read, functions when the request was not successful.

Remarks

None.

USB_DEVICE_AUDIO_EVENT Enumeration

USB Device Audio Function Driver events.

File

usb_device_audio_v1_0.h

C

```
typedef enum {
  USB_DEVICE_AUDIO_EVENT_WRITE_COMPLETE,
  USB_DEVICE_AUDIO_EVENT_READ_COMPLETE,
  USB_DEVICE_AUDIO_EVENT_INTERFACE_SETTING_CHANGED,
  USB_DEVICE_AUDIO_EVENT_CONTROL_TRANSFER_DATA_RECEIVED,
  USB_DEVICE_AUDIO_EVENT_CONTROL_TRANSFER_DATA_SENT,
  USB_DEVICE_AUDIO_EVENT_CONTROL_TRANSFER_UNKNOWN,
  USB_DEVICE_AUDIO_EVENT_CONTROL_SET_CUR,
  USB_DEVICE_AUDIO_EVENT_CONTROL_SET_MIN,
  USB_DEVICE_AUDIO_EVENT_CONTROL_SET_MAX,
  USB_DEVICE_AUDIO_EVENT_CONTROL_SET_RES,
  USB_DEVICE_AUDIO_EVENT_ENTITY_SET_MEM,
```

```
    USB_DEVICE_AUDIO_EVENT_CONTROL_GET_CUR,
    USB_DEVICE_AUDIO_EVENT_CONTROL_GET_MIN,
    USB_DEVICE_AUDIO_EVENT_CONTROL_GET_MAX,
    USB_DEVICE_AUDIO_EVENT_CONTROL_GET_RES,
    USB_DEVICE_AUDIO_EVENT_ENTITY_GET_MEM,
    USB_DEVICE_AUDIO_EVENT_ENTITY_GET_STAT
} USB_DEVICE_AUDIO_EVENT;
```

Members

Members	Description
USB_DEVICE_AUDIO_EVENT_WRITE_COMPLETE	This event occurs when a write operation scheduled by calling the USB_DEVICE_AUDIO_Write() function has completed. The pData member in the event handler will point to USB_DEVICE_AUDIO_EVENT_WRITE_COMPLETE_DATA type.
USB_DEVICE_AUDIO_EVENT_READ_COMPLETE	This event occurs when a read operation scheduled by calling the USB_DEVICE_AUDIO_Read() function has completed. The pData member in the event handler will point to USB_DEVICE_AUDIO_EVENT_READ_COMPLETE_DATA type.
USB_DEVICE_AUDIO_EVENT_INTERFACE_SETTING_CHANGED	This event occurs when the Host requests the Audio USB device to set an alternate setting on an interface present in this audio function. An Audio USB Device will typically feature a default interface setting and one or more alternate interface settings. The pData member in the event handler will point to USB_DEVICE_AUDIO_EVENT_DATA_INTERFACE_SETTING_CHANGED type. This contains the index of the interface whose setting must be changed and the index of the alternate setting. The application may enable or disable audio functions based on the interface setting.
USB_DEVICE_AUDIO_EVENT_CONTROL_TRANSFER_DATA_RECEIVED	This event occurs when the data stage of a control write transfer has completed. This would occur after the application would respond with a USB_DEVICE_ControlReceive function, which may possibly have been called in response to a USB_DEVICE_AUDIO_EVENT_ENTITY_SETTINGS_RECEIVED event This event notifies the application that the data is received from Host and is available at the location passed by the USB_DEVICE_ControlReceive function. If the received data is acceptable to the application, it should acknowledge the data by calling the USB_DEVICE_ControlStatus function with a USB_DEVICE_CONTROL_STATUS_OK flag.The application can reject the received data by calling the USB_DEVICE_ControlStatus function with the USB_DEVICE_CONTROL_STATUS_ERROR flag. The pData parameter will be NULL.
USB_DEVICE_AUDIO_EVENT_CONTROL_TRANSFER_DATA_SENT	This event occurs when the data stage of a control read transfer has completed. This would occur when the application has called the USB_DEVICE_ControlSend function to complete the data stage of a control transfer. The event indicates that the data has been transmitted to the host. The pData parameter will be NULL.
USB_DEVICE_AUDIO_EVENT_CONTROL_TRANSFER_UNKNOWN	This event occurs when the Audio function driver receives a control transfer request that could not be decoded by Audio Function driver.The pData parameter will point to a USB_SETUP_PACKET type containing the SETUP packet. The application must analyze this SETUP packet and use the USB_DEVICE_ControlSend or USB_DEVICE_ControlReceive or the USB_DEVICE_ControlStatus functions to advance the control transfer or complete it.
USB_DEVICE_AUDIO_EVENT_CONTROL_SET_CUR	This event occurs when the Host sends an Audio Control specific Set Current Setting Attribute Control Transfer request to an Audio Device Control. The pData member in the event handler will point to USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_CUR type. The application must use the entityID, interface, endpoint and the wValue field in the event data to determine the entity and control type and then respond to the control transfer with a USB_DEVICE_ControlStatus and USB_DEVICE_ControlReceive functions.

USB_DEVICE_AUDIO_EVENT_CONTROL_SET_MIN	This event occurs when the Host sends an Audio Control specific Set Minimum Setting Attribute Control Transfer request to an Audio Device Control. The pData member in the event handler will point to USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MIN type. The application must use the entityID, interface, endpoint and the wValue field in the event data to determine the entity and control type and then respond to the control transfer with a USB_DEVICE_ControlStatus and USB_DEVICE_ControlReceive functions.
USB_DEVICE_AUDIO_EVENT_CONTROL_SET_MAX	This event occurs when the Host sends an Audio Control specific Set Maximum Setting Attribute Control Transfer request to an Audio Device Control. The pData member in the event handler will point to USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MAX type. The application must use the entityID, interface, endpoint and the wValue field in the event data to determine the entity and control type and then respond to the control transfer with a USB_DEVICE_ControlStatus and USB_DEVICE_ControlReceive functions.
USB_DEVICE_AUDIO_EVENT_CONTROL_SET_RES	This event occurs when the Host sends an Audio Control specific Set Resolution Attribute Control Transfer request to an Audio Device Control. The pData member in the event handler will point to USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_RES type. The application must use the entityID, interface, endpoint and the wValue field in the event data to determine the entity and control type and then respond to the control transfer with a USB_DEVICE_ControlStatus USB_DEVICE_ControlSend and/or USB_DEVICE_ControlReceive functions.
USB_DEVICE_AUDIO_EVENT_ENTITY_SET_MEM	This event occurs when the Host sends an Audio Entity specific Set Memory Space Attribute Control Transfer request to an Audio Device Entity. The pData member in the event handler will point to USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MEM type. The application must use the entityID, interface, endpoint and the wValue field in the event data to determine the entity and control type and then respond to the control transfer with a USB_DEVICE_ControlStatus USB_DEVICE_ControlSend and/or USB_DEVICE_ControlReceive functions.
USB_DEVICE_AUDIO_EVENT_CONTROL_GET_CUR	This event occurs when the Host sends an Audio Control specific Get Current Setting Attribute Control Transfer request to an Audio Device Control. The pData member in the event handler will point to USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_CUR type. The application must use the entityID, interface, endpoint and the wValue field in the event data to determine the entity and control type and then respond to the control transfer with a USB_DEVICE_ControlStatus and USB_DEVICE_ControlSend functions.
USB_DEVICE_AUDIO_EVENT_CONTROL_GET_MIN	This event occurs when the Host sends an Audio Control specific Get Minimum Setting Attribute Control Transfer request to an Audio Device Control. The pData member in the event handler will point to USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MIN type. The application must use the entityID, interface, endpoint and the wValue field in the event data to determine the entity and control type and then respond to the control transfer with a USB_DEVICE_ControlStatus and USB_DEVICE_ControlSend functions.
USB_DEVICE_AUDIO_EVENT_CONTROL_GET_MAX	This event occurs when the Host sends an Audio Control specific Get Maximum Setting Attribute Control Transfer request to an Audio Device Control. The pData member in the event handler will point to USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MAX type. The application must use the entityID, interface, endpoint and the wValue field in the event data to determine the entity and control type and then respond to the control transfer with a USB_DEVICE_ControlStatus and USB_DEVICE_ControlSend functions.

USB_DEVICE_AUDIO_EVENT_CONTROL_GET_RES	This event occurs when the Host sends an Audio Control specific Get Resolution Setting Attribute Control Transfer request to an Audio Device Control. The pData member in the event handler will point to USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_RES type. The application must use the entityID, interface, endpoint and the wValue field in the event data to determine the entity and control type and then respond to the control transfer with a USB_DEVICE_ControlStatus and USB_DEVICE_ControlSend functions.
USB_DEVICE_AUDIO_EVENT_ENTITY_GET_MEM	This event occurs when the Host sends an Audio Entity specific Get Memory Space Attribute Control Transfer request to an Audio Device Entity. The pData member in the event handler will point to USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MEM type. The application must use the entityID, interface, endpoint and the wValue field in the event data to determine the entity and control type and then respond to the control transfer with a USB_DEVICE_ControlStatus or USB_DEVICE_ControlSend functions.
USB_DEVICE_AUDIO_EVENT_ENTITY_GET_STAT	This event occurs when the Host sends a Audio Entity specific Get Status Control Transfer request to an Audio Device Entity. The pData member in the event handler will point to USB_DEVICE_AUDIO_EVENT_DATA_ENTITY_GET_STAT type. The application mus use the entityID, interface, endpoint and the wValue field in the event data to determine the entity and control type and then respond to the control transfer with a USB_DEVICE_ControlSend and or USB_DEVICE_ControlStatus functions.

Description

USB Device Audio Function Driver Events

These events are specific to a USB Device Audio Function Driver instance. An event may have some data associated with it. This is provided to the event handling function. Each event description contains details about this event data (pData) and other parameters passed along with the event, to the event handler.

Events associated with the Audio Function Driver Specific Control Transfers require application response. The application should respond to these events by using the USB_DEVICE_ControlReceive, USB_DEVICE_ControlSend and USB_DEVICE_ControlStatus functions.

Calling the USB_DEVICE_ControlStatus function with a USB_DEVICE_CONTROL_STATUS_ERROR will stall the control transfer request. The application would do this if the control transfer request is not supported. Calling the USB_DEVICE_ControlStatus function with a USB_DEVICE_CONTROL_STATUS_OK will complete the status stage of the control transfer request. The application would do this if the control transfer request is supported.

The following code shows an example of a possible event handling scheme.

```
// This code example shows all USB Audio Function Driver possible events and
// a possible scheme for handling these events. In this case event responses
// are not deferred.

void APP_USBDeviceAudioEventHandler
(
    USB_DEVICE_AUDIO_INDEX instanceIndex ,
    USB_DEVICE_AUDIO_EVENT event ,
    void * pData,
    uintptr_t context
)
{
    switch (event)
    {
        case USB_DEVICE_AUDIO_EVENT_READ_COMPLETE:

            // This event indicates that a Audio Read Transfer request
            // has completed. pData should be interpreted as a
            // USB_DEVICE_AUDIO_EVENT_DATA_READ_COMPLETE pointer type.
            // This contains the transfer handle of the read transfer
            // that completed and amount of data that was read.

            break;

        case USB_DEVICE_AUDIO_EVENT_WRITE_COMPLETE:

            // This event indicates that a Audio Write Transfer request
            // has completed. pData should be interpreted as a
```

```
            // USB_DEVICE_AUDIO_EVENT_DATA_WRITE_COMPLETE pointer type.
            // This contains the transfer handle of the write transfer
            // that completed and amount of data that was written.

            break;

        case USB_DEVICE_AUDIO_EVENT_INTERFACE_SETTING_CHANGED:

            // This event occurs when the host sends Set Interface request
            // to the Audio USB Device. pData will be a pointer to a
            // USB_DEVICE_AUDIO_EVENT_DATA_INTERFACE_SETTING_CHANGED. This
            // contains the interface number whose setting was
            // changed and the index of the alternate setting.
            // The application should typically enable the audio function
            // if the interfaceAlternateSettting member of pData is greater
            // than 0.

            break;

        case USB_DEVICE_AUDIO_EVENT_CONTROL_TRANSFER_UNKNOWN:

            // This event indicates that the Audio function driver has
            // received a control transfer which it cannot decode. pData
            // will be a pointer to USB_SETUP_PACKET type pointer. The
            // application should decode the packet and take the required
            // action using the USB_DEVICE_ControlStatus(),
            // USB_DEVICE_ControlSend() and USB_DEVICE_ControlReceive()
            // functions.

            break;

        case USB_DEVICE_AUDIO_EVENT_CONTROL_TRANSFER_DATA_SENT:

            // This event indicates the data send request associated with
            // the latest USB_DEVICE_ControlSend() function was
            // completed. pData will be NULL.

        case USB_DEVICE_AUDIO_EVENT_CONTROL_TRANSFER_DATA_RECEIVED:

            // This event indicates the data receive request associated with
            // the latest USB_DEVICE_ControlReceive() function was
            // completed. pData will be NULL. The application can either
            // acknowledge the received data or reject it by calling the
            // USB_DEVICE_ControlStatus() function.

            break;

        case USB_DEVICE_AUDIO_EVENT_CONTROL_SET_CUR:

            // This event indicates that the host is trying to set the
            // current setting attribute of a control. The data type will be
            // USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_CUR type.  The
            // application should identify the entity type based on the
            // entity ID. This mapping is application specific. The
            // following example assumes entity type to be a Feature Unit.

            if(APP_EntityIdentify(((USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_CUR *)pData)->entityID)
                    == APP_AUDIO_ENTITY_FEATURE_UNIT)
            {
                // The entity type is a feature unit. Type cast pData as
                // a USB_AUDIO_FEATURE_UNIT_CONTROL_REQUEST type and find
                // identify the control selector. This example shows the
                // handling for VOLUME control

                switch(((USB_AUDIO_FEATURE_UNIT_CONTROL_REQUEST *)pData)->controlSelector)
                {
                    case USB_AUDIO_VOLUME_CONTROL:
                        // This means the host is trying to set the volume.
                        // Use the USB_DEVICE_ControlReceive() function to
```

```
                        // receive the volume settings for each channel.

                        USB_DEVICE_ControlReceive(usbDeviceHandle, volumeSetting,
                                ((USB_AUDIO_FEATURE_UNIT_CONTROL_REQUEST *)pData)->wLength);
                    default:
                        // Only volume control is supported in this example.
                        // So everything else is stalled.
                        USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_ERROR);
                }
            }
            break;

        case USB_DEVICE_AUDIO_EVENT_CONTROL_GET_CUR:

            // This event indicates that the host is trying to get the
            // current setting attribute of a control. The data type will be
            // USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_CUR type.  The
            // application should identify the entity type based on the
            // entity ID. This mapping is application specific. The
            // following example assumes entity type to be a Feature Unit.

            if(APP_EntityIdentify(((USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_CUR *)pData)->entityID)
                    == APP_AUDIO_ENTITY_FEATURE_UNIT)
            {
                // The entity type is a feature unit. Type cast pData as
                // a USB_AUDIO_FEATURE_UNIT_CONTROL_REQUEST type and find
                // identify the control selector. This example shows the
                // handling for VOLUME control

                switch(((USB_AUDIO_FEATURE_UNIT_CONTROL_REQUEST *)pData)->controlSelector)
                {
                    case USB_AUDIO_VOLUME_CONTROL:
                        // This means the host is trying to get the volume.
                        // Use the USB_DEVICE_ControlReceive() function to
                        // receive the volume settings for each channel.

                        USB_DEVICE_ControlSend(usbDeviceHandle, volumeSetting,
                                ((USB_AUDIO_FEATURE_UNIT_CONTROL_REQUEST *)pData)->wLength);
                    default:
                        // Only volume control is supported in this example.
                        // So everything else is stalled.
                        USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_ERROR);
                }
            }
            break;

        case USB_DEVICE_AUDIO_EVENT_CONTROL_SET_MAX:
        case USB_DEVICE_AUDIO_EVENT_CONTROL_SET_MIN:
        case USB_DEVICE_AUDIO_EVENT_CONTROL_SET_RES:
        case USB_DEVICE_AUDIO_EVENT_CONTROL_SET_MEM:
        case USB_DEVICE_AUDIO_EVENT_CONTROL_GET_MAX:
        case USB_DEVICE_AUDIO_EVENT_CONTROL_GET_MIN:
        case USB_DEVICE_AUDIO_EVENT_CONTROL_GET_RES:
        case USB_DEVICE_AUDIO_EVENT_CONTROL_GET_MEM:
            // In this example these request are not supported and so are
            // stalled.
            USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_ERROR);
            break;

        default:
            break;
    }

    return(USB_DEVICE_AUDIO_EVENT_RESPONSE_NONE);
}
```

Remarks

The application can defer responses to events triggered by control transfers. In that, the application can respond to the control transfer event after exiting the event handler. This allows the application some time to obtain the response data rather than having to respond to the event

immediately. Note that a USB host will typically wait for an event response for a finite time duration before timing out and canceling the event and associated transactions. Even when deferring response, the application must respond promptly if such time-out have to be avoided.

USB_DEVICE_AUDIO_EVENT_DATA_READ_COMPLETE Structure

USB Device Audio Function Driver audio read and write complete event data.

File

usb_device_audio_v1_0.h

C

```
typedef struct {
  USB_DEVICE_AUDIO_TRANSFER_HANDLE handle;
  uint16_t length;
  uint8_t interfaceNum;
  USB_DEVICE_AUDIO_RESULT status;
} USB_DEVICE_AUDIO_EVENT_DATA_WRITE_COMPLETE, USB_DEVICE_AUDIO_EVENT_DATA_READ_COMPLETE;
```

Members

Members	Description
USB_DEVICE_AUDIO_TRANSFER_HANDLE handle;	Transfer handle associated with this • read or write request
uint16_t length;	Indicates the amount of data (in bytes) that was • read or written
uint8_t interfaceNum;	Interface Number
USB_DEVICE_AUDIO_RESULT status;	Completion status of the transfer

Description

USB Device Audio Function Driver Read and Write Complete Event Data.

This data type defines the data structure returned by the driver along with USB_DEVICE_AUDIO_EVENT_READ_COMPLETE, USB_DEVICE_AUDIO_EVENT_WRITE_COMPLETE, events.

Remarks

None.

USB_DEVICE_AUDIO_EVENT_DATA_WRITE_COMPLETE Structure

USB Device Audio Function Driver audio read and write complete event data.

File

usb_device_audio_v1_0.h

C

```
typedef struct {
  USB_DEVICE_AUDIO_TRANSFER_HANDLE handle;
  uint16_t length;
  uint8_t interfaceNum;
  USB_DEVICE_AUDIO_RESULT status;
} USB_DEVICE_AUDIO_EVENT_DATA_WRITE_COMPLETE, USB_DEVICE_AUDIO_EVENT_DATA_READ_COMPLETE;
```

Members

Members	Description
USB_DEVICE_AUDIO_TRANSFER_HANDLE handle;	Transfer handle associated with this • read or write request
uint16_t length;	Indicates the amount of data (in bytes) that was • read or written
uint8_t interfaceNum;	Interface Number
USB_DEVICE_AUDIO_RESULT status;	Completion status of the transfer

Description

USB Device Audio Function Driver Read and Write Complete Event Data.

This data type defines the data structure returned by the driver along with USB_DEVICE_AUDIO_EVENT_READ_COMPLETE,

USB_DEVICE_AUDIO_EVENT_WRITE_COMPLETE, events.

Remarks

None.

USB_DEVICE_AUDIO_EVENT_HANDLER Type

USB Device Audio event handler function pointer type.

File

usb_device_audio_v1_0.h

C

```
typedef USB_DEVICE_AUDIO_EVENT_RESPONSE (* USB_DEVICE_AUDIO_EVENT_HANDLER)(USB_DEVICE_AUDIO_INDEX
instanceIndex , USB_DEVICE_AUDIO_EVENT event , void * pData, uintptr_t context);
```

Description

USB Device Audio Event Handler Function Pointer Type.

This data type defines the required function signature USB Device Audio Function Driver event handling callback function. The application must register a pointer to an Audio Function Driver events handling function whose function signature (parameter and return value types) match the types specified by this function pointer in order to receive event call backs from the Audio Function Driver. The function driver will invoke this function with event relevant parameters. The description of the event handler function parameters is given here.

instanceIndex - Instance index of the Audio Function Driver that generated the event.

event - Type of event generated.

pData - This parameter should be typecast to an event specific pointer type based on the event that has occurred. Refer to the USB_DEVICE_AUDIO_EVENT enumeration description for more details.

context - Value identifying the context of the application that registered the event handling function.

Remarks

The event handler function executes in the USB interrupt context when the USB Device Stack is configured for interrupt based operation. It is not advisable to call blocking functions or computationally intensive functions in the event handler. Where the response to a control transfer related event requires extended processing, the response to the control transfer should be deferred and the event handler should be allowed to complete execution.

USB_DEVICE_AUDIO_EVENT_RESPONSE Type

USB Device Audio Function Driver event callback response type.

File

usb_device_audio_v1_0.h

C

```
typedef void USB_DEVICE_AUDIO_EVENT_RESPONSE;
```

Description

USB Device Audio Function Driver Event Handler Response Type

This is the return type of the Audio Function Driver event handler.

Remarks

None.

USB_DEVICE_AUDIO_INDEX Type

USB Device Audio function driver index.

File

usb_device_audio_v1_0.h

C

```
typedef uintptr_t USB_DEVICE_AUDIO_INDEX;
```

Description

USB Device Audio Function Driver Index

This definition uniquely identifies a Audio Function Driver instance.

Remarks

None.

USB_DEVICE_AUDIO_RESULT Enumeration

USB Device Audio Function Driver USB Device Audio result enumeration.

File

usb_device_audio_v1_0.h

C

```
typedef enum {
  USB_DEVICE_AUDIO_RESULT_OK,
  USB_DEVICE_AUDIO_RESULT_ERROR_TRANSFER_QUEUE_FULL,
  USB_DEVICE_AUDIO_RESULT_ERROR_INSTANCE_INVALID,
  USB_DEVICE_AUDIO_RESULT_ERROR_INSTANCE_NOT_CONFIGURED,
  USB_DEVICE_AUDIO_RESULT_ERROR_PARAMETER_INVALID,
  USB_DEVICE_AUDIO_RESULT_ERROR_INVALID_INTERFACE_ID,
  USB_DEVICE_AUDIO_RESULT_ERROR_INVALID_BUFFER,
  USB_DEVICE_AUDIO_RESULT_ERROR_ENDPOINT_HALTED,
  USB_DEVICE_AUDIO_RESULT_ERROR_TERMINATED_BY_HOST,
  USB_DEVICE_AUDIO_RESULT_ERROR
} USB_DEVICE_AUDIO_RESULT;
```

Members

Members	Description
USB_DEVICE_AUDIO_RESULT_OK	The operation was successful
USB_DEVICE_AUDIO_RESULT_ERROR_TRANSFER_QUEUE_FULL	The transfer queue is full and no new transfers can be scheduled
USB_DEVICE_AUDIO_RESULT_ERROR_INSTANCE_INVALID	The specified instance is not provisioned in the system
USB_DEVICE_AUDIO_RESULT_ERROR_INSTANCE_NOT_CONFIGURED	The specified instance is not configured yet
USB_DEVICE_AUDIO_RESULT_ERROR_PARAMETER_INVALID	The event handler provided is NULL
USB_DEVICE_AUDIO_RESULT_ERROR_INVALID_INTERFACE_ID	Interface number passed to the read or write function is invalid.
USB_DEVICE_AUDIO_RESULT_ERROR_INVALID_BUFFER	A NULL buffer was specified in the read or write function
USB_DEVICE_AUDIO_RESULT_ERROR_ENDPOINT_HALTED	Transfer terminated because host halted the endpoint
USB_DEVICE_AUDIO_RESULT_ERROR_TERMINATED_BY_HOST	Transfer terminated by host because of a stall clear
USB_DEVICE_AUDIO_RESULT_ERROR	General Error

Description

USB Device Audio Function Driver USB Device Audio Result enumeration.

This enumeration lists the possible USB Device Audio Function Driver operation results.

Remarks

None.

USB_DEVICE_AUDIO_TRANSFER_HANDLE Type

USB Device Audio Function Driver transfer handle definition.

File

usb_device_audio_v1_0.h

C

```
typedef uintptr_t USB_DEVICE_AUDIO_TRANSFER_HANDLE;
```

Description

USB Device Audio Function Driver Transfer Handle Definition

This definition defines a USB Device Audio Function Driver Transfer Handle. A Transfer Handle is owned by the application but its value is

modified by the USB_DEVICE_AUDIO_Write, USB_DEVICE_AUDIO_Read functions. The transfer handle is valid for the life time of the transfer and expires when the transfer related event had occurred.

Remarks

None.

USB_DEVICE_AUDIO_FUNCTION_DRIVER Macro

USB Device Audio Function Driver function pointer.

File

usb_device_audio_v1_0.h

C

```
#define USB_DEVICE_AUDIO_FUNCTION_DRIVER
```

Description

USB Device Audio Function Driver Function Pointer

This is the USB Device Audio Function Driver function pointer. This should registered with the device layer in the function driver registration table.

Remarks

None.

USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_CUR Type

File

usb_device_audio_v1_0.h

C

```
typedef USB_AUDIO_CONTROL_INTERFACE_REQUEST USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_CUR;
```

Description

This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_CUR.

USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MAX Type

File

usb_device_audio_v1_0.h

C

```
typedef USB_AUDIO_CONTROL_INTERFACE_REQUEST USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MAX;
```

Description

This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MAX.

USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MEM Type

File

usb_device_audio_v1_0.h

C

```
typedef USB_AUDIO_CONTROL_INTERFACE_REQUEST USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MEM;
```

Description

This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MEM.

USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MIN Type

File

usb_device_audio_v1_0.h

C

```
typedef USB_AUDIO_CONTROL_INTERFACE_REQUEST USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MIN;
```

Description

This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_MIN.

USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_RES Type

File

usb_device_audio_v1_0.h

C

```
typedef USB_AUDIO_CONTROL_INTERFACE_REQUEST USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_RES;
```

Description

This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_GET_RES.

USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_CUR Type

USB Device Audio Function Driver set and get request data.

File

usb_device_audio_v1_0.h

C

```
typedef USB_AUDIO_CONTROL_INTERFACE_REQUEST USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_CUR;
```

Description

USB Device Audio Function Driver Set and Get request data.

This data type defines the data structure returned by the driver along with the USB_DEVICE_AUDIO_EVENT_CONTROL_SET_XXX, USB_DEVICE_AUDIO_EVENT_ENTITY_SET_MEM, USB_DEVICE_AUDIO_EVENT_CONTROL_GET_XXX and USB_DEVICE_AUDIO_EVENT_ENTITY_GET_MEM events.

Remarks

None.

USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MAX Type

File

usb_device_audio_v1_0.h

C

```
typedef USB_AUDIO_CONTROL_INTERFACE_REQUEST USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MAX;
```

Description

This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MAX.

USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MEM Type

File

usb_device_audio_v1_0.h

C

```
typedef USB_AUDIO_CONTROL_INTERFACE_REQUEST USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MEM;
```

Description

This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MEM.

USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MIN Type

File

usb_device_audio_v1_0.h

C

```
typedef USB_AUDIO_CONTROL_INTERFACE_REQUEST USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MIN;
```

Description

This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_MIN.

USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_RES Type

File

usb_device_audio_v1_0.h

C

```
typedef USB_AUDIO_CONTROL_INTERFACE_REQUEST USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_RES;
```

Description

This is type USB_DEVICE_AUDIO_EVENT_DATA_CONTROL_SET_RES.

USB_DEVICE_AUDIO_EVENT_DATA_INTERFACE_SETTING_CHANGED Structure

USB Device Audio Function Driver alternate interface setting event data.

File

usb_device_audio_v1_0.h

C

```
typedef struct {
  uint8_t interfaceNumber;
  uint8_t interfaceAlternateSetting;
} USB_DEVICE_AUDIO_EVENT_DATA_INTERFACE_SETTING_CHANGED;
```

Members

Members	Description
uint8_t interfaceNumber;	Interface number of the interface who setting is to be changed
uint8_t interfaceAlternateSetting;	Alternate setting number

Description

USB Device Audio Function Driver Alternate Interface Setting Event Data.

This data type defines the data structure returned by the driver along with USB_DEVICE_AUDIO_EVENT_DATA_INTERFACE_SETTING_CHANGED.

Remarks

None.

USB_DEVICE_AUDIO_INIT Structure

USB Device Audio Function Driver initialization data structure.

File

usb_device_audio_v1_0.h

C

```
typedef struct {
  size_t queueSizeRead;
  size_t queueSizeWrite;
} USB_DEVICE_AUDIO_INIT;
```

Members

Members	Description
size_t queueSizeRead;	Size of the read queue for this instance • of the Audio function driver
size_t queueSizeWrite;	Size of the write queue for this instance • of the Audio function driver

Description

USB Device Audio Function Driver Initialization Data Structure

This data structure must be defined for every instance of the Audio Function Driver. It is passed to the Audio function driver, by the Device Layer, at the time of initialization. The funcDriverInit member of the Device Layer Function Driver registration table entry must point to this data structure for an instance of the Audio function driver.

Remarks

The queue sizes that are specified in this data structure are also affected by the USB_DEVICE_AUDIO_QUEUE_DEPTH_COMBINED configuration macro.

USB_DEVICE_AUDIO_EVENT_DATA_ENTITY_GET_STAT Type

File

usb_device_audio_v1_0.h

C

```
typedef USB_AUDIO_CONTROL_INTERFACE_REQUEST USB_DEVICE_AUDIO_EVENT_DATA_ENTITY_GET_STAT;
```

Description

This is type USB_DEVICE_AUDIO_EVENT_DATA_ENTITY_GET_STAT.

USB_DEVICE_AUDIO_TRANSFER_ABORT_NOTIFY Macro

USB Audio Transfer abort notification enable

File

usb_device_audio_v1_0_config_template.h

C

```
#define USB_DEVICE_AUDIO_TRANSFER_ABORT_NOTIFY
```

Description

USB Audio Transfer abort notification

This macro enabled USB Audio Transfer abort notifications. Whenever a scheduled transfer request is aborted due to Device Unplug or Host resets the device, the transfer complete event with status as aborted would be send to application's event handler.

Remarks

None.

USB Audio 2.0 Device Library

This section describes the USB Audio 2.0 Device Library.

Introduction

This section provides information on library design, configuration, usage and the library interface for the USB Audio 2.0 Device Library.

Description

The MPLAB Harmony USB Audio 2.0 Device Library (also referred to as the Audio 2.0 Function Driver or library) features routines to implement a USB Audio 2.0 Device. Examples of Audio USB 2.0 Devices include USB Speakers, microphones, and voice telephony. The library provides a convenient abstraction of the USB Audio 2.0 Device specification and simplifies the implementation of USB Audio 2.0 Devices.

Using the Library

This topic describes the basic architecture of the Audio 2.0 Function Driver and provides information and examples on its use.

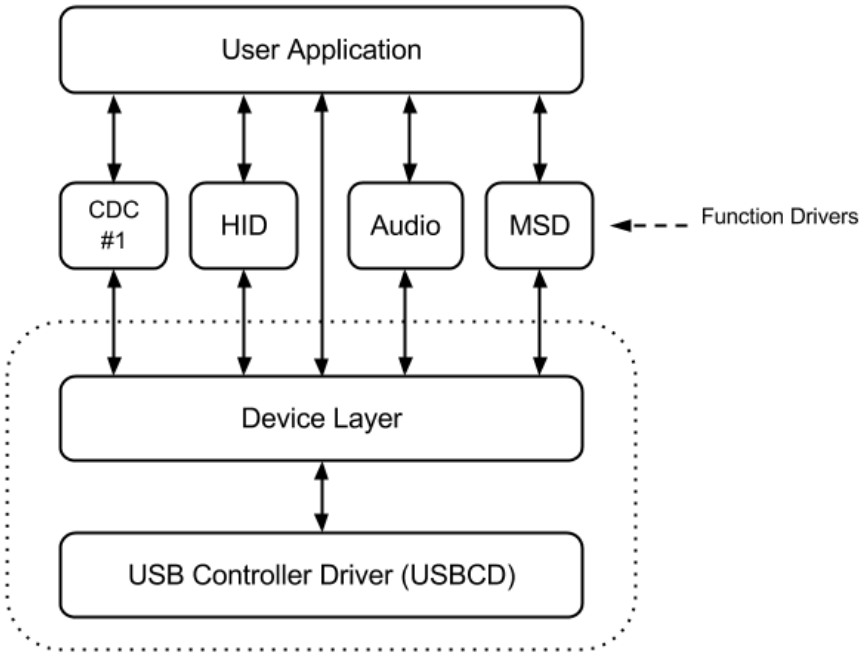
Abstraction Model

Describes the Abstraction Model of the USB Audio 2.0 Device Library.

Description

The Audio 2.0 Function Driver offers various services to the USB Audio 2.0 device to communicate with the host by abstracting USB specification details. It must be used along with the USB Device layer and USB controller to communicate with the USB host. Figure 1 shows a block diagram of the MPLAB Harmony USB Device Stack Architecture and where the Audio 2.0 Function Driver is placed.

Figure 1: USB Device Audio Device Driver



The USB controller driver takes the responsibility of managing the USB peripheral on the device. The USB Device Layer handles the device enumeration, etc. The USB Device Layer forwards all Audio-specific control transfers to the Audio 2.0 Function Driver. The Audio 2.0 Function Driver interprets the control transfers and requests application's intervention through event handlers and a well-defined set of API. The application must respond to the Audio events either in or out of the event handler. Some of these events are related to Audio 2.0 Device Class specific control transfers. The application must complete these control transfers within the timing constraints defined by USB.

Library Overview

The USB Audio 2.0 Device Library mainly interacts with the system, its clients and function drivers, as shown in the Abstraction Model.

The library interface routines are divided into sub-sections, which address one of the blocks or the overall operation of the USB Audio 2.0 Device Library.

Library Interface Section	Description
Functions	Provides event handler, read/write, and transfer cancellation functions.

How the Library Works

Initializing the Library

Describes how the USB Audio 2.0 Device driver is initialized.

Description

The Audio 2.0 Function Driver instance for a USB device configuration is initialized by the Device Layer when the configuration is set by the host. This process does not require application intervention. Each instance of the Audio 2.0 Function Driver should be registered with the Device layer through the Device Layer Function Driver Registration Table. The Audio 2.0 Function Driver requires a initialization data structure to be specified. This is a USB_DEVICE_AUDIO_2_0_INIT data type that specifies the size of the read and write queues. The funcDriverInit member of the function driver registration table entry of the Audio 2.0 Function Driver instance should point to this initialization data structure. The

USB_DEVICE_AUDIO_2_0_FUNCTION_DRIVER object is a global object provided by the Audio 2.0 Function Driver and provides the Device Layer with an entry point into the Audio 2.0 Function Driver. The following code shows an example of how the Audio 2.0 Function Driver can be registered with the Device Layer.

```
/* This code shows an example of how an Audio 2.0 function driver instances
 * can be registered with the Device Layer via the Device Layer Function Driver
 * Registration Table.  In this case Device Configuration 1 consists of one
 * Audio 2.0 function driver instance. */

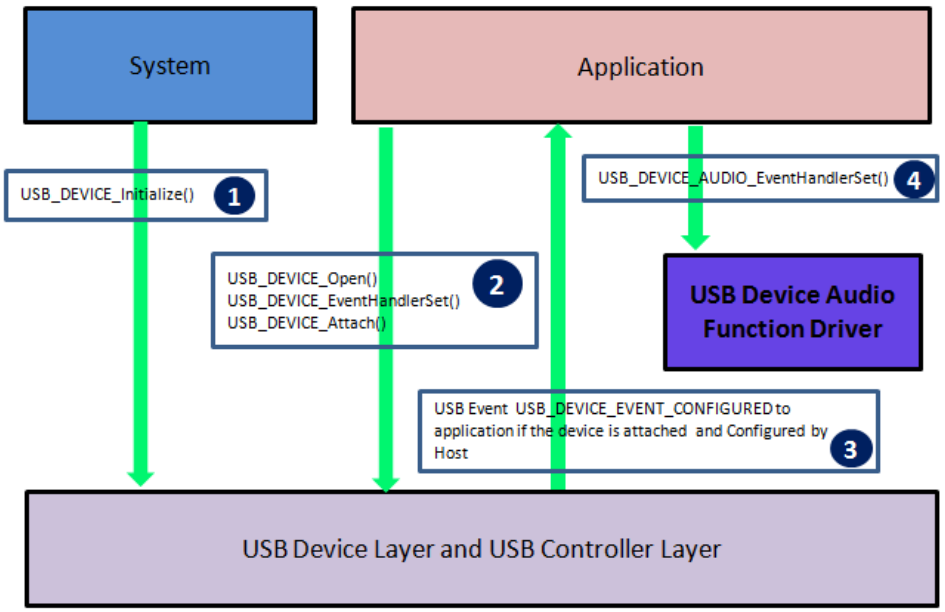
/* The Audio 2.0 Function Driver requires an initialization data structure that
 * specifies the read and write buffer queue sizes. Note that these settings are
 * also affected by the USB_DEVICE_AUDIO_QUEUE_DEPTH_COMBINED configuration
 * macro. */

const USB_DEVICE_AUDIO_2_0_INIT audioDeviceInit =
{
    .queueSizeRead = 1,
    .queueSizeWrite = 1
};

const USB_DEVICE_FUNC_REGISTRATION_TABLE funcRegistrationTable[1] =
{
    {
        .speed = USB_SPEED_FULL,                        // Supported speed
        .configurationValue = 1,                        // To be initialized for Configuration 1
        .interfaceNumber = 0,                           // Starting interface number.
        .numberOfInterfaces = 2,                        // Number of interfaces in this instance
        .funcDriverIndex = 0,                           // Function Driver instance index is 0
        .funcDriverInit = &audioDeviceInit,             // Function Driver does not need initialization
data structure
        .driver = USB_DEVICE_AUDIO_2_0_FUNCTION_DRIVER  // Pointer to Function Driver - Device Layer
interface functions
    },
};
```

The following figure illustrates the typical sequence that is followed in the application when using the Audio 2.0 Function Driver.

Typical USB Audio 2.0 Device Sequence



1. Call set of APIs to initialize USB Device Layer (refer to the USB Device Layer Library section for details about these APIs).
2. The Device Layer provides a callback to the application for any USB Device events like attached, powered, configured, etc. The application should receive a callback with an event USB_DEVICE_EVENT_CONFIGURED to proceed.
3. Once the Device Layer is configured, the application needs to register a callback function with the Audio 2.0 Function Driver to receive Audio 2.0 Control transfers, and also other Audio 2.0 Function Driver events. Now the application can use Audio 2.0 Function Driver APIs to communicate with the USB Host.

Event Handling

Describes Audio 2.0 Function Driver event handler registration and event handling.

Description

Registering a Audio 2.0 Function Driver Callback Function

While creating a USB Audio 2.0 Device application, an event handler must be registered with the Device Layer (the Device Layer Event Handler) and every Audio 2.0 Function Driver instance (Audio 2.0 Function Driver Event Handler). The application needs to register the event handler with the Audio 2.0 Function Driver:

- For receiving Audio 2.0 Control Requests from Host like Volume Control, Mute Control, etc.
- For handling other events from USB Audio 2.0 Device Driver (e.g., Data Write Complete or Data Read Complete)

The event handler should be registered before the USB device layer acknowledges the SET CONFIGURATION request from the USB Host. To ensure this, the callback function should be set in the USB_DEVICE_EVENT_CONFIGURED event that is generated by the device layer. The following code example shows how this can be done.

```
/* This a sample Application Device Layer Event Handler
 * Note how the USB Audio 2.0 Device Driver callback function
 * USB_DEVICE_AUDIO_2_0_EventHandlerSet()
 * is registered in the USB_DEVICE_EVENT_CONFIGURED event.  */

void APP_UsbDeviceEventCallBack( USB_DEVICE_EVENT event, void * pEventData, uintptr_t context )
{
    uint8_t * configuredEventData;
    switch( event )
    {
        case USB_DEVICE_EVENT_RESET:
            break;
        case USB_DEVICE_EVENT_DECONFIGURED:
            // USB device is reset or device is de-configured.
            // This means that USB device layer is about to de-initialize
            // all function drivers. So close handles to previously opened
            // function drivers.
            break;

        case USB_DEVICE_EVENT_CONFIGURED:
            /* check the configuration */
             /* Initialize the Application */
            configuredEventData = pEventData;
            if(*configuredEventData == 1)
            {
                USB_DEVICE_AUDIO_V2_EventHandlerSet
                (
                    0,
                    APP_USBDeviceAudioEventHandler ,
                    (uintptr_t)NULL
                );
                /* mark that set configuration is complete */
                appData.isConfigured = true;
            }
            break;

        case USB_DEVICE_EVENT_SUSPENDED:
            break;

        case USB_DEVICE_EVENT_POWER_DETECTED:
            /* Attach the device */
            USB_DEVICE_Attach (appData.usbDevHandle);
            break;

        case USB_DEVICE_EVENT_POWER_REMOVED:
                /* VBUS is not available. We can detach the device */
                USB_DEVICE_Detach(appData.usbDevHandle);
                break;

        case USB_DEVICE_EVENT_RESUMED:
        case USB_DEVICE_EVENT_ERROR:
```

```
            default:
                break;
        }
    }
```

Event Handling

The Audio 2.0 Function Driver provides events to the application through the event handler function registered by the application. These events indicate:

- Completion of a read or a write data transfer
- Audio 2.0 Control Interface requests
- Completion of data and the status stages of Audio 2.0 Control Interface related control transfer

The Audio 2.0 Control Interface Request events and the related control transfer events typically require the application to respond with the Device Layer Control Transfer routines to complete the control transfer. Based on the generated event, the application may be required to:

- Respond with a USB_DEVICE_ControlSend function, which is completes the data stage of a Control Read Transfer
- Respond with a USB_DEVICE_ControlReceive function, which provisions the data stage of a Control Write Transfer
- Respond with a USB_DEVICE_ControlStatus function, which completes the handshake stage of the Control Transfer. The application can either STALL or Acknowledge the handshake stage through the USB_DEVICE_ControlStatus function.

The following table shows the Audio 2.0 Function Driver Control Transfer related events and the required application control transfer actions.

Audio 2.0 Function Driver Control Transfer Event	Required Application Action
USB_DEVICE_AUDIO_V2_CUR_ENTITY_SETTINGS_RECEIVED	Identify the control type using the associated event data. If a data stage is expected, use the USB_DEVICE_ControlReceive function to receive expected data. If a data stage is not required or if the request is not supported, use the USB_DEVICE_ControlStatus function to Acknowledge or Stall the request.
USB_DEVICE_AUDIO_V2_RANGE_ENTITY_SETTINGS _RECEIVED	Identify the control type using the associated event data. If a data stage is expected, use the USB_DEVICE_ControlReceive function to receive expected data. If a data stage is not required or if the request is not supported, use the USB_DEVICE_ControlStatus function to Acknowledge or Stall the request.
USB_DEVICE_AUDIO_V2_EVENT_CONTROL_TRANSFER _DATA_RECEIVED	Acknowledge or stall using the USB_DEVICE_ControlStatus function.
USB_DEVICE_AUDIO_V2_EVENT_CONTROL_TRANSFER _DATA_SENT	Action not required.

The application must analyze the wIndex field of the event data (received with the control transfer event) to identify the entity that is being addressed. The application must be aware of all entities included in the application and their IDs. Once identified, the application can then type cast the event data to entity type the specific control request type. For example, if the Host sends a control request to set the clock source for the Audio 2.0 device, the following occurs in this order:

1. The Audio 2.0 Function Driver will generate a USB_DEVICE_AUDIO_V2_CUR_ENTITY_SETTINGS_RECEIVED event.
2. The application must type cast the event data to a USB_AUDIO_V2_CONTROL_INTERFACE_REQUEST type and check the entityID field.
3. The entityID field will be identified by the application as a Clock Source.
4. The application must now type cast the event data type as a USB_AUDIO_V2_CLOCKSOURCE_CONTROL_REQUEST data type and check the controlSelector field.
5. If the controlSelector field is AUDIO_V2_CS_SAM_FREQ_CONTROL, the application can then call the USB_DEVICE_ControlReceive function to receive the clock source.

Based on the type of event, the application should analyze the event data parameter of the event handler. This data member should be type cast to an event specific data type. The following table shows the event and the data type to use while type casting. Note that the event data member is not required for all events.

Audio 2.0 Function Driver Event	Related Event Data Type
USB_DEVICE_AUDIO_V2_CUR_ENTITY_SETTINGS_RECEIVED	USB_AUDIO_V2_CONTROL_INTERFACE_REQUEST*
USB_DEVICE_AUDIO_V2_RANGE_ENTITY_SETTINGS _RECEIVED	USB_AUDIO_V2_CONTROL_INTERFACE_REQUEST*
USB_DEVICE_AUDIO_V2_EVENT_CONTROL_TRANSFER _DATA_RECEIVED	NULL
USB_DEVICE_AUDIO_V2_EVENT_CONTROL_TRANSFER _DATA_SENT	NULL
USB_DEVICE_AUDIO_V2_EVENT_INTERFACE_SETTING_CHANGED	USB_DEVICE_AUDIO_V2_EVENT_DATA_SET_ALTERNATE_INTERFACE *

USB_DEVICE_AUDIO_V2_EVENT_READ_COMPLETE	USB_DEVICE_AUDIO_V2_EVENT_DATA_READ_COMPLETE *
USB_DEVICE_AUDIO_V2_EVENT_WRITE_COMPLETE	USB_DEVICE_AUDIO_V2_EVENT_DATA_READ_COMPLETE *

Handling Audio Control Requests:

When the Audio 2.0 Function Driver receives an Audio 2.0 Class Specific Control Transfer Request, it passes this control transfer to the application as a Audio 2.0 Function Driverevent. The following code example shows how to handle an Audio 2.0 Control request.

```
void APP_USBDeviceAudioEventHandler
(
    USB_DEVICE_AUDIO_V2_INDEX iAudio ,
    USB_DEVICE_AUDIO_V2_EVENT event ,
    void * pData,
    uintptr_t context
)
{
    USB_DEVICE_AUDIO_V2_EVENT_DATA_SET_ALTERNATE_INTERFACE * interfaceInfo;
    USB_DEVICE_AUDIO_V2_EVENT_DATA_READ_COMPLETE * readEventData;
    USB_DEVICE_AUDIO_V2_EVENT_DATA_WRITE_COMPLETE * writeEventData;
   USB_AUDIO_V2_CONTROL_INTERFACE_REQUEST* controlRequest;
    if ( iAudio == 0 )
    {
        switch (event)
        {
            case USB_DEVICE_AUDIO_V2_EVENT_READ_COMPLETE:
                readEventData = (USB_DEVICE_AUDIO_V2_EVENT_DATA_READ_COMPLETE *)pData;
                //We have received an audio frame from the Host.
                //Now send this audio frame to Audio Codec for Playback.

            break;

            case USB_DEVICE_AUDIO_V2_EVENT_WRITE_COMPLETE:

            break;

            case USB_DEVICE_AUDIO_V2_EVENT_INTERFACE_SETTING_CHANGED:
                //We have received a request from USB host to change the Interface-
                //Alternate setting.
                interfaceInfo = (USB_DEVICE_AUDIO_V2_EVENT_DATA_SET_ALTERNATE_INTERFACE *)pData;
                appData.activeInterfaceAlternateSetting = interfaceInfo->interfaceAlternateSetting;
                appData.state = APP_USB_INTERFACE_ALTERNATE_SETTING_RCVD;

            break;
            case USB_DEVICE_AUDIO_V2_CUR_ENTITY_SETTINGS_RECEIVED:
                controlRequest = (USB_AUDIO_V2_CONTROL_INTERFACE_REQUEST*) setupPkt;
    USB_AUDIO_V2_CLOCKSOURCE_CONTROL_REQUEST* clockSourceRequest;

        switch(controlRequest->entityID)
        {
       case APP_ID_CLOCK_SOURCE:
          clockSourceRequest = (USB_AUDIO_V2_CLOCKSOURCE_CONTROL_REQUEST*) controlRequest;
                    switch(clockSourceRequest->controlSelector)
                   {
                         case AUDIO_V2_CS_SAM_FREQ_CONTROL:
                        {
                       if ((controlRequest->bmRequestType & 0x80) == 0)
                       {
                           //A control write transfer received from Host. Now receive data from Host.
                          USB_DEVICE_ControlReceive(appData.usbDevHandle, (void *) &(appData.clockSource),
4 );
                          appData.currentAudioControl = APP_USB_AUDIO_CLOCKSOURCE_CONTROL;
                                  }
                             else
                             {
                       /*Handle Get request*/
                       USB_DEVICE_ControlSend(appData.usbDevHandle, (void *)&(appData.clockSource), 4 );
                       appData.currentAudioControl = APP_USB_CONTROL_NONE;
                              }
                     }
```

```
}
                break;

            case USB_DEVICE_AUDIO_V2_RANGE_ENTITY_SETTINGS_RECEIVED:

                break;

            case USB_DEVICE_AUDIO_V2_EVENT_CONTROL_TRANSFER_DATA_RECEIVED:
                USB_DEVICE_ControlStatus(appData.usbDevHandle, USB_DEVICE_CONTROL_STATUS_OK );
                switch (appData.currentAudioControl)
                {
                    case APP_USB_AUDIO_MUTE_CONTROL:
                    {
                        appData.state = APP_MUTE_AUDIO_PLAYBACK;
                        appData.currentAudioControl = APP_USB_CONTROL_NONE;
                    }
                    break;
                    case APP_USB_AUDIO_CLOCKSOURCE_CONTROL:
                    {
                        // Handle Clock Source Control here.
                        appData.state = APP_CLOCKSOURCE_SET;
                        appData.currentAudioControl = APP_USB_CONTROL_NONE;
                    }
                    break;
                    case APP_USB_AUDIO_CLOCKSELECT_CONTROL:
                    {
                        // Handle Clock Source Control here.
                        appData.currentAudioControl = APP_USB_CONTROL_NONE;

                    }
                    break;
                }
            break;
            case  USB_DEVICE_AUDIO_V2_EVENT_CONTROL_TRANSFER_DATA_SENT:
            break;
            default:
                SYS_ASSERT ( false , "Invalid callback" );
            break;
        } //end of switch ( callback )
    }//end of if  if ( iAudio == 0 )
}//end of function APP_AudioEventCallback
```

Transferring Data

Describes how to send/receive data to/from USB Host using this USB Audio 2.0 Device Driver.

Description

The USB Audio 2.0 Device Driver provides functions to send and receive data.

Receiving Data

The USB_DEVICE_AUDIO_V2_Read function schedules a data read. When the host transfers data to the device, the Audio 2.0 Function Driver receives the data and invokes the USB_DEVICE_AUDIO_V2_EVENT_READ_COMPLETE event. This event indicates that audio data is now available in the application specified buffer.

The Audio 2.0 Function Driver supports buffer queuing. The application can schedule multiple read requests. Each request is assigned a unique buffer handle, which is returned with the USB_DEVICE_AUDIO_V2_EVENT_READ_COMPLETE event. The application can use the buffer handle to track completion to queued requests. Using this feature allows the application to implement audio buffering schemes such as ping-pong buffering.

Sending Data

The USB_DEVICE_AUDIO_V2_Write schedules a data write. When the host sends a request for the data, the Audio 2.0 Function Driver transfers the data and invokes the USB_DEVICE_AUDIO_V2_EVENT_WRITE_COMPLETE event.

The Audio 2.0 Function Driver supports buffer queuing. The application can schedule multiple write requests. Each request is assigned a unique buffer handle, which is returned with the USB_DEVICE_AUDIO_V2_EVENT_WRITE_COMPLETE event. The application can use the buffer handle to track completion to queued requests. Using this feature allows the application to implement audio buffering schemes such as ping-pong buffering.

Configuring the Library

Macros

	Name	Description
	USB_DEVICE_AUDIO_V2_INSTANCES_NUMBER	Specifies the number of Audio 2.0 Function Driver instances.
	USB_DEVICE_AUDIO_V2_MAX_ALTERNATE_SETTING	Specifies the maximum number of Alternate Settings per streaming interface.
	USB_DEVICE_AUDIO_V2_MAX_STREAMING_INTERFACES	Specifies the maximum number of Audio 2.0 Streaming interfaces in an Audio 2.0 Function Driver instance.
	USB_DEVICE_AUDIO_V2_QUEUE_DEPTH_COMBINED	Specifies the combined queue size of all Audio 2.0 function driver instances.

Description

The application designer must specify the following configuration parameters while using the USB Audio 2.0 Device Driver. The configuration macros that implement these parameters must be located in the `system_config.h` file in the application project and a compiler include path (to point to the folder that contains this file) should be specified.

USB_DEVICE_AUDIO_V2_INSTANCES_NUMBER Macro

Specifies the number of Audio 2.0 Function Driver instances.

File

usb_device_audio_v2_0_config_template.h

C

```
#define USB_DEVICE_AUDIO_V2_INSTANCES_NUMBER
```

Description

USB device Audio 2.0 Maximum Number of instances

This macro defines the number of instances of the Audio 2.0 Function Driver. For example, if the application needs to implement two instances of the Audio 2.0 Function Driver (to create two composite Audio Device) on one USB Device, the macro should be set to 2. Note that implementing a USB Device that features multiple Audio 2.0 interfaces requires appropriate USB configuration descriptors.

Remarks

None.

USB_DEVICE_AUDIO_V2_MAX_ALTERNATE_SETTING Macro

Specifies the maximum number of Alternate Settings per streaming interface.

File

usb_device_audio_v2_0_config_template.h

C

```
#define USB_DEVICE_AUDIO_V2_MAX_ALTERNATE_SETTING
```

Description

Maximum number of Alternate Settings

This macro defines the maximum number of Alternate Settings per streaming interface. If the Audio 2.0 Device features multiple streaming interfaces, this configuration constant should be equal to the the maximum number of alternate required amongst the streaming interfaces.

Remarks

None.

USB_DEVICE_AUDIO_V2_MAX_STREAMING_INTERFACES Macro

Specifies the maximum number of Audio 2.0 Streaming interfaces in an Audio 2.0 Function Driver instance.

File

usb_device_audio_v2_0_config_template.h

C

```
#define USB_DEVICE_AUDIO_V2_MAX_STREAMING_INTERFACES
```

Description

Maximum Audio 2.0 Streaming Interfaces

This macro defines the maximum number of streaming interfaces in an Audio 2.0 Function Driver instance. In case of multiple Audio 2.0 Function Driver instances, this constant should be equal to the maximum number of interfaces amongst the Audio 2.0 Function Driver instances.

Remarks

None.

USB_DEVICE_AUDIO_V2_QUEUE_DEPTH_COMBINED Macro

Specifies the combined queue size of all Audio 2.0 function driver instances.

File

usb_device_audio_v2_0_config_template.h

C

```
#define USB_DEVICE_AUDIO_V2_QUEUE_DEPTH_COMBINED
```

Description

USB device Audio 2.0 Combined Queue Size

This macro defines the number of entries in all queues in all instances of the Audio 2.0 function driver. This value can be obtained by adding up the read and write queue sizes of each Audio Function driver instance. In a simple single instance USB Audio 2.0 device application, that does not require buffer queuing, the USB_DEVICE_AUDIO_QUEUE_DEPTH_COMBINED macro can be set to 2. Consider a case of a Audio 2.0 function driver instances, with has a read queue size of 2 and write queue size of 3, this macro should be set to 5 (2 + 3).

Remarks

None.

Building the Library

This section lists the files that are available in the USB Audio 2.0 Device Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/usb`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
usb_device_audio_v2_0.h	This header file must be included in every source file that needs to invoke USB Audio 2.0 Device Driver APIs.
usb_audio_v2_0.h	This header file must be included when the audio 2.0 descriptor macros are used.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/dynamic/usb_device_audio_v2_0.c	This file contains all of functions, macros, definitions, variables, datatypes, etc., that are specific to the USB Audio v2.0 Specification implementation of the Audio 2.0 Function Driver.
/src/dynamic/usb_device_audio2_read_write.c	Contains implementation of the audio 2.0 function driver read and write functions.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The USB Audio 2.0 Device Library depends on the following modules:

- USB Device Library

Library Interface

This section describes the Application Programming Interface (API) functions of the USB Device Audio Library

Refer to each section for a detailed description.

a) Functions

Functions

	Name	Description
	USB_DEVICE_AUDIO_V2_EventHandlerSet	This function registers an event handler for the specified Audio function driver instance.
	USB_DEVICE_AUDIO_V2_Read	This function requests a data read from the USB Device Audio v2.0 Function Driver Layer.
	USB_DEVICE_AUDIO_V2_TransferCancel	This function cancels a scheduled Audio v2.0 Device data transfer.
	USB_DEVICE_AUDIO_V2_Write	This function requests a data write to the USB Device Audio v2.0 Function Driver Layer.

Description

USB_DEVICE_AUDIO_V2_EventHandlerSet Function

This function registers an event handler for the specified Audio function driver instance.

File

usb_device_audio_v2_0.h

C

```
USB_DEVICE_AUDIO_V2_RESULT USB_DEVICE_AUDIO_V2_EventHandlerSet(USB_DEVICE_AUDIO_V2_INDEX instanceIndex,
USB_DEVICE_AUDIO_V2_EVENT_HANDLER eventHandler, uintptr_t context);
```

Returns

- USB_DEVICE_AUDIO_V2_RESULT_OK - The operation was successful
- USB_DEVICE_AUDIO_V2_RESULT_ERROR_INSTANCE_INVALID - The specified instance does not exist.
- USB_DEVICE_AUDIO_V2_RESULT_ERROR_PARAMETER_INVALID - The eventHandler parameter is NULL

Description

This function registers a event handler for the specified Audio function driver instance. This function should be called by the application when it receives a SET CONFIGURATION event from the device layer. The application must register an event handler with the function driver in order to receive and respond to function driver specific events and control transfers. If the event handler is not registered, the device layer will stall function driver specific commands and the USB device may not function.

Remarks

None.

Preconditions

This function should be called when the function driver has been initialized as a result of a set configuration.

Example

```
// The following code shows an example registering an event handler. The
// application specifies the context parameter as a pointer to an
// application object (appObject) that should be associated with this
// instance of the Audio function driver.

USB_DEVICE_AUDIO_V2_RESULT result;

USB_DEVICE_AUDIO_V2_EVENT_RESPONSE APP_USBDeviceAUDIOEventHandler
(
    USB_DEVICE_AUDIO_V2_INDEX instanceIndex ,
    USB_DEVICE_AUDIO_V2_EVENT event ,
    void* pData,
    uintptr_t context
)
{
    // Event Handling comes here

    switch(event)
    {
        ...
    }

    return(USB_DEVICE_AUDIO_V2_EVENT_RESPONSE_NONE);
}

result = USB_DEVICE_AUDIO_V2_EventHandlerSet ( USB_DEVICE_AUDIO_V2_INSTANCE_0 ,
            &APP_USBDeviceAUDIOEventHandler, (uintptr_t) &appObject);

if(USB_DEVICE_AUDIO_V2_RESULT_OK != result)
{
    // Do error handling here
}
```

Parameters

Parameters	Description
instance	Instance of the Audio v2.0 Function Driver.
eventHandler	A pointer to event handler function.
context	Application specific context that is returned in the event handler.

Function

```
USB_DEVICE_AUDIO_V2_RESULT USB_DEVICE_AUDIO_V2_EventHandlerSet
(
    USB_DEVICE_AUDIO_V2_INDEX instance ,
    USB_DEVICE_AUDIO_V2_EVENT_HANDLER eventHandler ,
uintptr_t context
);
```

USB_DEVICE_AUDIO_V2_Read Function

This function requests a data read from the USB Device Audio v2.0 Function Driver Layer.

File

usb_device_audio_v2_0.h

C

```
USB_DEVICE_AUDIO_V2_RESULT USB_DEVICE_AUDIO_V2_Read(USB_DEVICE_AUDIO_V2_INDEX instanceIndex,
USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE* transferHandle, uint8_t interfaceNumber, void * data, size_t size);
```

Returns

- USB_DEVICE_AUDIO_V2_RESULT_OK - The read request was successful. transferHandle contains a valid transfer handle.
- USB_DEVICE_AUDIO_V2_RESULT_ERROR_TRANSFER_QUEUE_FULL - internal request queue is full. The read request could not be

added.

- USB_DEVICE_AUDIO_V2_RESULT_ERROR_INSTANCE_NOT_CONFIGURED - The specified instance is not configured yet.
- USB_DEVICE_AUDIO_V2_RESULT_ERROR_INSTANCE_INVALID - The specified instance was not provisioned in the application and is invalid.

Description

This function requests a data read from the USB Device Audio v2.0 Function Driver Layer. The function places a requests with driver, the request will get serviced as data is made available by the USB Host. A handle to the request is returned in the transferHandle parameter. The termination of the request is indicated by the USB_DEVICE_AUDIO_V2_EVENT_READ_COMPLETE event. The amount of data read and the transfer handle associated with the request is returned along with the event. The transfer handle expires when event handler for the USB_DEVICE_AUDIO_V2_EVENT_READ_COMPLETE exits. If the read request could not be accepted, the function returns an error code and transferHandle will contain the value USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE_INVALID.

Remarks

While the using the Audio Function Driver with PIC32MZ USB module, the audio buffer provided to the USB_DEVICE_AUDIO_V2_Read function should be placed in coherent memory and aligned at a 16 byte boundary. This can be done by declaring the buffer using the __attribute__((coherent, aligned(16))) attribute, as shown in the following example:

```
uint8_t data[256] __attribute__((coherent, aligned(16)));
```

Preconditions

The function driver should have been configured.

Example

```
// Shows an example of how to read. This assumes that
// device had been configured. The example attempts to read
// data from interface 1.

USB_DEVICE_AUDIO_V2_INDEX instanceIndex;
USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE transferHandle;
unit8_t interfaceNumber;
// Use this attribute for PIC32MZ __attribute__((coherent, aligned(16)))
unit8_t rxBuffer[192];
USB_DEVICE_AUDIO_V2_RESULT readRequestResult;

instanceIndex = 0; //specify the Audio v2.0 Function driver instance number.
interfaceNumber = 1; //Specify the Audio v2.0 Streaming interface number.

readRequestResult = USB_DEVICE_AUDIO_V2_Read ( instanceIndex, &transferHandle,
                        interfaceNumber, &rxBuffer, 192);

if(USB_DEVICE_AUDIO_V2_RESULT_OK != readRequestResult)
{
    //Do Error handling here
}

// The completion of the read request will be indicated by the
// USB_DEVICE_AUDIO_V2_EVENT_READ_COMPLETE event. The transfer handle
// and the amount of data read will be returned along with the
// event.
```

Parameters

Parameters	Description
instance	USB Device Audio v2.0 Function Driver instance.
transferHandle	Pointer to a USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE type of variable. This variable will contain the transfer handle in case the read request was successful.
interfaceNum	The USB Audio v2.0 streaming interface number on which read request is to placed.
data	pointer to the data buffer where read data will be stored. In case of PIC32MZ device, this buffer should be located in coherent memory and should be aligned a 16 byte boundary.
size	Size of the data buffer. Refer to the description section for more details on how the size affects the transfer.

Function

```
USB_DEVICE_AUDIO_V2_RESULT USB_DEVICE_AUDIO_V2_Read
(
    USB_DEVICE_AUDIO_V2_INDEX instanceIndex ,
```

```
    USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE* transferHandle,
uint8_t interfaceNum ,
void * data ,
size_t size
);
```

USB_DEVICE_AUDIO_V2_TransferCancel Function

This function cancels a scheduled Audio v2.0 Device data transfer.

File

usb_device_audio_v2_0.h

C

```
USB_DEVICE_AUDIO_V2_RESULT USB_DEVICE_AUDIO_V2_TransferCancel(USB_DEVICE_AUDIO_V2_INDEX instanceIndex,
USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE transferHandle);
```

Returns

- USB_DEVICE_AUDIO_V2_RESULT_OK - The transfer will be canceled completely or partially.
- USB_DEVICE_AUDIO_V2_RESULT_ERROR - The transfer could not be canceled because it has either completed, the transfer handle is invalid or the last transaction is in progress.

Description

This function cancels a scheduled Audio v2.0 Device data transfer. The transfer could have been scheduled using the USB_DEVICE_AUDIO_V2_Read, USB_DEVICE_AUDIO_V2_Write, or the USB_DEVICE_AUDIO_V2_SerialStateNotificationSend function. If a transfer is still in the queue and its processing has not started, the transfer is canceled completely. A transfer that is in progress may or may not get canceled depending on the transaction that is presently in progress. If the last transaction of the transfer is in progress, the transfer will not be canceled. If it is not the last transaction in progress, the in-progress will be allowed to complete. Pending transactions will be canceled. The first transaction of an in progress transfer cannot be canceled.

Remarks

None.

Preconditions

The USB Device should be in a configured state.

Example

```
// The following code example cancels an Audio transfer.

USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE transferHandle;
USB_DEVICE_AUDIO_V2_RESULT result;

result = USB_DEVICE_AUDIO_V2_TransferCancel(instanceIndex, transferHandle);

if(USB_DEVICE_AUDIO_V2_RESULT_OK == result)
{
    // The transfer cancellation was either completely or
    // partially successful.
}
```

Parameters

Parameters	Description
instanceIndex	AUDIO v2.0 Function Driver instance index.
transferHandle	Transfer handle of the transfer to be canceled.

Function

```
  USB_DEVICE_AUDIO_V2_RESULT USB_DEVICE_AUDIO_V2_TransferCancel
(
    USB_DEVICE_AUDIO_V2_INDEX instanceIndex,
    USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE transferHandle
);
```

USB_DEVICE_AUDIO_V2_Write Function

This function requests a data write to the USB Device Audio v2.0 Function Driver Layer.

File

usb_device_audio_v2_0.h

C

```
USB_DEVICE_AUDIO_V2_RESULT USB_DEVICE_AUDIO_V2_Write(USB_DEVICE_AUDIO_V2_INDEX instanceIndex,
USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE * transferHandle, uint8_t interfaceNumber, void * data, size_t size);
```

Returns

- USB_DEVICE_AUDIO_V2_RESULT_OK - The read request was successful. transferHandle contains a valid transfer handle.
- USB_DEVICE_AUDIO_V2_RESULT_ERROR_TRANSFER_QUEUE_FULL - internal request queue is full. The write request could not be added.
- USB_DEVICE_AUDIO_V2_RESULT_ERROR_INSTANCE_NOT_CONFIGURED - The specified instance is not configured yet.
- USB_DEVICE_AUDIO_V2_RESULT_ERROR_INSTANCE_INVALID - The specified instance was not provisioned in the application and is invalid.

Description

This function requests a data write to the USB Device Audio v2.0 Function Driver Layer. The function places a requests with driver, the request will get serviced as data is requested by the USB Host. A handle to the request is returned in the transferHandle parameter. The termination of the request is indicated by the USB_DEVICE_AUDIO_V2_EVENT_WRITE_COMPLETE event. The amount of data written and the transfer handle associated with the request is returned along with the event in writeCompleteData member of the pData parameter in the event handler.

The transfer handle expires when event handler for the USB_DEVICE_AUDIO_V2_EVENT_WRITE_COMPLETE exits. If the write request could not be accepted, the function returns an error code and transferHandle will contain the value USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE_INVALID.

Remarks

While the using the Audio Function Driver with the PIC32MZ USB module, the audio buffer provided to the USB_DEVICE_AUDIO_V2_Write function should be placed in coherent memory and aligned at a 16 byte boundary. This can be done by declaring the buffer using the __attribute__((coherent, aligned(16))) attribute. An example is shown here

```
uint8_t data[256] __attribute__((coherent, aligned(16)));
```

Preconditions

The function driver should have been configured.

Example

```
// Shows an example of how to write audio data to the audio streaming
// interface. This assumes that device is configured and the audio
// streaming interface is 1.

USB_DEVICE_AUDIO_V2_INDEX instanceIndex;
USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE transferHandle;
unit8_t interfaceNumber;
unit8_t txBuffer[192]; // Use this attribute for PIC32MZ __attribute__((coherent, aligned(16)))
USB_DEVICE_AUDIO_V2_RESULT writeRequestResult;

instanceIndex = 0; //specify the Audio Function driver instance number.
interfaceNumber = 1; //Specify the Audio Streaming interface number.

writeRequestResult = USB_DEVICE_AUDIO_V2_Write ( instanceIndex, &transferHandle,
                            interfaceNumber, &txBuffer, 192);

if(USB_DEVICE_AUDIO_V2_RESULT_OK != writeRequestResult)
{
    //Do Error handling here
}

// The completion of the write request will be indicated by the
// USB_DEVICE_AUDIO_V2_EVENT_WRITE_COMPLETE event. The transfer handle
// and transfer size is provided along with this event.
```

Parameters

Parameters	Description
instance	USB Device Audio Function Driver instance.
transferHandle	Pointer to a USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE type of variable. This variable will contain the transfer handle in case the write request was successful.
interfaceNum	The USB Audio streaming interface number on which the write request is to placed.
data	pointer to the data buffer contains the data to be written. In case of PIC32MZ device, this buffer should be located in coherent memory and should be aligned a 16 byte boundary.
size	Size of the data buffer.

Function

```
USB_DEVICE_AUDIO_V2_RESULT USB_DEVICE_AUDIO_V2_Write
(
    USB_DEVICE_AUDIO_V2_INDEX instance ,
    USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE* transferHandle,
uint8_t interfaceNum ,
void * data ,
size_t size
);
```

b) Data Types and Constants

Enumerations

} USB_DEVICE_AUDIO_V2_EVENT;
```

Members

Members	Description
USB_DEVICE_AUDIO_V2_EVENT_WRITE_COMPLETE	This event occurs when a write operation scheduled by calling the USB_DEVICE_AUDIO_V2_Write function has completed. The pData member in the event handler will point to USB_DEVICE_AUDIO_V2_EVENT_WRITE_COMPLETE_DATA type.
USB_DEVICE_AUDIO_V2_EVENT_READ_COMPLETE	This event occurs when a read operation scheduled by calling the USB_DEVICE_AUDIO_V2_Read function has completed. The pData member in the event handler will point to USB_DEVICE_AUDIO_V2_EVENT_READ_COMPLETE_DATA type.
USB_DEVICE_AUDIO_V2_EVENT_INTERFACE_SETTING_CHANGED	This event occurs when the Host requests the Audio v2.0 USB Device to set an alternate setting on an interface present in this audio function. An Audio v2.0 USB Device will typically feature a default interface setting and one or more alternate interface settings. The pData member in the event handler will point to the USB_DEVICE_AUDIO_V2_EVENT_DATA_INTERFACE_SETTING_CHANGED type. This contains the index of the interface whose setting must be changed and the index of the alternate setting. The application may enable or disable audio functions based on the interface setting.
USB_DEVICE_AUDIO_V2_EVENT_CONTROL_TRANSFER_DATA_RECEIVED	This event occurs when the data stage of a control write transfer has completed. This would occur after the application would respond with a USB_DEVICE_ControlReceive function, which may possibly have been called in response to a USB_DEVICE_AUDIO_V2_EVENT_ENTITY_SETTINGS_RECEIVED event This event notifies the application that the data is received from Host and is available at the location passed by the USB_DEVICE_ControlReceive function. If the received data is acceptable to the application, it should acknowledge the data by calling the USB_DEVICE_ControlStatus function with a USB_DEVICE_CONTROL_STATUS_OK flag.The application can reject the received data by calling the USB_DEVICE_ControlStatus function with the USB_DEVICE_CONTROL_STATUS_ERROR flag. The pData parameter will be NULL.
USB_DEVICE_AUDIO_V2_EVENT_CONTROL_TRANSFER_DATA_SENT	This event occurs when the data stage of a control read transfer has completed. This would occur when the application has called the USB_DEVICE_ControlSend function to complete the data stage of a control transfer. The event indicates that the data has been transmitted to the host. The pData parameter will be NULL.

USB_DEVICE_AUDIO_V2_CUR_ENTITY_SETTINGS_RECEIVED	This event occurs when the Host sends an Audio 2.0 Control specific Set Current Setting Attribute Control Transfer request to an Audio Device Control. The pData member in the event handler will point to type. The application must use the entityID, interface, endpoint and the wValue field in the event data to determine the entity and control type and then respond to the control transfer with the USB_DEVICE_ControlStatus and USB_DEVICE_ControlReceive functions.
USB_DEVICE_AUDIO_V2_RANGE_ENTITY_SETTINGS_RECEIVED	This event occurs when the Host sends an Audio 2.0 Control specific Set Range Setting Attribute Control Transfer request to an Audio Device Control. The pData member in the event handler will point to type. The application must use the entityID, interface, endpoint and the wValue field in the event data to determine the entity and control type and then respond to the control transfer with a USB_DEVICE_ControlStatus and USB_DEVICE_ControlReceive functions.
USB_DEVICE_AUDIO_V2_EVENT_CONTROL_TRANSFER_UNKNOWN	This event occurs when the Audio v2.0 function driver receives a control transfer request that could not be decoded by Audio Function driver.The pData parameter will point to a USB_SETUP_PACKET type containing the setup packet. The application must analyze this Setup packet and use the USB_DEVICE_ControlSend, USB_DEVICE_ControlReceive, or the USB_DEVICE_ControlStatus function to advance the control transfer or complete it.

Description

USB Device Audio v2.0 Function Driver Events

These events are specific to a USB Device Audio v2.0 Function Driver instance. An event may have some data associated with it. This is provided to the event handling function. Each event description contains details about this event data (pData) and other parameters passed along with the event, to the event handler.

Events associated with the Audio v2.0 Function Driver Specific Control Transfers require application response. The application should respond to these events by using the USB_DEVICE_ControlReceive(), USB_DEVICE_ControlSend() and USB_DEVICE_ControlStatus() functions.

Calling the USB_DEVICE_ControlStatus() function with a USB_DEVICE_CONTROL_STATUS_ERROR will stall the control transfer request. The application would do this if the control transfer request is not supported. Calling the USB_DEVICE_ControlStatus() function with a USB_DEVICE_CONTROL_STATUS_OK will complete the status stage of the control transfer request. The application would do this if the control transfer request is supported.

The following code shows an example of a possible event handling scheme.

```
// This code example shows all USB Audio v2.0 Function Driver possible
// events and a possible scheme for handling these events.
// In this case event responses are not deferred.

void APP_USBDeviceAudioEventHandler
(
    USB_DEVICE_AUDIO_V2_INDEX instanceIndex ,
    USB_DEVICE_AUDIO_V2_EVENT event ,
    void * pData,
    uintptr_t context
)
{
    switch (event)
    {
        case USB_DEVICE_AUDIO_V2_EVENT_READ_COMPLETE:

            // This event indicates that a Audio v2.0 Read Transfer request
            // has completed. pData should be interpreted as a
            // USB_DEVICE_AUDIO_V2_EVENT_DATA_READ_COMPLETE pointer type.
            // This contains the transfer handle of the read transfer
            // that completed and amount of data that was read.

            break;

        case USB_DEVICE_AUDIO_V2_EVENT_WRITE_COMPLETE:

            // This event indicates that a Audio v2.0 Write Transfer request
            // has completed. pData should be interpreted as a
            // USB_DEVICE_AUDIO_V2_EVENT_DATA_WRITE_COMPLETE pointer type.
            // This contains the transfer handle of the write transfer
            // that completed and amount of data that was written.
```

```
            break;

        case USB_DEVICE_AUDIO_V2_EVENT_INTERFACE_SETTING_CHANGED:

            // This event occurs when the host sends Set Interface request
            // to the Audio v2.0 USB Device. pData will be a pointer to a
            // USB_DEVICE_AUDIO_V2_EVENT_DATA_INTERFACE_SETTING_CHANGED. This
            // contains the interface number whose setting was
            // changed and the index of the alternate setting.
            // The application should typically enable the audio function
            // if the interfaceAlternateSettting member of pData is greater
            // than 0.

            break;

        case USB_DEVICE_AUDIO_V2_EVENT_CONTROL_TRANSFER_UNKNOWN:

            // This event indicates that the Audio v2.0 function driver has
            // received a control transfer which it cannot decode. pData
            // will be a pointer to USB_SETUP_PACKET type pointer. The
            // application should decode the packet and take the required
            // action using the USB_DEVICE_ControlStatus(),
            // USB_DEVICE_ControlSend() and USB_DEVICE_ControlReceive()
            // functions.

            break;

        case USB_DEVICE_AUDIO_V2_EVENT_CONTROL_TRANSFER_DATA_SENT:

            // This event indicates the data send request associated with
            // the latest USB_DEVICE_ControlSend() function was
            // completed. pData will be NULL.

        case USB_DEVICE_AUDIO_V2_EVENT_CONTROL_TRANSFER_DATA_RECEIVED:

            // This event indicates the data receive request associated with
            // the latest USB_DEVICE_ControlReceive() function was
            // completed. pData will be NULL. The application can either
            // acknowledge the received data or reject it by calling the
            // USB_DEVICE_ControlStatus() function.

            break;

        case USB_DEVICE_AUDIO_V2_CUR_ENTITY_SETTINGS_RECEIVED:
            // This event indicates the Current entity request has been
            // received.
            USB_AUDIO_CONTROL_INTERFACE_REQUEST* controlRequest;
            controlRequest = (USB_AUDIO_CONTROL_INTERFACE_REQUEST*) setupPkt;
            switch(controlRequest->entityID)

                            //This USB Audio Speaker application does
                            //not support any other feature unit request
                            //from Host. So Stall if any other feature
                            //unit request received from Host.
                            USB_DEVICE_ControlStatus (
                                                appData.usbDevHandle,
                                 USB_DEVICE_CONTROL_STATUS_ERROR);
                        break;

                    }
                }

            case USB_DEVICE_AUDIO_V2_RANGE_ENTITY_SETTINGS_RECEIVED:
                // This event indicates the Range entity request has been
                // received.
                USB_AUDIO_CONTROL_INTERFACE_REQUEST* controlRequest;
                controlRequest = (USB_AUDIO_CONTROL_INTERFACE_REQUEST*)setupPkt;
                switch(controlRequest->entityID)
                {
                    case APP_ID_CLOCK_SOURCE:
                        USB_AUDIO_CLOCKSOURCE_CONTROL_REQUEST* clockSourceRequest;
                        clockSourceRequest =
                        (USB_AUDIO_CLOCKSOURCE_CONTROL_REQUEST*) controlRequest;
                        if (clockSourceRequest->bRequest == RANGE)
                        {
                            switch(clockSourceRequest->controlSelector)
                            {
                                case CS_SAM_FREQ_CONTROL:
```

```
                {
                    if ((controlRequest->bmRequestType & 0x80)
                                                        == 0x80)
                    {
                        //A control read transfer received from
                        // Host. Now send data to Host.
                        USB_DEVICE_ControlSend(
                                            appData.usbDevHandle,
                            void *) &(appData.clockSourceRange),
                              sizeof(appData.clockSourceRange));
                    }
                    else
                    {
                        //Handle Get request
                        // USB_DEVICE_ControlReceive(
                                            appData.usbDevHandle,
                         (void *)&(appData.clockSourceRange[0]),
                             sizeof(appData.clockSourceRange) );
                        USB_DEVICE_ControlStatus(
                                            appData.usbDevHandle,
                               USB_DEVICE_CONTROL_STATUS_ERROR);
                    }
                }
                break;

                default:
                    //This USB Audio Speaker application does
                    // not support any other feature unit
                    // request from Host. So Stall if any other
                    // feature unit request received from Host.
                    USB_DEVICE_ControlStatus (
                                            appData.usbDevHandle,
                               USB_DEVICE_CONTROL_STATUS_ERROR);
                break;

            }
        }

    }
```

Remarks

The application can defer responses to events triggered by control transfers. In that, the application can respond to the control transfer event after exiting the event handler. This allows the application some time to obtain the response data rather than having to respond to the event immediately. Note that a USB host will typically wait for an event response for a finite time duration before timing out and canceling the event and associated transactions. Even when deferring response, the application must respond promptly if such time-out have to be avoided.

USB_DEVICE_AUDIO_V2_RESULT status;	Completion status of the transfer

Description

USB Device Audio v2.0 Function Driver Read and Write Complete Event Data.

This data type defines the data structure returned by the driver along with USB_DEVICE_AUDIO_V2_EVENT_READ_COMPLETE, USB_DEVICE_AUDIO_V2_EVENT_WRITE_COMPLETE, events.

Remarks

None.

USB_DEVICE_AUDIO_V2_EVENT_HANDLER Type

USB Device Audio v2.0 Event Handler Function Pointer Type.

File

usb_device_audio_v2_0.h

C

```
typedef USB_DEVICE_AUDIO_V2_EVENT_RESPONSE (* USB_DEVICE_AUDIO_V2_EVENT_HANDLER)(USB_DEVICE_AUDIO_V2_INDEX instanceIndex , USB_DEVICE_AUDIO_V2_EVENT event , void * pData, uintptr_t context);
```

Description

USB Device Audio v2.0 Event Handler Function Pointer Type.

This data type defines the required function signature USB Device Audio Function Driver event handling callback function. The application must register a pointer to an Audio Function Driver events handling function who's function signature (parameter and return value types) match the types specified by this function pointer in order to receive event call backs from the Audio Function Driver. The function driver will invoke this function with event relevant parameters. The description of the event handler function parameters is given here.

instanceIndex - Instance index of the Audio v2.0 Function Driver that generated the event.

event - Type of event generated.

pData - This parameter should be type casted to an event specific pointer type based on the event that has occurred. Refer to the USB_DEVICE_AUDIO_V2_EVENT enumeration description for more details.

context - Value identifying the context of the application that registered the event handling function.

Remarks

The event handler function executes in the USB interrupt context when the USB Device Stack is configured for interrupt based operation. It is not advisable to call blocking functions or computationally intensive functions in the event handler. Where the response to a control transfer related event requires extended processing, the response to the control transfer should be deferred and the event handler should be allowed to complete execution.

USB_DEVICE_AUDIO_V2_EVENT_RESPONSE Type

USB Device Audio v2.0 Function Driver event callback response type.

File

usb_device_audio_v2_0.h

C

```
typedef void USB_DEVICE_AUDIO_V2_EVENT_RESPONSE;
```

Description

USB Device Audio v2.0 Function Driver Event Handler Response Type

This is the return type of the Audio Function Driver event handler.

Remarks

None.

USB_DEVICE_AUDIO_V2_INDEX Type

USB Device Audio v2.0 Function Driver index.

File

usb_device_audio_v2_0.h

C

```
typedef uintptr_t USB_DEVICE_AUDIO_V2_INDEX;
```

Description

USB Device Audio v2.0 Function Driver Index

This definition uniquely identifies a Audio v2.0 Function Driver instance.

Remarks

None.

USB_DEVICE_AUDIO_V2_INIT Structure

USB Device Audio v2.0 Function Driver initialization data structure.

File

usb_device_audio_v2_0.h

C

```
typedef struct {
  size_t queueSizeRead;
  size_t queueSizeWrite;
} USB_DEVICE_AUDIO_V2_INIT;
```

Members

Members	Description
size_t queueSizeRead;	Size of the read queue for this instance • of the Audio function driver
size_t queueSizeWrite;	Size of the write queue for this instance • of the Audio function driver

Description

USB Device Audio v2.0 Function Driver Initialization Data Structure

This data structure must be defined for every instance of the Audio function driver. It is passed to the Audio v2.0 function driver, by the Device Layer, at the time of initialization. The funcDriverInit member of the Device Layer Function Driver registration table entry must point to this data structure for an instance of the Audio function driver.

Remarks

The queue sizes that are specified in this data structure are also affected by the USB_DEVICE_AUDIO_V2_QUEUE_DEPTH_COMBINED configuration macro.

USB_DEVICE_AUDIO_V2_RESULT Enumeration

USB Device Audio Function Driver USB Device Audio v2.0 result enumeration.

File

usb_device_audio_v2_0.h

C

```
typedef enum {
  USB_DEVICE_AUDIO_V2_RESULT_OK,
  USB_DEVICE_AUDIO_V2_RESULT_ERROR_TRANSFER_QUEUE_FULL,
  USB_DEVICE_AUDIO_V2_RESULT_ERROR_INSTANCE_INVALID,
  USB_DEVICE_AUDIO_V2_RESULT_ERROR_INSTANCE_NOT_CONFIGURED,
  USB_DEVICE_AUDIO_V2_RESULT_ERROR_PARAMETER_INVALID,
  USB_DEVICE_AUDIO_V2_RESULT_ERROR_INVALID_INTERFACE_ID,
  USB_DEVICE_AUDIO_V2_RESULT_ERROR_INVALID_BUFFER,
  USB_DEVICE_AUDIO_V2_RESULT_ERROR_ENDPOINT_HALTED,
  USB_DEVICE_AUDIO_V2_RESULT_ERROR_TERMINATED_BY_HOST,
  USB_DEVICE_AUDIO_V2_RESULT_ERROR
} USB_DEVICE_AUDIO_V2_RESULT;
```

Members

Members	Description
USB_DEVICE_AUDIO_V2_RESULT_OK	The operation was successful
USB_DEVICE_AUDIO_V2_RESULT_ERROR_TRANSFER_QUEUE_FULL	The transfer queue is full and no new transfers can be scheduled
USB_DEVICE_AUDIO_V2_RESULT_ERROR_INSTANCE_INVALID	The specified instance is not provisioned in the system
USB_DEVICE_AUDIO_V2_RESULT_ERROR_INSTANCE_NOT_CONFIGURED	The specified instance is not configured yet
USB_DEVICE_AUDIO_V2_RESULT_ERROR_PARAMETER_INVALID	The event handler provided is NULL
USB_DEVICE_AUDIO_V2_RESULT_ERROR_INVALID_INTERFACE_ID	Interface number passed to the read or write function is invalid.
USB_DEVICE_AUDIO_V2_RESULT_ERROR_INVALID_BUFFER	A NULL buffer was specified in the read or write function
USB_DEVICE_AUDIO_V2_RESULT_ERROR_ENDPOINT_HALTED	Transfer terminated because host halted the endpoint
USB_DEVICE_AUDIO_V2_RESULT_ERROR_TERMINATED_BY_HOST	Transfer terminated by host because of a stall clear
USB_DEVICE_AUDIO_V2_RESULT_ERROR	General Error

Description

USB Device Audio v2.0 Function Driver USB Device Audio v2.0 Result enumeration.

This enumeration lists the possible USB Device Audio v2.0 Function Driver operation results.

Remarks

None.

USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE Type

USB Device Audio v2.0 Function Driver Transfer Handle Definition.

File

usb_device_audio_v2_0.h

C

```
typedef uintptr_t USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE;
```

Description

USB Device Audio v2.0 Function Driver Transfer Handle Definition

This definition defines a USB Device Audio v2.0 Function Driver Transfer Handle. A Transfer Handle is owned by the application but its value is modified by the USB_DEVICE_AUDIO_V2_Write and USB_DEVICE_AUDIO_V2_Read functions. The transfer handle is valid for the life time of the transfer and expires when the transfer related event had occurred.

Remarks

None.

USB_DEVICE_AUDIO_V2_EVENT_RESPONSE_NONE Macro

USB Device Audio v2.0 Function Driver event handler response type none.

File

usb_device_audio_v2_0.h

C

```
#define USB_DEVICE_AUDIO_V2_EVENT_RESPONSE_NONE
```

Description

USB Device Audio v2.0 Function Driver Event Handler Response None

This is the definition of the Audio v2.0 Function Driver event handler response type none.

Remarks

Intentionally defined to be empty.

USB_DEVICE_AUDIO_V2_FUNCTION_DRIVER Macro

USB Device Audio v2.0 Function Driver function pointer.

File

usb_device_audio_v2_0.h

C

```
#define USB_DEVICE_AUDIO_V2_FUNCTION_DRIVER
```

Description

USB Device Audio v2.0 Function Driver Function Pointer

This is the USB Device Audio v2.0 Function Driver Function pointer. This should registered with the device layer in the function driver registration table.

Remarks

None.

USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE_INVALID Macro

USB Device Audio v2.0 Function Driver Invalid Transfer Handle Definition.

File

usb_device_audio_v2_0.h

C

```
#define USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE_INVALID
```

Description

USB Device Audio v2.0 Function Driver Invalid Transfer Handle Definition

This definition defines a USB Device Audio v2.0 Function Driver Invalid Transfer Handle. A Invalid Transfer Handle is returned by the USB_DEVICE_Audio_V2_Write and USB_DEVICE_Audio_V2_Read functions when the request was not successful.

Remarks

None.

Enumerations

	Name	Description
	USB_DEVICE_AUDIO_V2_EVENT	USB Device Audio v2.0 Function Driver events.
	USB_DEVICE_AUDIO_V2_RESULT	USB Device Audio Function Driver USB Device Audio v2.0 result enumeration.

Functions

	Name	Description
	USB_DEVICE_AUDIO_V2_EventHandlerSet	This function registers an event handler for the specified Audio function driver instance.

	USB_DEVICE_AUDIO_V2_Read	This function requests a data read from the USB Device Audio v2.0 Function Driver Layer.
	USB_DEVICE_AUDIO_V2_TransferCancel	This function cancels a scheduled Audio v2.0 Device data transfer.
	USB_DEVICE_AUDIO_V2_Write	This function requests a data write to the USB Device Audio v2.0 Function Driver Layer.

Macros

	Name	Description
	USB_DEVICE_AUDIO_V2_EVENT_RESPONSE_NONE	USB Device Audio v2.0 Function Driver event handler response type none.
	USB_DEVICE_AUDIO_V2_FUNCTION_DRIVER	USB Device Audio v2.0 Function Driver function pointer.
	USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE_INVALID	USB Device Audio v2.0 Function Driver Invalid Transfer Handle Definition.

Structures

	Name	Description
	USB_DEVICE_AUDIO_V2_EVENT_DATA_READ_COMPLETE	USB Device Audio Function Driver Audio v2.0 read and write complete event data.
	USB_DEVICE_AUDIO_V2_EVENT_DATA_SET_ALTERNATE_INTERFACE	USB Device Audio v2.0 Function Driver alternate interface setting event data.
	USB_DEVICE_AUDIO_V2_EVENT_DATA_WRITE_COMPLETE	USB Device Audio Function Driver Audio v2.0 read and write complete event data.
	USB_DEVICE_AUDIO_V2_INIT	USB Device Audio v2.0 Function Driver initialization data structure.

Types

	Name	Description
	USB_DEVICE_AUDIO_V2_EVENT_HANDLER	USB Device Audio v2.0 Event Handler Function Pointer Type.
	USB_DEVICE_AUDIO_V2_EVENT_RESPONSE	USB Device Audio v2.0 Function Driver event callback response type.
	USB_DEVICE_AUDIO_V2_INDEX	USB Device Audio v2.0 Function Driver index.
	USB_DEVICE_AUDIO_V2_TRANSFER_HANDLE	USB Device Audio v2.0 Function Driver Transfer Handle Definition.

Description

USB Device Audio Function Driver Interface

This file describes the USB Device Audio v2.0 Function Driver interface. This file should be included by the application if it needs to use the Audio v2.0 Function Driver API.

File Name

usb_device_audio_v2.0.h

Company

Microchip Technology Inc.

usb_device_audio_v2_0_config_template.h

USB device Audio 2.0 Class configuration definitions template

Macros

	Name	Description
	USB_DEVICE_AUDIO_V2_INSTANCES_NUMBER	Specifies the number of Audio 2.0 Function Driver instances.
	USB_DEVICE_AUDIO_V2_MAX_ALTERNATE_SETTING	Specifies the maximum number of Alternate Settings per streaming interface.
	USB_DEVICE_AUDIO_V2_MAX_STREAMING_INTERFACES	Specifies the maximum number of Audio 2.0 Streaming interfaces in an Audio 2.0 Function Driver instance.
	USB_DEVICE_AUDIO_V2_QUEUE_DEPTH_COMBINED	Specifies the combined queue size of all Audio 2.0 function driver instances.

Description

USB Device Audio 2.0 Class Configuration Definitions

This file contains configurations macros needed to configure the Audio 2.0 Function Driver. This file is a template file only. It should not be included

by the application. The configuration macros defined in the file should be defined in the configuration specific system_config.h.

USB Device Layer Library

This section describes the USB Device Layer Library.

Introduction

Introduces the MPLAB Harmony USB Device Layer Library.

Description

The MPLAB Harmony USB Device Layer Library (also referred to as the Device Layer) is part of the MPLAB Harmony USB Device Stack. Within the USB Device Stack, the Device Layer responds to enumeration requests from the Hosts. It receives control transfers from the Host and responds to these control transfers in case of standard device requests. It dispatches function driver and application specific control transfers to the respective function drivers and to the application. It provides the application and function drivers with API routines that allow them to respond and complete a control transfer, with a possibility of deferring such responses. The Device Layer also provides the application with events and functions that allow the application to track the state of the device.

The Device Layer plays the role of a system in the MPLAB Harmony USB Device Stack. In that, it initializes the USB Driver, the device function drivers and maintains their state machines by invoking the Tasks routines of these modules. The Device Layer thus treats the USB Driver and function drivers as sub modules.

The device layer features the following:

- Supports both USB Full-Speed and Hi-Speed operation
- Based on a modular and event-driven architecture
- Supports the PIC32MX and PIC32MZ families of microcontrollers
- Supports composite USB devices
- Supports different types of function drivers (i.e., CDC, HID, MSD, etc.)
- Supports non-blocking operation and is RTOS friendly
- Designed to integrate readily with other MPLAB Harmony middleware
- Supports both interrupt and polling operation
- Reduces the required application intervention in maintaining the USB state of the device
- Allows implementation of a multi-configuration USB device
- Functions to implement Generic USB Devices

Using the Library

This topic describes the basic architecture of the USB Device Layer Library and provides information and examples on its use.

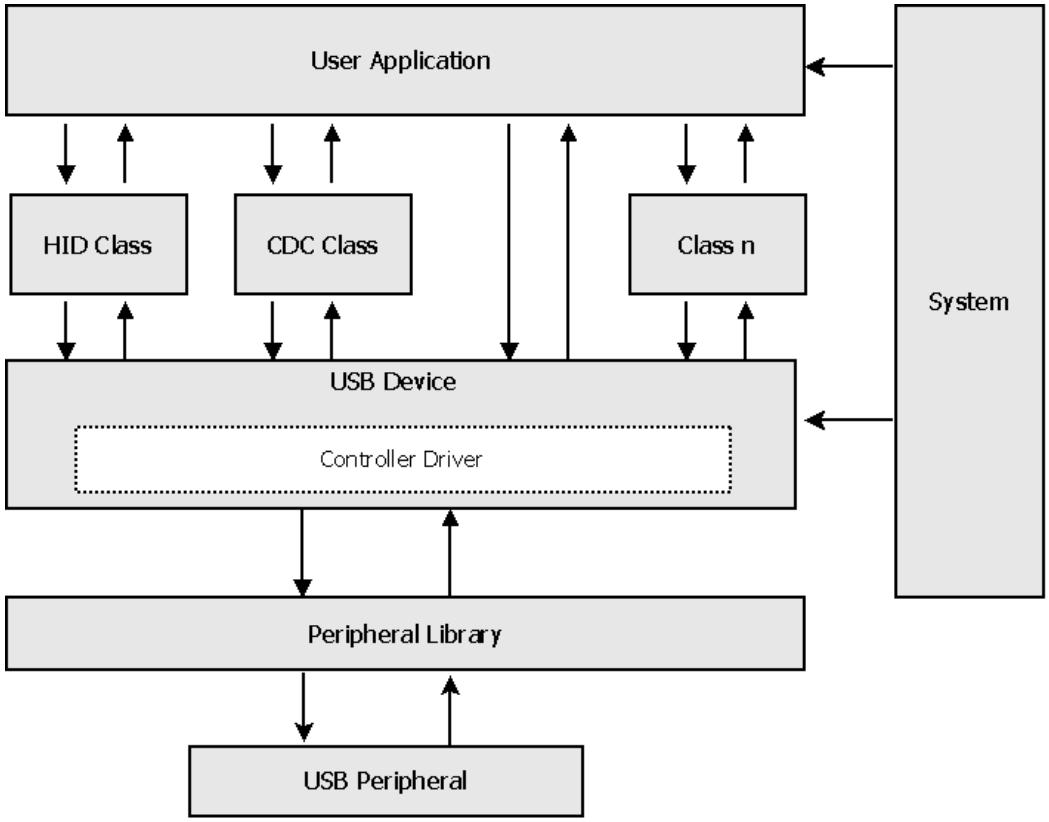
Abstraction Model

Describes the Abstraction Model of the USB Device Layer.

Description

The block diagram shows USB Device Layer interaction with USB controller driver, function drivers, user application and the system.

USB Device Layer Software Abstraction Block Diagram



System Interaction

The system is responsible for initializing and deinitializing the device layer. It is also responsible for calling the USB Device Layer task routine.

Function Driver Interaction

The USB Device Layer interacts with a function driver for following reasons:

- Initializes the function driver when device is configured by the Host. This can happen when the Host issues a set configuration request to the device. The device layer initializes only those function drivers that are valid for the selected configuration.
- Deinitializes the function driver when the Host issues a bus reset or when device is detached from the host or when the Host unconfigures the device by setting configuration value to '0'.
- Function driver and USB Controller Driver task routines are run by the device layer. This means that these task routines run at the same priority as a device layer task.
- Forwards class/interface specific setup requests from host to function drivers for processing. The function drivers can use device layer APIs to read and write data to Endpoint 0.

All of these interactions are initiated by the device layer, and therefore, it is required for a function driver to register a set of standard APIs with the device layer for initializing/deinitializing the function driver, for handling control transfers and for running the task routines. Registering of these callback functions with the device layer is a compile time step and is done using the function driver registration table. Function driver registration is explained in subsequent sections.

User Application (Client) Interaction

User application clients can register a callback function with the device layer to get USB device events. Apart from device events, the clients can interact with USB device layer to determine other status such as USB speed and remote wake-up. The Device Layer will forward Control Transfers whose Recipient field is set to Other, to the application. The application must use the Device Layer Control Transfer Routines to complete the control transfer.

Library Overview

The USB device layer mainly interacts with the system, its clients and function drivers, as shown in the Abstraction Model.

The library interface routines are divided into sub-sections, which address one of the blocks or the overall operation of the USB Device Layer Library.

Library Interface Section	Description
System Interaction Functions	Provides system module interfaces, device initialization, deinitialization, reinitialization and task functions.
Client Core Functions	Provides function to register callbacks, mechanism to pass events to clients and functions to know the status.

Device Power State Management Functions	These functions manage the power state of the device (self or bus powered) and remote wake-up.
Endpoint Management Functions	These functions allow the application to manage endpoints (enable, disable and stall).
Device Management Functions	These functions allow the application to manage the state of the device (attach, detach etc.).
Control Transfer Functions	These functions allow the application to respond to complete control transfers.

How the Library Works

Library Initialization

Describes how the USB Device Layer must be initialized.

Description

The Device Layer initialization process requires the following components:

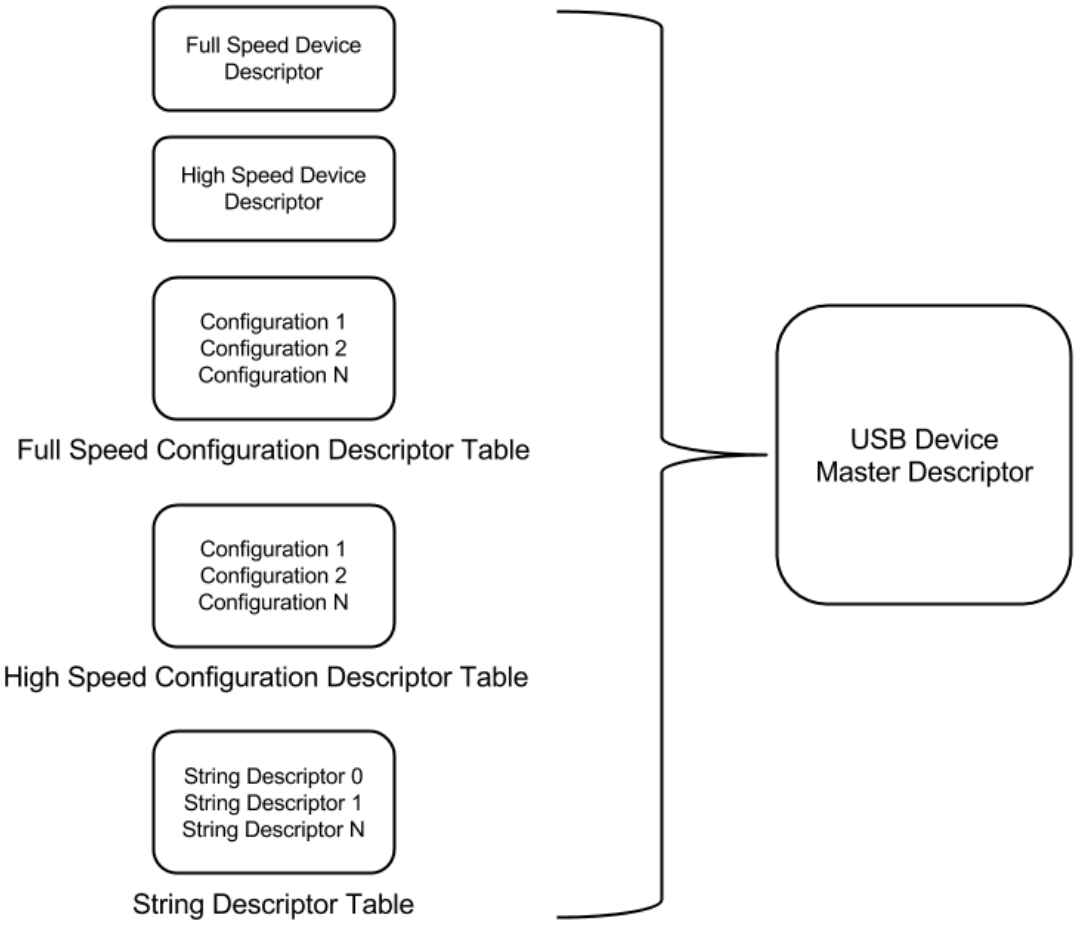
- USB Standard Descriptors that define the device functionality. The definitions of these descriptors are defined by the USB 2.0 and Device Class specification.
- Device Master Descriptor Table
- Function Driver Registration Table

The USB Standard Descriptors that define the device functionality are discussed in detail in the USB 2.0 and Device Class Specifications. The reader is encouraged to refer to these specifications for a detailed understanding of this topic.

Master Descriptor Table

Describes the USB Device Layer Master Descriptor Table.

Description



As seen in the figure, the Device Master Descriptor Table (specified by the USB_DEVICE_MASTER_DESCRIPTOR data type) is a container for all descriptor related information that is needed by the Device Layer for its operation. This table contains the following information:

- Pointer to the Full-Speed and High-Speed Device Descriptor
- Number of Full-Speed and High-Speed Configurations
- Pointers to Table of Full-Speed and High-Speed Configuration Descriptors
- Number of String Descriptors
- Pointer to a Table of String Descriptors
- Pointers to Full-Speed and High-Speed Device Qualifier

In a case where a particular item in the Device Master Descriptor Table is not applicable, that entry can be either set to '0' or NULL as applicable. For example for a Full-Speed-only device, the number of High Speed Configuration should be set to '0' and the pointer to the table of High-Speed Configuration Descriptors should be set to NULL.

The following code shows an example of a USB Device Master Descriptor design for a Full-Speed USB HID Keyboard.

```
/*********************************************
 * USB Device Layer Master Descriptor Table
 *********************************************/
const USB_DEVICE_MASTER_DESCRIPTOR usbMasterDescriptor =
{
    &fullSpeedDeviceDescriptor,     /* Full-speed descriptor */
    1,                              /* Total number of full-speed configurations available */
    &fullSpeedConfigDescSet[0],     /* Pointer to array of full-speed configurations descriptors*/

    NULL,                           /* High-speed device descriptor is not supported*/
    0,                              /* Total number of high-speed configurations available */
    NULL,                           /* Pointer to array of high-speed configurations descriptors. Not
supported*/

    3,                              /* Total number of string descriptors available */
    stringDescriptors,              /* Pointer to array of string descriptors */

    NULL,                           /* Pointer to full-speed device qualifier. Not supported */
    NULL,                           /* Pointer to high-speed device qualifier. Not supported */
};
```

The following code shows an example of a USB Device Master Descriptor design for a Full Speed/High Speed USB HID Keyboard.

```
/*********************************************
 * USB Device Layer Master Descriptor Table
 *********************************************/
const USB_DEVICE_MASTER_DESCRIPTOR usbMasterDescriptor =
{
    &fullSpeedDeviceDescriptor,     /* Full-speed descriptor */
    1,                              /* Total number of full-speed configurations available */
    &fullSpeedConfigDescSet[0],     /* Pointer to array of full-speed configurations descriptors*/

    &highSpeedDeviceDescriptor,     /* High-speed descriptor */
    1,                              /* Total number of high-speed configurations available */
    &highSpeedConfigDescSet[0],     /* Pointer to array of high-speed configurations descriptors*/

    3,                              /* Total number of string descriptors available */
    stringDescriptors,              /* Pointer to array of string descriptors */

    &deviceQualifierDescriptor1,    /* Pointer to full-speed device qualifier. */
    NULL,                           /* Pointer to high-speed device qualifier. Not supported */
};
```

The USB Device Layer Master Descriptor table can be placed in the data or program memory of the PIC32 device. The contents of this table could be modified while the application is running. Doing this will affect the operation of the Device Stack. A typical USB device application will not need to change the contents of this table while the application is running.

Function Driver Registration Table

This section explains how function drivers can be registered with the USB Device Layer using the Function Registration Table.

Description

The Function Driver Registration Table (defined by the USB_DEVICE_FUNCTION_REGISTRATION_TABLE data type) contains information about the function drivers that are present in the application. The Device Layer needs this information to establish the intended functionality of the USB Device and then manage the operation of the device.

The Function Driver Registration Table contains an entry for every function driver instance contained in the application. Each entry is configuration specific. Hence in a case of device that features multiple configurations, the Function Driver Registration Table will contains an entry for every function driver in each configuration. Entries are instance and configuration specific. Hence if a configuration contains two instances of the same

function driver type, the Function Driver Registration Table will contain two entries to for the same function driver but with different instance indexes. A description of each member of the Function Driver Registration Table entry is as follows:

- The configurationValue member of the entry specifies to which configuration this entry belongs. The Device Layer will process this entry when the configurationValue configuration is set.
- The driver member of the entry should be set to Function Driver – Device Layer Interface Functions Object exported by the function driver. This object is provided by the function driver. In case of the CDC function driver, this is USB_DEVICE_CDC_FUNCTION_DRIVER. In case of HID function driver, this is USB_DEVICE_HID_FUNCTION_DRIVER. . Refer to the "Library Initialization" topic in Function Driver Specific help section for more details.
- The funcDriverIndex member of the entry specifies the instance of the function driver that this entry relates to. The Device Layer will use this instance when communicating with the function driver. In a case where there are multiple instances of the same function driver in a configuration, the funcDriverIndex allows the Device Layer to uniquely identify the function driver.
- The funcDriverInit member of the entry must point to the function driver instance specific initialization data structure. Function Drivers typically require an initialization data structure to be specified. The Device Layer passes the pointer to the initialization data structure when the function driver is initialized. Refer to the "Library Initialization" topic in Function Driver Specific help section for more details.
- The interfaceNumber member of the entry must contain the interface number of the first interface that is owned by this function driver instance. The information is available from the Device Configuration Descriptor.
- The numberOfInterfaces member of the entry must contain the number of interfaces following the interfaceNumber interface that is owned by this function driver instance. For example, a CDC Device requires two interfaces. The interfaceNumber member of Function Driver Registration Table entry for this function driver would be 0 and the numberOfInterfaces member would be 2. This indicates that Interface 0 and Interface 1 in the Device Configuration Descriptor are owned by this function driver.
- The speed member of the entry specifies the device speeds for which this function driver should be initialized. This can be set to either USB_SPEED_FULL, USB_SPEED_HIGH or a logical OR combination of both. The Device Layer will initialize the function if the device attach speed matches the speed mention in the speed member of the entry.

The following code shows an example of Function Driver Registration Table for one function driver. The CDC Function Driver in this case has two interfaces.

```
/*********************************************
 * USB Device Layer Function Driver Registration
 * Table
 *********************************************/
const USB_DEVICE_FUNCTION_REGISTRATION_TABLE funcRegistrationTable[1] =
{
    {
         .configurationValue = 1 ,                  // Configuration descriptor index
         .driver = USB_DEVICE_CDC_FUNCTION_DRIVER,  // CDC APIs exposed to the device layer
         .funcDriverIndex = 0 ,                     // Instance index of CDC function driver
         .funcDriverInit = (void *)&cdcInit,        // CDC init data
         .interfaceNumber = 0 ,                     // Start interface number of this instance
         .numberOfInterfaces = 2 ,                  // Total number of interfaces contained in this instance
         .speed = USB_SPEED_FULL|USB_SPEED_HIGH     // USB Speed
    }
};
```

The following code shows an example of Function Driver Registration Table for two function drivers. This example demonstrates a Composite (CDC + MSD) device. The CDC Function Driver uses two interfaces starting from interface 0. The MSD Function Driver has one interface starting from interface 2.

```
/*********************************************
 * Function Driver Registration Table
 *********************************************/
USB_DEVICE_FUNCTION_REGISTRATION_TABLE funcRegistrationTable[2] =
{
    {
        .speed = USB_SPEED_FULL|USB_SPEED_HIGH,     // Speed at which this device can operate
        .configurationValue = 1,                    // Configuration number to which this device belongs
        .interfaceNumber = 1,                       // Starting interface number for this function driver
        .numberOfInterfaces = 2,                    // Number of interfaces that this function driver owns.
        .funcDriverIndex = 0,                       // Function Driver index
        .funcDriverInit = &cdcInit,                 // Function Driver initialization data structure
        .driver = USB_DEVICE_CDC_FUNCTION_DRIVER    // CDC Function Driver.
    },
    {
        .speed = USB_SPEED_FULL|USB_SPEED_HIGH,     // Speed at which this device can operate
        .configurationValue = 1,                    // Configuration number to which this device belongs
        .interfaceNumber = 0,                       // Starting interface number for this function driver
        .numberOfInterfaces = 1,                    // Number of interfaces that this function driver owns.
        .funcDriverIndex = 0,                       // Function Driver index
        .funcDriverInit = &msdInit,                 // Function Driver initialization data structure
        .driver = USB_DEVICE_MSD_FUNCTION_DRIVER    // MSD Function Driver.
    },
};
```

The USB Device Layer Function Driver registration table can be placed in the data or program memory of the PIC32 device. The contents of this table could be modified while the application is running. Doing this will affect the operation of the device stack. A typical USB device application will not need to change the contents of this table while the application is running.

Initializing the Device Layer

This section describes the USB Device Layer initialization.

Description

With the USB Device Master Descriptor and the Function Driver Registration Table available, the application can now create the Device Layer Initialization Data structure. This data structure is a USB_DEVICE_INIT type and contains the information need to initialize the Device Layer and the USB Controller Driver. The Device Layer uses the USB Controller Driver initialization data to initialize the USB Controller driver. The actual initialization is performed by calling the USB_DEVICE_Initialize function. This function returns a Device Layer System Module Object which must be used with the other Device Layer System Routines (such as the USB_DEVICE_Tasks and USB_DEVICE_Tasks_ISR functions). In case of PIC32MX device, the Device Layer requires the allocation of an endpoint table. This table (an array of type uint8_t) should aligned at a 512 byte aligned address boundary. Its size should be USB_DEVICE_ENDPOINT_TABLE_SIZE. The table is not required for PIC32MZ devices. The value of USB_DEVICE_ENDPOINT_TABLE_SIZE while designing for PIC32MZ device will be automatically set to '0'.

The following code shows an example of initializing the Device Layer.

```
/*************************************************
 * Endpoint Table needed by the Device Layer.
 *************************************************/

uint8_t __attribute__((aligned(512))) endpointTable[USB_DEVICE_ENDPOINT_TABLE_SIZE];

/*********************************************
 * USB Device Layer Initialization.
 *********************************************/

USB_DEVICE_INIT usbDevInitData =
{
    /* System module initialization */
    .moduleInit = {SYS_MODULE_POWER_RUN_FULL},

     /* Identifies peripheral (PLIB-level) ID */
    .usbID = USB_ID_1,

    /* Stop in idle */
    .stopInIdle = false,

    /* Stop in sleep */
    .suspendInSleep = false,

    /* Interrupt source */
    .interruptSource = INT_SOURCE_USB_1,

    /* Endpoint Table */
    .endpointTable = endpointTable,

    /* Number of function drivers registered to this instance of the
    USB device layer */
    .registeredFuncCount = 2,

    /* Function driver table registered to this instance of the USB device layer*/
    .registeredFunctions = (USB_DEVICE_FUNCTION_REGISTRATION_TABLE*)funcRegistrationTable,

    /* Pointer to USB Descriptor structure */
    .usbMasterDescriptor = (USB_DEVICE_MASTER_DESCRIPTOR*)&usbMasterDescriptor
};

/*************************************
 * System Initialization Routine
 *************************************/
void SYS_Initialize ( void * data )
{
     /* Set up cache and wait states for maximum performance. */
    SYS_DEVCON_Initialize(SYS_DEVCON_INDEX_0, (SYS_MODULE_INIT *)&devconInit);
    SYS_DEVCON_PerformanceConfig(80000000);

    /* Initialize the BSP */
```

```
    BSP_Initialize( );

     /* Initialize the USB device layer */
    sysObjects.usbDevObject = USB_DEVICE_Initialize (USB_DEVICE_INDEX_0 ,
                                                     ( SYS_MODULE_INIT* ) & usbDevInitData);

    /* check if the object returned by the device layer is valid */
    SYS_ASSERT((SYS_MODULE_OBJ_INVALID != sysObjects.usbDevObject), "Invalid USB DEVICE object");

    /* Initialize the Application */
    APP_Initialize ( );

    /* Initialize the interrupt system  */
    SYS_INT_Initialize();

       /* set priority for USB interrupt source */
    SYS_INT_VectorPrioritySet(INT_VECTOR_USB, INT_PRIORITY_LEVEL3);

    /* set sub-priority for USB interrupt source */
    SYS_INT_VectorSubprioritySet(INT_VECTOR_USB, INT_SUBPRIORITY_LEVEL3);

    /* Initialize the global interrupts */
    SYS_INT_Enable();
}
```

Device Layer Task Routines

Describes the Device Layer task routines.

Description

In a case where the USB Controller driver is configured for interrupt mode operation (DRV_USB_INTERRUPT_MODE is true), the USB_DEVICE_Tasks_ISR() function should be called in the USB module interrupt associated with the Device Layer. The following code shows an example of this.

```
/*********************************************
 * Example of instantiating the USB Interrupt
 * and call the Device Layer ISR Tasks Routines.
 *********************************************/

void __ISR ( _USB_1_VECTOR, ipl3 ) _InterruptHandler_USB_stub ( void )
{
    USB_DEVICE_Tasks_ISR(sysObjects.usbDevObject);
}
```

If the USB Controller driver is configured for polled mode, the Device Layer will automatically invoke the USB_DEVICE_Tasks_ISR() functions from the USB_DEVICE_Tasks() function. Irrespective of whether the USB Controller driver is configured for polled or interrupt mode, the USB_DEVICE_Tasks() function should be called from SYS_Tasks() function. This will ensure that this function is called periodically. The USB_DEVICE_Tasks() function in turn calls the tasks routines of the applicable functions drivers and the USB Controller Driver (when the driver is configured for polled mode). The following code shows an example of how the USB_DEVICE_Tasks() function is called in the SYS_Tasks() function.

```
void SYS_Tasks ( void )
{
    /* Device layer tasks routine. Function Driver tasks gets called
     * from device layer tasks */

    USB_DEVICE_Tasks(sysObjects.usbDevObject);

    /* Call the application's tasks routine */
    APP_Tasks ();
}
```

Application Client Interaction

Describes application client interaction.

Description

Once initialized, Device Layer becomes ready for operation. The application must open the Device Layer by calling the USB_DEVICE_Open() function. Opening the Device Layer makes the application a Device Layer client. The Device Layer returns a valid Device Layer Handle when opened successfully. It will return an invalid Device Layer Handle when the open function fails. The application in this case should try opening the Device Layer again. The application can use a valid Device Layer handle to access the Device Layer functionality.

The client must now register a Device Layer Event Handler with the Device Layer. This is a mandatory step that enables USB Device Layer Events. The application must use the USB_DEVICE_EventHandlerSet function to register the event handler. The Application Event Handler should be of the type USB_DEVICE_EVENT_HANDLER. The Device Layer, when an event needs to be generated, calls this event handler function with the event type and event relevant information. The application must register an event handler for proper functioning of the USB Device. Not registering an event handler may cause the USB Device to malfunction and become non-compliant.

With an event handler register, the client can now attach the USB Device on the bus. The application must attach the in response to the USB_DEVICE_EVENT_POWER_DETECTED event. Attaching the device on the bus makes the device visible to the host (if it is already attached to the bus) and will cause the host to interact with the device.

The following code shows an example of the application opening the Device Layer, registering the event handler and then attaching the device on the bus.

```
/*************************************************
 * Here the application tries to open the Device Layer
 * and then register an event handler and then attach
 * the device on the bus.
 *************************************************/
void APP_Tasks(void)
{
    switch(appData.state)
    {
        case APP_STATE_INIT:

            /* Open the device layer */
            appData.deviceHandle = USB_DEVICE_Open( USB_DEVICE_INDEX_0,
                    DRV_IO_INTENT_READWRITE );

            if(appData.deviceHandle != USB_DEVICE_HANDLE_INVALID)
            {
                /* Register a callback with device layer to get event notification */
                USB_DEVICE_EventHandlerSet(appData.deviceHandle,
                        APP_USBDeviceEventCallBack, 0);

                appData.state = APP_STATE_WAIT_FOR_CONFIGURATION;
            }
            else
            {
                /* The Device Layer is not ready to be opened. We should try
                 * again later. */
            }

            break;
    }
}
```

Event Handling

Describes USB Device Layer event handling.

Description

The Device Layer generates events to let the application client know about the state of the bus. Some of these events require the application to respond in a specific manner. Not doing so, could cause the USB device to malfunction and become non-compliant. Code inside the event handler executes in an interrupt context when the Device Layer is configured for interrupt mode operation. The application must avoid calling computationally intensive functions or blocking functions in the event handler.

The following table shows a summary of the events that the Device Layer generates and the required Application client response.

Event	Required Application Response
USB_DEVICE_EVENT_POWER_DETECTED	Attach the device.
USB_DEVICE_EVENT_POWER_REMOVED	Detach the device.
USB_DEVICE_EVENT_RESET	No response required.
USB_DEVICE_EVENT_SUSPENDED	No response required.
USB_DEVICE_EVENT_RESUMED	No response required.
USB_DEVICE_EVENT_ERROR	The application can try detaching the device and reattaching. This should be done after exiting from the event handler.
USB_DEVICE_EVENT_SOF	No response required.

USB_DEVICE_EVENT_CONFIGURED	No response required.
USB_DEVICE_EVENT_DECONFIGURED	No response required.
USB_DEVICE_EVENT_CONTROL_TRANSFER_SETUP_REQUEST	Application must either respond with a USB_DEVICE_ControlSend() to send data, USB_DEVICE_ControlReceive() to receive data or stall or acknowledge the control request by calling the USB_DEVICE_ControlStatus() function.
USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_SENT	No response required.
USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_RECEIVED	Application must either or stall or acknowledge the control request by calling the USB_DEVICE_ControlStatus() function.
USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_ABORTED	No response required.

The Device Layer generates events with event relevant data. The pData parameter in the event handler functions points to this event specific data. The application can access this data by type casting the pData parameter of the event handler to a event specific data type. The following table shows a summary of the USB Device Layer events and the event data generated along with the event.

Event	Related pData Type
USB_DEVICE_EVENT_POWER_DETECTED	NULL
USB_DEVICE_EVENT_POWER_REMOVED	NULL
USB_DEVICE_EVENT_RESET	NULL
USB_DEVICE_EVENT_SUSPENDED	NULL
USB_DEVICE_EVENT_RESUMED	NULL
USB_DEVICE_EVENT_ERROR	NULL
USB_DEVICE_EVENT_SOF	USB_DEVICE_EVENT_DATA_SOF *
USB_DEVICE_EVENT_CONFIGURED	USB_DEVICE_EVENT_DATA_CONFIGURED *
USB_DEVICE_EVENT_DECONFIGURED	NULL
USB_DEVICE_EVENT_CONTROL_TRANSFER_SETUP_REQUEST	USB_SETUP_PACKET *
USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_SENT	NULL
USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_RECEIVED	NULL

A detailed description of each Device Layer event along with the required application client response, the likely follow-up event (if applicable) and the event specific data is provided here.

USB_DEVICE_EVENT_POWER_DETECTED

Application Response: This event indicates that the device has detected a valid VBUS to the host. The device is yet to be enumerated and configured. The application should not access the function drivers at this point. The application can use this event to attach the device on the bus.

Event Specific Data(pData): The pData parameter will be NULL.

Likely Follow Up Event: None.

USB_DEVICE_EVENT_POWER_REMOVED

Application Response: This event is an indication to the application client that the device is detached from the host. The application can use this event to detach the device.

Event Specific Data(pData): The pData parameter will be NULL

Likely Follow Up Event: None.

USB_DEVICE_EVENT_SUSPENDED

Application Response: This event is an indication to the application client that device is suspended and it can put the device to sleep mode if required. Power saving routines should not be called in the event handler.

Event Specific Data: The pData parameter will be NULL.

Likely Follow Up Event: None.

USB_DEVICE_EVENT_RESET

Application Response: USB bus reset occurred. This event is an indication to the application client that device layer has deinitialized all function drivers. The application should not use the function drivers in this state.

Event Specific Data: The pData parameter will be NULL.

Likely Follow Up Event: None.

USB_DEVICE_EVENT_RESUMED

Application Response: This event indicates that device has resumed from suspended state. The application can use this event to resume the operational state of the device.

Event Specific Data: The pData parameter will be NULL.

Likely Follow Up Event: None.

USB_DEVICE_EVENT_ERROR

Application Response: This event is an indication to the application client that an error occurred on the USB bus. The application can try detaching and reattaching the device.

Event Specific Data: The pData parameter will be NULL.

Likely Follow Up Event: None.

USB_DEVICE_EVENT_SOF

Application Response: This event occurs when the device receives a Start Of Frame packet. The application can use this event for synchronizing purposes. This event will be received every 1 millisecond for Full Speed USB and every one 125 micro seconds for High Speed USB. No application response is required.

Event Specific Data: Will point to USB_DEVICE_EVENT_DATA_SOF data type containing the frame number

Likely Follow Up Event: None.

USB_DEVICE_CONFIGURED

Application Response: This event is an indication to the application client that device layer has initialized all function drivers. The application can check the configuration set by the host. The application should use the event to register event handlers with the function drivers that are provisioned in the system.

Event Specific Data: The pData parameter will point to a USB_DEVICE_EVENT_DATA_CONFIGURED data type that contains configuration set by the host

Likely Follow Up Event: None.

USB_DEVICE_DECONFIGURED

Application Response: The host has deconfigured the device. This happens when the host sends a Set Configuration request with configuration number 0. The device layer will deinitialize all function drivers and then generate this event. No application response is required.

Event Specific Data:: The pData parameter will be NULL

Likely Follow Up Event: None.

USB_DEVICE_CONTROL_TRANSFER_ABORTED

Application Response: An on-going control transfer was aborted. The application can use this event to reset it's control transfer state machine.

Event Specific Data: The pData parameter will be NULL

Likely Follow Up Event: None.

USB_DEVICE_CONTROL_TRANSFER_DATA_RECEIVED

Application Response: The data stage of a Control write transfer has completed. This event occurs after the application has used the USB_DEVICE_ControlReceive() function to receive data in the control transfer (in response to the USB_DEVICE_CONTROL_TRANSFER_SETUP_REQUEST event) . The application can inspect the received data and stall or acknowledge the control transfer by calling the USB_DEVICE_ControlStatus() function with the USB_DEVICE_CONTROL_STATUS_ERROR flag or USB_DEVICE_CONTROL_STATUS_OK flag respectively. The application can call the USB_DEVICE_ControlStatus() function in the event handler or after exiting the event handler.

Event Specific Data: The pData parameter will be NULL

Likely Follow Up Event: None.

USB_DEVICE_CONTROL_TRANSFER_SETUP_REQUEST

Application Response: A setup packet of a control transfer has been received. The recipient field of the received setup packet is Other. The application can initiate the data stage by using the USB_DEVICE_ControlReceive() and USB_DEVICE_ControlSend() functions. It can end the control transfer by calling the USB_DEVICE_ControlStatus() function.

Event Specific Data: The pData parameter in the event handler will point to USB_SETUP_PACKET data type.

Likely Follow Up Event: USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_SENT if the USB_DEVICE_ControlSend() function was called to send data to the host. USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_RECEIVED if the USB_DEVICE_ControlReceive() function was called to receive data from the host.

USB_DEVICE_CONTROL_TRANSFER_DATA_SENT

Application Response: The data stage of a Control Read transfer has completed. This event occurs after the application has used the USB_DEVICE_ControlSend() function to send data in the control transfer. No application response is required.

Event Specific Data: The pData parameter will be NULL

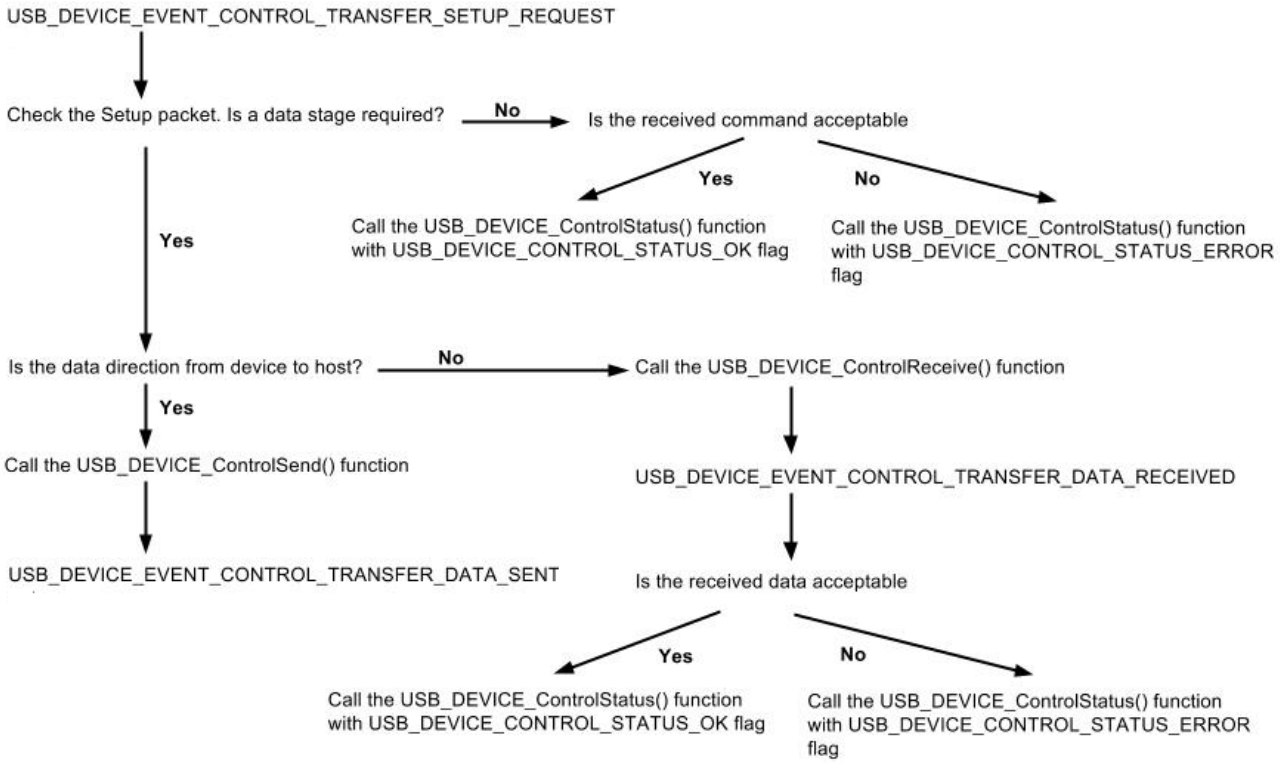
Likely Follow Up Event: None.

Device Layer Control Transfers

Describes USB Device Layer control transfers.

Description

The USB Device Layer forwards control transfer setup packets, where the Recipient field in the Setup packet is "Other", to the application for handling. The application must respond appropriately to this event. The following flow chart shows the possible sequences of events and application responses.



The Device Layer provides the USB_DEVICE_ControlReceive(), USB_DEVICE_ControlSend() and USB_DEVICE_ControlStatus() functions to complete the control transfers. These functions should be called only in response to the USB_DEVICE_EVENT_CONTROL_TRANSFER_SETUP_REQUEST event. In response to this event, the application can use the USB_DEVICE_ControlReceive( ) function to receive data in the data stage of a Control Write transfer. The reception of data is indicated by the USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_RECEIVED event. The application can then complete the Control Write transfer by either:

- accepting the received data and acknowledging the Status Stage of the Control transfer. This is done by calling the USB_DEVICE_ControlStatus() function with the USB_DEVICE_CONTROL_STATUS_OK flag.
- rejecting the received data and stalling the Status Stage of the Control transfer. This is done by calling the USB_DEVICE_ControlStatus() function with the USB_DEVICE_CONTROL_STATUS_ERROR flag.

The application can use the USB_DEVICE_ControlSend() function to send data in the data stage of a Control Read transfer. The transmission of data is indicated by the USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_SENT event.

In a case where the Control Transfer does not contain a data stage or if the application does not support the Setup Request, the application can end the Control Transfer by calling the USB_DEVICE_ControlStatus() function in response to the USB_DEVICE_EVENT_CONTROL_TRANSFER_SETUP_REQUEST event. Here the application can

- accepting the command by acknowledging the Status Stage of the Zero Data Stage of the Control transfer. This is done by calling the USB_DEVICE_ControlStatus() function with the USB_DEVICE_CONTROL_STATUS_OK flag.
- rejecting the Setup Request and stalling the Status Stage of the Control transfer. This is done by calling the USB_DEVICE_ControlStatus() function with the USB_DEVICE_CONTROL_STATUS_ERROR flag.

The application can also defer the response to Control transfer events. In that, the application does not have to respond to Control Transfer Events in the event handler. This may be needed in cases where resources required to respond to the Control Transfer Events are not readily available. The application, even while deferring the response, must however complete the Control Transfer in a time fashion. Failing to do so, will cause the host to cancel and retry the control transfer. This could also cause the USB device to malfunction and become non-compliant.

The following code shows an example of handling Device Layer events.

```
USB_DEVICE_EVENT_RESPONSE APP_USBDeviceEventHandler
(
    USB_DEVICE_EVENT event,
    void * pData,
    uintptr_t context
)
{
    uint8_t     activeConfiguration;
    uint16_t    frameNumber;
    USB_SPEED   attachSpeed;
    USB_SETUP_PACKET * setupEventData;

    // Handling of each event
    switch(event)
    {
        case USB_DEVICE_EVENT_POWER_DETECTED:

            // This means the device detected a valid VBUS voltage
            // and is attached to the USB if the device is bus powered.
            break;

        case USB_DEVICE_EVENT_POWER_REMOVED:

            // This means the device is not attached to the USB.
            break;

        case USB_DEVICE_EVENT_SUSPENDED:

            // The bus is idle. There was no activity detected.
            // The application can switch to a low power mode after
            // exiting the event handler.
            break;

        case USB_DEVICE_EVENT_SOF:

            // A start of frame was received. This is a periodic
            // event and can be used the application for time
            // related activities. pData will point to a USB_DEVICE_EVENT_DATA_SOF type data
            // containing the frame number.

            frameNumber = ((USB_DEVICE_EVENT_DATA_SOF *)(pData))->frameNumber;
            break;

        case USB_DEVICE_EVENT_RESET :

            // Reset signalling was detected on the bus. The
            // application can find out the attach speed.

            attachedSpeed = USB_DEVICE_ActiveSpeedGet(usbDeviceHandle);
            break;

        case USB_DEVICE_EVENT_DECONFIGURED :

            // This indicates that host has deconfigured the device i.e., it
            // has set the configuration as 0. All function driver instances
            // would have been deinitialized.

            break;

        case USB_DEVICE_EVENT_ERROR :

            // This means an unknown error has occurred on the bus.
            // The application can try detaching and attaching the
            // device again.
            break;

        case USB_DEVICE_EVENT_CONFIGURED :

            // This means that device is configured and the application can
```

```
            // start using the device functionality. The application must
            // register function driver event handlers within this event.
            // The pData parameter will be a pointer to a USB_DEVICE_EVENT_DATA_CONFIGURED data type
            // that contains the active configuration number.

            activeConfiguration = ((USB_DEVICE_EVENT_DATA_CONFIGURED *)(pData))->configurationValue;
            break;

        case USB_DEVICE_EVENT_RESUMED:

            // This means that the resume signalling was detected on the
            // bus. The application can bring the device out of power
            // saving mode.

            break;

        case USB_DEVICE_EVENT_CONTROL_TRANSFER_SETUP_REQUEST:

            // This means that the setup stage of the control transfer is in
            // progress and a setup packet has been received. The pData
            // parameter will point to a USB_SETUP_PACKET data type The
            // application can process the command and update its control
            // transfer state machine. The application for example could call
            // the USB_DEVICE_ControlReceive() function (as shown here) to
            // submit the buffer that would receive data in case of a
            // control read transfer.

            setupPacket = (USB_SETUP_PACKET *)pData;

            // Submit a buffer to receive 32 bytes in the  control write transfer.
            USB_DEVICE_ControlReceive(usbDeviceHandle, data, 32);
            break;

        case USB_DEVICE_CONTROL_TRANSFER_EVENT_DATA_RECEIVED:

            // This means that data in the data stage of the control write
            // transfer has been received. The application can either accept
            // the received data by calling the USB_DEVICE_ControlStatus()
            // function with USB_DEVICE_CONTROL_STATUS_OK flag (as shown in
            // this example) or it can reject it by calling the
            // USB_DEVICE_ControlStatus() function with
            // USB_DEVICE_CONTROL_STATUS_ERROR flag.

            USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_OK);
            break;

        case USB_DEVICE_CONTROL_TRANSFER_EVENT_DATA_SENT:

            // This means that data in the data stage of the control
            // read transfer has been sent. The application would typically
            // end the control transfer by calling the
            // USB_DEVICE_ControlStatus() function with
            // USB_DEVICE_CONTROL_STATUS_OK flag (as shown in this example).

            USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_OK);
            break;

        case USB_DEVICE_CONTROL_TRANSFER_EVENT_ABORTED:

            // This means the host has aborted the control transfer. The
            // application can reset it's control transfer state machine.

            break;

        default:
            break;
    }

    return USB_DEVICE_EVENT_REPONSE_NONE;
```

```
    }
```

String Descriptor Table

Describes the String Descriptor Table o the device layer.

Description

The Device Layer allows the application to specify string descriptors via a String Descriptor Table. When the USB Host requests for a string by its index and language ID, the Device Layer looks for the corresponding string descriptor in the String Descriptor Table. There are two possible methods of specifying this String Descriptor Table, Basic and Advanced. These methods are discussed here.

Basic String Descriptor Table

The Basic String Descriptor Table should be used when the USB Device Application has equal number of string descriptors for each language string indexes exist without any intervals. This method is the default method of specifying the String Descriptor Table. Each entry in the table contains the following information

- The size of the entry
- The descriptor type, which is always set to USB_DESCRIPTOR_STRING
- The array containing the string

The first entry in the String Descriptor Table, at index 0 of the table, will always contain the Lang ID string. This string specifies the one language ID of the String Descriptor that this application intends to support. The subsequent entries in the String Descriptor Table contain the actual string descriptor. Each language must have an equal set of the string descriptors. The Device layer will associate each set of string descriptors with language ID specified in the language ID string descriptor. The following code shows an example of a Basic String Descriptor table.

Example:

```
/* This code shows an example of a Basic String Descriptor Table. In
 * this example, the table contains five entries. The first entry is the
 * language ID string. The second entry in the manufacturer string and the third
 * entry is the product string for language ID 0x0409. The fourth and the fifth
 * entry is the manufacture and product string, respectively for the language ID
 * 0x040C. */

/*******************************************************************
*  Language ID string descriptor. Note that this contains two Language IDs.
*******************************************************************/
const struct
{
    uint8_t bLength;
    uint8_t bDscType;
    uint16_t string[1];
}
sd000 =
{
    sizeof(sd000),          // Size of this descriptor in bytes
    USB_DESCRIPTOR_STRING,  // STRING descriptor type
    {0x0409, 0x040C}        // Language ID
};

/***************************************
 *  Manufacturer string descriptor
 ***************************************/
const struct
{
    uint8_t bLength;        // Size of this descriptor in bytes
    uint8_t bDscType;       // STRING descriptor type
    uint16_t string[25];    // String
}
sd001 =
{
    sizeof(sd001),
    USB_DESCRIPTOR_STRING,
    {'M','i','c','r','o','c','h','i','p',' ',
     'T','e','c','h','n','o','l','o','g','y',' ','I','n','c','.'}
};

/***************************************
 *  Product string descriptor
 ***************************************/
```

```
const struct
{
    uint8_t bLength;        // Size of this descriptor in bytes
    uint8_t bDscType;       // STRING descriptor type
    uint16_t string[22];    // String
}
sd002 =
{
    sizeof(sd002),
    USB_DESCRIPTOR_STRING,
    {'S','i','m','p','l','e',' ','C','D','C',' ','D','e','v','i','c','e',' ','D','e','m','o' }
};

/**************************************
 *  Manufacturer string descriptor
 **************************************/
const struct
{
    uint8_t bLength;        // Size of this descriptor in bytes
    uint8_t bDscType;       // STRING descriptor type
    uint16_t string[25];    // String
}
sd003 =
{
    sizeof(sd003),
    USB_DESCRIPTOR_STRING,
    {'M','i','c','r','o','c','h','i','p',' ',
     'T','e','c','h','n','o','l','o','g','y',' ','I','n','c','.'}
};

/**************************************
 *  Product string descriptor
 **************************************/
const struct
{
    uint8_t bLength;        // Size of this descriptor in bytes
    uint8_t bDscType;       // STRING descriptor type
    uint16_t string[22];    // String
}
sd004 =
{
    sizeof(sd004),
    USB_DESCRIPTOR_STRING,
    {'S','i','m','p','l','e',' ','C','D','C',' ','D','e','v','i','c','e',' ','D','e','m','o' }
};

/**************************************
 * Array of string descriptors
 **************************************/
USB_DEVICE_STRING_DESCRIPTORS_TABLE stringDescriptors[3]=
{
    /* This is the language ID string */
    (const uint8_t *const)&sd000,

    /* This string descriptor at index 1 will be returned when the host request
     * for a string descriptor with index 1 and language ID 0x0409. */
    (const uint8_t *const)&sd001,

    /* This string descriptor at index 2 will be returned when the host request
     * for a string descriptor with index 2 and language ID 0x0409. */
    (const uint8_t *const)&sd002,

    /* This string descriptor at index 3 will be returned when the host request
     * for a string descriptor with index 1 and language ID 0x040C. */
    (const uint8_t *const)&sd003,

    /* This string descriptor at index 4 will be returned when the host request
     * for a string descriptor with index 2 and language ID 0x040C. */
    (const uint8_t *const)&sd004
```

```
};
```

Advanced String Descriptor Table

The Advanced String Descriptor Table should be used when the application needs to specify string descriptors with string indexes that are not continuous. One such example is the Microsoft OS String Descriptor. The index of this string descriptor is 0xEE. If the application were to use the Basic String Descriptor Table , this would require the String Descriptor Table to have at least 0xED entries (valid or invalid) before the entry for the Microsoft OS String Descriptor. This may result in waste of RAM. Using the Ad Advanced String Descriptor Table mitigates this problem. The Advanced String Descriptor Table format is enabled only when USB_DEVICE_STRING_DESCRIPTOR_TABLE_ADVANCED_ENABLE configuration option is specified in the `system_config.h`. Each entry in the Advanced String Descriptor Table contains the following information:

- The index of the string descriptor
- The language ID of the string descriptor
- The size of the entry, which is two more than the length of the string
- The descriptor type, which is always set to USB_DESCRIPTOR_STRING
- The array containing the string

The first such entry in the Advanced String Descriptor Table specifies the language ID string. The string index and the language ID of this entry should be zero. This first entry is then followed by the actual string descriptors. Unlike the Basic String Descriptor Table, the index of an entry in the Advanced String Descriptor Table is not the same as the String Descriptor Index that the host uses to identify the string. In the Advanced String Descriptor Table, the index of the string is specified by the stringIndex member of the Advanced String Descriptor Table table entry. The following code shows an example of the Advanced String Descriptor table.

Example:

```
/* This code shows an example of an Advanced String Descriptor Table.
 * The Advanced String Descriptor table should be used when multiple languages
 * are needed to be supported. In this example, two languages are supported*/

/*******************************************************
 * Language ID string descriptor. Note that stringIndex and
 * language ID are always 0 for this descriptor.
 *******************************************************/
const struct __attribute__ ((packed))
{
    uint8_t stringIndex;    // Index of the string descriptor
    uint16_t languageID ;   // Language ID of this string.
    uint8_t bLength;        // Size of this descriptor in bytes
    uint8_t bDscType;       // STRING descriptor type
    uint16_t string[2];     // String
}
sd000 =
{
    0,                      // Index of this string is 0
    0,                      // This field is always blank for String Index 0
    sizeof(sd000)- 3,       // Should always be set to this.
    USB_DESCRIPTOR_STRING,
    {0x0409, 0x040C}        // Language ID
};

/*************************************************
 *  Manufacturer string descriptor for language 0x0409
 *************************************************/
const struct __attribute__ ((packed))
{
    uint8_t stringIndex;    // Index of the string descriptor
    uint16_t languageID ;   // Language ID of this string.
    uint8_t bLength;        // Size of this descriptor in bytes
    uint8_t bDscType;       // STRING descriptor type
    uint16_t string[25];    // String
}
sd001 =
{
    1,      // Index of this string descriptor is 1.
    0x0409, // Language ID of this string descriptor is 0x0409 (English)
    sizeof(sd001) - 3,
    USB_DESCRIPTOR_STRING,
    {'M','i','c','r','o','c','h','i','p',' ',
    'T','e','c','h','n','o','l','o','g','y',' ','I','n','c','.'}
};

};
```

BOS Descriptor Support

Provides information on the BOS descriptor.

Description

The USB 3.0 and the USB 2.0 LPM specifications define a new descriptor called the Binary Device Object Store (BOS) descriptor. This descriptor contains information of the capability of the device. When the bcdUSB value in the Device Descriptor is greater than 0x0200, the USB Host Operating System may request for the BOS descriptor.

The MPLAB Harmony USB Device Library allows the application to support the BOS descriptor requests. This support is enabled by adding the USB_DEVICE_BOS_DESCRIPTOR_SUPPORT_ENABLE configuration macro in `system_config.h`. The application must set the bosDescriptor member of the USB_DEVICE_INIT data structure (this data structure is passed in the USB_DEVICE_Initialize function) to point to the data to be returned in the data stage of the BOS descriptor request.

If the USB_DEVICE_BOS_DESCRIPTOR_SUPPORT_ENABLE configuration macro is not specified, the Device Layer will stall the Host request BOS descriptor.

Configuring the Library

Describes how to configure the USB Device Library.

Macros

	Name	Description
	USB_DEVICE_INSTANCES_NUMBER	Number of Device Layer instances to provisioned in the application.
	USB_DEVICE_ENDPOINT_QUEUE_DEPTH_COMBINED	Specifies the combined endpoint queue depth in case of a vendor USB device implementation.
	USB_DEVICE_SET_DESCRIPTOR_EVENT_ENABLE	Enables the Device Layer Set Descriptor Event.
	USB_DEVICE_SOF_EVENT_ENABLE	Enables the Device Layer SOF event.
	USB_DEVICE_SYNCH_FRAME_EVENT_ENABLE	Enables the Device Layer Synch Frame Event.
	USB_DEVICE_EP0_BUFFER_SIZE	Buffer Size in Bytes for Endpoint 0.
	USB_DEVICE_MICROSOFT_OS_DESCRIPTOR_SUPPORT_ENABLE	Specifies if the USB Device stack should support Microsoft OS Descriptor.

Description

The USB Device Layer initializes and configures the USB Controller Driver (the driver that manages the USB peripheral when operating as device) and maintains its task routine. For completeness, the following table lists the configuration macros that are needed by the USB Controller Driver. These macros should be defined in `system_config.h` file along with the Device Layer Configuration macros.

USB_DEVICE_INSTANCES_NUMBER Macro

Number of Device Layer instances to provisioned in the application.

File

usb_device_config_template.h

C

```
#define USB_DEVICE_INSTANCES_NUMBER 1
```

Description

Number of Device Layer Instances.

This configuration macro defines the number of Device Layer instances in the application. In cases of microcontrollers that feature multiple USB peripherals, this allows the application to run multiple instances of the Device Layer. As an example, for a microcontroller containing two USB peripherals, setting USB_DEVICE_INSTANCES_NUMBER to 2 will cause 2 instances of the Device Layer to execute.

Remarks

Setting this value to more than the number of USB peripheral will result if unused RAM consumption.

USB_DEVICE_ENDPOINT_QUEUE_DEPTH_COMBINED Macro

Specifies the combined endpoint queue depth in case of a vendor USB device implementation.

File

usb_device_config_template.h

C

```
#define USB_DEVICE_ENDPOINT_QUEUE_DEPTH_COMBINED 2
```

Description

USB Device Layer Combined Endpoint Queue Depth

This configuration constant specifies the combined endpoint queue depth in a case where the endpoint read and endpoint write functions are used to implement a vendor USB device. This constant should be used in conjunction with the usb_device_endpoint_functions.c file.

This macro defines the number of entries in all IN and OUT endpoint queues in all instances of the USB Device Layer. This value can be obtained by adding up the endpoint read and write queue sizes of each USB Device Layer instance . In a simple single instance USB Device Layer, that requires only one read and one write endpoint with one buffer each, the USB_DEVICE_ENDPOINT_QUEUE_DEPTH_COMBINED macro can be set to 2. Consider a case with one Device Layer instance using 2 IN and 2 OUT endpoints, each requiring 2 buffers, this macro should be set to 8 (2 + 2 + 2 + 2).

Remarks

This constant needs to be specified only if a Vendor USB Device is to be implemented and the usb_device_endpoint_functions.c file is included in the project. This constant does not have any effect on queues of other standard function drivers that are included in the USB device implementation.

USB_DEVICE_SET_DESCRIPTOR_EVENT_ENABLE Macro

Enables the Device Layer Set Descriptor Event.

File

usb_device_config_template.h

C

```
#define USB_DEVICE_SET_DESCRIPTOR_EVENT_ENABLE
```

Description

USB Device Layer Set Descriptor Event Enable

Specifying this configuration macro will cause the USB Device Layer to generate the USB_DEVICE_EVENT_SET_DESCRIPTOR event when a Set Descriptor request is received. If this macro is not defined, the USB Device Layer will stall the Set Descriptor control transfer request.

Remarks

None.

USB_DEVICE_SOF_EVENT_ENABLE Macro

Enables the Device Layer SOF event.

File

usb_device_config_template.h

C

```
#define USB_DEVICE_SOF_EVENT_ENABLE
```

Description

USB Device Layer SOF Event Enable

Specifying this configuration macro will cause the USB Device Layer to generate the USB_DEVICE_EVENT_SOF event. On Full Speed USB Devices, this event will be generated every 1 millisecond. On High Speed USB devices, this event will be generated every 125 microsecond.

Remarks

None.

USB_DEVICE_SYNCH_FRAME_EVENT_ENABLE Macro

Enables the Device Layer Synch Frame Event.

File

usb_device_config_template.h

C

```
#define USB_DEVICE_SYNCH_FRAME_EVENT_ENABLE
```

Description

USB Device Layer Synch Frame Event Enable

Specifying this configuration macro will cause the USB Device Layer to generate the USB_DEVICE_EVENT_SYNCH_FRAME event when a Synch Frame control transfer request is received. If this macro is not defined, the USB Device Layer will stall the control transfer request associated with this event.

Remarks

None.

USB_DEVICE_EP0_BUFFER_SIZE Macro

Buffer Size in Bytes for Endpoint 0.

File

usb_device_config_template.h

C

```
#define USB_DEVICE_EP0_BUFFER_SIZE
```

Description

Endpoint 0 Buffer Size

This number defines the size (in bytes) of Endpoint 0. For High Speed USB Devices, this number should be 64. For Full Speed USB Devices, this number can be 8, 16, 32 or 64 bytes. This number will be applicable to all USB Device Stack instances.

Remarks

None.

USB_DEVICE_MICROSOFT_OS_DESCRIPTOR_SUPPORT_ENABLE Macro

Specifies if the USB Device stack should support Microsoft OS Descriptor.

File

usb_device_config_template.h

C

```
#define USB_DEVICE_MICROSOFT_OS_DESCRIPTOR_SUPPORT_ENABLE
```

Description

USB Device Layer Microsoft OS Descriptor Support Enable

This macro needs to be defined to enable Microsoft OS descriptor support. If this macro is defined all Vendor Interface requests are forwarded to client unconditionally and Device layer does not validate the recipient interface field in a Control transfer.

Device and Class Control Requests are not affected by this configuration. The Device Layer will validate the recipient interface in Device and Class Control Requests, irrespective of this configuration constant, and will stall these requests if the interface is provisioned in the Function Driver Registration Table.

If this macro is not defined, then USB Device Layer will validate the interface number in a Vendor Interface request and stall the request if Interface number is not available in the Function registration table.

Remarks

None.

Building the Library

This section lists the files that are available in the USB Device Layer Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/usb`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
usb_device.h	This header file should be included in any `.c` file that accesses the USB Device Layer API.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/dynamic/usb_device.c`	This file implements the USB Device Layer interface and should be included in project if USB Device mode operation is desired.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The USB Device Layer Library depends on the following modules:

- USB Driver Library (Device mode files)

Library Interface

a) System Interaction Functions

	Name	Description
	USB_DEVICE_Initialize	Creates and initializes an instance of the USB device layer.
	USB_DEVICE_Deinitialize	De-initializes the specified instance of the USB device layer.
	USB_DEVICE_Status	Provides the current status of the USB device layer
	USB_DEVICE_Tasks	USB Device layer calls all other function driver tasks in this function. It also generates and forwards events to its clients.
	USB_DEVICE_Tasks_ISR	USB Device Layer Tasks routine to be called in the USB Interrupt Service Routine.
	USB_DEVICE_Tasks_ISR_USBDMA	This is function USB_DEVICE_Tasks_ISR_USBDMA.

b) Client Core Functions

	Name	Description
	USB_DEVICE_Open	Opens the specified USB device layer instance and returns a handle to it.
	USB_DEVICE_Close	Closes an opened handle to an instance of the USB device layer.
	USB_DEVICE_ClientStatusGet	Returns the client specific status.
	USB_DEVICE_EventHandlerSet	USB Device Layer Event Handler Callback Function set function.

c) Device Power State Management Functions

	Name	Description
	USB_DEVICE_PowerStateSet	Sets power state of the device.
	USB_DEVICE_RemoteWakeupStatusGet	Gets the "Remote wake-up" status of the device.
	USB_DEVICE_IsSuspended	Returns true if the device is in a suspended state.
	USB_DEVICE_RemoteWakeupStart	This function will start the resume signaling.
	USB_DEVICE_RemoteWakeupStartTimed	This function will start a self timed Remote Wake-up.
	USB_DEVICE_RemoteWakeupStop	This function will stop the resume signaling.

d) Device Management Functions

	Name	Description
	USB_DEVICE_StateGet	Returns the current state of the USB device.
	USB_DEVICE_Attach	This function will attach the device to the USB.
	USB_DEVICE_Detach	This function will detach the device from the USB.
	USB_DEVICE_ActiveConfigurationGet	Informs the client of the current USB device configuration set by the USB host.
	USB_DEVICE_ActiveSpeedGet	Informs the client of the current operation speed of the USB bus.

e) Endpoint Management Functions

	Name	Description
	USB_DEVICE_EndpointIsStalled	This function returns the stall status of the specified endpoint and direction.
	USB_DEVICE_EndpointStall	This function stalls an endpoint in the specified direction.
	USB_DEVICE_EndpointStallClear	This function clears the stall on an endpoint in the specified direction.
	USB_DEVICE_EndpointDisable	Disables a device endpoint.
	USB_DEVICE_EndpointEnable	Enables a device endpoint.
	USB_DEVICE_EndpointIsEnabled	Returns true if the endpoint is enabled.
	USB_DEVICE_EndpointRead	Reads data received from host on the requested endpoint.
	USB_DEVICE_EndpointTransferCancel	This function cancels a transfer scheduled on an endpoint.
	USB_DEVICE_EndpointWrite	This function requests a data write to a USB Device Endpoint.

f) Control Transfer Functions

	Name	Description
	USB_DEVICE_ControlReceive	Receives data stage of the control transfer from host to device.
	USB_DEVICE_ControlSend	Sends data stage of the control transfer from device to host.
	USB_DEVICE_ControlStatus	Initiates status stage of the control transfer.

g) Data Types and Constants

	Name	Description
	USB_DEVICE_INDEX_0	USB device layer index definitions.
	USB_DEVICE_INDEX_1	This is macro USB_DEVICE_INDEX_1.
	USB_DEVICE_INDEX_2	This is macro USB_DEVICE_INDEX_2.
	USB_DEVICE_INDEX_3	This is macro USB_DEVICE_INDEX_3.
	USB_DEVICE_INDEX_4	This is macro USB_DEVICE_INDEX_4.
	USB_DEVICE_INDEX_5	This is macro USB_DEVICE_INDEX_5.
	USB_DEVICE_CONTROL_STATUS	USB Device Layer Control Transfer Status Stage flags.
	USB_DEVICE_CONTROL_TRANSFER_RESULT	Enumerated data type identifying results of a control transfer.
	USB_DEVICE_EVENT	USB Device Layer Events.
	USB_DEVICE_HANDLE	Data type for USB device handle.
	USB_DEVICE_INIT	USB Device Initialization Structure
	USB_DEVICE_POWER_STATE	Enumerated data type that identifies if the device is self powered or bus powered .
	USB_DEVICE_REMOTE_WAKEUP_STATUS	Enumerated data type that identifies if the remote wakeup status of the device.
	USB_DEVICE_EVENT_DATA_CONFIGURED	USB Device Set Configuration Event Data type.
	USB_DEVICE_HANDLE_INVALID	Constant that defines the value of an Invalid Device Handle.
	USB_DEVICE_EVENT_RESPONSE_NONE	Device Layer Event Handler Function Response Type.
	USB_DEVICE_CLIENT_STATUS	Enumerated data type that identifies the USB Device Layer Client Status.
	USB_DEVICE_CONFIGURATION_DESCRIPTORS_TABLE	Pointer to an array that contains pointer to configuration descriptors.
	USB_DEVICE_EVENT_HANDLER	USB Device Layer Event Handler Function Pointer Type
	USB_DEVICE_EVENT_RESPONSE	Device Layer Event Handler function return type.
	USB_DEVICE_FUNCTION_REGISTRATION_TABLE	USB Device Function Registration Structure
	USB_DEVICE_MASTER_DESCRIPTOR	USB Device Master Descriptor Structure.

	USB_DEVICE_STRING_DESCRIPTORS_TABLE	Pointer to an array that contains pointer to string descriptors.
	USB_DEVICE_EVENT_DATA_ENDPOINT_READ_COMPLETE	USB Device Layer Endpoint Read and Write Complete Event Data type.
	USB_DEVICE_EVENT_DATA_ENDPOINT_WRITE_COMPLETE	USB Device Layer Endpoint Read and Write Complete Event Data type.
	USB_DEVICE_EVENT_DATA_SET_DESCRIPTOR	USB Device Set Descriptor Event Data type.
	USB_DEVICE_EVENT_DATA_SOF	USB Device Start Of Frame Event Data Type
	USB_DEVICE_EVENT_DATA_SYNCH_FRAME	USB Device Synch Frame Event Data type.
	USB_DEVICE_RESULT	USB Device Layer Results Enumeration
	USB_DEVICE_TRANSFER_FLAGS	Enumerated data type that identifies the USB Device Layer Transfer Flags.
	USB_DEVICE_TRANSFER_HANDLE	Data type for USB Device Endpoint Data Transfer Handle.
	USB_DEVICE_TRANSFER_HANDLE_INVALID	Constant that defines the value of an Invalid Device Endpoint Data Transfer Handle.
	_USB_DEVICE_IRP	This structure defines the USB Device Mode IRP data structure.
	_USB_HOST_IRP	This structure defines the USB Host Mode IRP data structure.
	_USB_HOST_IRP_STATUS	Enumerates the possible status options of USB Host IRP.
	USB_DEVICE_IRP	This structure defines the USB Device Mode IRP data structure.
	USB_DEVICE_IRP_FLAG	USB Device IRP flags enumeration
	USB_DEVICE_IRP_STATUS	Enumerates the possible status options of USB Device IRP.
	USB_ENDPOINT	Defines a type to store Endpoint and Direction. The MSB defines the direction. The lower 4 bits defines the endpoint.
	USB_ERROR	Enumeration of all possible error codes that are returned by various components functions in the USB Stack.
	USB_HOST_IRP	This structure defines the USB Host Mode IRP data structure.
	USB_HOST_IRP_FLAG	USB Host IRP flags enumeration
	USB_HOST_IRP_STATUS	Enumerates the possible status options of USB Host IRP.
	USB_SPEED	Provides enumeration of USB 2.0 speeds.
	USB_ENDPOINT_AND_DIRECTION	This macro helps in setting up the USB_ENDPOINT type.
	USB_DATA_DIRECTION	Defines the communication direction
	USB_DEVICE_BOS_DESCRIPTOR_SUPPORT_ENABLE	Specifies if the Device Layer should process a Host request for a BOS descriptor.
	USB_DEVICE_DRIVER_INITIALIZE_EXPLICIT	Specifies if the USB Controller Driver must be initialized explicitly as opposed to being initialized by the Device Layer.
	USB_DEVICE_STRING_DESCRIPTOR_TABLE_ADVANCED_ENABLE	Specifying this macro enables the Advanced String Descriptor Table Entry Format.

Description

This section describes the Application Programming Interface (API) functions of the USB Device Layer Library.

Refer to each section for a detailed description.

a) System Interaction Functions

USB_DEVICE_Initialize Function

Creates and initializes an instance of the USB device layer.

File

usb_device.h

C

```
SYS_MODULE_OBJ USB_DEVICE_Initialize(const SYS_MODULE_INDEX instanceIndex, const SYS_MODULE_INIT * const
init);
```

Returns

If successful, returns a valid handle to a device layer object. Otherwise, it returns SYS_MODULE_OBJ_INVALID.

Description

This function initializes an instance of USB device layer, making it ready for clients to open and use it. The number of instances is limited by the value of macro USB_DEVICE_MAX_INSTANCES defined in system_config.h file.

Remarks

This routine must be called before any other USB Device Layer routine is called and after the initialization of USB Device Driver. This routine should only be called once during system initialization.

Preconditions

None.

Example

```
// This code example shows the initialization of the
// the USB Device Layer. Note how an endpoint table is
// created and assigned.

USB_DEVICE_INIT deviceLayerInit;
SYS_MODULE_OBJ usbDeviceObj;
uint8_t __attribute__((aligned(512))) endpointTable[USB_DEVICE_ENDPOINT_TABLE_SIZE];

// System module initialization
deviceLayerInit.moduleInit.value = SYS_MODULE_POWER_RUN_FULL;

// Identifies peripheral (PLIB-level) ID
deviceLayerInit.usbID = USB_ID_1;

// Boolean flag: true -> Stop USB module in Idle Mode
deviceLayerInit.stopInIdle = false;

// Boolean flag: true -> Suspend USB in Sleep Mode
deviceLayerInit.suspendInSleep = false;

// Interrupt Source for USB module
deviceLayerInit.interruptSource = INT_SOURCE_USB_1;

// Number of function drivers registered to this instance of the
// USB device layer
deviceLayerInit.registeredFuncCount = 1;

// Function driver table registered to this instance of the USB device layer
deviceLayerInit.registeredFunctions = funcRegistrationTable;

// Pointer to USB Descriptor structure
deviceLayerInit.usbMasterDescriptor   = &usbMasterDescriptor;

// Pointer to an endpoint table.
deviceLayerInit.endpointTable = endpointTable;

// USB device initialization
usbDeviceObj = USB_DEVICE_Initialize(USB_DEVICE_INDEX_0, &deviceLayerInit);

if (SYS_MODULE_OBJ_INVALID == usbDeviceObj)
{
    // Handle error
}
```

Parameters

Parameters	Description
instanceIndex	In case of microcontrollers with multiple USB peripherals, user can create multiple instances of USB device layer. Parameter instanceIndex identifies this instance.
init	Pointer to a data structure containing any data necessary to initialize the USB device layer

Function

SYS_MODULE_OBJ USB_DEVICE_Initialize
(
const SYS_MODULE_INDEX instanceIndex,
const SYS_MODULE_INIT * const init
)

USB_DEVICE_Deinitialize Function

De-initializes the specified instance of the USB device layer.

File

usb_device.h

C

```
void USB_DEVICE_Deinitialize(SYS_MODULE_OBJ usbDeviceObj);
```

Returns

None.

Description

This function deinitializes the specified instance of the USB device layer, disabling its operation (and any hardware) and invalidates all of the internal data.

Remarks

Once the Initialize operation has been called, the deinitialize operation must be called before the Initialize operation can be called again.

Preconditions

Function USB_DEVICE_Initialize must have been called before calling this routine and a valid SYS_MODULE_OBJ must have been returned.

Example

```
// This code example shows how the USB
// Device Layer can be deinitialized. It is assumed the
// USB Device Layer was already initialized.

SYS_MODULE_OBJ usbDeviceobj;

USB_DEVICE_Deinitialize(usbDeviceobj);
```

Parameters

Parameters	Description
object	USB device layer object handle, returned by USB_DEVICE_Initialize

Function

void USB_DEVICE_Deinitialize (SYS_MODULE_OBJ usbDeviceobj)

USB_DEVICE_Status Function

Provides the current status of the USB device layer

File

usb_device.h

C

```
SYS_STATUS USB_DEVICE_Status(SYS_MODULE_OBJ object);
```

Returns

SYS_STATUS_READY - Indicates that the device is busy with a previous system level operation and cannot start another

SYS_STATUS_UNINITIALIZED - Indicates that the device layer is in a deinitialized state

Description

This function provides the current status of the USB device layer.

Remarks

None.

Preconditions

The USB_DEVICE_Initialize function must have been called before calling this function.

Example

```
// This code example shows how the USB_DEVICE_Status function
// can be used to check if the USB Device Layer is ready
// for client operations.

SYS_MODULE_OBJ      object;     // Returned from DRV_USB_Initialize
SYS_STATUS          status;

status = USB_DEVICE_Status(object);

if (SYS_STATUS_READY != status)
{
    // Handle error
}
```

Parameters

Parameters	Description
object	Driver object handle, returned from USB_DEVICE_Initialize

Function

SYS_STATUS USB_DEVICE_Status (SYS_MODULE_OBJ object)

USB_DEVICE_Tasks Function

USB Device layer calls all other function driver tasks in this function. It also generates and forwards events to its clients.

File

usb_device.h

C

```
void USB_DEVICE_Tasks(SYS_MODULE_OBJ object);
```

Returns

None.

Description

This function must be periodically called by the user application. The USB Device layer calls all other function driver tasks in this function. It also generates and forwards events to its clients.

Remarks

None.

Preconditions

Device layer must have been initialized by calling USB_DEVICE_Initialize.

Example

```
// The USB_DEVICE_Tasks() function should be placed in the
// SYS_Tasks() function of a MPLAB Harmony application.

SYS_MODULE_OBJ usbDeviceLayerObj; // Returned by USB_DEVICE_Initialize().
```

```
void SYS_Tasks(void)
{
    USB_DEVICE_Tasks(usbDeviceLayerObj);
}
```

Parameters

Parameters	Description
devLayerObj	Pointer to the Device Layer Object that is returned from USB_DEVICE_Initialize

Function

void USB_DEVICE_Tasks(SYS_MODULE_OBJ devLayerObj)

USB_DEVICE_Tasks_ISR Function

USB Device Layer Tasks routine to be called in the USB Interrupt Service Routine.

File

usb_device.h

C

```
void USB_DEVICE_Tasks_ISR(SYS_MODULE_OBJ object);
```

Returns

None.

Description

This function must be called in the USB Interrupt Service Routine if the Device Stack is configured for interrupt mode. In case the Device Stack is configured for polling mode, this function is automatically called from the USB_DEVICE_Tasks function. devLayerObj must be the system module object associated with the USB module generating the interrupt.

Remarks

None.

Preconditions

Device layer must have been initialized.

Example

```
// devLayerObj is returned while initializing the USB1 module.
// The USB_DEVICE_Tasks_ISR function should be placed in the
// USB1 module ISR.

SYS_MODULE_OBJ devLayerObj; // Returned by USB_DEVICE_Initialize().

void __ISR(_USB_1_VECTOR, ipl4) USB1InterruptHandle(void)
{
    USB_DEVICE_Tasks_ISR(usbDeviceLayerObj);
}
```

Parameters

Parameters	Description
devLayerObj	Pointer to the Device Layer Object that is returned from USB_DEVICE_Initialize

Function

void USB_DEVICE_Tasks_ISR(SYS_MODULE_OBJ devLayerObj)

USB_DEVICE_Tasks_ISR_USBDMA Function

File

usb_device.h

C

```
void USB_DEVICE_Tasks_ISR_USBDMA(SYS_MODULE_OBJ devLayerObj);
```

Description

This is function USB_DEVICE_Tasks_ISR_USBDMA.

b) Client Core Functions

USB_DEVICE_Open Function

Opens the specified USB device layer instance and returns a handle to it.

File

usb_device.h

C

```
USB_DEVICE_HANDLE USB_DEVICE_Open(const SYS_MODULE_INDEX instanceIndex, const DRV_IO_INTENT intent);
```

Returns

If successful, returns a valid device layer handle. Otherwise, it returns USB_DEVICE_HANDLE_INVALID.

Description

This function opens the USB device layer instance specified by instance index and returns a handle. This handle must be provided to all other client operations to identify the caller and the instance of the USB device layer. An instance of the Device Layer can be opened only once. Trying to open the Device Layer more than once will return a invalid device layer handle.

Remarks

None.

Preconditions

This function must be called after USB device driver initialization and after the initialization of USB Device Layer.

Example

```
// This code example shows how the
// USB Device Layer can be opened.

USB_DEVICE_HANDLE usbDeviceHandle;

// Before opening a handle, USB device must have been initialized
// by calling USB_DEVICE_Initialize().

usbDeviceHandle = USB_DEVICE_Open( USB_DEVICE_INDEX_0,
                                   DRV_IO_INTENT_READWRITE );

if(USB_DEVICE_HANDLE_INVALID == usbDeviceHandle)
{
    //Failed to open handle.
}
```

Parameters

Parameters	Description
instanceIndex	USB device layer instance index
intent	This parameter is ignored. The Device Layer will always open in read/write and exclusive mode.

Function

USB_DEVICE_HANDLE USB_DEVICE_Open

(

const SYS_MODULE_INDEX instanceIndex,

const DRV_IO_INTENT intent

)

USB_DEVICE_Close Function

Closes an opened handle to an instance of the USB device layer.

File

usb_device.h

C

```
void USB_DEVICE_Close(USB_DEVICE_HANDLE usbDeviceHandle);
```

Returns

None

Description

This function closes an opened handle to an instance of the USB device layer, invalidating the handle.

Remarks

After calling this routine, the handle passed in "usbDevHandle" must not be used with any of the remaining driver routines. A new handle must be obtained by calling USB_DEVICE_Open() before the client may use the device layer again.

Preconditions

The USB_DEVICE_Initialize function must have been called for the specified device layer instance. USB_DEVICE_Open must have been called to obtain a valid opened device handle.

Example

```
USB_DEVICE_HANDLE usbDeviceHandle;

// Before opening a handle, USB device must have been initialized
// by calling USB_DEVICE_Initialize().
usbDeviceHandle = USB_DEVICE_Open( USB_DEVICE_INDEX_0 );

if(USB_DEVICE_HANDLE_INVALID == usbDeviceHandle)
{
    //Failed to open handle.
}

//..................
//..................
// User's code
//..................
//..................
// Close handle
USB_DEVICE_Close( usbDevHandle );
```

Parameters

Parameters	Description
handle	A valid open-instance handle, returned from USB_DEVICE_Open

Function

void USB_DEVICE_Close(USB_DEVICE_HANDLE usbDeviceHandle)

USB_DEVICE_ClientStatusGet Function

Returns the client specific status.

File

usb_device.h

C

```
USB_DEVICE_CLIENT_STATUS USB_DEVICE_ClientStatusGet(USB_DEVICE_HANDLE usbDeviceHandle);
```

Returns

USB_DEVICE_CLIENT_STATUS type of client status.

Description

This function returns the status of the client (ready or closed). The application can use this function to query the present state of a client. Some of the USB Device Layer functions do not have any effect if the client handle is invalid. The USB_DEVICE_ClientStatusGet function in such cases can be used for debugging or trouble shooting.

Remarks

The application may ordinarily not find the need to use this function. It can be used for troubleshooting or debugging purposes.

Preconditions

The USB device layer must have been initialized and opened before calling this function.

Example

```
// This code example shows usage of the
// USB_DEVICE_ClientStatusGet function.

if(USB_DEVICE_CLIENT_STATUS_READY == USB_DEVICE_ClientStatusGet(usbDeviceHandle))
{
    // Client handle is valid.
    if(USB_DEVICE_IsSuspended(usbDeviceHandle))
    {
        // Device is suspended. Do something here.
    }
}
```

Parameters

Parameters	Description
usbDeviceHandle	Pointer to the device layer handle that is returned from USB_DEVICE_Open

Function

USB_DEVICE_CLIENT_STATUS USB_DEVICE_ClientStatusGet

(

USB_DEVICE_HANDLE usbDeviceHandle

)

USB_DEVICE_EventHandlerSet Function

USB Device Layer Event Handler Callback Function set function.

File

usb_device.h

C

```
void USB_DEVICE_EventHandlerSet(USB_DEVICE_HANDLE usbDeviceHandle, const USB_DEVICE_EVENT_HANDLER
callBackFunc, uintptr_t context);
```

Returns

None.

Description

This is the USB Device Layer Event Handler Callback Set function. A client can receive USB Device Layer event by using this function to register and event handler callback function. The client can additionally specify a specific context which will returned with the event handler callback function.

Remarks

None.

Preconditions

The device layer must have been initialized by calling USB_DEVICE_Initialize and a valid handle to the instance must have been obtained by calling USB_DEVICE_Open.

Example

```
// This code example shows how the application can set
```

```
// a Device Layer Event Handler.

// Application states
typedef enum
{
    //Application's state machine's initial state.
    APP_STATE_INIT=0,
    APP_STATE_SERVICE_TASKS,
    APP_STATE_WAIT_FOR_CONFIGURATION,
} APP_STATES;

USB_DEVICE_HANDLE usbDeviceHandle;
APP_STATES appState;

// This is the application device layer event handler function.

USB_DEVICE_EVENT_RESPONSE APP_USBDeviceEventHandler
(
    USB_DEVICE_EVENT event,
    void * pData,
    uintptr_t context
)
{
    USB_SETUP_PACKET * setupPacket;
    switch(event)
    {
        case USB_DEVICE_EVENT_POWER_DETECTED:
            // This event in generated when VBUS is detected. Attach the device
            USB_DEVICE_Attach(usbDeviceHandle);
            break;

        case USB_DEVICE_EVENT_POWER_REMOVED:
            // This event is generated when VBUS is removed. Detach the device
            USB_DEVICE_Detach (usbDeviceHandle);
            break;

        case USB_DEVICE_EVENT_CONFIGURED:
            // This event indicates that Host has set Configuration in the Device.
            break;

        case USB_DEVICE_EVENT_CONTROL_TRANSFER_SETUP_REQUEST:
            // This event indicates a Control transfer setup stage has been completed.
            setupPacket = (USB_SETUP_PACKET *)pData;

            // Parse the setup packet and respond with a USB_DEVICE_ControlSend(),
            // USB_DEVICE_ControlReceive or USB_DEVICE_ControlStatus().

            break;

        case USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_SENT:
            // This event indicates that a Control transfer Data has been sent to Host.
            break;

        case USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_RECEIVED:
            // This event indicates that a Control transfer Data has been received from Host.
            break;

        case USB_DEVICE_EVENT_CONTROL_TRANSFER_ABORTED:
            // This event indicates a control transfer was aborted.
            break;

        case USB_DEVICE_EVENT_SUSPENDED:
            break;

        case USB_DEVICE_EVENT_RESUMED:
            break;

        case USB_DEVICE_EVENT_ERROR:
            break;
```

```
            case USB_DEVICE_EVENT_RESET:
                break;

            case USB_DEVICE_EVENT_SOF:
                // This event indicates an SOF is detected on the bus. The  USB_DEVICE_SOF_EVENT_ENABLE
                // macro should be defined to get this event.
                break;
            default:
                break;
        }
    }

    void APP_Tasks ( void )
    {
        // Check the application's current state.
        switch ( appState )
        {
            // Application's initial state.
            case APP_STATE_INIT:
                // Open the device layer
                usbDeviceHandle = USB_DEVICE_Open( USB_DEVICE_INDEX_0,
                    DRV_IO_INTENT_READWRITE );

                if(usbDeviceHandle != USB_DEVICE_HANDLE_INVALID)
                {
                    // Register a callback with device layer to get event notification
                    USB_DEVICE_EventHandlerSet(usbDeviceHandle,
                        APP_USBDeviceEventHandler, 0);
                    appState = APP_STATE_WAIT_FOR_CONFIGURATION;
                }
                else
                {
                    // The Device Layer is not ready to be opened. We should try
                    // gain later.
                }
                break;

            case APP_STATE_SERVICE_TASKS:
                break;

                // The default state should never be executed.
            default:
                break;
        }
    }
```

Parameters

Parameters	Description
usbDeviceHandle	Pointer to the device layer handle that is returned from USB_DEVICE_Open
callBackFunc	Pointer to the call back function. The device layer calls notifies the client about bus event by calling this function.
context	Client specific context

Function

void USB_DEVICE_EventHandlerSet

(

USB_DEVICE_HANDLE usbDeviceHandle,

USB_DEVICE_EVENT_HANDLER *callBackFunc,

uintptr_t context

)

c) Device Power State Management Functions

USB_DEVICE_PowerStateSet Function

Sets power state of the device.

File

usb_device.h

C

```
void USB_DEVICE_PowerStateSet(USB_DEVICE_HANDLE usbDeviceHandle, USB_DEVICE_POWER_STATE powerState);
```

Returns

None.

Description

Application clients can use this function to set the power state of the device. A USB device can be bus powered or self powered. Based on hardware configuration, this power state may change while the device is on operation. The application can call this function to update the Device Layer on the present power status of the device.

Remarks

By default, the device is bus powered.

Preconditions

The device layer should have been initialized and opened.

Example

```
// The following code example shows how the application can
// change the power state of the device. In this case the application checks
// if a battery is charged and if so, the application set the device power
// state to self-powered.

if(APP_BATTERY_IS_CHARGED == APP_BatteryChargeStatusGet())
{
    // The application switches if power source.

    APP_PowerSourceSwitch(APP_POWER_SOURCE_BATTERY);
    USB_DEVICE_PowerStateSet(usbDeviceHandle, USB_DEVICE_POWER_STATE_SELF_POWERED);
}
else
{
    // The battery is still not charged. The application uses the USB power.

    USB_DEVICE_PowerStateSet(usbDeviceHandle, USB_DEVICE_POWER_STATE_BUS_POWERED);
}
```

Parameters

Parameters	Description
usbDeviceHandle	USB device handle returned by USB_DEVICE_Open().
powerState	USB_DEVICE_POWER_STATE_BUS_POWERED/ USB_DEVICE_POWER_STATE_SELF_POWERED

Function

void USB_DEVICE_PowerStateSet

(

USB_DEVICE_HANDLE usbDeviceHandle,

USB_DEVICE_POWER_STATE powerState

)

USB_DEVICE_RemoteWakeupStatusGet Function

Gets the "Remote wake-up" status of the device.

File

usb_device.h

C

```
USB_DEVICE_REMOTE_WAKEUP_STATUS USB_DEVICE_RemoteWakeupStatusGet(USB_DEVICE_HANDLE usbDeviceHandle);
```

Returns

USB_DEVICE_REMOTE_WAKEUP_ENABLED - Remote wakeup is enabled. USB_DEVICE_REMOTE_WAKEUP_DISABLED - Remote wakeup is disabled.

Description

This function returns the present "Remote Wake-up" status of the device. If the device supports remote wake-up, the host may enable of disable this feature. The client can use this function to find out the status of this feature.

Remarks

None.

Preconditions

The device layer should have been initialized and opened.

Example

```
// This code example checks if the host has enabled the remote wake-up
// feature and then starts resume signaling. It is assumed
// that the device is in suspended mode.

USB_DEVICE_HANDLE usbDeviceHandle;

if(USB_DEVICE_RemoteWakeupStatusGet(usbDeviceHandle))
{
    // Start resume signaling.

    USB_DEVICE_RemoteWakeupStart(usbDeviceHandle);
}
```

Parameters

Parameters	Description
usbDeviceHandle	USB device handle returned by USB_DEVICE_Open().

Function

USB_DEVICE_REMOTE_WAKEUP_STATUS USB_DEVICE_RemoteWakeupStatusGet

(

USB_DEVICE_HANDLE usbDeviceHandle

)

USB_DEVICE_IsSuspended Function

Returns true if the device is in a suspended state.

File

usb_device.h

C

```
bool USB_DEVICE_IsSuspended(USB_DEVICE_HANDLE usbDeviceHandle);
```

Returns

Returns true if the device is suspended.

Description

This function returns true is the device is presently in suspended state. The application can use this function in conjunction with the USB_DEVICE_StateGet function to obtain the detailed state of the device (such as addressed and suspended, configured and suspended etc.). The Device Layer also provides the macro USB_DEVICE_EVENT_SUSPENDED event to indicate entry into suspend state.

Remarks

None.

Preconditions

The USB Device Layer must have been initialized and opened before calling this function.

Example

```
// This code example shows how the application
// can find out if the device is in a configured but suspended state.

if(USB_DEVICE_IsSuspended(usbDeviceHandle))
{
    // Device is in a suspended state.

    if(USB_DEVICE_STATE_CONFIGURED == USB_DEVICE_StateGet(usbDeviceHandle))
    {
        // This means the device is in configured and suspended state.

    }
}
```

Parameters

Parameters	Description
usbDeviceHandle	Pointer to the Device Layer Handle that is returned from USB_DEVICE_Open

Function

bool USB_DEVICE_IsSuspended(USB_DEVICE_HANDLE usbDeviceHandle)

USB_DEVICE_RemoteWakeupStart Function

This function will start the resume signaling.

File

usb_device.h

C

```
void USB_DEVICE_RemoteWakeupStart(USB_DEVICE_HANDLE usbDeviceHandle);
```

Returns

None.

Description

This function will start the resume signaling on the bus. The client calls this function after it has detected a idle bus (through the USB_DEVICE_EVENT_SUSPENDED event). The remote wake-up feature should have been enabled by the host, before the client can call this function. The client can use the USB_DEVICE_RemoteWakeupStatusGet function to check if the host has enabled the remote wake-up feature.

Remarks

None.

Preconditions

Client handle should be valid. The remote wake-up feature should have been enabled by the host.

Example

```
// This code example shows how the device can enable and disable
// Resume signaling on the bus. These function should only be called if the
// device support remote wakeup and the host has enabled this
// feature.

USB_DEVICE_HANDLE usbDeviceHandle;

// Start resume signaling.
USB_DEVICE_RemoteWakeupStart(usbDeviceHandle);
```

```
// As per section 7.1.7.7 of the USB specification, device can
// drive resume signaling for at least 1 millisecond but no
// more than 15 milliseconds.

APP_DelayMilliseconds(10);

// Stop resume signaling.
USB_DEVICE_RemoteWakeupStop(usbDeviceHandle);
```

Parameters

Parameters	Description
usbDeviceHandle	Client's driver handle (returned from USB_DEVICE_Open)

Function

void USB_DEVICE_RemoteWakeupStart(USB_DEVICE_HANDLE usbDeviceHandle)

USB_DEVICE_RemoteWakeupStartTimed Function

This function will start a self timed Remote Wake-up.

File

usb_device.h

C

```
void USB_DEVICE_RemoteWakeupStartTimed(USB_DEVICE_HANDLE usbDeviceHandle);
```

Returns

None.

Description

This function will start a self timed Remote Wake-up sequence. The function will cause the device to generate resume signaling for 10 milliseconds. The resume signaling will stop after 10 milliseconds. The application can use this function instead of the USB_DEVICE_RemoteWakeupStart and USB_DEVICE_RemoteWakeupStop functions, which require the application to manually start, maintain duration and then stop the resume signaling.

Remarks

None.

Preconditions

Client handle should be valid. The host should have enabled the Remote Wake-up feature for this device.

Example

```
// This code example shows how the device can use the
// USB_DEVICE_RemoteWakeupStartTimed function to drive resume signaling
// on the bus for 10 milliseconds.

USB_DEVICE_HANDLE usbDeviceHandle;

// Check if host has enabled remote wake-up for the device.
if(USB_DEVICE_REMOTE_WAKEUP_ENABLED == USB_DEVICE_RemoteWakeupStatusGet(usbDeviceHandle))
{
    // Remote wake-up is enabled

    USB_DEVICE_RemoteWakeupStartTimed(usbDeviceHandle);
}
```

Parameters

Parameters	Description
usbDeviceHandle	Client's driver handle (returned from USB_DEVICE_Open)

Function

void USB_DEVICE_RemoteWakeupStartTimed (USB_DEVICE_HANDLE usbDeviceHandle)

USB_DEVICE_RemoteWakeupStop Function

This function will stop the resume signaling.

File

usb_device.h

C

```
void USB_DEVICE_RemoteWakeupStop(USB_DEVICE_HANDLE usbDeviceHandle);
```

Returns

None.

Description

This function will stop the resume signaling. This function should be called after the client has called the USB_DEVICE_RemoteWakeupStart() function.

Remarks

None.

Preconditions

Client handle should be valid. The host should have enabled the Remote Wakeup feature for this device.

Example

```
// This code example shows how the device can enable and disable
// Resume signaling on the bus. These function should only be called if the
// device support remote wake-up and the host has enabled this
// feature.

USB_DEVICE_HANDLE usbDeviceHandle;

// Start resume signaling.
USB_DEVICE_RemoteWakeupStart(usbDeviceHandle);

// As per section 7.1.7.7 of the USB specification, device must
// drive resume signaling for at least 1 millisecond but no
// more than 15 milliseconds.

APP_DelayMilliseconds(10);

// Stop resume signaling.
USB_DEVICE_RemoteWakeupStop(usbDeviceHandle);
```

Parameters

Parameters	Description
usbDeviceHandle	Client's driver handle (returned from USB_DEVICE_Open)

Function

void USB_DEVICE_RemoteWakeupStop (USB_DEVICE_HANDLE usbDeviceHandle)

d) Device Management Functions

USB_DEVICE_StateGet Function

Returns the current state of the USB device.

File

usb_device.h

C

```
USB_DEVICE_STATE USB_DEVICE_StateGet(USB_DEVICE_HANDLE usbDeviceHandle);
```

Returns

USB_DEVICE_STATE_DETACHED - Device is not in any of the known states

USB_DEVICE_STATE_ATTACHED - Device is attached to the USB, but is not powered

USB_DEVICE_STATE_POWERED - Device is attached to the USB and powered, but has not been reset

USB_DEVICE_STATE_DEFAULT - Device is attached to the USB and powered and has been reset, but has not been assigned a unique address

USB_DEVICE_STATE_ADDRESS - Device is attached to the USB, powered, has been reset, and a unique device address has been assigned

USB_DEVICE_STATE_CONFIGURED - Device is attached to the USB, powered, has been reset, has a unique address, is configured, and is not suspended

Description

This function returns the current state of the USB device, as described in Chapter 9 of the USB 2.0 Specification.

Remarks

None.

Preconditions

The USB device layer must have been initialized and opened before calling this function.

Example

```
USB_DEVICE_STATE usbDevState;

// Get USB Device State.
usbDevState = USB_DEVICE_StateGet( usbDeviceHandle );

switch(usbDevState)
{
    case USB_DEVICE_STATE_ATTACHED:
        // Add code here
        break;

    case USB_DEVICE_STATE_POWERED:
       // Add code here
       break;

    default:
        break;
 }
```

Parameters

Parameters	Description
usbDeviceHandle	Pointer to the device layer handle that is returned from USB_DEVICE_Open

Function

USB_DEVICE_STATE USB_DEVICE_StateGet(USB_DEVICE_HANDLE usbDeviceHandle)

USB_DEVICE_Attach Function

This function will attach the device to the USB.

File

usb_device.h

C

```
void USB_DEVICE_Attach(USB_DEVICE_HANDLE usbDeviceHandle);
```

Returns

None.

Description

This function will attach the device to the USB. It does this by enabling the pull up resistors on the D+ or D- lines. This function should be called after the USB device layer has generated the USB_DEVICE_EVENT_POWER_DETECTED event.

Remarks

None.

Preconditions

Client handle should be valid. The device layer should have been initialized and an device layer event handler function should have been assigned.

Example

```
// This code example shows the set
// of steps to follow before attaching the
// device on the bus. It is assumed that the
// device layer is already initialized.

USB_DEVICE_HANDLE usbDeviceHandle;

// Get an handle to the USB device layer.
usbDeviceHandle = USB_DEVICE_Open( USB_DEVICE_INDEX_0,
                                                DRV_IO_INTENT_READWRITE );

if(USB_DEVICE_HANDLE_INVALID == usbDeviceHandle)
{
    // Failed to open handle.
    // Handle error.
}

// Register an event handler call back function with device layer
// so that we are ready to receive events when the device is
// attached to the bus.

USB_DEVICE_EventHandlerSet(usbDeviceHandle, APP_USBDeviceEventHandler, NULL);

// Now, connect device to USB
USB_DEVICE_Attach(usbDeviceHandle);
```

Parameters

Parameters	Description
usbDeviceHandle	Client's USB device layer handle (returned from USB_DEVICE_Open)

Function

void USB_DEVICE_Attach(USB_DEVICE_HANDLE usbDeviceHandle)

USB_DEVICE_Detach Function

This function will detach the device from the USB.

File

usb_device.h

C

```
void USB_DEVICE_Detach(USB_DEVICE_HANDLE usbDeviceHandle);
```

Returns

None.

Description

This function will detach the device from the USB. It does this by disabling the pull up resistors on the D+ or D- lines. This function should be called when the application wants to disconnect the device from the bus (typically to implement a soft detach or switch to host mode operation). It should be called when the Device Layer has generated the USB_DEVICE_EVENT_POWER_REMOVED event.

Remarks

None.

Preconditions

The device layer should have been initialized and opened.

Example

```
USB_DEVICE_HANDLE usbDeviceHandle;

// Detach the device from the USB
USB_DEVICE_Detach( usbDeviceHandle );
```

Parameters

Parameters	Description
usbDeviceHandle	Client's driver handle (returned from USB_DEVICE_Open)

Function

void USB_DEVICE_Detach(USB_DEVICE_HANDLE usbDeviceHandle);

USB_DEVICE_ActiveConfigurationGet Function

Informs the client of the current USB device configuration set by the USB host.

File

usb_device.h

C

```
uint8_t USB_DEVICE_ActiveConfigurationGet(USB_DEVICE_HANDLE usbDeviceHandle);
```

Returns

Present active configuration.

Description

This function returns the current active USB device configuration.

Remarks

None.

Preconditions

The USB Device Layer must have been initialized and opened before calling this function.

Example

```
// This code example shows how the
// USB_DEVICE_ActiveConfigurationGet function can be called to obtain
// the configuration that has been set by the host. Note that this
// information is also available in the macro USB_DEVICE_EVENT_CONFIGURED.

uint8_t currentConfiguration;
USB_DEVICE_HANDLE usbDeviceHandle;

currentConfiguration = USB_DEVICE_ActiveConfigurationGet(usbDeviceHandle);
```

Parameters

Parameters	Description
usbDeviceHandle	Pointer to the Device Layer Handle that is returned from USB_DEVICE_Open

Function

uint8_t USB_DEVICE_ActiveConfigurationGet(USB_DEVICE_HANDLE usbDeviceHandle)

USB_DEVICE_ActiveSpeedGet Function

Informs the client of the current operation speed of the USB bus.

File

usb_device.h

C

```
USB_SPEED USB_DEVICE_ActiveSpeedGet(USB_DEVICE_HANDLE usbDeviceHandle);
```

Returns

USB_SPEED_LOW - USB module is at low-speed USB_SPEED_FULL - USB module is at full-speed USB_SPEED_HIGH - USB module is at high-speed

Description

The USB device stack supports both high speed and full speed operations. This function returns the current operation speed of the USB bus. This function should be called after the USB_DEVICE_EVENT_RESET event has occurred.

Remarks

None.

Preconditions

The USB device layer must have been initialized and a valid handle to USB device layer must have been opened.

Example

```
// This code example shows how the
// USB_DEVICE_GetDeviceSpeed function can be called to obtain
// the current device speed. This information is also
// available in the USB_DEVICE_EVENT_CONFIGURED event.

if(USB_DEVICE_ActiveSpeedGet(usbDeviceHandle) == USB_SPEED_FULL)
{
    // This means the device attached at full speed.
}
else if(USB_DEVICE_ActiveSpeedGet(usbDeviceHandle) == USB_SPEED_HIGH)
{
    // This means the device attached at high speed.
}
```

Parameters

Parameters	Description
usbDeviceHandle	Pointer to device layer handle that is returned from USB_DEVICE_Open

Function

USB_SPEED USB_DEVICE_ActiveSpeedGet(USB_DEVICE_HANDLE usbDeviceHandle)

e) Endpoint Management Functions

USB_DEVICE_EndpointIsStalled Function

This function returns the stall status of the specified endpoint and direction.

File

usb_device.h

C

```
bool USB_DEVICE_EndpointIsStalled(USB_DEVICE_HANDLE usbDeviceHandle, USB_ENDPOINT_ADDRESS endpoint);
```

Returns

Returns true if endpoint is stalled, false otherwise.

Description

This function returns the stall status of the specified endpoint and direction.

Remarks

None.

Preconditions

The USB Device should be in a configured state.

Example

```
// This code example shows of how the
// USB_DEVICE_EndpointIsStalled function can be used to obtain the
// stall status of the endpoint 1 and IN direction.

USB_ENDPOINT_ADDRESS ep;

ep = 0x1|USB_EP_DIRECTION_IN;

if(true == USB_DEVICE_EndpointIsStalled (handle, ep))
{
    // Endpoint stall is enabled. Clear the stall.

    USB_DEVICE_EndpointStallClear(handle, ep);

}
```

Parameters

Parameters	Description
usbDeviceHandle	USB device handle returned by USB_DEVICE_Open
endpoint	Specifies the endpoint and direction

Function

bool USB_DEVICE_EndpointIsStalled

(

USB_DEVICE_HANDLE usbDeviceHandle,

USB_ENDPOINT_ADDRESS endpoint

)

USB_DEVICE_EndpointStall Function

This function stalls an endpoint in the specified direction.

File

usb_device.h

C

```
void USB_DEVICE_EndpointStall(USB_DEVICE_HANDLE usbDeviceHandle, USB_ENDPOINT_ADDRESS endpoint);
```

Returns

None.

Description

This function stalls an endpoint in the specified direction.

Remarks

The application may typically, not find the need to stall an endpoint. Stalling an endpoint erroneously could potentially make the device non-compliant.

Preconditions

Client handle should be valid.

Example

```
// This code example shows how to stall an endpoint. In
// this case, endpoint 1 IN direction is stalled.

USB_ENDPOINT_ADDRESS ep;

ep = 0x1|USB_EP_DIRECTION_IN;

USB_DEVICE_EndpointStall(usbDeviceHandle, ep);
```

Parameters

Parameters	Description
usbDeviceHandle	USB device handle returned by USB_DEVICE_Open
endpoint	Specifies the endpoint and direction

Function

void USB_DEVICE_EndpointStall
(
USB_DEVICE_HANDLE usbDeviceHandle,
USB_ENDPOINT_ADDRESS endpoint
)

USB_DEVICE_EndpointStallClear Function

This function clears the stall on an endpoint in the specified direction.

File

usb_device.h

C

```
void USB_DEVICE_EndpointStallClear(USB_DEVICE_HANDLE usbDeviceHandle, USB_ENDPOINT_ADDRESS endpoint);
```

Returns

None.

Description

This function clear the stall on an endpoint in the specified direction.

Remarks

None.

Preconditions

Client handle should be valid.

Example

```
// This code example shows how to clear a stall on an
// endpoint. In this case, the stall on endpoint 1 IN direction is
// cleared.

USB_ENDPOINT_ADDRESS ep;

ep = USB_ENDPOINT_AND_DIRECTION(USB_DATA_DIRECTION_DEVICE_TO_HOST, 1);

USB_DEVICE_EndpointStallClear(usbDeviceHandle, ep);
```

Parameters

Parameters	Description
usbDeviceHandle	USB device handle returned by USB_DEVICE_Open().
endpoint	Specifies the endpoint and direction.

Function

void USB_DEVICE_EndpointStallClear
(
USB_DEVICE_HANDLE usbDeviceHandle,
USB_ENDPOINT_ADDRESS endpoint
)

USB_DEVICE_EndpointDisable Function

Disables a device endpoint.

File

usb_device.h

C

```
USB_DEVICE_RESULT USB_DEVICE_EndpointDisable(USB_DEVICE_HANDLE usbDeviceHandle, USB_ENDPOINT_ADDRESS
endpoint);
```

Returns

USB_DEVICE_RESULT_OK - The endpoint was enabled successfully.

USB_DEVICE_RESULT_ERROR_ENDPOINT_INVALID - The specified instance was not provisioned in the application and is invalid.

Description

This function disables a device endpoint. The application may need to disable the endpoint when it want to change the endpoint characteristics. This could happen when the device features interfaces with multiple alternate settings. If such cases, the host may request the device to switch to specific alternate setting by sending the Set Interface request. The device application must then disable the endpoint (if it was enabled) before re-enabling it with the new settings.The application can use the USB_DEVICE_EndpointIsEnabled function to check the status of the endpoint and USB_DEVICE_EndpointEnable function to enable the endpoint.

Remarks

None.

Preconditions

The device should have been configured.

Example

```
// The following code example checks if an Set Alternate request has
// been received and changes the endpoint characteristics based on the
// alternate setting. Endpoint is 1 and direction is device to host.
// Assume that endpoint size was 32 bytes in alternate setting 0.

if(setAlternateRequest)
{
    if(alternateSetting == 1)
    {
        // Check if the endpoint is already enabled.
        if(USB_DEVICE_EndpointIsEnabled(usbDeviceHandle, (0x1|USB_EP_DIRECTION_IN)))
        {
            // Disable the endpoint.
            USB_DEVICE_EndpointDisable(usbDeviceHandle, (0x1|USB_EP_DIRECTION_IN));
        }

        // Re-enable the endpoint with new settings
        USB_DEVICE_EndpointEnable(usbDeviceHandle, (0x1|USB_EP_DIRECTION_IN)
                    USB_TRANSFER_TYPE_BULK, 64);
    }
}
```

Parameters

Parameters	Description
usbDeviceHandle	USB Device Layer Handle.
endpoint	Endpoint to disable.

Function

USB_DEVICE_RESULT USB_DEVICE_EndpointDisable

(

USB_DEVICE_HANDLE usbDeviceHandle,

USB_ENDPOINT_ADDRESS endpoint,

);

USB_DEVICE_EndpointEnable Function

Enables a device endpoint.

File

usb_device.h

C

```
USB_DEVICE_RESULT USB_DEVICE_EndpointEnable(USB_DEVICE_HANDLE usbDeviceHandle, uint8_t interface,
USB_ENDPOINT_ADDRESS endpoint, USB_TRANSFER_TYPE transferType, size_t size);
```

Returns

USB_DEVICE_RESULT_OK - The endpoint was enabled successfully.

USB_DEVICE_RESULT_ERROR_ENDPOINT_INVALID - The specified instance was not provisioned in the application and is invalid.

Description

This function enables a device endpoint for the specified transfer type and size. A Vendor specific device application may typically call this function in response to a Set Interface request from the host. Note that Device Layer will enable endpoints contained in Alternate Setting 0 of an interface, when the host configures the device. If there is only one alternate setting in an interface, the application may not need to call the USB_DEVICE_EndpointEnable function.

If the device supports multiple alternate settings in an Interface, the device application must then disable an endpoint (if it was enabled) before re-enabling it with the new settings.The application can use the USB_DEVICE_EndpointIsEnabled function to check the status of the endpoint and USB_DEVICE_EndpointDisable function to disable the endpoint.

Remarks

None.

Preconditions

The device should have been configured.

Example

```
// The following code example checks if an Set Alternate request has
// been received and changes the endpoint characteristics based on the
// alternate setting. Endpoint is 1 and direction is device to host.
// Assume that endpoint size was 32 bytes in alternate setting 0.

if(setAlternateRequest)
{
    if(alternateSetting == 1)
    {
        // Check if the endpoint is already enabled.
        if(USB_DEVICE_EndpointIsEnabled(usbDeviceHandle, (0x1|USB_EP_DIRECTION_IN)))
        {
            // Disable the endpoint.
            USB_DEVICE_EndpointDisable(usbDeviceHandle, (0x1|USB_EP_DIRECTION_IN));
        }

        // Re-enable the endpoint with new settings
        USB_DEVICE_EndpointEnable(usbDeviceHandle, 0, (0x1|USB_EP_DIRECTION_IN)
                    USB_TRANSFER_TYPE_BULK, 64);
    }
}
```

Parameters

Parameters	Description
usbDeviceHandle	USB Device Layer Handle.
interface	This parameter is ignored in the PIC32 USB Device Stack implementation.
endpoint	Endpoint to enable.
transferType	Type of transfer that this is endpoint will support. This should match the type reported to the host
size	Maximum endpoint size. This should match the value reported to the host.

Function

USB_DEVICE_RESULT USB_DEVICE_EndpointEnable
(
USB_DEVICE_HANDLE usbDeviceHandle,
uint8_t interface,
USB_ENDPOINT_ADDRESS endpoint,
USB_TRANSFER_TYPE transferType
size_t size
);

USB_DEVICE_EndpointIsEnabled Function

Returns true if the endpoint is enabled.

File

usb_device.h

C

```
bool USB_DEVICE_EndpointIsEnabled(USB_DEVICE_HANDLE usbDeviceHandle, USB_ENDPOINT_ADDRESS endpoint);
```

Returns

true - The endpoint is enabled.

false - The endpoint is not enabled or the specified endpoint is not provisioned in the system and is invalid.

Description

This function returns true if the endpoint is enabled. The application can use this function when handling Set Interface requests in case of Vendor or Custom USB devices.

Remarks

None.

Preconditions

The device should have been configured.

Example

```
// The following code example checks if an Set Alternate request has
// been received and changes the endpoint characteristics based on the
// alternate setting. Endpoint is 1 and direction is device to host.
// Assume that endpoint size was 32 bytes in alternate setting 0.

if(setAlternateRequest)
{
    if(alternateSetting == 1)
    {
        // Check if the endpoint is already enabled.
        if(USB_DEVICE_EndpointIsEnabled(usbDeviceHandle, (0x1|USB_EP_DIRECTION_IN)))
        {
            // Disable the endpoint.
            USB_DEVICE_EndpointDisable(usbDeviceHandle, (0x1|USB_EP_DIRECTION_IN));
        }

        // Re-enable the endpoint with new settings
        USB_DEVICE_EndpointEnable(usbDeviceHandle, (0x1|USB_EP_DIRECTION_IN)
                    USB_TRANSFER_TYPE_BULK, 64);
    }
}
```

Parameters

Parameters	Description
usbDeviceHandle	USB Device Layer Handle.

endpoint	Endpoint to disable.

Function

bool USB_DEVICE_EndpointIsEnabled
(
USB_DEVICE_HANDLE usbDeviceHandle,
USB_ENDPOINT_ADDRESS endpoint,
);

USB_DEVICE_EndpointRead Function

Reads data received from host on the requested endpoint.

File

usb_device.h

C

```
USB_DEVICE_RESULT USB_DEVICE_EndpointRead(USB_DEVICE_HANDLE usbDeviceHandle, USB_DEVICE_TRANSFER_HANDLE *
transferHandle, USB_ENDPOINT_ADDRESS endpoint, void * buffer, size_t bufferSize);
```

Returns

USB_DEVICE_RESULT_OK - The read request was successful. transferHandle contains a valid transfer handle.

USB_DEVICE_RESULT_ERROR_TRANSFER_QUEUE_FULL - internal request queue is full. The write request could not be added.

USB_DEVICE_RESULT_ERROR_TRANSFER_SIZE_INVALID - The specified transfer size was not a multiple of endpoint size or is 0.

USB_DEVICE_RESULT_ERROR_ENDPOINT_NOT_CONFIGURED - The specified endpoint is not configured yet and is not ready for data transfers.

USB_DEVICE_RESULT_ERROR_ENDPOINT_INVALID - The specified instance was not provisioned in the application and is invalid.

Description

This function requests a endpoint data read from the USB Device Layer. The function places a requests with driver, the request will get serviced as data is made available by the USB Host. A handle to the request is returned in the transferHandle parameter. The termination of the request is indicated by the USB_DEVICE_EVENT_ENDPOINT_READ_COMPLETE event. The amount of data read and the transfer handle associated with the request is returned along with the event in the pData parameter of the event handler. The transfer handle expires when event handler for the USB_DEVICE_EVENT_ENDPOINT_READ_COMPLETE exits. If the read request could not be accepted, the function returns an error code and transferHandle will contain the value USB_DEVICE_TRANSFER_HANDLE_INVALID.

If the size parameter is not a multiple of maxPacketSize or is 0, the function returns USB_DEVICE_TRANSFER_HANDLE_INVALID in transferHandle and returns an error code as a return value. If the size parameter is a multiple of maxPacketSize and the host sends less than maxPacketSize data in any transaction, the transfer completes and the function driver will issue a USB_DEVICE_EVENT_ENDPOINT_READ_COMPLETE event along with the USB_DEVICE_EVENT_DATA_ENDPOINT_READ_COMPLETE_DATA data structure. If the size parameter is a multiple of maxPacketSize and the host sends maxPacketSize amount of data, and total data received does not exceed size, then the function driver will wait for the next packet.

Remarks

While the using the device layer with PIC32MZ USB module, the receive buffer provided to the USB_DEVICE_EndpointRead should be placed in coherent memory and aligned at a 16 byte boundary. This can be done by declaring the buffer using the __attribute__((coherent, aligned(16))) attribute. An example is shown here

```
uint8_t data[256] __attribute__((coherent, aligned(16)));
```

Preconditions

The device should have been configured.

Example

```
// Shows an example of how to read. This assumes that
// driver was opened successfully. Note how the endpoint
// is specified. The most significant bit is cleared while
// the lower nibble specifies the endpoint (which is 1).

USB_DEVICE_TRANSFER_HANDLE transferHandle;
USB_DEVICE_RESULT readRequestResult;
USB_DEVICE_HANDLE usbDeviceHandle;
USB_ENDPOINT_ADDRESS endpoint = 0x01;
```

```
readRequestResult = USB_DEVICE_EndpointRead(usbDeviceHandle,
                        &transferHandle, endpoint, data, 128);

if(USB_DEVICE_RESULT_OK != readRequestResult)
{
    //Do Error handling here
}

// The completion of the read request will be indicated by the
// USB_DEVICE_EVENT_ENDPOINT_READ_COMPLETE event.
```

Parameters

Parameters	Description
usbDeviceHandle	USB Device Layer Handle.
transferHandle	Pointer to a USB_DEVICE_TRANSFER_HANDLE type of variable. This variable will contain the transfer handle in case the read request was successful.
endpoint	Endpoint from which the data should be read.
data	pointer to the data buffer where read data will be stored.
size	Size of the data buffer. Refer to the description section for more details on how the size affects the transfer.

Function

```
  USB_DEVICE_RESULT USB_DEVICE_EndpointRead
(
    USB_DEVICE_HANDLE usbDeviceHandle,
    USB_DEVICE_TRANSFER_HANDLE * transferHandle,
USB_ENDPOINT_ADDRESS endpoint,
void * buffer,
size_t bufferSize
);
```

USB_DEVICE_EndpointTransferCancel Function

This function cancels a transfer scheduled on an endpoint.

File

usb_device.h

C

```
USB_DEVICE_RESULT USB_DEVICE_EndpointTransferCancel(USB_DEVICE_HANDLE usbDeviceHandle, USB_ENDPOINT_ADDRESS
endpoint, USB_DEVICE_TRANSFER_HANDLE transferHandle);
```

Returns

USB_DEVICE_RESULT_OK - The transfer will be canceled completely or partially.

USB_DEVICE_RESULT_ERROR - The transfer could not be canceled because it has either completed, the transfer handle is invalid or the last transaction is in progress.

Description

This function cancels a transfer scheduled on an endpoint using the USB_DEVICE_EndpointRead and USB_DEVICE_EndpointWrite functions. If a transfer is still in the queue and its processing has not started, the transfer is canceled completely. A transfer that is in progress may or may not get canceled depending on the transaction that is presently in progress. If the last transaction of the transfer is in progress, the transfer will not be canceled. If it is not the last transaction in progress, the in progress transfer will be allowed to complete. Pending transactions will be canceled. The first transaction of an in progress transfer cannot be canceled.

Remarks

None.

Preconditions

The USB Device should be in a configured state.

Example

```
// The following code example cancels a transfer on endpoint 1, IN direction.
```

```
USB_DEVICE_TRANSFER_HANDLE transferHandle;
USB_DEVICE_RESULT result;

result = USB_DEVICE_EndpointTransferCancel(usbDeviceHandle,
            (0x1|USB_EP_DIRECTION_IN), transferHandle);

if(USB_DEVICE_RESULT_OK == result)
{
    // The transfer cancellation was either completely or
    // partially successful.
}
```

Parameters

Parameters	Description
usbDeviceHandle	USB Device Layer Handle.
endpoint	Endpoint of which the transfer needs to be canceled.
handle	Transfer handle of the transfer to be canceled.

Function

USB_DEVICE_RESULT USB_DEVICE_EndpointTransferCancel
(
USB_DEVICE_HANDLE usbDeviceHandle,
USB_ENDPOINT_ADDRESS endpoint,
USB_DEVICE_TRANSFER_HANDLE handle
);

USB_DEVICE_EndpointWrite Function

This function requests a data write to a USB Device Endpoint.

File

usb_device.h

C

```
USB_DEVICE_RESULT USB_DEVICE_EndpointWrite(USB_DEVICE_HANDLE usbDeviceHandle, USB_DEVICE_TRANSFER_HANDLE *
transferHandle, USB_ENDPOINT_ADDRESS endpoint, const void * data, size_t size, USB_DEVICE_TRANSFER_FLAGS
flags);
```

Returns

USB_DEVICE_RESULT_OK - The write request was successful. transferHandle contains a valid transfer handle.

USB_DEVICE_RESULT_ERROR_TRANSFER_QUEUE_FULL - Internal request queue is full. The write request could not be added.

USB_DEVICE_RESULT_ERROR_ENDPOINT_INVALID - Endpoint is not provisioned in the system.

USB_DEVICE_RESULT_ERROR_TRANSFER_SIZE_INVALID - The combination of the transfer size and the specified flag is invalid.

USB_DEVICE_RESULT_ERROR_ENDPOINT_NOT_CONFIGURED - Endpoint is not enabled because device is not configured.

USB_DEVICE_RESULT_ERROR_PARAMETER_INVALID - Device Layer handle is not valid.

Description

This function requests a data write to the USB Device Endpoint. The function places a requests with Device layer, the request will get serviced as and when the data is requested by the USB Host. A handle to the request is returned in the transferHandle parameter. The termination of the request is indicated by the USB_DEVICE_EVENT_ENDPOINT_WRITE_COMPLETE event. The amount of data written and the transfer handle associated with the request is returned along with the event in length member of the pData parameter in the event handler. The transfer handle expires when event handler for the USB_DEVICE_EVENT_ENDPOINT_WRITE_COMPLETE exits. If the write request could not be accepted, the function returns an error code and transferHandle will contain the value USB_DEVICE_TRANSFER_HANDLE_INVALID.

The behavior of the write request depends on the flags and size parameter. If the application intends to send more data in a request, then it should use the USB_DEVICE_TRANSFER_FLAGS_MORE_DATA_PENDING flag. If there is no more data to be sent in the request, the application must use the USB_DEVICE_TRANSFER_FLAGS_DATA_COMPLETE flag. This is explained in more detail here:

- If size is a multiple of maxPacketSize and flag is set as

USB_DEVICE_TRANSFER_FLAGS_DATA_COMPLETE, the write function will append a Zero Length Packet (ZLP) to complete the transfer.

- If size is a multiple of maxPacketSize and flag is set as

USB_DEVICE_TRANSFER_FLAGS_MORE_DATA_PENDING, the write function will not append a ZLP and hence will not complete the transfer.

- If size is greater than but not a multiple of maxPacketSize and flags is

set as USB_DEVICE_TRANSFER_FLAGS_DATA_COMPLETE, the write function complete the transfer without appending a ZLP.

- If size is greater than but not a multiple of maxPacketSize and flags is

set as USB_DEVICE_TRANSFER_FLAGS_MORE_DATA_PENDING, the write function returns an error code and sets the transferHandle parameter to USB_DEVICE_TRANSFER_HANDLE_INVALID.

- If size is less than maxPacketSize and flag is set as

USB_DEVICE_TRANSFER_FLAGS_DATA_COMPLETE, the write function schedules one packet.

- If size is less than maxPacketSize and flag is set as

USB_DEVICE_TRANSFER_FLAGS_MORE_DATA_PENDING, the write function returns an error code and sets the transferHandle parameter to USB_DEVICE_TRANSFER_HANDLE_INVALID.

Remarks

While the using the device layer with PIC32MZ USB module, the transmit buffer provided to the USB_DEVICE_EndpointWrite should be placed in coherent memory and aligned at a 16 byte boundary. This can be done by declaring the buffer using the __attribute__((coherent, aligned(16))) attribute. An example is shown here

```
uint8_t data[256] __attribute__((coherent, aligned(16)));
```

Preconditions

The USB Device should be in a configured state.

Example

```
// Below is a set of examples showing various conditions trying to
// send data with the Write command.
//
// This assumes that Device Layer was opened successfully.
// Assume maxPacketSize is 64.

USB_DEVICE_TRANSFER_HANDLE transferHandle;
USB_DEVICE_RESULT writeRequestHandle;
USB_DEVICE_HANDLE usbDeviceHandle;

//-------------------------------------------------------
// In this example we want to send 34 bytes only.

writeRequestResult = USB_DEVICE_EndpointWrite(usbDeviceHandle,
                        &transferHandle, data, 34,
                        USB_DEVICE_TRANSFER_FLAGS_DATA_COMPLETE);

if(USB_DEVICE_RESULT_OK != writeRequestResult)
{
    //Do Error handling here
}

//-------------------------------------------------------
// In this example we want to send 64 bytes only.
// This will cause a ZLP to be sent.

writeRequestResult = USB_DEVICE_EndpointWrite(usbDeviceHandle,
                        &transferHandle, data, 64,
                        USB_DEVICE_TRANSFER_FLAGS_DATA_COMPLETE);

if(USB_DEVICE_RESULT_OK != writeRequestResult)
{
    //Do Error handling here
}

//-------------------------------------------------------
// This example will return an error because size is less
// than maxPacketSize and the flag indicates that more
// data is pending.

writeRequestResult = USB_DEVICE_EndpointWrite(usbDeviceHandle,
                        &transferHandle, data, 32,
                        USB_DEVICE_TRANSFER_FLAGS_MORE_DATA_PENDING);

//-------------------------------------------------------
```

```
// In this example we want to place a request for a 70 byte transfer.
// The 70 bytes will be sent out in a 64 byte transaction and a 6 byte
// transaction completing the transfer.

writeRequestResult = USB_DEVICE_EndpointWrite(usbDeviceHandle,
                        &transferHandle, data, 70,
                        USB_DEVICE_TRANSFER_FLAGS_DATA_COMPLETE);

if(USB_DEVICE_RESULT_OK != writeRequestResult)
{
    //Do Error handling here
}

//------------------------------------------------------
// This example would result in an error because the transfer size is
// not an exact multiple of the endpoint size and the
// USB_DEVICE_TRANSFER_FLAGS_MORE_DATA_PENDING flag indicate that the
// transfer should continue.

writeRequestResult = USB_DEVICE_EndpointWrite(usbDeviceHandle,
                        &transferHandle, data, 70,
                        USB_DEVICE_TRANSFER_FLAGS_MORE_DATA_PENDING);

if(USB_DEVICE_RESULT_OK != writeRequestResult)
{
    //Do Error handling here
}

// The completion of the write request will be indicated by the
// USB_DEVICE_EVENT_ENDPOINT_WRITE_COMPLETE event.
```

Parameters

Parameters	Description
instance	Handle to the device layer.
transferHandle	Pointer to a USB_DEVICE_TRANSFER_HANDLE type of variable. This variable will contain the transfer handle in case the write request was successful.
endpoint	Endpoint to which the data should be written. Note that is a combination of direction and the endpoint number. Refer to the description of USB_ENDPOINT_ADDRESS for more details.
data	Pointer to the data buffer that contains the data to written.
size	Size of the data buffer. Refer to the description section for more details on how the size affects the transfer.
flags	Flags that indicate whether the transfer should continue or end. Refer to the description for more details.

Function

```
  USB_DEVICE_RESULT USB_DEVICE_EndpointWrite
(
    USB_DEVICE_HANDLE usbDeviceHandle,
    USB_DEVICE_TRANSFER_HANDLE * transferHandle,
USB_ENDPOINT_ADDRESS endpoint,
const void * data,
size_t size,
    USB_DEVICE_TRANSFER_FLAGS flag
);
```

f) Control Transfer Functions

USB_DEVICE_ControlReceive Function

Receives data stage of the control transfer from host to device.

File

usb_device.h

C

```
USB_DEVICE_CONTROL_TRANSFER_RESULT USB_DEVICE_ControlReceive(USB_DEVICE_HANDLE usbDeviceHandle, void *
data, size_t length);
```

Returns

USB_DEVICE_CONTROL_TRANSFER_RESULT_FAILED - If control transfer failed due to host aborting the previous control transfer.

USB_DEVICE_CONTROL_TRANSFER_RESULT_SUCCESS - The request was submitted successfully.

Description

This function allows the application to specify the data buffer that would be needed to receive the data stage of a control write transfer. It should be called when the application receives the USB_DEVICE_CONTROL_TRANSFER_EVENT_SETUP_REQUEST event and has identified this setup request as the setup stage of a control write transfer. The function can be called in the Application Control Transfer Event handler or can be called after the application has returned from the control transfer event handler.

Calling this function after returning from the event handler defers the response to the event. This allows the application to prepare the data buffer out of the event handler context, especially if the data buffer to receive the data is not readily available. Note however, that there are timing considerations when responding to the control transfer. Exceeding the response time will cause the host to cancel the control transfer and may cause USB host to reject the device.

Remarks

None.

Preconditions

Client handle should be valid.

Example

```
// The following code example shows an example of how the
// USB_DEVICE_ControlReceive function is called in response to the
// USB_DEVICE_CONTROL_TRANSFER_EVENT_SETUP_REQUEST event to enable a control
// write transfer.

void APP_USBDeviceControlTransferEventHandler
(
    USB_DEVICE_EVENT event,
    void * pData,
    uintptr_t context
)
{
    uint8_t * setupPkt;

    switch(event)
    {
        case USB_DEVICE_CONTROL_TRANSFER_EVENT_SETUP_REQUEST:

            setupPkt = (uint8_t *)pData;

            // Submit a buffer to receive 32 bytes in the  control write transfer.
            USB_DEVICE_ControlReceive(usbDeviceHandle, data, 32);
            break;

        case USB_DEVICE_CONTROL_TRANSFER_EVENT_DATA_RECEIVED:

            // This means that data in the data stage of the control
            // write transfer has been received. The application can either
            // accept the received data by calling the
            // USB_DEVICE_ControlStatus function with
            // USB_DEVICE_CONTROL_STATUS_OK flag (as shown in this example)
            // or it can reject it by calling the USB_DEVICE_ControlStatus()
            // function with USB_DEVICE_CONTROL_STATUS_ERROR flag.

            USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_OK);
            break;
```

```
            case USB_DEVICE_CONTROL_TRANSFER_EVENT_DATA_SENT:

                // This means that data in the data stage of the control
                // read transfer has been sent. The application would typically
                // end the control transfer by calling the
                // USB_DEVICE_ControlStatus function with
                // USB_DEVICE_CONTROL_STATUS_OK flag (as shown in this example).

                USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_OK);
                break;

            case USB_DEVICE_CONTROL_TRANSFER_EVENT_ABORTED:

                // This means the host has aborted the control transfer. The
                // application can reset its control transfer state machine.
            break;
        }

    }
```

Parameters

Parameters	Description
usbDeviceHandle	USB device handle returned by USB_DEVICE_Open
data	Pointer to buffer that holds data
length	Size in bytes

Function

USB_DEVICE_CONTROL_TRANSFER_RESULT USB_DEVICE_ControlReceive

(

USB_DEVICE_HANDLE usbDeviceHandle,

void * data,

size_t length

)

USB_DEVICE_ControlSend Function

Sends data stage of the control transfer from device to host.

File

usb_device.h

C

```
USB_DEVICE_CONTROL_TRANSFER_RESULT USB_DEVICE_ControlSend(USB_DEVICE_HANDLE usbDeviceHandle, void * data,
size_t length);
```

Returns

USB_DEVICE_CONTROL_TRANSFER_RESULT_FAILED - If control transfer failed due to host aborting the previous control transfer.

USB_DEVICE_CONTROL_TRANSFER_RESULT_SUCCESS - The request was submitted successfully.

Description

This function allows the application to specify the data that would be sent to host in the data stage of a control read transfer. It should be called when the application has received the USB_DEVICE_CONTROL_TRANSFER_EVENT_SETUP_REQUEST event and has identified this setup request as the setup stage of a control read transfer. The Device Layer will generate a USB_DEVICE_CONTROL_TRANSFER_EVENT_DATA_SENT event when the data stage has completed. The function can be called in the Application Control Transfer Event handler or can be called after the application has returned from the control transfer event handler.

Calling this function after returning from the event handler defers the response to the event. This allows the application to prepare the data buffer out of the event handler context, especially if the data buffer to receive the data is not readily available. Note however, that there are timing considerations when responding to the control transfer. Exceeding the response time will cause the host to cancel the control transfer and may cause USB host to reject the device.

Remarks

None.

Preconditions

Client handle should be valid.

Example

```
// The following code example shows an example of how the
// USB_DEVICE_ControlSend() function is called in response to the
// USB_DEVICE_CONTROL_TRANSFER_EVENT_SETUP_REQUEST event to enable a control
// read transfer.

void APP_USBDeviceEventHandler
(
    USB_DEVICE_EVENT event,
    void * pData,
    uintptr_t context
)
{
    USB_SETUP_PACKET * setupPkt;

    switch(event)
    {
        case USB_DEVICE_CONTROL_TRANSFER_EVENT_SETUP_REQUEST:

            setupPkt = (USB_SETUP_PACKET *)pData;

            // Submit a buffer to send 32 bytes in the  control read transfer.
            USB_DEVICE_ControlSend(usbDeviceHandle, data, 32);
            break;

        case USB_DEVICE_CONTROL_TRANSFER_EVENT_DATA_RECEIVED:

            // This means that data in the data stage of the control
            // write transfer has been received. The application can either
            // accept the received data by calling the
            // USB_DEVICE_ControlStatus function with
            // USB_DEVICE_CONTROL_STATUS_OK flag (as shown in this example)
            // or it can reject it by calling the USB_DEVICE_ControlStatus
            // function with USB_DEVICE_CONTROL_STATUS_ERROR flag.

            USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_OK);
            break;

        case USB_DEVICE_CONTROL_TRANSFER_EVENT_DATA_SENT:

            // This means that data in the data stage of the control
            // read transfer has been sent. The application would typically
            // end the control transfer by calling the
            // USB_DEVICE_ControlStatus function with
            // USB_DEVICE_CONTROL_STATUS_OK flag (as shown in this example).

            USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_OK);
            break;

        case USB_DEVICE_CONTROL_TRANSFER_EVENT_ABORTED:

            // This means the host has aborted the control transfer. The
            // application can reset its control transfer state machine.
        break;
    }

}
```

Parameters

Parameters	Description
usbDeviceHandle	USB device handle returned by USB_DEVICE_Open
data	Pointer to buffer that holds data
length	Size in bytes

Function

USB_DEVICE_CONTROL_TRANSFER_RESULT USB_DEVICE_ControlSend
(
USB_DEVICE_HANDLE usbDeviceHandle,
void * data,
size_t length
)

USB_DEVICE_ControlStatus Function

Initiates status stage of the control transfer.

File

usb_device.h

C

```
USB_DEVICE_CONTROL_TRANSFER_RESULT USB_DEVICE_ControlStatus(USB_DEVICE_HANDLE usbDeviceHandle,
USB_DEVICE_CONTROL_STATUS status);
```

Returns

USB_DEVICE_CONTROL_TRANSFER_RESULT_FAILED - If control transfer failed due to host aborting the previous control transfer.

USB_DEVICE_CONTROL_TRANSFER_RESULT_SUCCESS - The request was submitted successfully.

Description

This function allows the application to complete the status stage of the of an on-going control transfer. The application must call this function when the data stage of the control transfer is complete or when a Setup Request has been received (in case of a zero data stage control transfer). The application can either accept the data stage/setup command or reject it. Calling this function with status set to USB_DEVICE_CONTROL_STATUS_OK will acknowledge the status stage of the control transfer. The control transfer can be stalled by setting the status parameter to USB_DEVICE_CONTROL_STATUS_ERROR.

The function can be called in the Application Control Transfer event handler or can be called after returning from this event handler. Calling this function after returning from the control transfer event handler defers the response to the event. This allows the application to analyze the event response outside the event handler. Note however, that there are timing considerations when responding to the control transfer. Exceeding the response time will cause the host to cancel the control transfer and may cause USB host to reject the device.

The application must be aware of events and associated control transfers that do or do not require data stages. Incorrect usage of the USB_DEVICE_ControlStatus function could cause the device function to be non-compliant.

Remarks

None.

Preconditions

Client handle should be valid. This function should only be called to complete an on-going control transfer.

Example

```
// The following code example shows an example of how the
// USB_DEVICE_ControlStatus() function is called in response to the
// USB_DEVICE_CONTROL_TRANSFER_EVENT_DATA_RECEIVED and
// USB_DEVICE_CONTROL_TRANSFER_EVENT_DATA_SENT event to complete the control
// transfer. Here, the application code acknowledges the status stage of the
// control transfer.

void APP_USBDeviceControlTransferEventHandler
(
    USB_DEVICE_EVENT event,
    void * data,
    uintptr_t context
)
{
    USB_SETUP_PACKET * setupPkt;

    switch(event)
    {
        case USB_DEVICE_CONTROL_TRANSFER_EVENT_SETUP_REQUEST:
```

```
            setupPkt = (USB_SETUP_PACKET *)pData;

            // Submit a buffer to receive 32 bytes in the  control write transfer.
            USB_DEVICE_ControlReceive(usbDeviceHandle, data, 32);
            break;

        case USB_DEVICE_CONTROL_TRANSFER_EVENT_DATA_RECEIVED:

            // This means that data in the data stage of the control
            // write transfer has been received. The application can either
            // accept the received data by calling the
            // USB_DEVICE_ControlStatus function with
            // USB_DEVICE_CONTROL_STATUS_OK flag (as shown in this example)
            // or it can reject it by calling the USB_DEVICE_ControlStatus
            // function with USB_DEVICE_CONTROL_STATUS_ERROR flag.

            USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_OK);
            break;

        case USB_DEVICE_CONTROL_TRANSFER_EVENT_DATA_SENT:

            // This means that data in the data stage of the control
            // read transfer has been sent. The application would typically
            // end the control transfer by calling the
            // USB_DEVICE_ControlStatus function with
            // USB_DEVICE_CONTROL_STATUS_OK flag (as shown in this example).

            USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_OK);
            break;

        case USB_DEVICE_CONTROL_TRANSFER_EVENT_ABORTED:

            // This means the host has aborted the control transfer. The
            // application can reset its control transfer state machine.
        break;
    }
}
```

Parameters

Parameters	Description
usbDeviceHandle	USB device handle returned by USB_DEVICE_Open
status	USB_DEVICE_CONTROL_STATUS_OK to acknowledge the status stage. USB_DEVICE_CONTROL_STATUS_ERROR to stall the status stage.

Function

```
USB_DEVICE_CONTROL_TRANSFER_RESULT USB_DEVICE_ControlStatus
(
    USB_DEVICE_HANDLE usbDeviceHandle,
    USB_DEVICE_CONTROL_STATUS status
)
```

g) Data Types and Constants

USB_DEVICE_INDEX_0 Macro

USB device layer index definitions.

File

usb_device.h

C

```
#define USB_DEVICE_INDEX_0 0
```

Description

USB Device Layer Index Numbers

These constants provide USB device layer index definitions.

Remarks

These constants should be used in place of hard-coded numeric literals. These values should be passed into the USB_DEVICE_Initialize and USB_DEVICE_Open routines to identify the device layer instance in use.

USB_DEVICE_INDEX_1 Macro

File

usb_device.h

C

```
#define USB_DEVICE_INDEX_1 1
```

Description

This is macro USB_DEVICE_INDEX_1.

USB_DEVICE_INDEX_2 Macro

File

usb_device.h

C

```
#define USB_DEVICE_INDEX_2 2
```

Description

This is macro USB_DEVICE_INDEX_2.

USB_DEVICE_INDEX_3 Macro

File

usb_device.h

C

```
#define USB_DEVICE_INDEX_3 3
```

Description

This is macro USB_DEVICE_INDEX_3.

USB_DEVICE_INDEX_4 Macro

File

usb_device.h

C

```
#define USB_DEVICE_INDEX_4 4
```

Description

This is macro USB_DEVICE_INDEX_4.

USB_DEVICE_INDEX_5 Macro

File

usb_device.h

C

```
#define USB_DEVICE_INDEX_5 5
```

Description

This is macro USB_DEVICE_INDEX_5.

USB_DEVICE_CONTROL_STATUS Enumeration

USB Device Layer Control Transfer Status Stage flags.

File

usb_device.h

C

```
typedef enum {
  USB_DEVICE_CONTROL_STATUS_OK,
  USB_DEVICE_CONTROL_STATUS_ERROR
} USB_DEVICE_CONTROL_STATUS;
```

Members

Members	Description
USB_DEVICE_CONTROL_STATUS_OK	Using this flag acknowledges the Control transfer. A Zero Length Packet will be transmitted in the status stage of the control transfer.
USB_DEVICE_CONTROL_STATUS_ERROR	Using this flag stalls the control transfer. This flags should be used if the control transfer request needs to be declined.

Description

Control Transfer Status Stage Flags

This enumeration defines the flags to be used with the USB_DEVICE_ControlStatus function.

Remarks

None.

USB_DEVICE_CONTROL_TRANSFER_RESULT Enumeration

Enumerated data type identifying results of a control transfer.

File

usb_device.h

C

```
typedef enum {
  USB_DEVICE_CONTROL_TRANSFER_RESULT_FAILED,
  USB_DEVICE_CONTROL_TRANSFER_RESULT_SUCCESS
} USB_DEVICE_CONTROL_TRANSFER_RESULT;
```

Members

Members	Description
USB_DEVICE_CONTROL_TRANSFER_RESULT_FAILED	Control transfer failed. This could be because the control transfer handle is no more valid since the control transfer was aborted by host by sending a new setup packet
USB_DEVICE_CONTROL_TRANSFER_RESULT_SUCCESS	Control transfer was successful

Description

USB Device Layer Control Transfer Result Enumeration

These enumerated values are the possible return values for control transfer operations. These values are returned by the USB_DEVICE_ControlStatus, USB_DEVICE_ControlSend and the USB_DEVICE_ControlReceive functions.

Remarks

None.

USB_DEVICE_EVENT Enumeration

USB Device Layer Events.

File

usb_device.h

C

```
typedef enum {
  USB_DEVICE_EVENT_RESET,
  USB_DEVICE_EVENT_SUSPENDED,
  USB_DEVICE_EVENT_RESUMED,
  USB_DEVICE_EVENT_ERROR,
  USB_DEVICE_EVENT_SOF,
  USB_DEVICE_EVENT_CONFIGURED,
  USB_DEVICE_EVENT_DECONFIGURED,
  USB_DEVICE_EVENT_CONTROL_TRANSFER_ABORTED,
  USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_RECEIVED,
  USB_DEVICE_EVENT_CONTROL_TRANSFER_SETUP_REQUEST,
  USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_SENT,
  USB_DEVICE_EVENT_ENDPOINT_READ_COMPLETE,
  USB_DEVICE_EVENT_ENDPOINT_WRITE_COMPLETE,
  USB_DEVICE_EVENT_SET_DESCRIPTOR,
  USB_DEVICE_EVENT_SYNCH_FRAME
} USB_DEVICE_EVENT;
```

Members

Members	Description
USB_DEVICE_EVENT_RESET	USB bus reset occurred. This event is an indication to the application client that device layer has deinitialized all function drivers. The application should not use the function drivers in this state. The pData parameter in the event handler function will be NULL.
USB_DEVICE_EVENT_SUSPENDED	This event is an indication to the application client that device is suspended and it can put the device to sleep mode if required. Power saving routines should not be called in the event handler. The pData parameter in the event handler function will be NULL.
USB_DEVICE_EVENT_RESUMED	This event indicates that device has resumed from suspended state. The pData parameter in the event handler function will be NULL.
USB_DEVICE_EVENT_ERROR	This event is an indication to the application client that an error occurred on the USB bus. The pData parameter in the event handler function will be NULL.
USB_DEVICE_EVENT_SOF	This event is generated at every start of frame detected on the bus. Application client can use this SOF event for general time based house keeping activities. The pData parameter in the event handler function will point to a USB_DEVICE_EVENT_DATA_SOF type that contains the frame number.
USB_DEVICE_EVENT_CONFIGURED	This event is an indication to the application client that device layer has initialized all function drivers and application can set the event handlers for the function drivers. The pData parameter will point to a USB_DEVICE_EVENT_DATA_CONFIGURED data type that contains configuration set by the host.
USB_DEVICE_EVENT_DECONFIGURED	The host has deconfigured the device. This happens when the host sends a Set Configuration request with configuration number 0. The device layer will deinitialize all function drivers and then generate this event.
USB_DEVICE_EVENT_CONTROL_TRANSFER_ABORTED	An on-going control transfer was aborted. The application can use this event to reset its control transfer state machine. The pData parameter in the event handler function will be NULL.
USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_RECEIVED	The data stage of a Control write transfer has completed. This event occurs after the application has used the USB_DEVICE_ControlReceive function to receive data in the control transfer. The pData parameter in the event handler function will be NULL.
USB_DEVICE_EVENT_CONTROL_TRANSFER_SETUP_REQUEST	A setup packet of a control transfer has been received. The recipient field of the received setup packet is Other. The application can initiate the data stage using the USB_DEVICE_ControlReceive and USB_DEVICE_ControlSend function. It can end the control transfer by calling the USB_DEVICE_ControlStatus function. The pData parameter in the event handler will point to USB_SETUP_PACKET data type.

USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_SENT	The data stage of a Control read transfer has completed. This event occurs after the application has used the USB_DEVICE_ControlSend function to send data in the control transfer. The pData parameter in the event handler function will be NULL.
USB_DEVICE_EVENT_ENDPOINT_READ_COMPLETE	This event occurs when a endpoint read transfer scheduled using the USB_DEVICE_EndpointRead function has completed. The pData parameter in the event handler function will be a pointer to a USB_DEVICE_EVENT_DATA_ENDPOINT_READ_COMPLETE data type.
USB_DEVICE_EVENT_ENDPOINT_WRITE_COMPLETE	This event occurs when a endpoint write transfer scheduled using the USB_DEVICE_EndpointWrite function has completed. The pData parameter in the event handler function will be a pointer to a USB_DEVICE_EVENT_DATA_ENDPOINT_WRITE_COMPLETE data type.
USB_DEVICE_EVENT_SET_DESCRIPTOR	A SET_DESCRIPTOR request is received. This event occurs when Host sends a SET_DESCRIPTOR request. The pData parameter in the event handler function will be a pointer to a USB_DEVICE_EVENT_DATA_SET_DESCRIPTOR data type. The application should initiate the data stage using the USB_DEVICE_ControlReceive function. In the PIC32 USB Device Stack, this event is generated if USB_DEVICE_EVENT_ENABLE_SET_DESCRIPTOR is defined in the system configuration.
USB_DEVICE_EVENT_SYNCH_FRAME	A SYNCH_FRAME request is received. This event occurs when Host sends a SYNCH_FRAME request. The pData parameter in the event handler function will be a pointer to a USB_DEVICE_EVENT_DATA_SYNCH_FRAME data type. The application should initiate the data stage using the USB_DEVICE_ControlSend function. In the PIC32 USB Device Stack, this event is generated if USB_DEVICE_EVENT_ENABLE_SYNCH_FRAME is defined in the system configuration.

Description

USB Device Layer Events.

This enumeration lists the possible events that the device layer can generate. The client should register an event handler of the type USB_DEVICE_EVENT_HANDLER to receive device layer events. The contents of pData in the event handler depends on the generated event. Refer to the description of the event for details on data provided along with that event. The events generated are device layer instance specific.

The client will receive control transfers for handling from the device layer, where the recipient field of the Control Transfer Setup packet is set to Other. The client can use the control transfer events and the Device Layer control transfer functions to complete such control transfers.

It is not mandatory for the client application to handle the control transfer event within the event handler. Indeed, it may be possible that the data stage of the control transfer requires extended processing. Because the event handler executes in an interrupt context, it is recommended to keep the processing in the event handler to a minimum. The client application can call the USB_DEVICE_ControlSend, USB_DEVICE_ControlReceive and USB_DEVICE_ControlStatus functions after returning from the event handler, thus deferring the control transfer event handling and responses.

Note that a USB host will typically wait for control transfer response for a finite time duration before timing out and canceling the transfer and associated transactions. Even when deferring response, the application must respond promptly if such timeouts have to be avoided.

The client must use the USB_DEVICE_EventHandlerSet function to register the event handler call back function. The following code example shows the handling of the USB Device Layer Events.

```
USB_DEVICE_EVENT_RESPONSE APP_USBDeviceEventHandler
(
    USB_DEVICE_EVENT event,
    void * pData,
    uintptr_t context
)
{
    uint8_t     activeConfiguration;
    uint16_t    frameNumber;
    USB_SPEED   attachSpeed;
    USB_SETUP_PACKET * setupEventData;

    // Handling of each event
    switch(event)
    {
        case USB_DEVICE_EVENT_POWER_DETECTED:

            // This means the device detected a valid VBUS voltage and is
            // attached to the USB. The application can now call
            // USB_DEVICE_Attach() function to enable D+/D- pull up
            // resistors.
            break;
```

```
        case USB_DEVICE_EVENT_POWER_REMOVED:

            // This means the device is not attached to the USB.
            // The application should now call the USB_DEVICE_Detach()
            // function.
            break;

        case USB_DEVICE_EVENT_SUSPENDED:

            // The bus is idle. There was no activity detected.
            // The application can switch to a low power mode after
            // exiting the event handler.
            break;

        case USB_DEVICE_EVENT_SOF:

            // A start of frame was received. This is a periodic event and
            // can be used by the application for timing related activities.
            // pData will point to a USB_DEVICE_EVENT_DATA_SOF type data
            // containing the frame number. In PIC32 USB Device Stack, this
            // event is generated if USB_DEVICE_SOF_EVENT_ENABLE is
            // defined in System Configuration.

            frameNumber = ((USB_DEVICE_EVENT_DATA_SOF *)pData)->frameNumber;
            break;

        case USB_DEVICE_EVENT_RESET :

            // Reset signaling was detected on the bus. The
            // application can find out the attach speed.

            attachedSpeed = USB_DEVICE_ActiveSpeedGet(usbDeviceHandle);
            break;

        case USB_DEVICE_EVENT_DECONFIGURED :

            // This indicates that host has deconfigured the device i.e., it
            // has set the configuration as 0. All function driver instances
            // would have been deinitialized.

            break;

        case USB_DEVICE_EVENT_ERROR :

            // This means an unknown error has occurred on the bus.
            // The application can try detaching and attaching the
            // device again.
            break;

        case USB_DEVICE_EVENT_CONFIGURED :

            // This means that device is configured and the application can
            // start using the device functionality. The application must
            // register function driver event handlersI have one device
            // level event.  The pData parameter will be a pointer to a
            // USB_DEVICE_EVENT_DATA_CONFIGURED data type that contains the
            // active configuration number.

            activeConfiguration = ((USB_DEVICE_EVENT_DATA_CONFIGURED *)pData)->configurationValue;
            break;

        case USB_DEVICE_EVENT_RESUMED:

            // This means that the resume signaling was detected on the
            // bus. The application can bring the device out of power
            // saving mode.

            break;
```

```
        case USB_DEVICE_EVENT_CONTROL_TRANSFER_SETUP_REQUEST:

            // This means that the setup stage of the control transfer is in
            // progress and a setup packet has been received. The pData
            // parameter will point to a USB_SETUP_PACKET data type The
            // application can process the command and update its control
            // transfer state machine. The application for example could call
            // the USB_DEVICE_ControlReceive function (as shown here) to
            // submit the buffer that would receive data in case of a
            // control read transfer.

            setupPacket = (USB_SETUP_PACKET *)pData;

            // Submit a buffer to receive 32 bytes in the  control write transfer.
            USB_DEVICE_ControlReceive(usbDeviceHandle, data, 32);
            break;

        case USB_DEVICE_CONTROL_TRANSFER_EVENT_DATA_RECEIVED:

            // This means that data in the data stage of the control write
            // transfer has been received. The application can either accept
            // the received data by calling the USB_DEVICE_ControlStatus
            // function with USB_DEVICE_CONTROL_STATUS_OK flag (as shown in
            // this example) or it can reject it by calling the
            // USB_DEVICE_ControlStatus function with
            // USB_DEVICE_CONTROL_STATUS_ERROR flag.

            USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_OK);
            break;

        case USB_DEVICE_CONTROL_TRANSFER_EVENT_DATA_SENT:

            // This means that data in the data stage of the control
            // read transfer has been sent.

            break;

        case USB_DEVICE_CONTROL_TRANSFER_EVENT_ABORTED:

            // This means the host has aborted the control transfer. The
            // application can reset its control transfer state machine.

            break;

        case USB_DEVICE_EVENT_ENDPOINT_READ_COMPLETE:

            // This means schedule endpoint read operation has completed.
            // The application should interpret pData as a pointer to
            // a USB_DEVICE_EVENT_DATA_ENDPOINT_READ_COMPLETE type.

            break;

        case USB_DEVICE_EVENT_ENDPOINT_WRITE_COMPLETE:

            // This means schedule endpoint write operation has completed.
            // The application should interpret pData as a pointer to
            // a USB_DEVICE_EVENT_DATA_ENDPOINT_WRITE_COMPLETE type.

            break;

        case USB_DEVICE_EVENT_SET_DESCRIPTOR:

            // This means the Host has sent a Set Descriptor request. The
            // application should interpret pData as a
            // USB_DEVICE_EVENT_DATA_SET_DESCRIPTOR pointer type containing the
            // details of the Set Descriptor request. In PIC32 USB Device
            // Stack, this event is generated if
            // USB_DEVICE_SET_DESCRIPTOR_EVENT_ENABLE is defined in the
```

```
            // system configuration. The application can use
            // USB_DEVICE_ControlSend, USB_DEVICE_ControlReceive and/or
            // the USB_DEVICE_ControlStatus functions to complete the
            // control transfer.

            break;

        case USB_DEVICE_EVENT_SYNCH_FRAME:

            // This means the host has sent a Sync Frame Request. The
            // application should interpret pData as a
            // USB_DEVICE_EVENT_DATA_SYNCH_FRAME pointer type. In PIC32 USB Device
            // Stack, this event is generated if
            // USB_DEVICE_SYNCH_FRAME_EVENT_ENABLE is defined in the
            // system configuration. The application should respond be
            // sending the 2 byte frame number using the
            // USB_DEVICE_ControlSend function.

            USB_DEVICE_ControlSend(usbDeviceHandle, &frameNumber, 2);
            break;

        default:
            break;
    }

    return USB_DEVICE_EVENT_REPONSE_NONE;
}
```

Remarks

Generation of some events required the definition of configuration macros. Refer to the event specific description for more details.

USB_DEVICE_HANDLE Type

Data type for USB device handle.

File

usb_device.h

C

```
typedef uintptr_t USB_DEVICE_HANDLE;
```

Description

Data type for USB device handle.

The data type of the handle that is returned from USB_DEVICE_Open function.

Remarks

None.

USB_DEVICE_INIT Structure

USB Device Initialization Structure

File

usb_device.h

C

```
typedef struct {
  SYS_MODULE_INIT moduleInit;
  unsigned int usbID;
  bool stopInIdle;
  bool suspendInSleep;
  INT_SOURCE interruptSource;
  INT_SOURCE interruptSourceUSBDma;
  void * endpointTable;
  uint16_t registeredFuncCount;
  USB_DEVICE_FUNCTION_REGISTRATION_TABLE * registeredFunctions;
```

```
  USB_DEVICE_MASTER_DESCRIPTOR * usbMasterDescriptor;
  USB_SPEED deviceSpeed;
  uint16_t queueSizeEndpointRead;
  uint16_t queueSizeEndpointWrite;
  SYS_MODULE_INDEX driverIndex;
  void * usbDriverInterface;
} USB_DEVICE_INIT;
```

Members

Members	Description
SYS_MODULE_INIT moduleInit;	System module initialization
unsigned int usbID;	Identifies peripheral (PLIB-level) ID. The use of this parameter is • deprecated.
bool stopInIdle;	If true, USB module will stop when CPU enters Idle Mode. The use of this • parameter is deprecated.
bool suspendInSleep;	If true, USB module will suspend when the microcontroller enters sleep • mode. The use of this parameter is deprecated.
INT_SOURCE interruptSource;	Interrupt Source for USB module. The use of this parameter is deprecated.
INT_SOURCE interruptSourceUSBDma;	Interrupt Source for USB DMA module. The use of this parameter is • deprecated.
void * endpointTable;	Pointer to an byte array whose size is USB_DEVICE_ENDPOINT_TABLE_SIZE and who start address is aligned at a 512 bytes address boundary. The • use of this parameter is deprecated.
uint16_t registeredFuncCount;	Number of function drivers registered to this instance of the USB device layer
USB_DEVICE_FUNCTION_REGISTRATION_TABLE * registeredFunctions;	Function driver table registered to this instance of the USB device layer
USB_DEVICE_MASTER_DESCRIPTOR * usbMasterDescriptor;	Pointer to USB Descriptor structure
USB_SPEED deviceSpeed;	Specify the speed at which this device will attempt to connect to the host. PIC32MX devices support Full Speed only. PIC32MZ devices support Full Speed and High Speed. Selecting High Speed will allow the device to work at both Full Speed and High Speed.
uint16_t queueSizeEndpointRead;	Enter Endpoint Read queue size. Application can place this many Endpoint Read requests in the queue. Each Endpoint Read queue element would consume 36 Bytes of RAM. Value of this field should be at least 1. This is applicable only for applications using Endpoint Read/Write functions like USB Vendor Device.
uint16_t queueSizeEndpointWrite;	Enter Endpoint Write queue size. Application can place this many Endpoint Read requests in the queue. Each Endpoint Write queue element would consume 36 Bytes of RAM. Value of this field should be at least 1. This is applicable only for applications using Endpoint Read/Write functions like USB Vendor Device.
SYS_MODULE_INDEX driverIndex;	System Module Index of the driver that this device layer should open
void * usbDriverInterface;	Interface to the USB Driver that this Device Layer should use

Description

USB Device Initialization Structure

This data type defines the USB Device Initialization data structure. A data structure of this type should be initialized and provided to USB_DEVICE_Initialize.

Remarks

This type is specific to the PIC32 implementation of the USB Device Stack API.

USB_DEVICE_POWER_STATE Enumeration

Enumerated data type that identifies if the device is self powered or bus powered .

File

usb_device.h

C

```
typedef enum {
  USB_DEVICE_POWER_STATE_BUS_POWERED,
  USB_DEVICE_POWER_STATE_SELF_POWERED
} USB_DEVICE_POWER_STATE;
```

Members

Members	Description
USB_DEVICE_POWER_STATE_BUS_POWERED	Device is bus powered
USB_DEVICE_POWER_STATE_SELF_POWERED	Device is self powered

Description

Device Power state

This enumeration defines the possible power states of the device. The application specifies this state to the device layer (through the USB_DEVICE_PowerStateSet function) to let the device layer know if this USB Device is presently bus or self powered.

Remarks

None.

USB_DEVICE_REMOTE_WAKEUP_STATUS Enumeration

Enumerated data type that identifies if the remote wakeup status of the device.

File

usb_device.h

C

```
typedef enum {
  USB_DEVICE_REMOTE_WAKEUP_DISABLED,
  USB_DEVICE_REMOTE_WAKEUP_ENABLED
} USB_DEVICE_REMOTE_WAKEUP_STATUS;
```

Members

Members	Description
USB_DEVICE_REMOTE_WAKEUP_DISABLED	Remote wakeup is disabled
USB_DEVICE_REMOTE_WAKEUP_ENABLED	Remote wakeup is enabled

Description

Remote Wakeup Status

This enumeration defines the possible status of the remote wake up capability. These values are returned by the USB_DEVICE_RemoteWakeupStatusGet function.

Remarks

None.

USB_DEVICE_EVENT_DATA_CONFIGURED Structure

USB Device Set Configuration Event Data type.

File

usb_device.h

C

```
typedef struct {
  uint8_t configurationValue;
} USB_DEVICE_EVENT_DATA_CONFIGURED;
```

Members

Members	Description
uint8_t configurationValue;	The configuration that was set

Description

USB Device Set Configuration Event Data type.

This data type defines the type of data that is returned by the Device Layer along with the USB_DEVICE_EVENT_CONFIGURED event.

Remarks

None.

USB_DEVICE_HANDLE_INVALID Macro

Constant that defines the value of an Invalid Device Handle.

File

usb_device.h

C

```
#define USB_DEVICE_HANDLE_INVALID
```

Description

USB Device Layer Invalid Handle

This constant is returned by the USB_DEVICE_Open() function when the function fails.

Remarks

None.

USB_DEVICE_EVENT_RESPONSE_NONE Macro

Device Layer Event Handler Function Response Type.

File

usb_device.h

C

```
#define USB_DEVICE_EVENT_RESPONSE_NONE
```

Description

Device Layer Event Handler Function Response Type None.

This is the definition of the Device Layer Event Handler Response Type None.

Remarks

Intentionally defined to be empty.

USB_DEVICE_CLIENT_STATUS Enumeration

Enumerated data type that identifies the USB Device Layer Client Status.

File

usb_device.h

C

```
typedef enum {
  USB_DEVICE_CLIENT_STATUS_CLOSED,
  USB_DEVICE_CLIENT_STATUS_READY
} USB_DEVICE_CLIENT_STATUS;
```

Members

Members	Description
USB_DEVICE_CLIENT_STATUS_CLOSED	Client is closed or the specified handle is invalid
USB_DEVICE_CLIENT_STATUS_READY	Client is ready

Description

USB Device Layer Client Status

This enumeration defines the possible status of the USB Device Layer Client. It is returned by the USB_DEVICE_ClientStatusGet function.

Remarks

None.

USB_DEVICE_CONFIGURATION_DESCRIPTORS_TABLE Type

Pointer to an array that contains pointer to configuration descriptors.

File

usb_device.h

C

```
typedef const uint8_t * const USB_DEVICE_CONFIGURATION_DESCRIPTORS_TABLE;
```

Description

Configuration descriptors pointer

This type defines a pointer to an array that contains pointers to configuration descriptors. This data type is used in USB_DEVICE_MASTER_DESCRIPTOR data type to point to the table of configuration descriptors.

Remarks

This type is specific to the PIC32 implementation of the USB Device Stack API.

USB_DEVICE_EVENT_HANDLER Type

USB Device Layer Event Handler Function Pointer Type

File

usb_device.h

C

```
typedef USB_DEVICE_EVENT_RESPONSE (* USB_DEVICE_EVENT_HANDLER)(USB_DEVICE_EVENT event, void * eventData,
uintptr_t context);
```

Description

USB Device Layer Event Handler Function Pointer Type

This data type defines the required function signature of the USB Device Layer Event handling callback function. The application must register a pointer to a Device Layer Event handling function whose function signature (parameter and return value types) match the types specified by this function pointer in order to receive event call backs from the Device Layer. The Device Layer will invoke this function with event relevant parameters. The description of the event handler function parameters is given here.

event - Type of event generated.

pData - This parameter should be type cast to an event specific pointer type based on the event that has occurred. Refer to the USB_DEVICE_EVENT enumeration description for more details.

context - Value identifying the context of the application that was registered along with the event handling function.

Remarks

None.

USB_DEVICE_EVENT_RESPONSE Type

Device Layer Event Handler function return type.

File

usb_device.h

C

```
typedef void USB_DEVICE_EVENT_RESPONSE;
```

Description

Device Layer Event Handler function return type.

This data type defines the return type of the Device Layer event handler function.

Remarks

None.

USB_DEVICE_FUNCTION_REGISTRATION_TABLE Structure

USB Device Function Registration Structure

File

usb_device.h

C

```
typedef struct {
  USB_SPEED speed;
  uint8_t configurationValue;
  uint8_t interfaceNumber;
  uint8_t numberOfInterfaces;
  uintptr_t funcDriverIndex;
  void * funcDriverInit;
  void * driver;
} USB_DEVICE_FUNCTION_REGISTRATION_TABLE;
```

Members

Members	Description
USB_SPEED speed;	Type of speed (high, full or low speed)
uint8_t configurationValue;	Configuration Value to which the function driver has to be tied
uint8_t interfaceNumber;	Interface number to which this function driver has to be tied
uint8_t numberOfInterfaces;	Number of interfaces used by the function
uintptr_t funcDriverIndex;	Function driver instance index
void * funcDriverInit;	Pointer to a structure that contains function driver initialization data
void * driver;	Pointer to a standard structure that exposes function driver APIs to USB device layer

Description

USB Device Function Registration Structure

This data type defines the USB Device Function Registration Structure. A table containing entries for each function driver instance should be registered with device layer.

Remarks

This type is specific to the PIC32 implementation of the USB Device Stack API.

USB_DEVICE_MASTER_DESCRIPTOR Structure

USB Device Master Descriptor Structure.

File

usb_device.h

C

```
typedef struct {
  const USB_DEVICE_DESCRIPTOR * deviceDescriptor;
  uint8_t configDescriptorCount;
  USB_DEVICE_CONFIGURATION_DESCRIPTORS_TABLE * configDescriptorTable;
  const USB_DEVICE_DESCRIPTOR * highSpeedDeviceDescriptor;
  uint8_t highSpeedConfigDescriptorCount;
  USB_DEVICE_CONFIGURATION_DESCRIPTORS_TABLE * highSpeedConfigDescriptorTable;
  uint8_t stringDescCount;
  USB_DEVICE_STRING_DESCRIPTORS_TABLE * stringDescriptorTable;
  const USB_DEVICE_QUALIFIER * fullSpeedDeviceQualifier;
  const USB_DEVICE_QUALIFIER * highSpeedDeviceQualifier;
  const uint8_t * bosDescriptor;
} USB_DEVICE_MASTER_DESCRIPTOR;
```

Members

Members	Description
const USB_DEVICE_DESCRIPTOR * deviceDescriptor;	Pointer to standard device descriptor (for low/full speed)
uint8_t configDescriptorCount;	Total number configurations available (for low/full speed)

USB_DEVICE_CONFIGURATION_DESCRIPTORS_TABLE * configDescriptorTable;	Pointer to array of configurations descriptor pointers (for low/full speed)
const USB_DEVICE_DESCRIPTOR * highSpeedDeviceDescriptor;	Pointer to array of high speed standard Device descriptor. Assign this to NULL if not supported.
uint8_t highSpeedConfigDescriptorCount;	Total number of high speed configurations available. Set this to zero if not supported
USB_DEVICE_CONFIGURATION_DESCRIPTORS_TABLE * highSpeedConfigDescriptorTable;	Pointer to array of high speed configurations descriptor pointers. Set this to NULL if not supported
uint8_t stringDescCount;	Total number of string descriptors available (common to all speeds)
USB_DEVICE_STRING_DESCRIPTORS_TABLE * stringDescriptorTable;	Pointer to array of string Descriptor pointers (common to all speeds)
const USB_DEVICE_QUALIFIER * fullSpeedDeviceQualifier;	Pointer to full speed device_qualifier descriptor. Device responds with this descriptor when it is operating at high speed
const USB_DEVICE_QUALIFIER * highSpeedDeviceQualifier;	Pointer to high speed device_qualifier descriptor. Device responds with this descriptor when it is operating at full speed
const uint8_t * bosDescriptor;	Pointer to BOS descriptor for this Device. Device responds with this descriptor when Host sends a GET_DESCRIPTOR request for BOS descriptor

Description

USB Device Master Descriptor Structure.

This data type defines the structure of the USB Device Master Descriptor. The application must provide such a structure for each instance of the device layer.

Remarks

This type is specific to the PIC32 implementation of the USB Device Stack API.

USB_DEVICE_STRING_DESCRIPTORS_TABLE Type

Pointer to an array that contains pointer to string descriptors.

File

usb_device.h

C

```
typedef const uint8_t * const USB_DEVICE_STRING_DESCRIPTORS_TABLE;
```

Description

String Descriptors Pointer

This type defines a pointer to an array that contains pointers to string descriptors. This data type is used in USB_DEVICE_MASTER_DESCRIPTOR data type to point to the table of string descriptors.

Remarks

This type is specific to the PIC32 implementation of the USB Device Stack API.

USB_DEVICE_EVENT_DATA_ENDPOINT_READ_COMPLETE Structure

USB Device Layer Endpoint Read and Write Complete Event Data type.

File

usb_device.h

C

```
typedef struct {
  USB_DEVICE_TRANSFER_HANDLE transferHandle;
  size_t length;
  USB_DEVICE_RESULT status;
} USB_DEVICE_EVENT_DATA_ENDPOINT_READ_COMPLETE, USB_DEVICE_EVENT_DATA_ENDPOINT_WRITE_COMPLETE;
```

Members

Members	Description
USB_DEVICE_TRANSFER_HANDLE transferHandle;	Transfer Handle

size_t length;	Size of transferred data
USB_DEVICE_RESULT status;	Completion status of the transfer

Description

USB Device Layer Endpoint Read and Write Complete Event Data type.

This data type defines the type of data that is returned by the Device Layer along with the USB_DEVICE_EVENT_ENDPOINT_WRITE_COMPLETE and USB_DEVICE_EVENT_ENDPOINT_READ_COMPLETE events.

Remarks

None.

USB_DEVICE_EVENT_DATA_ENDPOINT_WRITE_COMPLETE Structure

USB Device Layer Endpoint Read and Write Complete Event Data type.

File

usb_device.h

C

```
typedef struct {
  USB_DEVICE_TRANSFER_HANDLE transferHandle;
  size_t length;
  USB_DEVICE_RESULT status;
} USB_DEVICE_EVENT_DATA_ENDPOINT_READ_COMPLETE, USB_DEVICE_EVENT_DATA_ENDPOINT_WRITE_COMPLETE;
```

Members

Members	Description
USB_DEVICE_TRANSFER_HANDLE transferHandle;	Transfer Handle
size_t length;	Size of transferred data
USB_DEVICE_RESULT status;	Completion status of the transfer

Description

USB Device Layer Endpoint Read and Write Complete Event Data type.

This data type defines the type of data that is returned by the Device Layer along with the USB_DEVICE_EVENT_ENDPOINT_WRITE_COMPLETE and USB_DEVICE_EVENT_ENDPOINT_READ_COMPLETE events.

Remarks

None.

USB_DEVICE_EVENT_DATA_SET_DESCRIPTOR Structure

USB Device Set Descriptor Event Data type.

File

usb_device.h

C

```
typedef struct {
  uint8_t descriptorIndex;
  uint8_t descriptorType;
  uint16_t languageID;
  uint16_t descriptorLength;
} USB_DEVICE_EVENT_DATA_SET_DESCRIPTOR;
```

Description

USB Device Set Descriptor Event Data type.

This data type defines the type of data that is returned by the Device Layer along with the USB_DEVICE_EVENT_SET_DESCRIPTOR event.

Remarks

None.

USB_DEVICE_EVENT_DATA_SOF Structure

USB Device Start Of Frame Event Data Type

File

usb_device.h

C

```
typedef struct {
  uint16_t frameNumber;
} USB_DEVICE_EVENT_DATA_SOF;
```

Members

Members	Description
uint16_t frameNumber;	The Start Of Frame number

Description

USB Device Start Of Frame Event Data Type

This data type defines the type of data that is returned by the Device Layer along with the USB_DEVICE_EVENT_SOF event.

Remarks

None.

USB_DEVICE_EVENT_DATA_SYNCH_FRAME Structure

USB Device Synch Frame Event Data type.

File

usb_device.h

C

```
typedef struct {
  USB_ENDPOINT_ADDRESS endpoint;
} USB_DEVICE_EVENT_DATA_SYNCH_FRAME;
```

Members

Members	Description
USB_ENDPOINT_ADDRESS endpoint;	Endpoint for which the Synch Frame number is requested

Description

USB Device Synch Frame Event Data type.

This data type defines the type of data that is returned by the Device Layer along with the USB_DEVICE_EVENT_SYNCH_FRAME event.

Remarks

None.

USB_DEVICE_RESULT Enumeration

USB Device Layer Results Enumeration

File

usb_device.h

C

```
typedef enum {
  USB_DEVICE_RESULT_ERROR_TRANSFER_QUEUE_FULL,
  USB_DEVICE_RESULT_OK,
  USB_DEVICE_RESULT_ERROR_ENDPOINT_NOT_CONFIGURED,
  USB_DEVICE_RESULT_ERROR_ENDPOINT_INVALID,
  USB_DEVICE_RESULT_ERROR_PARAMETER_INVALID,
  USB_DEVICE_RESULT_ERROR_DEVICE_HANDLE_INVALID,
  USB_DEVICE_RESULT_ERROR_ENDPOINT_HALTED,
```

```
  USB_DEVICE_RESULT_ERROR_TERMINATED_BY_HOST,
  USB_DEVICE_RESULT_ERROR
} USB_DEVICE_RESULT;
```

Members

Members	Description
USB_DEVICE_RESULT_ERROR_TRANSFER_QUEUE_FULL	Queue is full
USB_DEVICE_RESULT_OK	No Error
USB_DEVICE_RESULT_ERROR_ENDPOINT_NOT_CONFIGURED	Endpoint not configured
USB_DEVICE_RESULT_ERROR_ENDPOINT_INVALID	Endpoint not provisioned in the system
USB_DEVICE_RESULT_ERROR_PARAMETER_INVALID	One or more parameter/s of the function is invalid
USB_DEVICE_RESULT_ERROR_DEVICE_HANDLE_INVALID	Device Handle passed to the function is invalid
USB_DEVICE_RESULT_ERROR_ENDPOINT_HALTED	Transfer terminated because host halted the endpoint
USB_DEVICE_RESULT_ERROR_TERMINATED_BY_HOST	Transfer terminated by host because of a stall clear
USB_DEVICE_RESULT_ERROR	An unspecified error has occurred

Description

USB Device Result Enumeration

This enumeration lists the possible USB Device Endpoint operation results. These values are returned by USB Device Endpoint functions.

Remarks

None.

USB_DEVICE_TRANSFER_FLAGS Enumeration

Enumerated data type that identifies the USB Device Layer Transfer Flags.

File

usb_device.h

C

```
typedef enum {
  USB_DEVICE_TRANSFER_FLAGS_DATA_COMPLETE,
  USB_DEVICE_TRANSFER_FLAGS_MORE_DATA_PENDING
} USB_DEVICE_TRANSFER_FLAGS;
```

Members

Members	Description
USB_DEVICE_TRANSFER_FLAGS_DATA_COMPLETE	This flag indicates there is no further data to be sent in this transfer and that the transfer should end. If the size of the transfer is a multiple of the maximum packet size for related endpoint configuration, the device layer will send a zero length packet to indicate end of the transfer to the host.
USB_DEVICE_TRANSFER_FLAGS_MORE_DATA_PENDING	This flag indicates there is more data to be sent in this transfer. If the size of the transfer is a multiple of the maximum packet size for the related endpoint configuration, the device layer will not send a zero length packet. This flags should not be specified if the size of the transfer is is not a multiple of the maximum packet size or if the transfer is less than maximum packet size.

Description

USB Device Layer Transfer Flags

This enumeration defines the possible USB Device Layer Transfer Flags. These flags are specified in USB_DEVICE_EndpointWrite() function to specify the handling of the transfer. Please refer to the description of the USB_DEVICE_EndpointWrite function for examples.

Remarks

None.

USB_DEVICE_TRANSFER_HANDLE Type

Data type for USB Device Endpoint Data Transfer Handle.

File

usb_device.h

C

```
typedef uintptr_t USB_DEVICE_TRANSFER_HANDLE;
```

Description

Data type for USB Device Endpoint Data Transfer Handle.

The data type of the handle that is returned by the USB_DEVICE_EndpointRead() and USB_DEVICE_EndpointWrite() functions.

Remarks

None.

USB_DEVICE_TRANSFER_HANDLE_INVALID Macro

Constant that defines the value of an Invalid Device Endpoint Data Transfer Handle.

File

usb_device.h

C

```
#define USB_DEVICE_TRANSFER_HANDLE_INVALID
```

Description

USB Device Layer Invalid Endpoint Data Transfer Handle

This constant defines the value that is returned by the USB_DEVICE_EndpointRead() and USB_DEVICE_EndpointWrite() functions, as a transfer handle, when the function is not successful.

Remarks

None.

USB_DEVICE_IRP Structure

This structure defines the USB Device Mode IRP data structure.

File

usb_common.h

C

```
typedef struct _USB_DEVICE_IRP {
  void * data;
  unsigned int size;
  USB_DEVICE_IRP_STATUS status;
  void (* callback)(struct _USB_DEVICE_IRP * irp);
  USB_DEVICE_IRP_FLAG flags;
  uintptr_t userData;
  uint32_t privateData[3];
} USB_DEVICE_IRP;
```

Members

Members	Description
void * data;	Pointer to the data buffer
unsigned int size;	Size of the data buffer
USB_DEVICE_IRP_STATUS status;	Status of the IRP
void (* callback)(struct _USB_DEVICE_IRP * irp);	IRP Callback. If this is NULL, • then there is no callback generated
USB_DEVICE_IRP_FLAG flags;	Request specific flags
uintptr_t userData;	User data
uint32_t privateData[3];	The following members should not be modified by the client

Description

USB Device Mode I/O Request Packet

This structure defines the USB Device Mode IRP data structure.

Remarks

None.

USB_DEVICE_IRP_FLAG Enumeration

USB Device IRP flags enumeration

File

usb_common.h

C

```
typedef enum {
  USB_DEVICE_IRP_FLAG_DATA_COMPLETE = 0x1,
  USB_DEVICE_IRP_FLAG_DATA_PENDING = 0x2
} USB_DEVICE_IRP_FLAG;
```

Members

Members	Description
USB_DEVICE_IRP_FLAG_DATA_COMPLETE = 0x1	Using this flag indicates that there is no • more data pending in the IRP. When data moves • from device to host, and if the IRP size is • a multiple of endpoint size, specifying this • flag sends the ZLP. The size is not a • multiple of endpoint size, no ZLP will be sent.
USB_DEVICE_IRP_FLAG_DATA_PENDING = 0x2	In case of data moving from device to host, and if the • size parameter of the IRP is an exact multiple of the • endpoint maximum packet size, specifying this flag, does • send the ZLP. If the size is less than endpoint size, • specifying this flag will return an error. If the size • is more than endpoint size but not a multiple, only • endpoint multiple size of data is sent.

Description

USB Device IRP Flags

This enumeration defines the possible flags that can be specified while adding the IRP.

Remarks

Not all flags are applicable in all conditions. Refer to API documentation for more details

USB_DEVICE_IRP_STATUS Enumeration

Enumerates the possible status options of USB Device IRP.

File

usb_common.h

C

```
typedef enum {
  USB_DEVICE_IRP_STATUS_TERMINATED_BY_HOST = -4,
  USB_DEVICE_IRP_STATUS_ABORTED_ENDPOINT_HALT = -3,
  USB_DEVICE_IRP_STATUS_ABORTED = -2,
  USB_DEVICE_IRP_STATUS_ERROR = -1,
  USB_DEVICE_IRP_STATUS_COMPLETED = 0,
  USB_DEVICE_IRP_STATUS_COMPLETED_SHORT = 1,
  USB_DEVICE_IRP_STATUS_SETUP = 2,
  USB_DEVICE_IRP_STATUS_PENDING = 3,
  USB_DEVICE_IRP_STATUS_IN_PROGRESS = 4
} USB_DEVICE_IRP_STATUS;
```

Members

Members	Description
USB_DEVICE_IRP_STATUS_TERMINATED_BY_HOST = -4	The IRP was aborted because the host cleared the stall on the endpoint
USB_DEVICE_IRP_STATUS_ABORTED_ENDPOINT_HALT = -3	IRP was aborted because the endpoint halted
USB_DEVICE_IRP_STATUS_ABORTED = -2	USB Device IRP was aborted by the function driver
USB_DEVICE_IRP_STATUS_ERROR = -1	An error occurred on the bus when the IRP was being • processed
USB_DEVICE_IRP_STATUS_COMPLETED = 0	The IRP was completed
USB_DEVICE_IRP_STATUS_COMPLETED_SHORT = 1	The IRP was completed but the amount of • data received was less than the requested • size
USB_DEVICE_IRP_STATUS_SETUP = 2	The IRP was completed and the received • token was a SETUP token. This is applicable • to IRP scheduled on CONTROL endpoint
USB_DEVICE_IRP_STATUS_PENDING = 3	The IRP is pending in the queue
USB_DEVICE_IRP_STATUS_IN_PROGRESS = 4	The IRP is currently being processed

Description

USB Device IRP Status Enumeration

Enumerates the possible status options of USB Device IRP.

Remarks

The application that schedules the IRP can check the status member of the USB Device IRP at any time to obtain current status of the IRP.

USB_ENDPOINT Type

Defines a type to store Endpoint and Direction. The MSB defines the direction. The lower 4 bits defines the endpoint.

File

usb_common.h

C

```
typedef uint8_t USB_ENDPOINT;
```

Description

USB Endpoint and Direction Type

Defines a type to store Endpoint and Direction. The MSB defines the direction. The lower 4 bits defines the endpoint.

Remarks

None.

USB_ERROR Enumeration

Enumeration of all possible error codes that are returned by various components functions in the USB Stack.

File

usb_common.h

C

```
typedef enum {
  USB_ERROR_IRP_QUEUE_FULL = SCHAR_MIN,
  USB_ERROR_OSAL_FUNCTION,
  USB_ERROR_IRP_SIZE_INVALID,
  USB_ERROR_PARAMETER_INVALID,
  USB_ERROR_DEVICE_ENDPOINT_INVALID,
  USB_ERROR_DEVICE_IRP_IN_USE,
  USB_ERROR_CLIENT_NOT_READY,
  USB_ERROR_IRP_OBJECTS_UNAVAILABLE,
  USB_ERROR_DEVICE_FUNCTION_INSTANCE_INVALID,
```

```
  USB_ERROR_DEVICE_FUNCTION_NOT_CONFIGURED,
  USB_ERROR_ENDPOINT_NOT_CONFIGURED,
  USB_ERROR_DEVICE_CONTROL_TRANSFER_FAILED,
  USB_ERROR_HOST_DEVICE_INSTANCE_INVALID,
  USB_ERROR_HOST_DRIVER_NOT_READY,
  USB_ERROR_HOST_DRIVER_NOT_FOUND,
  USB_ERROR_HOST_ENDPOINT_INVALID,
  USB_ERROR_HOST_PIPE_INVALID,
  USB_ERROR_HOST_ARGUMENTS_INVALID,
  USB_ERROR_HOST_HEADERSIZE_INVALID,
  USB_ERROR_HOST_MAX_INTERFACES_INVALID,
  USB_ERROR_HOST_ENDPOINT_DESC_SIZE_INVALID,
  USB_ERROR_HOST_DESCRIPTOR_INVALID,
  USB_ERROR_HOST_MAX_ENDPOINT_INVALID,
  USB_ERROR_HOST_ALT_SETTING_INVALID,
  USB_ERROR_HOST_BUSY,
  USB_HOST_OBJ_INVALID,
  USB_ERROR_HOST_POINTER_INVALID,
  USB_ERROR_HOST_ENDPOINT_NOT_FOUND,
  USB_ERROR_HOST_DRIVER_INSTANCE_INVALID,
  USB_ERROR_HOST_INTERFACE_NOT_FOUND,
  USB_ERROR_ENDPOINT_HALTED,
  USB_ERROR_TRANSFER_TERMINATED_BY_HOST,
  USB_ERROR_NONE = 0
} USB_ERROR;
```

Members

Members	Description
USB_ERROR_IRP_QUEUE_FULL = SCHAR_MIN	IRP Queue Full Error
USB_ERROR_OSAL_FUNCTION	OSAL Function fails
USB_ERROR_IRP_SIZE_INVALID	IRP Size parameter invalid
USB_ERROR_PARAMETER_INVALID	Some function parameter was not valid
USB_ERROR_DEVICE_ENDPOINT_INVALID	Device endpoint is not valid
USB_ERROR_DEVICE_IRP_IN_USE	IRP is already in use
USB_ERROR_CLIENT_NOT_READY	Client is not ready
USB_ERROR_IRP_OBJECTS_UNAVAILABLE	Free IRP object unavailable
USB_ERROR_DEVICE_FUNCTION_INSTANCE_INVALID	Function Driver instance was not provisioned
USB_ERROR_DEVICE_FUNCTION_NOT_CONFIGURED	Function Driver instance is not configured
USB_ERROR_ENDPOINT_NOT_CONFIGURED	Endpoint is not configured
USB_ERROR_DEVICE_CONTROL_TRANSFER_FAILED	Device Control Transfer Failed
USB_ERROR_HOST_DEVICE_INSTANCE_INVALID	Host device instance invalid
USB_ERROR_HOST_DRIVER_NOT_READY	Host driver not ready for communication
USB_ERROR_HOST_DRIVER_NOT_FOUND	Host driver not found
USB_ERROR_HOST_ENDPOINT_INVALID	Host endpoint invalid
USB_ERROR_HOST_PIPE_INVALID	Host pipe invalid
USB_ERROR_HOST_ARGUMENTS_INVALID	Invalid arguments
USB_ERROR_HOST_HEADERSIZE_INVALID	Header size invalid
USB_ERROR_HOST_MAX_INTERFACES_INVALID	Max interface Number
USB_ERROR_HOST_ENDPOINT_DESC_SIZE_INVALID	Endpoint descriptor size is invalid
USB_ERROR_HOST_DESCRIPTOR_INVALID	Invalid Descriptor
USB_ERROR_HOST_MAX_ENDPOINT_INVALID	Invalid number of endpoints
USB_ERROR_HOST_ALT_SETTING_INVALID	Host alternate setting is invalid
USB_ERROR_HOST_BUSY	Host is busy
USB_HOST_OBJ_INVALID	USB host invalid
USB_ERROR_HOST_POINTER_INVALID	Pointer is invalid
USB_ERROR_HOST_ENDPOINT_NOT_FOUND	Could not find endpoint
USB_ERROR_HOST_DRIVER_INSTANCE_INVALID	Driver Instance Invalid
USB_ERROR_HOST_INTERFACE_NOT_FOUND	Could not find endpoint
USB_ERROR_ENDPOINT_HALTED	Transfer terminated because endpoint was halted
USB_ERROR_TRANSFER_TERMINATED_BY_HOST	Transfer terminated by host because of a stall clear
USB_ERROR_NONE = 0	No Error, Operation was successful

Description

USB Error Codes

Enumeration of all possible error codes that are returned by various components functions in the USB Stack.

Remarks

None.

USB_HOST_IRP Structure

This structure defines the USB Host Mode IRP data structure.

File

usb_common.h

C

```
typedef struct _USB_HOST_IRP {
  void * setup;
  void * data;
  unsigned int size;
  USB_HOST_IRP_STATUS status;
  USB_HOST_IRP_FLAG flags;
  uintptr_t userData;
  void (* callback)(struct _USB_HOST_IRP * irp);
  uintptr_t privateData[7];
} USB_HOST_IRP;
```

Members

Members	Description
void * setup;	Points to the 8 byte setup command • packet in case this is a IRP is • scheduled on a CONTROL pipe. Should • be NULL otherwise
void * data;	Pointer to data buffer
unsigned int size;	Size of the data buffer
USB_HOST_IRP_STATUS status;	Status of the IRP
USB_HOST_IRP_FLAG flags;	Request specific flags
uintptr_t userData;	User data
void (* callback)(struct _USB_HOST_IRP * irp);	Pointer to function to be called • when IRP is terminated. Can be • NULL, in which case the function • will not be called.
uintptr_t privateData[7];	These members of the IRP should not be modified by client

Description

USB Host Mode I/O Request Packet

This structure defines the USB Host Mode IRP data structure.

Remarks

None.

USB_HOST_IRP_FLAG Enumeration

USB Host IRP flags enumeration

File

usb_common.h

C

```
typedef enum {
  USB_HOST_IRP_FLAG_NONE = 0,
  USB_HOST_IRP_FLAG_SEND_ZLP,
```

```
  USB_HOST_IRP_WAIT_FOR_ZLP
} USB_HOST_IRP_FLAG;
```

Members

Members	Description
USB_HOST_IRP_FLAG_NONE = 0	Does not do anything
USB_HOST_IRP_FLAG_SEND_ZLP	In case of data moving from host to device, and if the • size parameter of the IRP is an exact multiple of the • endpoint maximum packet size, specifying this flag sends • a Zero Length Packet before the IRP is completed.
USB_HOST_IRP_WAIT_FOR_ZLP	In case of data moving device to host, and if the • size parameter of the IRP is an exact multiple of • the endpoint maximum packet size, specifying this • flag will cause the IRP to completed only when the • a ZLP was requested and acknowledged and the amount • of data was a multiple of endpoint maximum packet size.

Description

USB Host IRP Flags

This enumeration defines the possible flags that can be specified while adding the IRP.

Remarks

Not all flags are applicable in all conditions. Refer to API documentation for more details

USB_HOST_IRP_STATUS Enumeration

Enumerates the possible status options of USB Host IRP.

File

usb_common.h

C

```
typedef enum _USB_HOST_IRP_STATUS {
  USB_HOST_IRP_STATUS_ERROR_UNKNOWN = -6,
  USB_HOST_IRP_STATUS_ABORTED = -5,
  USB_HOST_IRP_STATUS_ERROR_BUS = -4,
  USB_HOST_IRP_STATUS_ERROR_DATA = -3,
  USB_HOST_IRP_STATUS_ERROR_NAK_TIMEOUT = -2,
  USB_HOST_IRP_STATUS_ERROR_STALL = -1,
  USB_HOST_IRP_STATUS_COMPLETED = 0,
  USB_HOST_IRP_STATUS_COMPLETED_SHORT = 1,
  USB_HOST_IRP_STATUS_PENDING = 2,
  USB_HOST_IRP_STATUS_IN_PROGRESS = 3
} USB_HOST_IRP_STATUS;
```

Members

Members	Description
USB_HOST_IRP_STATUS_ERROR_UNKNOWN = -6	IRP was terminated due to an unknown error
USB_HOST_IRP_STATUS_ABORTED = -5	IRP was terminated by the application
USB_HOST_IRP_STATUS_ERROR_BUS = -4	IRP was terminated due to a bus error
USB_HOST_IRP_STATUS_ERROR_DATA = -3	IRP was terminated due to data error
USB_HOST_IRP_STATUS_ERROR_NAK_TIMEOUT = -2	IRP was terminated because of a NAK timeout
USB_HOST_IRP_STATUS_ERROR_STALL = -1	IRP was terminated because of a STALL
USB_HOST_IRP_STATUS_COMPLETED = 0	IRP has been completed
USB_HOST_IRP_STATUS_COMPLETED_SHORT = 1	IRP has been completed but the • amount of data processed was less • than requested.
USB_HOST_IRP_STATUS_PENDING = 2	IRP is waiting in queue
USB_HOST_IRP_STATUS_IN_PROGRESS = 3	IRP is currently being processed

Description

USB Host IRP Status Enumeration

Enumerates the possible status options of USB Host IRP.

Remarks

The application that schedules the IRP can check the status member of the USB Host IRP at any time to obtain current status of the IRP.

USB_SPEED Enumeration

Provides enumeration of USB 2.0 speeds.

File

usb_common.h

C

```
typedef enum {
  USB_SPEED_ERROR = 0,
  USB_SPEED_HIGH = 1,
  USB_SPEED_FULL = 2,
  USB_SPEED_LOW = 3
} USB_SPEED;
```

Members

Members	Description
USB_SPEED_ERROR = 0	Error in obtaining USB module speed
USB_SPEED_HIGH = 1	USB module is at high speed
USB_SPEED_FULL = 2	USB module is at full speed
USB_SPEED_LOW = 3	USB module is at low speed

Description

USB 2.0 Speeds Enumeration

Provides enumeration of USB 2.0 speeds.

Remarks

None.

USB_ENDPOINT_AND_DIRECTION Macro

This macro helps in setting up the USB_ENDPOINT type.

File

usb_common.h

C

```
#define USB_ENDPOINT_AND_DIRECTION(direction, endpoint) ((uint8_t)((direction << 7) | endpoint))
```

Description

USB Endpoint and Direction helper macro

This macro helps in setting up the USB_ENDPOINT type. Here x is the direction and can be either USB_DATA_DIRECTION_HOST_TO_DEVICE or USB_DATA_DIRECTION_DEVICE_TO_HOST. y is the endpoint.

Remarks

None.

USB_DATA_DIRECTION Enumeration

Defines the communication direction

File

usb_common.h

C

```
typedef enum {
  USB_DATA_DIRECTION_DEVICE_TO_HOST = 1,
  USB_DATA_DIRECTION_HOST_TO_DEVICE = 0
} USB_DATA_DIRECTION;
```

Members

Members	Description
USB_DATA_DIRECTION_DEVICE_TO_HOST = 1	Data moves from device to host
USB_DATA_DIRECTION_HOST_TO_DEVICE = 0	Data moves from host to device

Description

USB Communication direction definitions

This definitions define the communication direction and can be used to specify direction while using the DRV_USB_ENDPOINT type.

Remarks

None.

USB_DEVICE_BOS_DESCRIPTOR_SUPPORT_ENABLE Macro

Specifies if the Device Layer should process a Host request for a BOS descriptor.

File

usb_device_config_template.h

C

```
#define USB_DEVICE_BOS_DESCRIPTOR_SUPPORT_ENABLE
```

Description

USB Device Layer BOS Descriptor Support Enable

Specifying this configuration macro will enable support for BOS request. When the request is received, the device layer will transfer the data pointed to by the bosDescriptor member of the USB_DEVICE_INIT data structure. If this configuration macro is not specified, request for a BOS descriptor is stalled.

Remarks

The USB Host will request for a BOS descriptor when the bcdVersion field in the Device Descriptor is greater than 0x0200.

USB_DEVICE_DRIVER_INITIALIZE_EXPLICIT Macro

Specifies if the USB Controller Driver must be initialized explicitly as opposed to being initialized by the Device Layer.

File

usb_device_config_template.h

C

```
#define USB_DEVICE_DRIVER_INITIALIZE_EXPLICIT
```

Description

USB Device Layer USB Controller Driver Explicit Initialize

Specifying this macro indicates that the USB Controller Driver will be initialized explicitly in the SYS_Initialize() function. The Device Layer will not initialize the USB Controller Driver. All releases of the USB Device Layer starting from v1.04 of MPALB Harmony will specify this macro i.e the controller driver will be initialized explicitly.

If this macro is not specified, then the USB Device Layer will initialize the controller driver and run its tasks routines.

Remarks

None.

USB_DEVICE_STRING_DESCRIPTOR_TABLE_ADVANCED_ENABLE Macro

Specifying this macro enables the Advanced String Descriptor Table Entry Format.

File

usb_device_config_template.h

C

```
#define USB_DEVICE_STRING_DESCRIPTOR_TABLE_ADVANCED_ENABLE
```

Description

USB Device Layer Advanced String Descriptor Table Entry Format Enable.

Specifyin this macro enables the Advanced String Descriptor Table Entry Format. The advanced format allows the application to specify the String Index and the language in the entry itself. In the basic format, this information is obtained by the virtue of the entry index of the String Descriptor in the String Descriptor Table. Using the Advanced format allows the application to specify strings with arbitrary strings indexes. In basic format, the string indexes are forced to be contiguous.

Remarks

The basic string descriptor entry format is selected by default. The advanced format must be enabled explicitly by specifying this macro.

usb_device.h

USB Device Layer Interface Header

Enumerations

	Name	Description
	USB_DEVICE_CLIENT_STATUS	Enumerated data type that identifies the USB Device Layer Client Status.
	USB_DEVICE_CONTROL_STATUS	USB Device Layer Control Transfer Status Stage flags.
	USB_DEVICE_CONTROL_TRANSFER_RESULT	Enumerated data type identifying results of a control transfer.
	USB_DEVICE_EVENT	USB Device Layer Events.
	USB_DEVICE_POWER_STATE	Enumerated data type that identifies if the device is self powered or bus powered .
	USB_DEVICE_REMOTE_WAKEUP_STATUS	Enumerated data type that identifies if the remote wakeup status of the device.
	USB_DEVICE_RESULT	USB Device Layer Results Enumeration
	USB_DEVICE_TRANSFER_FLAGS	Enumerated data type that identifies the USB Device Layer Transfer Flags.

Functions

	Name	Description
	USB_DEVICE_ActiveConfigurationGet	Informs the client of the current USB device configuration set by the USB host.
	USB_DEVICE_ActiveSpeedGet	Informs the client of the current operation speed of the USB bus.
	USB_DEVICE_Attach	This function will attach the device to the USB.
	USB_DEVICE_ClientStatusGet	Returns the client specific status.
	USB_DEVICE_Close	Closes an opened handle to an instance of the USB device layer.
	USB_DEVICE_ControlReceive	Receives data stage of the control transfer from host to device.
	USB_DEVICE_ControlSend	Sends data stage of the control transfer from device to host.
	USB_DEVICE_ControlStatus	Initiates status stage of the control transfer.

	USB_DEVICE_Deinitialize	De-initializes the specified instance of the USB device layer.
	USB_DEVICE_Detach	This function will detach the device from the USB.
	USB_DEVICE_EndpointDisable	Disables a device endpoint.
	USB_DEVICE_EndpointEnable	Enables a device endpoint.
	USB_DEVICE_EndpointIsEnabled	Returns true if the endpoint is enabled.
	USB_DEVICE_EndpointIsStalled	This function returns the stall status of the specified endpoint and direction.
	USB_DEVICE_EndpointRead	Reads data received from host on the requested endpoint.
	USB_DEVICE_EndpointStall	This function stalls an endpoint in the specified direction.
	USB_DEVICE_EndpointStallClear	This function clears the stall on an endpoint in the specified direction.
	USB_DEVICE_EndpointTransferCancel	This function cancels a transfer scheduled on an endpoint.
	USB_DEVICE_EndpointWrite	This function requests a data write to a USB Device Endpoint.
	USB_DEVICE_EventHandlerSet	USB Device Layer Event Handler Callback Function set function.
	USB_DEVICE_Initialize	Creates and initializes an instance of the USB device layer.
	USB_DEVICE_IsSuspended	Returns true if the device is in a suspended state.
	USB_DEVICE_Open	Opens the specified USB device layer instance and returns a handle to it.
	USB_DEVICE_PowerStateSet	Sets power state of the device.
	USB_DEVICE_RemoteWakeupStart	This function will start the resume signaling.
	USB_DEVICE_RemoteWakeupStartTimed	This function will start a self timed Remote Wake-up.
	USB_DEVICE_RemoteWakeupStatusGet	Gets the "Remote wake-up" status of the device.
	USB_DEVICE_RemoteWakeupStop	This function will stop the resume signaling.
	USB_DEVICE_StateGet	Returns the current state of the USB device.
	USB_DEVICE_Status	Provides the current status of the USB device layer
	USB_DEVICE_Tasks	USB Device layer calls all other function driver tasks in this function. It also generates and forwards events to its clients.
	USB_DEVICE_Tasks_ISR	USB Device Layer Tasks routine to be called in the USB Interrupt Service Routine.
	USB_DEVICE_Tasks_ISR_USBDMA	This is function USB_DEVICE_Tasks_ISR_USBDMA.

Macros

	Name	Description
	USB_DEVICE_EVENT_RESPONSE_NONE	Device Layer Event Handler Function Response Type.
	USB_DEVICE_HANDLE_INVALID	Constant that defines the value of an Invalid Device Handle.
	USB_DEVICE_INDEX_0	USB device layer index definitions.
	USB_DEVICE_INDEX_1	This is macro USB_DEVICE_INDEX_1.
	USB_DEVICE_INDEX_2	This is macro USB_DEVICE_INDEX_2.
	USB_DEVICE_INDEX_3	This is macro USB_DEVICE_INDEX_3.
	USB_DEVICE_INDEX_4	This is macro USB_DEVICE_INDEX_4.
	USB_DEVICE_INDEX_5	This is macro USB_DEVICE_INDEX_5.
	USB_DEVICE_TRANSFER_HANDLE_INVALID	Constant that defines the value of an Invalid Device Endpoint Data Transfer Handle.

Structures

	Name	Description
	USB_DEVICE_EVENT_DATA_CONFIGURED	USB Device Set Configuration Event Data type.
	USB_DEVICE_EVENT_DATA_ENDPOINT_READ_COMPLETE	USB Device Layer Endpoint Read and Write Complete Event Data type.
	USB_DEVICE_EVENT_DATA_ENDPOINT_WRITE_COMPLETE	USB Device Layer Endpoint Read and Write Complete Event Data type.
	USB_DEVICE_EVENT_DATA_SET_DESCRIPTOR	USB Device Set Descriptor Event Data type.
	USB_DEVICE_EVENT_DATA_SOF	USB Device Start Of Frame Event Data Type
	USB_DEVICE_EVENT_DATA_SYNCH_FRAME	USB Device Synch Frame Event Data type.
	USB_DEVICE_FUNCTION_REGISTRATION_TABLE	USB Device Function Registration Structure
	USB_DEVICE_INIT	USB Device Initialization Structure
	USB_DEVICE_MASTER_DESCRIPTOR	USB Device Master Descriptor Structure.

Types

	Name	Description
	USB_DEVICE_CONFIGURATION_DESCRIPTORS_TABLE	Pointer to an array that contains pointer to configuration descriptors.
	USB_DEVICE_EVENT_HANDLER	USB Device Layer Event Handler Function Pointer Type
	USB_DEVICE_EVENT_RESPONSE	Device Layer Event Handler function return type.
	USB_DEVICE_HANDLE	Data type for USB device handle.
	USB_DEVICE_STRING_DESCRIPTORS_TABLE	Pointer to an array that contains pointer to string descriptors.
	USB_DEVICE_TRANSFER_HANDLE	Data type for USB Device Endpoint Data Transfer Handle.

Description

USB Device Layer Interface Definition

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the USB device layer. This application should include this file if it needs to use the USB Device Layer API.

Enumerations

	Name	Description
	_USB_HOST_IRP_STATUS	Enumerates the possible status options of USB Host IRP.
	USB_DATA_DIRECTION	Defines the communication direction
	USB_DEVICE_IRP_FLAG	USB Device IRP flags enumeration
	USB_DEVICE_IRP_STATUS	Enumerates the possible status options of USB Device IRP.
	USB_ERROR	Enumeration of all possible error codes that are returned by various components functions in the USB Stack.
	USB_HOST_IRP_FLAG	USB Host IRP flags enumeration
	USB_HOST_IRP_STATUS	Enumerates the possible status options of USB Host IRP.
	USB_SPEED	Provides enumeration of USB 2.0 speeds.

Macros

	Name	Description
	USB_ENDPOINT_AND_DIRECTION	This macro helps in setting up the USB_ENDPOINT type.

Structures

	Name	Description
	_USB_DEVICE_IRP	This structure defines the USB Device Mode IRP data structure.
	_USB_HOST_IRP	This structure defines the USB Host Mode IRP data structure.
	USB_DEVICE_IRP	This structure defines the USB Device Mode IRP data structure.
	USB_HOST_IRP	This structure defines the USB Host Mode IRP data structure.

Types

	Name	Description
	USB_ENDPOINT	Defines a type to store Endpoint and Direction. The MSB defines the direction. The lower 4 bits defines the endpoint.

Description

USB Common Definitions File

This file contains definitions that are used by various components of the USB stack. This file is included by the USB Device and Host stack files. The application may typically not need to include this file directly.

File Name

usb_common.h

Company

Microchip Technology Inc.

usb_device_config_template.h

USB device configuration template header file.

Macros

	Name	Description
	USB_DEVICE_BOS_DESCRIPTOR_SUPPORT_ENABLE	Specifies if the Device Layer should process a Host request for a BOS descriptor.
	USB_DEVICE_DRIVER_INITIALIZE_EXPLICIT	Specifies if the USB Controller Driver must be initialized explicitly as opposed to being initialized by the Device Layer.
	USB_DEVICE_ENDPOINT_QUEUE_DEPTH_COMBINED	Specifies the combined endpoint queue depth in case of a vendor USB device implementation.
	USB_DEVICE_EP0_BUFFER_SIZE	Buffer Size in Bytes for Endpoint 0.
	USB_DEVICE_INSTANCES_NUMBER	Number of Device Layer instances to provisioned in the application.
	USB_DEVICE_MICROSOFT_OS_DESCRIPTOR_SUPPORT_ENABLE	Specifies if the USB Device stack should support Microsoft OS Descriptor.
	USB_DEVICE_SET_DESCRIPTOR_EVENT_ENABLE	Enables the Device Layer Set Descriptor Event.
	USB_DEVICE_SOF_EVENT_ENABLE	Enables the Device Layer SOF event.
	USB_DEVICE_STRING_DESCRIPTOR_TABLE_ADVANCED_ENABLE	Specifying this macro enables the Advanced String Descriptor Table Entry Format.
	USB_DEVICE_SYNCH_FRAME_EVENT_ENABLE	Enables the Device Layer Synch Frame Event.

USB CDC Device Library

This section describes the USB CDC Device Library.

Introduction

This help section provides information on library design, configuration, usage and the Library Interface for the USB Communications Device Class (CDC) Device Library.

Description

The MPLAB Harmony USB Communications Device Class (CDC) Device Library (also referred to as the CDC function driver or library) provides functions and methods that allow application designers to implement a USB CDC Device. The current version of the library supports the Abstract Control Model (ACM) of the CDC specification revision 1.2 and specifically implements a subset of the AT250 command set. This library must be used in conjunction with the MPLAB Harmony USB Device Layer.

Using the Library

This topic describes the basic architecture of the USB CDC Device Library and provides information and examples on its use.

Library Overview

The USB CDC Device Library mainly interacts with the system, its clients and function drivers, as shown in the Abstraction Model.

The library interface routines are divided into sub-sections, which address one of the blocks or the overall operation of the USB CDC Device Library.

Library Interface Section	Description
Functions	Provides event handler, read/write, and serial state notification functions.

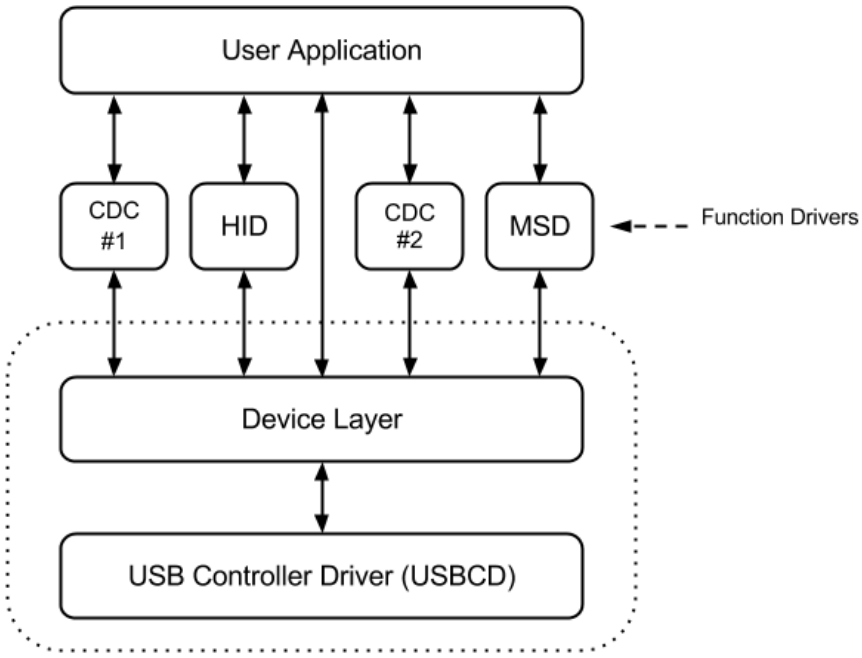
Abstraction Model

Provides an architectural overview of the CDC Function Driver.

Description

The CDC Function Driver offers services to a USB CDC Device to communicate with the host by abstracting the USB specification details. It must be used along with the USB Device Layer and USB controller to communicate with the USB Host. Figure 1 shows a block diagram of the MPLAB Harmony USB Architecture and where the CDC Function Driver is placed.

Figure 1: CDC Function Driver



As shown in Figure 1, the USB Controller Driver takes the responsibility of managing the USB peripheral on the device. The USB Device Layer handles the device enumeration, etc. The USB Device layer forwards all USB CDC specific control transfers to the CDC Function Driver. The CDC Function Driver ACM sub-layer interprets the control transfers and requests application's intervention through event handlers and well defined set of API. The application must register a event handler with the CDC Function Driver in the Device Layer Set Configuration Event. The application should respond to CDC ACM events. Response to CDC ACM event that require control transfer response can be deferred by responding to the event after returning from the event handler. The application interacts directly with the CDC Function Driver to send/receive data and to send serial state notifications.

As per the CDC specification,a USB CDC Device is a collection of the following interfaces:

- Communication Interface (Device Management) on Endpoint 0
- Optional Communication Interface (Notification) on an interrupt endpoint
- Optional Data Interface (either a bulk or isochronous endpoint)

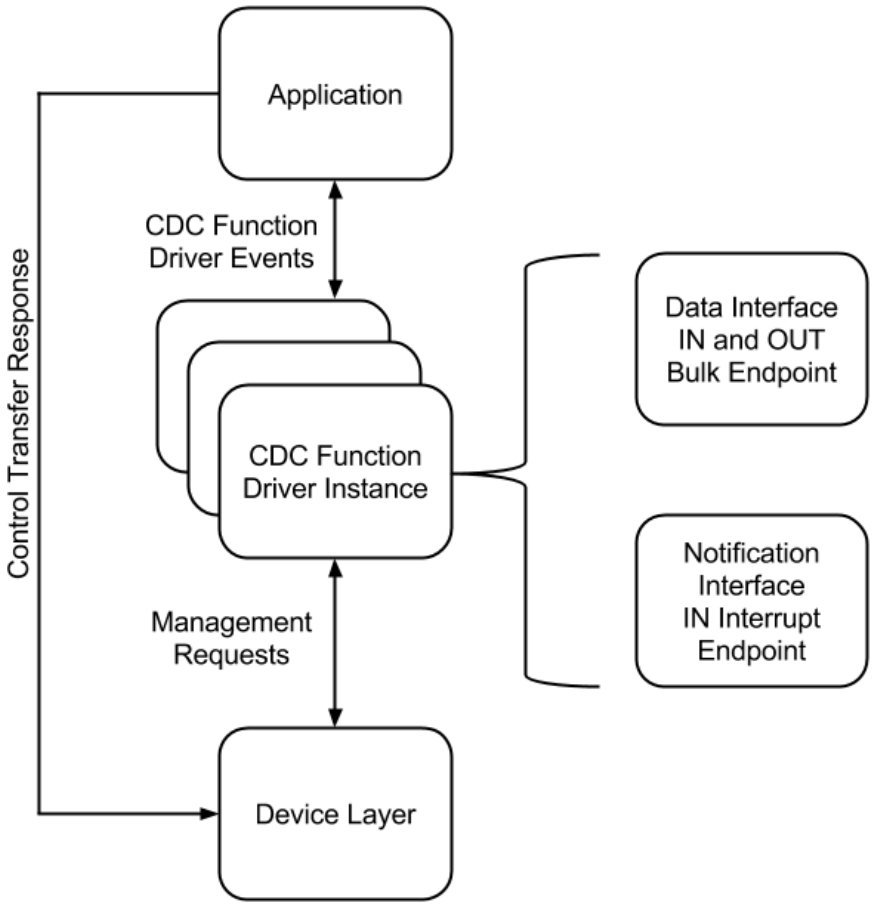


Figure 2: CDC Function Driver Architecture

Figure 2 shows the architecture of the CDC Function Driver. The device management on Endpoint 0 is handled by the device library(class specific requests are routed to the CDC Function Driver by the USB Device Layer). An instance of the CDC Function Driver actually consists of a data interface and a notification interface. The library is implemented in two `.c` files. The `usb_device_cdc.c` file implements the CDC data and serial state notification, while the `usb_device_cdc_acm.c` file implements the control transfer interpretation and event generation. The application must respond to control transfer related CDC ACM events by directly calling the Device Layer control transfer routines.

Abstract Control Model (ACM)

Describes the various Abstract Control Model (ACM) commands supported by this CDC Function Driver implementation.

Description

One of the basic supported models for communication by CDC is POTS (Plain Old Telephone Service). The POTS model is for devices that communicate via ordinary phone lines and generic COM port devices. The USB CDC specification refers to this basic model as PSTN (Public Switched Telephone Network).

Depending on the amount of data processing the device is responsible for POTS/PSTN is divided into several models. The processing of data can include modulation, demodulation, error correction and data compression.

Of the supported PSTN models, this CDC Function Driver implements ACM. In the ACM the device handles modulation, demodulation and handles V.25ter (AT) commands. This model (ACM) also supports requests and notifications to get and set RS-232 status, control, and asynchronous port part parameters. Virtual COM port devices use ACM.

The following sections describe the management requests and notifications supported by the CDC Function Driver ACM layer.

Management Requests

The Host requests/sends some information in the form of management requests on the bidirectional Endpoint 0. The following table shows the CDC specification ACM sub class management requests and how these request are handled by the CDC Function Driver.

Request Code	Required/Optional	Comments
SEND_ENCAPSULATED_COMMAND	Required	Implemented by the CDC Function Driver ACM layer. This request is stalled.
GET_ENCAPSULATED_RESPONSE	Required	Implemented by the CDC Function Driver ACM layer. This request is stalled.
SET_COMM_FEATURE	Optional	Not Implemented.

GET_COMM_FEATURE	Optional	Not Implemented.
CLEAR_COMM_FEATURE	Optional	Not Implemented.
SET_LINE_CODING	Optional	Implemented by the CDC Function Driver ACM layer. Requires application response.
GET_LINE_CODING	Optional	Implemented by the CDC Function Driver ACM layer. Requires application response.
SET_CONTROL_LINE_STATE	Optional	Implemented by the CDC Function Driver ACM layer. Requires application response.
SEND_BREAK	Optional	Implemented by the CDC Function Driver ACM layer. Requires application response.

How the Library Works

Library Initialization

Describes how the CDC Function Driver is initialized.

Description

The CDC Function Driver instance for a USB device configuration is initialized by the Device Layer when the configuration is set by the host. This process does not require application intervention. Each instance of the CDC Function Driver should be registered with the Device layer through the Device Layer Function Driver Registration Table. The CDC Function Driver does require a initialization data structure to be defined for each instance of the function driver. This initialization data structure should be of the type USB_DEVICE_CDC_INIT. This data structure specifies the read and write queue sizes. The funcDriverInit member of the function driver registration table entry for the CDC Function Driver instance should be set to point to the corresponding initialization data structure. The USB_DEVICE_CDC_FUNCTION_DRIVER object is a global object provided by the CDC Function Driver and points to the CDC Function Driver - Device Layer interface functions, which are required by the Device Layer. The following code an example of how multiple instances of CDC Function Driver can registered with the Device Layer.

```
/* This code shows an example of how two CDC function
 * driver instances can be registered with the Device Layer
 * via the Device Layer Function Driver Registration Table.
 * In this case Device Configuration 1 consists of two CDC
 * function driver instances. */

        .driver = USB_DEVICE_CDC_FUNCTION_DRIVER    // Pointer to Function Driver - Device Layer interface
functions
    },
};
```

Event Handling

Describes CDC Function Driver event handler registration and event handling.

Description

Registering a CDC Function Driver Event Handler

While creating USB CDC Device-based application, an event handler must be registered with the Device Layer (the Device Layer Event Handler) and every CDC Function Driver instance (CDC Function Driver Event Handler). The CDC Function Driver event handler receives CDC and CDC ACM events. This event handler should be registered before the USB device layer acknowledges the SET CONFIGURATION request from the USB Host. To ensure this, the event handler should be set in the USB_DEVICE_EVENT_CONFIGURED event that is generated by the device layer. While registering the CDC Function Driver event handler, the CDC Function Driver allows the application to also pass a data object in the event handler register function. This data object gets associated with the instance of the CDC Function Driver and is returned by the CDC Function Driver when a CDC Function Driver event occurs. The following code shows an example of how this can be done.

```
/* This is a sample Application Device Layer Event Handler
* Note how the CDC Function Driver event handler APP_USBDeviceCDCEventHandler()
* is registered in the USB_DEVICE_EVENT_CONFIGURED event. The appData
* object that is passed in the USB_DEVICE_CDC_EventHandlerSet()
* function will be returned as the userData parameter in the
* when the APP_USBDeviceCDCEventHandler() function is invoked */

   /* Application states */
    typedef enum
    {
        /* Application's state machine's initial state. */
        APP_STATE_INIT=0,
        APP_STATE_SERVICE_TASKS,
        APP_STATE_WAIT_FOR_CONFIGURATION,
    } APP_STATES;

    USB_DEVICE_HANDLE usbDeviceHandle;
    APP_STATES appState;

    /* This is the application device layer event handler function. */

    USB_DEVICE_EVENT_RESPONSE APP_USBDeviceEventHandler
    (
        USB_DEVICE_EVENT event,
        void * eventData,
        uintptr_t context
    )
    {
        uint8_t activeConfiguration;
        USB_SETUP_PACKET * setupPacket;
        switch(event)
        {
            case USB_DEVICE_EVENT_POWER_DETECTED:
                /* This event in generated when VBUS is detected. Attach the device */
                USB_DEVICE_Attach(usbDeviceHandle);
                break;

            case USB_DEVICE_EVENT_POWER_REMOVED:
                /* This event is generated when VBUS is removed. Detach the device */
                USB_DEVICE_Detach (usbDeviceHandle);
                break;

            case USB_DEVICE_EVENT_CONFIGURED:
                /* This event indicates that Host has set Configuration in the Device.*/
                /* Check the configuration */
                activeConfiguration = ((USB_DEVICE_EVENT_DATA_CONFIGURED *)pData)->configurationValue;
                if ( activeConfiguration == 1)
                {
```

```
                    /* Register the CDC Device application event handler here.
                    * Note how the appData object pointer is passed as the
                    * user data */
                    USB_DEVICE_CDC_EventHandlerSet(USB_DEVICE_CDC_INDEX_0, APP_USBDeviceCDCEventHandler,
                                                   (uintptr_t)&appData);
                    /* Mark that set configuration is complete */
                    appData.isConfigured = true;
                }
                break;

            case USB_DEVICE_EVENT_CONTROL_TRANSFER_SETUP_REQUEST:
                /* This event indicates a Control transfer setup stage has been completed. */
                setupPacket = (USB_SETUP_PACKET *)eventData;

                /* Parse the setup packet and respond with a USB_DEVICE_ControlSend(),
                   USB_DEVICE_ControlReceive or USB_DEVICE_ControlStatus(). */

                break;

            case USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_SENT:
                /* This event indicates that a Control transfer Data has been sent to Host. */
                break;

            case USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_RECEIVED:
                /* This event indicates that a Control transfer Data has been received from Host. */
                break;

            case USB_DEVICE_EVENT_CONTROL_TRANSFER_ABORTED:
                /* This event indicates a control transfer was aborted. */
                break;

            case USB_DEVICE_EVENT_SUSPENDED:
                break;

            case USB_DEVICE_EVENT_RESUMED:
                break;

            case USB_DEVICE_EVENT_ERROR:
                break;

            case USB_DEVICE_EVENT_RESET:
                break;

            case USB_DEVICE_EVENT_SOF:
                /* This event indicates an SOF is detected on the bus. The USB_DEVICE_SOF_EVENT_ENABLE
                   macro should be defined to get this event. */
                break;
            default:
                break;
        }
    }
```

The CDC Function Driver event handler executes in an interrupt context when the device stack is configured for Interrupt mode. In Polled mode, the event handler is invoked in the context of the SYS_Tasks function. The application should not call computationally intensive functions, blocking functions, functions that are not interrupt safe, or functions that poll on hardware conditions from the event handler. Doing so will affect the ability of the USB device stack to respond to USB events and could potentially make the USB device non-compliant.

CDC Function Driver Events

The CDC Function Driver generates events to which the application must respond. Some of these events are management requests communicated through control transfers. Therefore, the application must use the Device Layer Control Transfer routines to complete the control transfer. Based on the generated event, the application may be required to:

- Respond with a USB_DEVICE_ControlSend function, which is completes the data stage of a Control Read Transfer
- Respond with a USB_DEVICE_ControlReceive function, which provisions the data stage of a Control Write Transfer
- Respond with a USB_DEVICE_ControlStatus function, which completes the handshake stage of the Control Transfer. The application can either STALL or Acknowledge the handshake stage via the USB_DEVICE_ControlStatus function. The following table shows the CDC Function Driver Control Transfer related events and the required application control transfer actions.

CDC Function Driver Control Transfer Event	Required Application Action
USB_DEVICE_CDC_EVENT_SET_LINE_CODING	Call USB_DEVICE_ControlReceive function with a buffer to receive the USB_CDC_LINE_CODING type data.
USB_DEVICE_CDC_EVENT_SET_LINE_CODING	Call USB_DEVICE_ControlSend function with a buffer that contains the current USB_CDC_LINE_CODING type data.
USB_DEVICE_CDC_EVENT_SET_CONTROL_LINE_STATE	Acknowledge or stall using the USB_DEVICE_ControlStatus function.
USB_DEVICE_CDC_EVENT_SET_CONTROL_LINE_STATE	Acknowledge or stall using the USB_DEVICE_ControlStatus function.
USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_SENT	Action not required.
USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_RECEIVED	Acknowledge or stall using the USB_DEVICE_ControlStatus function.

Based on the type of event, the application should analyze the pData member of the event handler. This data member should be type cast to an event specific data type. The following table shows the event and the data type to use while type casting. Note that the pData member is not required for all events

CDC Function Driver Event	Related pData type
USB_DEVICE_CDC_EVENT_SET_LINE_CODING	NULL
USB_DEVICE_CDC_EVENT_GET_LINE_CODING	NULL
USB_DEVICE_CDC_EVENT_SET_CONTROL_LINE_STATE	USB_CDC_CONTROL_LINE_STATE *
USB_DEVICE_CDC_EVENT_SEND_BREAK	USB_DEVICE_CDC_EVENT_DATA_SEND_BREAK *
USB_DEVICE_CDC_EVENT_WRITE_COMPLETE	USB_DEVICE_CDC_EVENT_DATA_WRITE_COMPLETE *
USB_DEVICE_CDC_EVENT_READ_COMPLETE	USB_DEVICE_CDC_EVENT_DATA_READ_COMPLETE *
USB_DEVICE_CDC_EVENT_SERIAL_STATE_NOTIFICATION_COMPLETE	USB_DEVICE_CDC_EVENT_DATA_SERIAL_STATE_NOTIFICATION_COMPLETE *
USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_SENT	NULL
USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_RECEIVED	NULL

The possible CDC Function Driver events are described here with the required application response, event specific data, and likely follow-up function driver event:

USB_DEVICE_CDC_EVENT_SET_LINE_CODING

Application Response: This event occurs when the host issues a SET LINE CODING command. The application must provide a USB_CDC_LINE_CODING data structure to the device layer to receive the line coding data that the host will provide. The application must provide the buffer by calling the USB_DEVICE_CDC_ControlReceive function either in the event handler or in the application after returning from the event handler. The application can use the USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_SENT event to track completion of the command.

Event Specific Data (pData): The pData parameter will be NULL.

Likely Follow-up event: This event will likely be followed by the USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_RECEIVED event. This indicates that the data was received successfully. The application must either acknowledge or stall the handshake stage of the control transfer by calling the USB_DEVICE_ControlStatus function with the USB_DEVICE_CONTROL_STATUS_OK or USB_DEVICE_CONTROL_STATUS_ERROR flag, respectively.

USB_DEVICE_CDC_EVENT_GET_LINE_CODING

Application Response: This event occurs when the host issues a GET LINE CODING command. The application must provide a USB_CDC_LINE_CODING data structure to the device layer that contains the line coding data to be provided to the Host. The application must provide the buffer by calling the USB_DEVICE_ControlSend function either in the event handler or in the application after returning from the event handler. The size of the buffer is indicated by the length parameter. The application can use the USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_SENT event to track completion of the command.

Event Specific Data (pData): The pData parameter will be NULL.

Likely Follow-up event: This event will likely be followed by the USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_SENT event. This indicates that the data was sent to the Host successfully.

USB_DEVICE_CDC_EVENT_SET_CONTROL_LINE_STATE

Application Response: This event occurs when the host issues a SET CONTROL LINE STATE command. The application can then use the USB_DEVICE_ControlStatus function to indicate acceptance of rejection of the command. The USB_DEVICE_ControlStatus function can be

called from the event handler or in the application after returning from the event handler.

Event Specific Data (pData): The application must interpret the pData parameter as a pointer to a USB_CDC_CONTROL_LINE_STATE data type that contains the control line state data.

Likely Follow-up event: None.

USB_DEVICE_CDC_EVENT_SEND_BREAK

Application Response: This event occurs when the Host issues a SEND BREAK command. The application can then use the USB_DEVICE_ControlStatus function to indicate acceptance or rejection of the command. The USB_DEVICE_ControlStatus function can be called from the event handler or in the application after returning from the event handler.

Event Specific Data (pData): The application must interpret the pData parameter as a pointer to a uint16_t data type that contains the break duration data.

Likely Follow-up event: None.

USB_DEVICE_CDC_EVENT_WRITE_COMPLETE

Application Response: This event occurs when a write operation scheduled by calling the USB_DEVICE_CDC_Write function has completed. This event does not require the application to respond with any function calls.

Event Specific Data (pData): The pData member in the event handler will point to the USB_DEVICE_CDC_EVENT_DATA_WRITE_COMPLETE data type.

Likely Follow-up event: None.

USB_DEVICE_CDC_EVENT_READ_COMPLETE

Application Response: This event occurs when a read operation scheduled by calling the USB_DEVICE_CDC_Read function has completed. This event does not require the application to respond with any function calls.

Event Specific Data (pData): The pData member in the event handler will point to the USB_DEVICE_CDC_EVENT_DATA_READ_COMPLETE type.

Likely Follow-up event: None.

USB_DEVICE_CDC_EVENT_SERIAL_STATE_NOTIFICATION_COMPLETE

Application Response: This event occurs when a serial state notification send scheduled by calling the USB_DEVICE_CDC_SerialStateNotificationSend function has completed. This event does not require the application to respond with any function calls.

Event Specific Data (pData): The pData member in the event handler will point to the USB_DEVICE_CDC_EVENT_DATA_SERIAL_STATE_NOTIFICATION_COMPLETE data type.

Likely Follow-up event: None.

USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_SENT

Application Response: This event occurs when the data stage of a control read transfer has completed in response to the USB_DEVICE_ControlSend function (in the USB_DEVICE_CDC_EVENT_GET_LINE_CODING event). The application must acknowledge the handshake stage of the control transfer by calling the USB_DEVICE_ControlStatus function with the USB_DEVICE_CONTROL_STATUS_OK flag.

Event Specific Data (pData): The pData parameter will be NULL.

Likely Follow-up event: None.

USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_RECEIVED

Application Response: This event occurs when the data stage of a control write transfer has completed in response to the USB_DEVICE_ControlReceive function (in the USB_DEVICE_CDC_EVENT_SET_LINE_CODING event).

Event Specific Data (pData): The pData parameter will be NULL.

Likely Follow-up event: None.

CDC Function Driver Event Handling

The following code shows an event handling scheme example. The application always returns from the event handler with a USB_DEVICE_CDC_EVENT_RESPONSE_NONE value.

```
    // This code example shows all CDC Function Driver possible events
    // and a possible scheme for handling these events. In this case
    // event responses are not deferred.

    uint16_t * breakData;
    USB_DEVICE_HANDLE    usbDeviceHandle;
    USB_CDC_LINE_CODING  lineCoding;
    USB_CDC_CONTROL_LINE_STATE * controlLineStateData
```

```
USB_DEVICE_CDC_EVENT_RESPONSE USBDeviceCDCEventHandler
(
    USB_DEVICE_CDC_INDEX instanceIndex,
    USB_DEVICE_CDC_EVENT event,
    void * data,
    uintptr_t userData
)
{
    switch(event)
    {
        case USB_DEVICE_CDC_EVENT_SET_LINE_CODING:

            // In this case, the application should read the line coding
            // data that is sent by the host.

            USB_DEVICE_ControlReceive(usbDeviceHandle, &lineCoding,
                                sizeof(USB_CDC_LINE_CODING));
            break;

        case USB_DEVICE_CDC_EVENT_GET_LINE_CODING:

            // In this case, the application should send the line coding
            // data to the host.

            USB_DEVICE_ControlSend(usbDeviceHandle, &lineCoding,
                                sizeof(USB_CDC_LINE_CODING));
            break;

        case USB_DEVICE_CDC_EVENT_SET_CONTROL_LINE_STATE:

            // In this case, pData should be interpreted as a
            // USB_CDC_CONTROL_LINE_STATE pointer type.  The application
            // acknowledges the parameters by calling the
            // USB_DEVICE_ControlStatus() function with the
            // USB_DEVICE_CONTROL_STATUS_OK option.

            controlLineStateData = (USB_CDC_CONTROL_LINE_STATE *)pData;
            USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_OK);

            break;

        case USB_DEVICE_CDC_EVENT_SEND_BREAK:

            // In this case, pData should be interpreted as a uint16_t
            // pointer type to the break duration. The application
            // acknowledges the parameters by calling the
            // USB_DEVICE_ControlStatus() function with the
            // USB_DEVICE_CONTROL_STATUS_OK option.

            breakDuration = (USB_DEVICE_CDC_EVENT_DATA_SEND_BREAK *)pData;
            USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_OK);

            break;

        case USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_SENT:

            // This event indicates the data send request associated with
            // the latest USB_DEVICE_ControlSend() function was
            // completed.  The application could use this event to track
            // the completion of the USB_DEVICE_CDC_EVENT_GET_LINE_CODING
            // request.

            break;
        case USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_RECEIVED:

            // This means that the data stage is complete. The data in
            // setLineCodingData is valid or data in getLineCodingData was
            // sent to the host.  The application can now decide whether it
            // supports this data. It is not mandatory to do this in the
```

```
                // event handler.

                USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_OK);

            case USB_DEVICE_CDC_EVENT_WRITE_COMPLETE:

                // This means USB_DEVICE_CDC_Write() operation completed.
                // The pData member will point to a
                // USB_DEVICE_CDC_EVENT_DATA_WRITE_COMPLETE type of data.

                break;
            case USB_DEVICE_CDC_EVENT_READ_COMPLETE:

                // This means USB_DEVICE_CDC_Read() operation completed.
                // The pData member will point to a
                // USB_DEVICE_CDC_EVENT_DATA_READ_COMPLETE type of data.

                break;

            case USB_DEVICE_CDC_EVENT_SERIAL_STATE_NOTIFICATION_COMPLETE:

                // This means USB_DEVICE_CDC_SerialStateNotification() operation
                // completed. The pData member will point to a
                // USB_DEVICE_CDC_EVENT_DATA_SERIAL_STATE_NOTIFICATION_COMPLETE type of data.

                break;

             default:
                break;
        }

        return(USB_DEVICE_CDC_EVENT_RESPONSE_NONE);
    }
```

Refer to the USB_DEVICE_CDC_EVENT enumeration for more details on each event.

Sending Data

Describes how to send data to the CDC Host.

Description

The application may need to send data or serial state notification to the USB CDC Host. This is done by using the USB_DEVICE_CDC_Write and USB_DEVICE_CDC_SerialStateNotificationSend functions, respectively.

Sending Data to the USB Host

The application can send data to the Host by using the USB_DEVICE_CDC_Write function. This function returns a transfer handle that allows the application to track the write request. The request is completed when the Host has requested the data. The completion of the write transfer is indicated by a USB_DEVICE_CDC_EVENT_WRITE_COMPLETE event. A write request could fail if the function driver instance transfer queue is full.

The USB_DEVICE_CDC_Write function also allows the application to send data to the host without ending the transfer. This is done by specifying the USB_DEVICE_CDC_TRANSFER_FLAGS_DATA_PENDING flag. The application can use this option when the data to be sent is not readily available or when the application is memory constrained. The combination of the transfer flag and the transfer size affects how the function driver sends the data to the host:

- If size is a multiple of maxPacketSize (the IN endpoint size), and the flag is set as USB_DEVICE_CDC_TRANSFER_FLAGS_DATA_COMPLETE, the write function will append a Zero Length Packet (ZLP) to complete the transfer
- If size is a multiple of maxPacketSize, and the flag is set as USB_DEVICE_CDC_TRANSFER_FLAGS_MORE_DATA_PENDING, the write function will not append a ZLP and therefore, will not complete the transfer
- If size is greater than but not a multiple of maxPacketSize, and the flag is set as USB_DEVICE_CDC_TRANSFER_FLAGS_DATA_COMPLETE, the write function schedules (length/maxPacketSize) packets and one packet for the residual data
- If size if greater than but not a multiple of maxPacketSize, and the flag is set as USB_DEVICE_CDC_TRANSFER_FLAGS_MORE_DATA_PENDING, the write function returns an error code and sets the transferHandle parameter to USB_DEVICE_CDC_TRANSFER_HANDLE_INVALID
- If size is less than maxPacketSize, and the flag is set as USB_DEVICE_CDC_TRANSFER_FLAGS_DATA_COMPLETE, the write function schedules one packet
- If size is less than maxPacketSize, and the flag is set as USB_DEVICE_CDC_TRANSFER_FLAGS_MORE_DATA_PENDING, the write

function returns an error code and sets the transferHandle parameter to USB_DEVICE_CDC_TRANSFER_HANDLE_INVALID

The following code shows a set of examples of various conditions attempting to send data with the USB_DEVICE_CDC_Write command.

Example 1

```
// This example assume that the maxPacketSize is 64.
USB_DEVICE_CDC_TRANSFER_HANDLE transferHandle;
USB_DEVICE_CDC_INDEX instance;
USB_DEVICE_CDC_RESULT writeRequestResult;
uint8_t data[34];

// In this example we want to send 34 bytes only.
writeRequestResult = USB_DEVICE_CDC_Write(instance,&transferHandle, data, 34,
                                          USB_DEVICE_CDC_TRANSFER_FLAGS_DATA_COMPLETE);
if(USB_DEVICE_CDC_RESULT_OK != writeRequestResult)
{
    //Do Error handling here
}
```

Example 2

```
//------------------------------------------------------
// In this example we want to send 64 bytes only.
// This will cause a ZLP to be sent.

USB_DEVICE_CDC_TRANSFER_HANDLE transferHandle;
USB_DEVICE_CDC_INDEX instance;
USB_DEVICE_CDC_RESULT writeRequestResult;
uint8_t data[64];

writeRequestResult = USB_DEVICE_CDC_Write(instance,&transferHandle, data, 64,
                                          USB_DEVICE_CDC_TRANSFER_FLAGS_DATA_COMPLETE);
if(USB_DEVICE_CDC_RESULT_OK != writeRequestResult)
{
//Do Error handling here
}
```

Example 3

```
//------------------------------------------------------
// This example will return an error because size is less
// than maxPacketSize and the flag indicates that more
// data is pending.

USB_DEVICE_CDC_TRANSFER_HANDLE transferHandle;
USB_DEVICE_CDC_INDEX instance;
USB_DEVICE_CDC_RESULT writeRequestResult;
uint8_t data[64];

writeRequestResult = USB_DEVICE_CDC_Write(instance,&transferHandle, data, 32,
                                    USB_DEVICE_CDC_TRANSFER_FLAGS_MORE_DATA_PENDING);
```

Example 4

```
//------------------------------------------------------
// In this example we want to place a request for a 70 byte transfer.
// The 70 bytes will be sent out in a 64 byte transaction and a 6 byte
// transaction completing the transfer.

USB_DEVICE_CDC_TRANSFER_HANDLE transferHandle;
USB_DEVICE_CDC_INDEX instance;
USB_DEVICE_CDC_RESULT writeRequestResult;
uint8_t data[70];

writeRequestResult = USB_DEVICE_CDC_Write(instance,&transferHandle, data, 70,
                                          USB_DEVICE_CDC_TRANSFER_FLAGS_DATA_COMPLETE);

if(USB_DEVICE_CDC_RESULT_OK != writeRequestResult)
{
//Do Error handling here
}
```

Example 5

```
//------------------------------------------------------
// In this example we want to place a request for a 70 bytes to be sent
```

```
// but that we don't end the transfer as more data is coming. 64 bytes
// of the 70 will be sent out and the USB_DEVICE_CDC_EVENT_WRITE_COMPLETE
// with 64 bytes. This indicates that the extra 6 bytes weren't
// sent because it would cause the end of the transfer. Thus the
// user needs to add these 6 bytes back to the buffer for the next group
// of data that needs to be sent out.

USB_DEVICE_CDC_TRANSFER_HANDLE transferHandle;
USB_DEVICE_CDC_INDEX instance;
USB_DEVICE_CDC_RESULT writeRequestResult;
uint8_t data[70];

writeRequestResult = USB_DEVICE_CDC_Write(instance,&transferHandle, data, 70,
                                          USB_DEVICE_CDC_TRANSFER_FLAGS_MORE_DATA_PENDING);

if(USB_DEVICE_CDC_RESULT_OK != writeRequestResult)
{
//Do Error handling here
}
// The completion of the write request will be indicated by the
// USB_DEVICE_CDC_EVENT_WRITE_COMPLETE event.
```

Sending a Serial State Notification

The application can send a Serial State Notification by using the USB_DEVICE_CDC_SerialStateSend function. This function returns a transfer handle that allows the application to track the read request. The request is completed when the Host has requested the data. The completion of the transfer is indicated by a USB_DEVICE_CDC_EVENT_SERIAL_STATE_NOTIFICATION_COMPLETE event. The transfer request could fail if the function driver transfer queue is full. The following code shows an example of how this can be done.

```
USB_DEVICE_CDC_INDEX instanceIndex;
USB_DEVICE_CDC_TRANSFER_HANDLE transferHandle;
USB_DEVICE_CDC_SERIAL_STATE_NOTIFICATION_DATA notificationData;

// This application function could possibly update the notificationData
// data structure.

APP_UpdateNotificationData(&notificationData);

// Now send the updated notification data to the host.

result = USB_DEVICE_CDC_SerialStateDataSend(instanceIndex, &transferHandle,
                                          &notificationData);

if(USB_DEVICE_CDC_RESULT_OK != result)
{
    // Error handling here
}
```

Receiving Data

Describes how the CDC device can read data from the Host.

Description

The application can receive data from the host by using the USB_DEVICE_CDC_Read function. This function returns a transfer handle that allows the application to track the read request. The request is completed when the Host sends the required amount or less than required amount of data. The application must make sure that it allocates a buffer size that is at least the size or a multiple of the receive endpoint size. The return value of the function indicates the success of the request. A read request could fail if the function driver transfer queue is full. The completion of the read transfer is indicated by the USB_DEVICE_CDC_EVENT_READ_COMPLETE event. The request completes based on the amount of the data that was requested and size of the transaction initiated by the Host:

- If the size parameter is not a multiple of maxPacketSize or is '0', the function returns USB_DEVICE_CDC_TRANSFER_HANDLE_INVALID in transferHandle and returns USB_DEVICE_CDC_RESULT_ERROR_TRANSFER_SIZE_INVALID as a return value
- If the size parameter is a multiple of maxPacketSize and the Host sends less than maxPacketSize data in any transaction, the transfer completes and the function driver will issue a USB_DEVICE_CDC_EVENT_READ_COMPLETE event along with the USB_DEVICE_CDC_EVENT_READ_COMPLETE_DATA data structure
- If the size parameter is a multiple of maxPacketSize and the Host sends maxPacketSize amount of data, and total data received does not exceed size, the function driver will wait for the next packet

The following code shows an example of the USB_DEVICE_CDC_Read function:

```
// Shows an example of how to read. This assumes that
// driver was opened successfully.
```

```
USB_DEVICE_CDC_TRANSFER_HANDLE transferHandle;
USB_DEVICE_CDC_RESULT readRequestResult;
USB_DEVICE_CDC_HANDLE instanceHandle;

readRequestResult = USB_DEVICE_CDC_Read(instanceHandle,
                        &transferHandle, data, 128);

if(USB_DEVICE_CDC_RESULT_OK != readRequestResult)
{
    //Do Error handling here
}

// The completion of the read request will be indicated by the
// USB_DEVICE_CDC_EVENT_READ_COMPLETE event.
```

Configuring the Library

Describes how to configure the CDC Function Driver.

Macros

	Name	Description
	USB_DEVICE_CDC_INSTANCES_NUMBER	Specifies the number of CDC instances.
	USB_DEVICE_CDC_QUEUE_DEPTH_COMBINED	Specifies the combined queue size of all CDC instances.

Description

The application designer must specify the following configuration parameters while using the CDC Function Driver. The configuration macros that implement these parameters must be located in the `system_config.h` file in the application project and a compiler include path (to point to the folder that contains this file) should be specified.

USB_DEVICE_CDC_INSTANCES_NUMBER Macro

Specifies the number of CDC instances.

File

usb_device_cdc_config_template.h

C

```
#define USB_DEVICE_CDC_INSTANCES_NUMBER
```

Description

USB device CDC Maximum Number of instances

This macro defines the number of instances of the CDC Function Driver. For example, if the application needs to implement two instances of the CDC Function Driver (to create two COM ports) on one USB Device, the macro should be set to 2. Note that implementing a USB Device that features multiple CDC interfaces requires appropriate USB configuration descriptors.

Remarks

None.

USB_DEVICE_CDC_QUEUE_DEPTH_COMBINED Macro

Specifies the combined queue size of all CDC instances.

File

usb_device_cdc_config_template.h

C

```
#define USB_DEVICE_CDC_QUEUE_DEPTH_COMBINED
```

Description

USB device CDC Combined Queue Size

This macro defines the number of entries in all queues in all instances of the CDC function driver. This value can be obtained by adding up the read and write queue sizes of each CDC Function driver instance. In a simple single instance USB CDC device application, that does not require

buffer queuing and serial state notification, the USB_DEVICE_CDC_QUEUE_DEPTH_COMBINED macro can be set to 2. Consider a case with two CDC function driver instances, CDC 1 has a read queue size of 2 and write queue size of 3, CDC 2 has a read queue size of 4 and write queue size of 1, this macro should be set to 10 (2 +3 + 4 + 1).

Remarks

None.

Building the Library

Describes the files to be included in the project while using the CDC Function Driver.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/usb`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
usb_device_cdc.h	This header file should be included in any `.c` file that accesses the USB Device CDC Function Driver API.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/dynamic/usb_device_cdc.c`	This file implements the CDC Data Interface and Communications interface and should be included in the project if the CDC Device function is desired.
`/src/dynamic/usb_device_cdc_acm.c`	This file implements the CDC-ACM layer and should be included in the project if the CDC Device function is desired.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The USB CDC Device Library depends on the following modules:

- USB Device Layer Library

Library Interface

a) Functions

	Name	Description
	USB_DEVICE_CDC_EventHandlerSet	This function registers a event handler for the specified CDC function driver instance.
	USB_DEVICE_CDC_Read	This function requests a data read from the USB Device CDC Function Driver Layer.
	USB_DEVICE_CDC_Write	This function requests a data write to the USB Device CDC Function Driver Layer.
	USB_DEVICE_CDC_SerialStateNotificationSend	This function schedules a request to send serial state notification to the host.

b) Data Types and Constants

	Name	Description
	USB_DEVICE_CDC_EVENT	USB Device CDC Function Driver Events

	USB_DEVICE_CDC_EVENT_DATA_READ_COMPLETE	USB Device CDC Function Driver Read and Write Complete Event Data.
	USB_DEVICE_CDC_EVENT_DATA_SERIAL_STATE_NOTIFICATION_COMPLETE	USB Device CDC Function Driver Read and Write Complete Event Data.
	USB_DEVICE_CDC_EVENT_DATA_WRITE_COMPLETE	USB Device CDC Function Driver Read and Write Complete Event Data.
	USB_DEVICE_CDC_EVENT_HANDLER	USB Device CDC Event Handler Function Pointer Type.
	USB_DEVICE_CDC_EVENT_RESPONSE	USB Device CDC Function Driver Event Callback Response Type
	USB_DEVICE_CDC_EVENT_DATA_SEND_BREAK	USB Device CDC Function Driver Send Break Event Data
	USB_DEVICE_CDC_INDEX	USB Device CDC Function Driver Index
	USB_DEVICE_CDC_INIT	USB Device CDC Function Driver Initialization Data Structure
	USB_DEVICE_CDC_RESULT	USB Device CDC Function Driver USB Device CDC Result enumeration.
	USB_DEVICE_CDC_TRANSFER_FLAGS	USB Device CDC Function Driver Transfer Flags
	USB_DEVICE_CDC_TRANSFER_HANDLE	USB Device CDC Function Driver Transfer Handle Definition.
	USB_DEVICE_CDC_EVENT_RESPONSE_NONE	USB Device CDC Function Driver Event Handler Response Type None.
	USB_DEVICE_CDC_TRANSFER_HANDLE_INVALID	USB Device CDC Function Driver Invalid Transfer Handle Definition.
	USB_DEVICE_CDC_FUNCTION_DRIVER	USB Device CDC Function Driver Function pointer
	USB_DEVICE_CDC_INDEX_0	Use this to specify CDC Function Driver Instance 0
	USB_DEVICE_CDC_INDEX_1	Use this to specify CDC Function Driver Instance 1
	USB_DEVICE_CDC_INDEX_2	Use this to specify CDC Function Driver Instance 2
	USB_DEVICE_CDC_INDEX_3	Use this to specify CDC Function Driver Instance 3
	USB_DEVICE_CDC_INDEX_4	Use this to specify CDC Function Driver Instance 4
	USB_DEVICE_CDC_INDEX_5	Use this to specify CDC Function Driver Instance 5
	USB_DEVICE_CDC_INDEX_6	Use this to specify CDC Function Driver Instance 6
	USB_DEVICE_CDC_INDEX_7	Use this to specify CDC Function Driver Instance 7

Description

This section describes the Application Programming Interface (API) functions of the USB CDC Device Library.

Refer to each section for a detailed description.

a) Functions

USB_DEVICE_CDC_EventHandlerSet Function

This function registers a event handler for the specified CDC function driver instance.

File

usb_device_cdc.h

C

```
USB_DEVICE_CDC_RESULT USB_DEVICE_CDC_EventHandlerSet(USB_DEVICE_CDC_INDEX instanceIndex,
USB_DEVICE_CDC_EVENT_HANDLER eventHandler, uintptr_t context);
```

Returns

USB_DEVICE_CDC_RESULT_OK - The operation was successful USB_DEVICE_CDC_RESULT_ERROR_INSTANCE_INVALID - The specified instance does not exist USB_DEVICE_CDC_RESULT_ERROR_PARAMETER_INVALID - The eventHandler parameter is NULL

Description

This function registers a event handler for the specified CDC function driver instance. This function should be called by the client when it receives a SET CONFIGURATION event from the device layer. A event handler must be registered for function driver to respond to function driver specific commands. If the event handler is not registered, the device layer will stall function driver specific commands and the USB device may not function.

Remarks

None.

Preconditions

This function should be called when the function driver has been initialized as a result of a set configuration.

Example

```
// This code snippet shows an example registering an event handler. Here
// the application specifies the context parameter as a pointer to an
// application object (appObject) that should be associated with this
// instance of the CDC function driver.

// Application states
typedef enum
{
    //Application's state machine's initial state.
    APP_STATE_INIT=0,
    APP_STATE_SERVICE_TASKS,
    APP_STATE_WAIT_FOR_CONFIGURATION,
} APP_STATES;

USB_DEVICE_HANDLE usbDeviceHandle;

APP_STATES appState;

// Get Line Coding Data
USB_CDC_LINE_CODING getLineCodingData;

// Control Line State
USB_CDC_CONTROL_LINE_STATE controlLineStateData;

// Set Line Coding Data
USB_CDC_LINE_CODING setLineCodingData;

USB_DEVICE_CDC_RESULT result;

        default:
            break;
    }
}
```

Parameters

Parameters	Description
instance	Instance of the CDC Function Driver.
eventHandler	A pointer to event handler function.
context	Application specific context that is returned in the event handler.

Function

USB_DEVICE_CDC_RESULT USB_DEVICE_CDC_EventHandlerSet
(
USB_DEVICE_CDC_INDEX instance
USB_DEVICE_CDC_EVENT_HANDLER eventHandler
uintptr_t context
);

USB_DEVICE_CDC_Read Function

This function requests a data read from the USB Device CDC Function Driver Layer.

File

usb_device_cdc.h

C

```
USB_DEVICE_CDC_RESULT USB_DEVICE_CDC_Read(USB_DEVICE_CDC_INDEX instanceIndex,
USB_DEVICE_CDC_TRANSFER_HANDLE * transferHandle, void * data, size_t size);
```

Returns

USB_DEVICE_CDC_RESULT_OK - The read request was successful. transferHandle contains a valid transfer handle.

USB_DEVICE_CDC_RESULT_ERROR_TRANSFER_QUEUE_FULL - internal request queue is full. The write request could not be added.

USB_DEVICE_CDC_RESULT_ERROR_TRANSFER_SIZE_INVALID - The specified transfer size was not a multiple of endpoint size or is 0.

USB_DEVICE_CDC_RESULT_ERROR_INSTANCE_NOT_CONFIGURED - The specified instance is not configured yet.

USB_DEVICE_CDC_RESULT_ERROR_INSTANCE_INVALID - The specified instance was not provisioned in the application and is invalid.

Description

This function requests a data read from the USB Device CDC Function Driver Layer. The function places a requests with driver, the request will get serviced as data is made available by the USB Host. A handle to the request is returned in the transferHandle parameter. The termination of the request is indicated by the USB_DEVICE_CDC_EVENT_READ_COMPLETE event. The amount of data read and the transfer handle associated with the request is returned along with the event in the pData parameter of the event handler. The transfer handle expires when event handler for the USB_DEVICE_CDC_EVENT_READ_COMPLETE exits. If the read request could not be accepted, the function returns an error code and transferHandle will contain the value USB_DEVICE_CDC_TRANSFER_HANDLE_INVALID.

If the size parameter is not a multiple of maxPacketSize or is 0, the function returns USB_DEVICE_CDC_TRANSFER_HANDLE_INVALID in transferHandle and returns an error code as a return value. If the size parameter is a multiple of maxPacketSize and the host send less than maxPacketSize data in any transaction, the transfer completes and the function driver will issue a USB_DEVICE_CDC_EVENT_READ_COMPLETE event along with the USB_DEVICE_CDC_EVENT_READ_COMPLETE_DATA data structure. If the size parameter is a multiple of maxPacketSize and the host sends maxPacketSize amount of data, and total data received does not exceed size, then the function driver will wait for the next packet.

Remarks

While the using the CDC Function Driver with the PIC32MZ USB module, the receive buffer provided to the USB_DEVICE_CDC_Read function should be placed in coherent memory and aligned at a 16 byte boundary. This can be done by declaring the buffer using the __attribute__((coherent, aligned(16))) attribute. An example is shown here

```
uint8_t data[256] __attribute__((coherent, aligned(16)));
```

Preconditions

The function driver should have been configured.

Example

```
// Shows an example of how to read. This assumes that
// driver was opened successfully.

USB_DEVICE_CDC_TRANSFER_HANDLE transferHandle;
USB_DEVICE_CDC_RESULT readRequestResult;
USB_DEVICE_CDC_HANDLE instanceHandle;

readRequestResult = USB_DEVICE_CDC_Read(instanceHandle,
                        &transferHandle, data, 128);

if(USB_DEVICE_CDC_RESULT_OK != readRequestResult)
{
    //Do Error handling here
}

// The completion of the read request will be indicated by the
// USB_DEVICE_CDC_EVENT_READ_COMPLETE event.
```

Parameters

Parameters	Description
instance	USB Device CDC Function Driver instance.
transferHandle	Pointer to a USB_DEVICE_CDC_TRANSFER_HANDLE type of variable. This variable will contain the transfer handle in case the read request was successful.
data	pointer to the data buffer where read data will be stored.
size	Size of the data buffer. Refer to the description section for more details on how the size affects the transfer.

Function

```
  USB_DEVICE_CDC_RESULT USB_DEVICE_CDC_Read
(
    USB_DEVICE_CDC_INDEX instance,
USB_CDC_DEVICE_TRANSFER_HANDLE * transferHandle,
void * data,
size_t size
);
```

USB_DEVICE_CDC_Write Function

This function requests a data write to the USB Device CDC Function Driver Layer.

File

usb_device_cdc.h

C

```
USB_DEVICE_CDC_RESULT USB_DEVICE_CDC_Write(USB_DEVICE_CDC_INDEX instanceIndex,
USB_DEVICE_CDC_TRANSFER_HANDLE * transferHandle, const void * data, size_t size,
USB_DEVICE_CDC_TRANSFER_FLAGS flags);
```

Returns

USB_DEVICE_CDC_RESULT_OK - The write request was successful. transferHandle contains a valid transfer handle.

USB_DEVICE_CDC_RESULT_ERROR_TRANSFER_QUEUE_FULL - internal request queue is full. The write request could not be added.

USB_DEVICE_CDC_RESULT_ERROR_TRANSFER_SIZE_INVALID - The specified transfer size and flag parameter are invalid.

USB_DEVICE_CDC_RESULT_ERROR_INSTANCE_NOT_CONFIGURED - The specified instance is not configured yet.

USB_DEVICE_CDC_RESULT_ERROR_INSTANCE_INVALID - The specified instance was not provisioned in the application and is invalid.

Description

This function requests a data write to the USB Device CDC Function Driver Layer. The function places a requests with driver, the request will get serviced as data is requested by the USB Host. A handle to the request is returned in the transferHandle parameter. The termination of the request is indicated by the USB_DEVICE_CDC_EVENT_WRITE_COMPLETE event. The amount of data written and the transfer handle associated with the request is returned along with the event in writeCompleteData member of the pData parameter in the event handler. The transfer handle expires when event handler for the USB_DEVICE_CDC_EVENT_WRITE_COMPLETE exits. If the read request could not be accepted, the function returns an error code and transferHandle will contain the value USB_DEVICE_CDC_TRANSFER_HANDLE_INVALID.

The behavior of the write request depends on the flags and size parameter. If the application intends to send more data in a request, then it should use the USB_DEVICE_CDC_TRANSFER_FLAGS_MORE_DATA_PENDING flag. If there is no more data to be sent in the request, the application must use the USB_DEVICE_CDC_EVENT_WRITE_COMPLETE flag. This is explained in more detail here:

- If size is a multiple of maxPacketSize and flag is set as

USB_DEVICE_CDC_TRANSFER_FLAGS_DATA_COMPLETE, the write function will append a Zero Length Packet (ZLP) to complete the transfer.

- If size is a multiple of maxPacketSize and flag is set as

USB_DEVICE_CDC_TRANSFER_FLAGS_MORE_DATA_PENDING, the write function will not append a ZLP and hence will not complete the transfer.

- If size is greater than but not a multiple of maxPacketSize and flags is

set as USB_DEVICE_CDC_TRANSFER_FLAGS_DATA_COMPLETE, the write function returns an error code and sets the transferHandle parameter to USB_DEVICE_CDC_TRANSFER_HANDLE_INVALID.

- If size is greater than but not a multiple of maxPacketSize and flags is

set as USB_DEVICE_CDC_TRANSFER_FLAGS_MORE_DATA_PENDING, the write function fails and return an error code and sets the transferHandle parameter to USB_DEVICE_CDC_TRANSFER_HANDLE_INVALID.

- If size is less than maxPacketSize and flag is set as

USB_DEVICE_CDC_TRANSFER_FLAGS_DATA_COMPLETE, the write function schedules one packet.

- If size is less than maxPacketSize and flag is set as

USB_DEVICE_CDC_TRANSFER_FLAGS_MORE_DATA_PENDING, the write function returns an error code and sets the transferHandle parameter to USB_DEVICE_CDC_TRANSFER_HANDLE_INVALID.

- If size is 0 and the flag is set

USB_DEVICE_CDC_TRANSFER_FLAGS_DATA_COMPLETE, the function driver will schedule a Zero Length Packet.

Completion of the write transfer is indicated by the USB_DEVICE_CDC_EVENT_WRITE_COMPLETE event. The amount of data written along with the transfer handle is returned along with the event.

Remarks

While the using the CDC Function Driver with the PIC32MZ USB module, the transmit buffer provided to the USB_DEVICE_CDC_Write function should be placed in coherent memory and aligned at a 16 byte boundary. This can be done by declaring the buffer using the __attribute__((coherent, aligned(16))) attribute. An example is shown here

```
uint8_t data[256] __attribute__((coherent, aligned(16)));
```

Preconditions

The function driver should have been configured.

Example

```
// Below is a set of examples showing various conditions trying to
```

```
// send data with the Write command.
//
// This assumes that driver was opened successfully.
// Assume maxPacketSize is 64.

USB_DEVICE_CDC_TRANSFER_HANDLE transferHandle;
USB_DEVICE_CDC_RESULT writeRequestHandle;
USB_DEVICE_CDC_INDEX instance;

//------------------------------------------------------
// In this example we want to send 34 bytes only.

writeRequestResult = USB_DEVICE_CDC_Write(instance,
                        &transferHandle, data, 34,
                        USB_DEVICE_CDC_TRANSFER_FLAGS_DATA_COMPLETE);

if(USB_DEVICE_CDC_RESULT_OK != writeRequestResult)
{
    //Do Error handling here
}

//------------------------------------------------------
// In this example we want to send 64 bytes only.
// This will cause a ZLP to be sent.

writeRequestResult = USB_DEVICE_CDC_Write(instance,
                        &transferHandle, data, 64,
                        USB_DEVICE_CDC_TRANSFER_FLAGS_DATA_COMPLETE);

if(USB_DEVICE_CDC_RESULT_OK != writeRequestResult)
{
    //Do Error handling here
}

//------------------------------------------------------
// This example will return an error because size is less
// than maxPacketSize and the flag indicates that more
// data is pending.

writeRequestResult = USB_DEVICE_CDC_Write(instanceHandle,
                        &transferHandle, data, 32,
                        USB_DEVICE_CDC_TRANSFER_FLAGS_MORE_DATA_PENDING);

//------------------------------------------------------
// In this example we want to place a request for a 70 byte transfer.
// The 70 bytes will be sent out in a 64 byte transaction and a 6 byte
// transaction completing the transfer.

writeRequestResult = USB_DEVICE_CDC_Write(instanceHandle,
                        &transferHandle, data, 70,
                        USB_DEVICE_CDC_TRANSFER_FLAGS_DATA_COMPLETE);

if(USB_DEVICE_CDC_RESULT_OK != writeRequestResult)
{
    //Do Error handling here
}

//------------------------------------------------------
// In this example we want to place a request for a 70 bytes and the flag
// is set to data pending. This will result in an error. The size of data
// when the data pending flag is specified should be a multiple of the
// endpoint size.

writeRequestResult = USB_DEVICE_CDC_Write(instanceHandle,
                        &transferHandle, data, 70,
                        USB_DEVICE_CDC_TRANSFER_FLAGS_MORE_DATA_PENDING);

if(USB_DEVICE_CDC_RESULT_OK != writeRequestResult)
{
```

```
    //Do Error handling here
}

// The completion of the write request will be indicated by the
// USB_DEVICE_CDC_EVENT_WRITE_COMPLETE event.
```

Parameters

Parameters	Description
instance	USB Device CDC Function Driver instance.
transferHandle	Pointer to a USB_DEVICE_CDC_TRANSFER_HANDLE type of variable. This variable will contain the transfer handle in case the write request was successful.
data	pointer to the data buffer that contains the data to written.
size	Size of the data buffer. Refer to the description section for more details on how the size affects the transfer.
flags	Flags that indicate whether the transfer should continue or end. Refer to the description for more details.

Function

```
  USB_DEVICE_CDC_RESULT USB_DEVICE_CDC_Write
(
    USB_DEVICE_CDC_INDEX instance,
USB_CDC_DEVICE_TRANSFER_HANDLE * transferHandle,
const void * data,
size_t size,
    USB_DEVICE_CDC_TRANSFER_FLAGS flags
);
```

USB_DEVICE_CDC_SerialStateNotificationSend Function

This function schedules a request to send serial state notification to the host.

File

usb_device_cdc.h

C

```
USB_DEVICE_CDC_RESULT USB_DEVICE_CDC_SerialStateNotificationSend(USB_DEVICE_CDC_INDEX instanceIndex,
USB_DEVICE_CDC_TRANSFER_HANDLE * transferHandle, USB_CDC_SERIAL_STATE * notificationData);
```

Returns

USB_DEVICE_CDC_RESULT_OK - The request was successful. transferHandle contains a valid transfer handle.

USB_DEVICE_CDC_RESULT_ERROR_TRANSFER_QUEUE_FULL - Internal request queue is full. The request could not be added.

USB_DEVICE_CDC_RESULT_ERROR_INSTANCE_NOT_CONFIGURED - The specified instance is not configured yet.

USB_DEVICE_CDC_RESULT_ERROR_INSTANCE_INVALID - The specified instance was not provisioned in the application and is invalid.

Description

This function places a request to send serial state notification data to the host. The function will place the request with the driver, the request will get serviced when the data is requested by the USB host. A handle to the request is returned in the transferHandle parameter. The termination of the request is indicated by the USB_DEVICE_CDC_EVENT_SERIAL_STATE_NOTIFICATION_COMPLETE event. The amount of data transmitted and the transfer handle associated with the request is returned along with the event in the serialStateNotificationCompleteData member of pData parameter of the event handler. The transfer handle expires when the event handler for the USB_DEVICE_CDC_EVENT_SERIAL_STATE_NOTIFICATION_COMPLETE event exits. If the send request could not be accepted, the function returns an error code and transferHandle will contain the value USB_DEVICE_CDC_TRANSFER_HANDLE_INVALID.

Remarks

While the using the CDC Function Driver with the PIC32MZ USB module, the notification data buffer provided to the USB_DEVICE_CDC_SerialStateNotificationSend function should be placed in coherent memory and aligned at a 16 byte boundary. This can be done by declaring the buffer using the __attribute__((coherent, aligned(16))) attribute. An example is shown here

```
uint8_t data[256] __attribute__((coherent, aligned(16)));
```

Preconditions

The function driver should have been configured

Example

```
USB_CDC_SERIAL_STATE notificationData;

// This application function could possibly update the notificationData
// data structure.

APP_UpdateNotificationData(&notificationData);

// Now send the updated notification data to the host.

result = USB_DEVICE_CDC_SerialStateNotificationSend
            (instanceIndex, &transferHandle, &notificationData);

if(USB_DEVICE_CDC_RESULT_OK != result)
{
    // Error handling here. The transferHandle will contain
    // USB_DEVICE_CDC_TRANSFER_HANDLE_INVALID in this case.
}
```

Parameters

Parameters	Description
instance	USB Device CDC Function Driver instance.
transferHandle	Pointer to a output only variable that will contain transfer handle.
notificationData	USB_DEVICE_CDC_SERIAL_STATE_NOTIFICATION type of notification data to be sent to the host.

Function

```
USB_DEVICE_CDC_RESULT USB_DEVICE_CDC_SerialStateNotificationSend
(
    USB_DEVICE_CDC_INDEX instanceIndex,
    USB_DEVICE_CDC_TRANSFER_HANDLE * transferHandle,
USB_CDC_SERIAL_STATE * notificationData
);
```

b) Data Types and Constants

USB_DEVICE_CDC_EVENT Enumeration

USB Device CDC Function Driver Events

File

usb_device_cdc.h

C

```
typedef enum {
  USB_DEVICE_CDC_EVENT_SET_LINE_CODING,
  USB_DEVICE_CDC_EVENT_GET_LINE_CODING,
  USB_DEVICE_CDC_EVENT_SET_CONTROL_LINE_STATE,
  USB_DEVICE_CDC_EVENT_SEND_BREAK,
  USB_DEVICE_CDC_EVENT_WRITE_COMPLETE,
  USB_DEVICE_CDC_EVENT_READ_COMPLETE,
  USB_DEVICE_CDC_EVENT_SERIAL_STATE_NOTIFICATION_COMPLETE,
  USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_SENT,
  USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_RECEIVED,
  USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_ABORTED
} USB_DEVICE_CDC_EVENT;
```

Members

Members	Description
USB_DEVICE_CDC_EVENT_SET_LINE_CODING	This event occurs when the host issues a SET LINE CODING command. The application must provide a USB_CDC_LINE_CODING data structure to the device layer to receive the line coding data that the host will provide. The application must provide the buffer by calling the USB_DEVICE_ControlReceive function either in the event handler or in the application, after returning from the event handler function. The pData parameter will be NULL. The application can use the USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_RECEIVED event to track completion of the command.
USB_DEVICE_CDC_EVENT_GET_LINE_CODING	This event occurs when the host issues a GET LINE CODING command. The application must provide a USB_CDC_LINE_CODING data structure to the device layer that contains the line coding data to be provided to the host. The application must provide the buffer by calling the USB_DEVICE_ControlSend function either in the event handler or in the application, after returning from the event handler function. The application can use the USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_SENT event to track completion of the command.
USB_DEVICE_CDC_EVENT_SET_CONTROL_LINE_STATE	This event occurs when the host issues a SET CONTROL LINE STATE command. The application must interpret the pData parameter as USB_CDC_CONTROL_LINE_STATE pointer type. This data structure contains the control line state data. The application can then use the USB_DEVICE_ControlStatus function to indicate acceptance or rejection of the command. The USB_DEVICE_ControlStatus function can be called from the event handler or in the application, after returning from the event handler.
USB_DEVICE_CDC_EVENT_SEND_BREAK	This event occurs when the host issues a SEND BREAK command. The application must interpret the pData parameter as a USB_DEVICE_CDC_EVENT_DATA_SEND_BREAK pointer type. This data structure contains the break duration data. The application can then use the USB_DEVICE_ControlStatus function to indicate acceptance of rejection of the command. The USB_DEVICE_ControlStatus function can be called from the event handler or in the application, after returning from the event handler.
USB_DEVICE_CDC_EVENT_WRITE_COMPLETE	This event occurs when a write operation scheduled by calling the USB_DEVICE_CDC_Write function has completed. The pData parameter should be interpreted as a USB_DEVICE_CDC_EVENT_DATA_WRITE_COMPLETE pointer type. This will contain the transfer handle associated with the completed write transfer and the amount of data written.
USB_DEVICE_CDC_EVENT_READ_COMPLETE	This event occurs when a read operation scheduled by calling the USB_DEVICE_CDC_Read function has completed. The pData parameter should be interpreted as a USB_DEVICE_CDC_EVENT_DATA_READ_COMPLETE pointer type. This will contain the transfer handle associated with the completed read transfer and the amount of data read.
USB_DEVICE_CDC_EVENT_SERIAL_STATE_NOTIFICATION_COMPLETE	This event occurs when a serial state notification scheduled using the USB_DEVICE_CDC_SerialStateNotificationSend function, was sent to the host. The pData parameter should be interpreted as a USB_DEVICE_CDC_EVENT_DATA_SERIAL_STATE_NOTIFICATION_COMPLETE pointer type and will contain the transfer handle associated with the completed send transfer and the amount of data sent.
USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_SENT	This event occurs when the data stage of a control read transfer has completed. This event would occur after the application uses the USB_DEVICE_ControlSend function to respond to the USB_DEVICE_CDC_EVENT_GET_LINE_CODING event.

USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_RECEIVED	This event occurs when the data stage of a control write transfer has completed. This would occur after the application would respond with a USB_DEVICE_ControlReceive function to the USB_DEVICE_CDC_EVENT_SET_LINE_CODING_EVENT and the data has been received. The application should respond to this event by calling the USB_DEVICE_ControlStatus function with the USB_DEVICE_CONTROL_STATUS_OK flag to acknowledge the received data or the USB_DEVICE_CONTROL_STATUS_ERROR flag to reject it and stall the control transfer
USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_ABORTED	This event occurs when a control transfer that this instance of CDC function driver responded to was aborted by the host. The application can use this event to reset its CDC function driver related control transfer state machine

Description

USB Device CDC Function Driver Events

These events are specific to the USB Device CDC Function Driver instance. Each event description contains details about the parameters passed with event. The contents of pData depends on the generated event.

Events associated with the CDC Function Driver Specific Control Transfers require application response. The application should respond to these events by using the USB_DEVICE_ControlReceive, USB_DEVICE_ControlSend and USB_DEVICE_ControlStatus functions.

Calling the USB_DEVICE_ControlStatus function with a USB_DEVICE_CONTROL_STATUS_ERROR will stall the control transfer request. The application would do this if the control transfer request is not supported. Calling the USB_DEVICE_ControlStatus function with a USB_DEVICE_CONTROL_STATUS_OK will complete the status stage of the control transfer request. The application would do this if the control transfer request is supported

The following code snippet shows an example of a possible event handling scheme.

```
// This code example shows all CDC Function Driver events
// and a possible scheme for handling these events. In this example
// event responses are not deferred. usbDeviceHandle is obtained while
// opening the USB Device Layer through the USB_DEVICE_Open function.

uint16_t * breakData;
USB_DEVICE_HANDLE    usbDeviceHandle;
USB_CDC_LINE_CODING  lineCoding;
USB_CDC_CONTROL_LINE_STATE * controlLineStateData;

USB_DEVICE_CDC_EVENT_RESPONSE USBDeviceCDCEventHandler
(
    USB_DEVICE_CDC_INDEX instanceIndex,
    USB_DEVICE_CDC_EVENT event,
    void * pData,
    uintptr_t userData
)
{
    switch(event)
    {
        case USB_DEVICE_CDC_EVENT_SET_LINE_CODING:

            // In this case, the application should read the line coding
            // data that is sent by the host. The application must use the
            // USB_DEVICE_ControlReceive function to receive the
            // USB_CDC_LINE_CODING type of data.

            USB_DEVICE_ControlReceive(usbDeviceHandle, &lineCoding, sizeof(USB_CDC_LINE_CODING));
            break;

        case USB_DEVICE_CDC_EVENT_GET_LINE_CODING:

            // In this case, the application should send the line coding
            // data to the host. The application must send the
            // USB_DEVICE_ControlSend function to send the data.

            USB_DEVICE_ControlSend(usbDeviceHandle, &lineCoding, sizeof(USB_CDC_LINE_CODING));
            break;

        case USB_DEVICE_CDC_EVENT_SET_CONTROL_LINE_STATE:

            // In this case, pData should be interpreted as a
```

```
            // USB_CDC_CONTROL_LINE_STATE pointer type.  The application
            // acknowledges the parameters by calling the
            // USB_DEVICE_ControlStatus function with the
            // USB_DEVICE_CONTROL_STATUS_OK option.

            controlLineStateData = (USB_CDC_CONTROL_LINE_STATE *)pData;
            USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_OK);
            break;

        case USB_DEVICE_CDC_EVENT_SEND_BREAK:

            // In this case, pData should be interpreted as a uint16_t
            // pointer type to the break duration. The application
            // acknowledges the parameters by calling the
            // USB_DEVICE_ControlStatus() function with the
            // USB_DEVICE_CONTROL_STATUS_OK option.

            breakDuration = (uint16_t *)pData;
            USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_OK);
            break;

        case USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_SENT:

            // This event indicates the data send request associated with
            // the latest USB_DEVICE_ControlSend function was
            // completed.  The application could use this event to track
            // the completion of the USB_DEVICE_CDC_EVENT_GET_LINE_CODING
            // request.

            break;

        case USB_DEVICE_CDC_EVENT_CONTROL_TRANSFER_DATA_RECEIVED:

            // This event indicates the data that was requested using the
            // USB_DEVICE_ControlReceive function is available for the
            // application to peruse. The application could use this event
            // to track the completion of the
            // USB_DEVICE_CDC_EVENT_SET_LINE_CODING_EVENT event. The
            // application can then either accept the line coding data (as
            // shown here) or decline it by using the
            // USB_DEVICE_CONTROL_STATUS_ERROR flag in the
            // USB_DEVICE_ControlStatus function.

            USB_DEVICE_ControlStatus(usbDeviceHandle, USB_DEVICE_CONTROL_STATUS_OK);
            break;

        case USB_DEVICE_CDC_EVENT_WRITE_COMPLETE:

            // This event indicates that a CDC Write Transfer request has
            // completed.  pData should be interpreted as a
            // USB_DEVICE_CDC_EVENT_DATA_WRITE_COMPLETE pointer type. This
            // contains the transfer handle of the write transfer that
            // completed and amount of data that was written.

            break;

        case USB_DEVICE_CDC_EVENT_READ_COMPLETE:

            // This event indicates that a CDC Read Transfer request has
            // completed.  pData should be interpreted as a
            // USB_DEVICE_CDC_EVENT_DATA_READ_COMPLETE pointer type. This
            // contains the transfer handle of the read transfer that
            // completed and amount of data that was written.

            break;

        case USB_DEVICE_CDC_EVENT_SERIAL_STATE_NOTIFICATION_COMPLETE:

            // This event indicates that a CDC Serial State Notification
```

```
            // Send request has completed. pData should be interpreted as a
            // USB_DEVICE_CDC_EVENT_DATA_SERIAL_STATE_NOTIFICATION_COMPLETE
            // pointer type. This will contain the transfer handle
            // associated with the send request and the amount of data that
            // was sent.

        break

         default:
            break;
      }

    return(USB_DEVICE_CDC_EVENT_RESPONSE_NONE);
}
```

Remarks

The USB Device CDC control transfer related events allow the application to defer responses. This allows the application some time to obtain the response data rather than having to respond to the event immediately. Note that a USB host will typically wait for event response for a finite time duration before timing out and canceling the event and associated transactions. Even when deferring response, the application must respond promptly if such time outs have to be avoided.

USB_DEVICE_CDC_EVENT_HANDLER Type

USB Device CDC Event Handler Function Pointer Type.

File

usb_device_cdc.h

C

```
typedef USB_DEVICE_CDC_EVENT_RESPONSE (* USB_DEVICE_CDC_EVENT_HANDLER)(USB_DEVICE_CDC_INDEX instanceIndex,
USB_DEVICE_CDC_EVENT event, void * pData, uintptr_t context);
```

Description

USB Device CDC Event Handler Function Pointer Type.

This data type defines the required function signature of the USB Device CDC Function Driver event handling callback function. The application must register a pointer to a CDC Function Driver events handling function whose function signature (parameter and return value types) match the types specified by this function pointer in order to receive event call backs from the CDC Function Driver. The function driver will invoke this function with event relevant parameters. The description of the event handler function parameters is given here.

instanceIndex - Instance index of the CDC Function Driver that generated the event.

event - Type of event generated.

pData - This parameter should be type cast to an event specific pointer type based on the event that has occurred. Refer to the USB_DEVICE_CDC_EVENT enumeration description for more details.

context - Value identifying the context of the application that was registered along with the event handling function.

Remarks

The event handler function executes in the USB interrupt context when the USB Device Stack is configured for interrupt based operation. It is not advisable to call blocking functions or computationally intensive functions in the event handler. Where the response to a control transfer related event requires extended processing, the response to the control transfer should be deferred and the event handler should be allowed to complete execution.

USB_DEVICE_CDC_EVENT_RESPONSE Type

USB Device CDC Function Driver Event Callback Response Type

File

usb_device_cdc.h

C

```
typedef void USB_DEVICE_CDC_EVENT_RESPONSE;
```

Description

USB Device CDC Function Driver Event Handler Response Type

This is the return type of the CDC Function Driver event handler.

Remarks

None.

USB_DEVICE_CDC_EVENT_DATA_SEND_BREAK Structure

USB Device CDC Function Driver Send Break Event Data

File

} USB_DEVICE_CDC_EVENT_DATA_SEND_BREAK;
```

Members

Members	Description
uint16_t breakDuration;	Duration of break signal

Description

USB Device CDC Function Driver Send Break Event Data

This data type defines the data structure returned by the driver along with USB_DEVICE_CDC_EVENT_SEND_BREAK event.

Remarks

None.

USB_DEVICE_CDC_INDEX Type

USB Device CDC Function Driver Index

File

usb_device_cdc.h

C

```
typedef uintptr_t USB_DEVICE_CDC_INDEX;
```

Description

USB Device CDC Function Driver Index

This uniquely identifies a CDC Function Driver instance.

Remarks

None.

USB_DEVICE_CDC_INIT Structure

USB Device CDC Function Driver Initialization Data Structure

File

usb_device_cdc.h

C

```
typedef struct {
  size_t queueSizeRead;
  size_t queueSizeWrite;
  size_t queueSizeSerialStateNotification;
} USB_DEVICE_CDC_INIT;
```

Members

Members	Description
size_t queueSizeRead;	Size of the read queue for this instance • of the CDC function driver
size_t queueSizeWrite;	Size of the write queue for this instance • of the CDC function driver
size_t queueSizeSerialStateNotification;	Size of the serial state notification • queue size

Description

USB Device CDC Function Driver Initialization Data Structure

This data structure must be defined for every instance of the CDC function driver. It is passed to the CDC function driver, by the Device Layer, at the time of initialization. The funcDriverInit member of the Device Layer Function Driver registration table entry must point to this data structure for an instance of the CDC function driver.

Remarks

The queue sizes that are specified in this data structure are also affected by the USB_DEVICE_CDC_QUEUE_DEPTH_COMBINED configuration macro.

```

```
  USB_DEVICE_CDC_RESULT_ERROR_TERMINATED_BY_HOST,
  USB_DEVICE_CDC_RESULT_ERROR
} USB_DEVICE_CDC_RESULT;
```

Members

Members	Description
USB_DEVICE_CDC_RESULT_OK	The operation was successful
USB_DEVICE_CDC_RESULT_ERROR_TRANSFER_SIZE_INVALID	The transfer size is invalid. Refer to the description • of the read or write function for more details
USB_DEVICE_CDC_RESULT_ERROR_TRANSFER_QUEUE_FULL	The transfer queue is full and no new transfers can be • scheduled
USB_DEVICE_CDC_RESULT_ERROR_INSTANCE_INVALID	The specified instance is not provisioned in the system
USB_DEVICE_CDC_RESULT_ERROR_INSTANCE_NOT_CONFIGURED	The specified instance is not configured yet
USB_DEVICE_CDC_RESULT_ERROR_PARAMETER_INVALID	The event handler provided is NULL
USB_DEVICE_CDC_RESULT_ERROR_ENDPOINT_HALTED	Transfer terminated because host halted the endpoint
USB_DEVICE_CDC_RESULT_ERROR_TERMINATED_BY_HOST	Transfer terminated by host because of a stall clear
USB_DEVICE_CDC_RESULT_ERROR	General CDC Function driver error

Description

USB Device CDC Function Driver USB Device CDC Result enumeration.

This enumeration lists the possible USB Device CDC Function Driver operation results. These values are returned by USB Device CDC Library functions.

Remarks

None.

USB_DEVICE_CDC_TRANSFER_FLAGS Enumeration

USB Device CDC Function Driver Transfer Flags

File

usb_device_cdc.h

C

```
typedef enum {
  USB_DEVICE_CDC_TRANSFER_FLAGS_DATA_COMPLETE,
  USB_DEVICE_CDC_TRANSFER_FLAGS_MORE_DATA_PENDING
} USB_DEVICE_CDC_TRANSFER_FLAGS;
```

Members

Members	Description
USB_DEVICE_CDC_TRANSFER_FLAGS_DATA_COMPLETE	This flag indicates there is no further data to be sent in this transfer and that the transfer should end. If the size of the transfer is a multiple of the maximum packet size for related endpoint configuration, the function driver will send a zero length packet to indicate end of the transfer to the host.
USB_DEVICE_CDC_TRANSFER_FLAGS_MORE_DATA_PENDING	This flag indicates there is more data to be sent in this transfer. If the size of the transfer is a multiple of the maximum packet size for the related endpoint configuration, the function driver will not send a zero length packet. If the size of the transfer is greater than (but not a multiple of) the maximum packet size, the function driver will only send maximum packet size amount of data. If the size of the transfer is greater than endpoint size but not an exact multiple of endpoint size, only the closest endpoint size multiple bytes of data will be sent. This flag should not be specified if the size of the transfer is less than maximum packet size.

Description

USB Device CDC Transfer Flags

These flags are used to indicate status of the pending data while sending data to the host by using the USB_DEVICE_CDC_Write function.

Remarks

The relevance of the specified flag depends on the size of the buffer. Refer to the individual flag descriptions for more details.

USB_DEVICE_CDC_TRANSFER_HANDLE Type

USB Device CDC Function Driver Transfer Handle Definition.

File

usb_device_cdc.h

C

```
typedef uintptr_t USB_DEVICE_CDC_TRANSFER_HANDLE;
```

Description

USB Device CDC Function Driver Transfer Handle Definition

This definition defines a USB Device CDC Function Driver Transfer Handle. A Transfer Handle is owned by the application but its value is modified by the USB_DEVICE_CDC_Write, USB_DEVICE_CDC_Read and the USB_DEVICE_CDC_SerialStateNotificationSend functions. The transfer handle is valid for the life time of the transfer and expires when the transfer related event had occurred.

Remarks

None.

USB_DEVICE_CDC_EVENT_RESPONSE_NONE Macro

USB Device CDC Function Driver Event Handler Response Type None.

File

usb_device_cdc.h

C

```
#define USB_DEVICE_CDC_EVENT_RESPONSE_NONE
```

Description

USB Device CDC Function Driver Event Handler Response None

This is the definition of the CDC Function Driver Event Handler Response Type none.

Remarks

Intentionally defined to be empty.

USB_DEVICE_CDC_TRANSFER_HANDLE_INVALID Macro

USB Device CDC Function Driver Invalid Transfer Handle Definition.

File

usb_device_cdc.h

C

```
#define USB_DEVICE_CDC_TRANSFER_HANDLE_INVALID ((USB_DEVICE_CDC_TRANSFER_HANDLE)(-1))
```

Description

USB Device CDC Function Driver Invalid Transfer Handle Definition

This definition defines a USB Device CDC Function Driver Invalid Transfer Handle. A Invalid Transfer Handle is returned by the USB_DEVICE_CDC_Write, USB_DEVICE_CDC_Read and the USB_DEVICE_CDC_SerialStateNotificationSend functions when the request was not successful.

Remarks

None.

USB_DEVICE_CDC_FUNCTION_DRIVER Macro

USB Device CDC Function Driver Function pointer

File

usb_device_cdc.h

C

```
#define USB_DEVICE_CDC_FUNCTION_DRIVER
```

Description

USB Device CDC Function Driver Function Pointer

This is the USB Device CDC Function Driver Function pointer. This should registered with the device layer in the function driver registration table.

Remarks

None.

USB_DEVICE_CDC_INDEX_0 Macro

File

usb_device_cdc.h

C

```
#define USB_DEVICE_CDC_INDEX_0 0
```

Description

Use this to specify CDC Function Driver Instance 0

USB_DEVICE_CDC_INDEX_1 Macro

File

usb_device_cdc.h

C

```
#define USB_DEVICE_CDC_INDEX_1 1
```

Description

Use this to specify CDC Function Driver Instance 1

USB_DEVICE_CDC_INDEX_2 Macro

File

usb_device_cdc.h

C

```
#define USB_DEVICE_CDC_INDEX_2 2
```

Description

Use this to specify CDC Function Driver Instance 2

USB_DEVICE_CDC_INDEX_3 Macro

File

usb_device_cdc.h

C

```
#define USB_DEVICE_CDC_INDEX_3 3
```

Description

Use this to specify CDC Function Driver Instance 3

USB_DEVICE_CDC_INDEX_4 Macro

File

usb_device_cdc.h

C

```
#define USB_DEVICE_CDC_INDEX_4 4
```

Description

Use this to specify CDC Function Driver Instance 4

USB_DEVICE_CDC_INDEX_5 Macro

File

usb_device_cdc.h

C

```
#define USB_DEVICE_CDC_INDEX_5 5
```

Description

Use this to specify CDC Function Driver Instance 5

USB_DEVICE_CDC_INDEX_6 Macro

File

usb_device_cdc.h

C

```
#define USB_DEVICE_CDC_INDEX_6 6
```

Description

Use this to specify CDC Function Driver Instance 6

USB_DEVICE_CDC_INDEX_7 Macro

File

usb_device_cdc.h

C

```
#define USB_DEVICE_CDC_INDEX_7 7
```

Description

Use this to specify CDC Function Driver Instance 7

USB HID Device Library

This section describes the USB HID Device Library.

Introduction

Introduces the MPLAB Harmony USB Human Interface Device (HID) Device Library.

Description

The MPLAB Harmony USB Human Interface Device (HID) Device Library (also referred to as the HID Function Driver or Library) provides a high-level abstraction of the Human Interface Device (HID) class under the Universal Serial Bus (USB) communication with a convenient C language interface. This library supports revision 1.11 of the USB HID specification released by the USB Implementers forum. This library is part of the MPLAB Harmony USB Device stack.

The USB HID Device Class supports devices that are used by humans to control the operation of computer systems. The HID class of devices include a wide variety of human interface, data indicator, and data feedback devices with various types of output directed to the end user. Some common examples of HID class devices include:

- Keyboards
- Pointing devices such as a standard mouse, joysticks, and trackballs
- Front-panel controls like knobs, switches, buttons, and sliders
- Controls found on telephony, gaming or simulation devices such as steering wheels, rudder pedals, and dial pads
- Data devices such as bar-code scanners, thermometers, analyzers

The USB HID Device Library offers services to the application to interact and respond to the host requests. Additional information about the HID class can be obtained from the HID specification available from the USB Implementers Forum at: www.usbif.org.

Using the Library

This topic describes the basic architecture of the HID Function Driver and provides information and examples on its use.

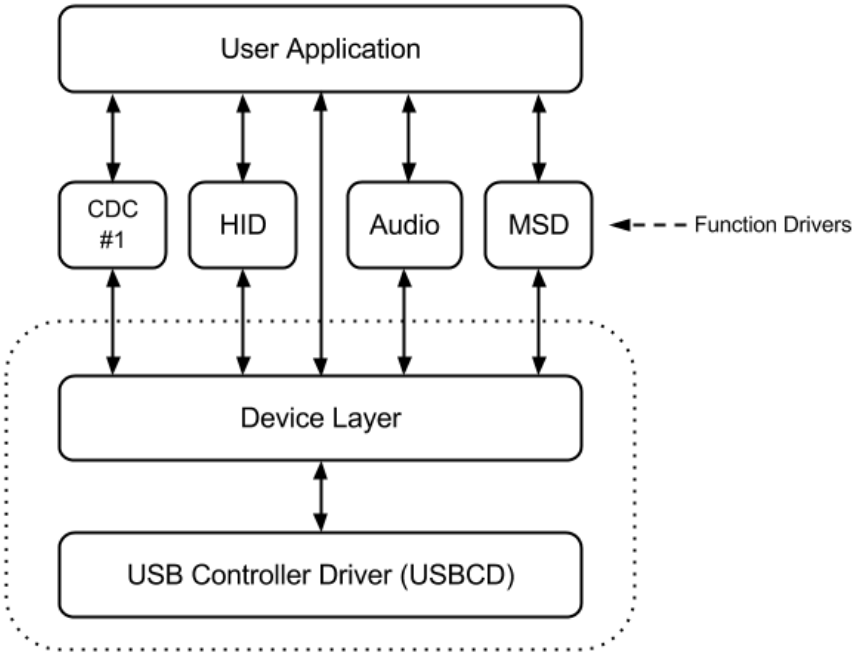
Abstraction Model

Provides an architectural overview of the USB HID Function Driver.

Description

The HID Function Driver offers services to a USB HID device to communicate with the host by abstracting the HID specification details. It must be used along with the USB Device Layer and USB Controller Driver to communicate with the USB Host. Figure 1 shows a block diagram of the MPLAB Harmony USB Architecture and where the HID Function Driver is placed.

Figure 1: HID Function Driver



The HID Function Driver together with USB Device Layer and the USB Controller Driver forms the basic library entity through which a HID device can communicate with the USB Host. The USB Controller Driver takes the responsibility of managing the USB peripheral on the device. The USB Device Layer handles the device enumeration, etc. The USB Device layer forwards all HID-specific control transfers to the HID Function Driver. The HID Function Driver interprets the control transfers and requests application's intervention through event handlers and a well-defined set of API functions. The application must register a event handler with the HID Function Driver in the Device Layer Set Configuration Event. While the application must respond to the HID Function Driver events, it can do this either in the HID Function Driver event handler or after the event handler routine has returned. The application interacts with HID Function Driver routines to send and receive HID reports over the USB.

Figure 2 shows the architecture of the HID Function Driver. The HID Function Driver maintains the state of each instance. It receives HID class-specific control transfers from the USB Device Layer. Class-specific control transfers that require application response are forwarded to the application as function driver events. The application responds to these class specific control transfer event by directly calling Device Layer control transfer routines. Depending on the type of device, the HID Function Driver can use the control endpoint and/or interrupt endpoints for data transfers. The USB HID Device Driver exchanges data with the Host through data objects called reports. The report data format is described by the HID report descriptor, which is provided to the Host when requested. Refer to the HID specification available from www.usb.org for more details on the USB HID Device class and how report descriptors can be created. The HID Function Driver allows report descriptors to be specified for every instance. This allow the application to implement a composite HID device.

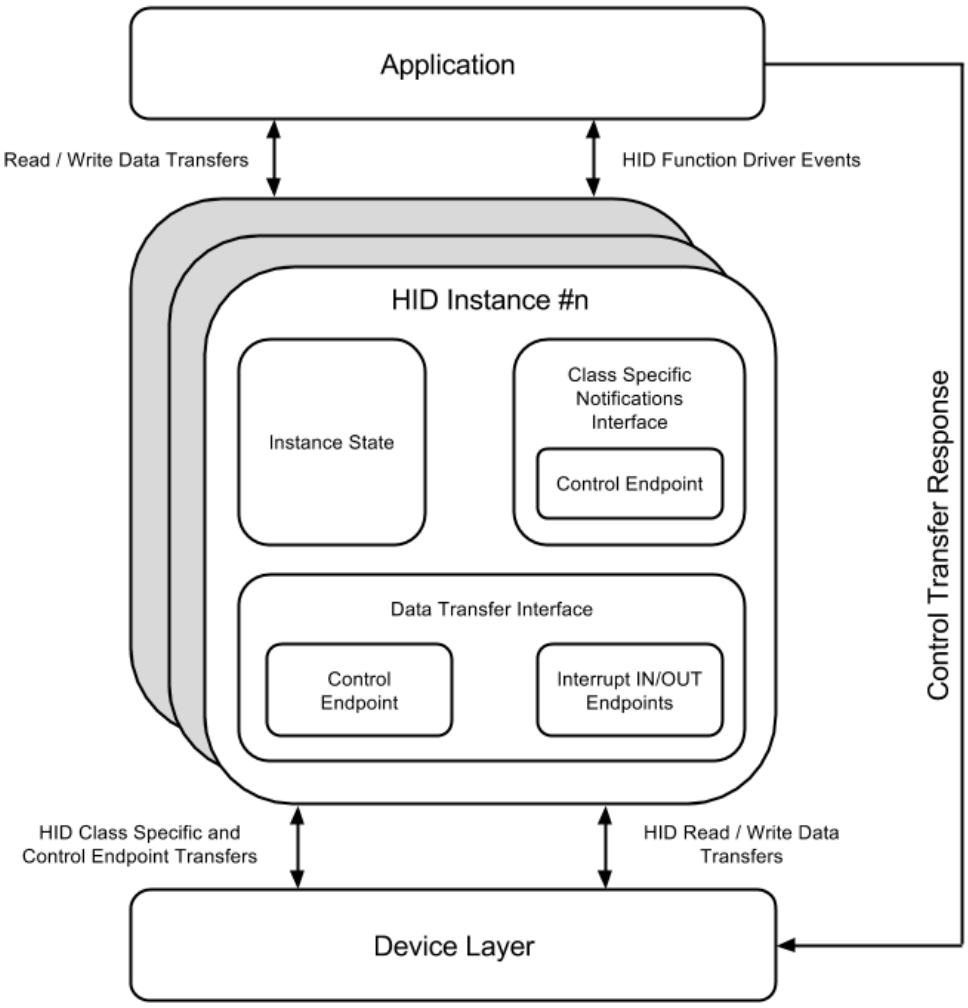


Figure 2: Architecture of the HID Function Driver

Library Overview

The USB HID Device Library mainly interacts with the system, its clients and function drivers, as shown in the Abstraction Model.

The library interface routines are divided into sub-sections, which address one of the blocks or the overall operation of the USB HID Device Library.

Library Interface Section	Description
Functions	Provides event handler, report send/receive, and transfer cancellation functions.

How the Library Works

Library Initialization

Describes how the HID Function Driver is initialized.

Description

The HID Function Driver instance for a USB device configuration is initialized by the Device Layer when the configuration is set by the Host. This process does not require application intervention. Each instance of the HID Function be registered with the Device Layer through the Device Layer Function Driver Registration Table. The HID function driver requires a initialization data structure that contains details about the report descriptor and the reports send/receive queue size associated with the specific instance of the HID Function Driver. The funcDriver member of the registration entry must be set to USB_DEVICE_HID_FUNCTION_DRIVER. This object is a global object provided by the HID Function Driver and points to the HID Function Driver - Device Layer interface functions, which are required by the Device Layer. The following code shows an

example of how a HID Function Driver instance (implementing a USB HID Mouse) can be registered with the Device Layer.

```
/* This code shows an example of registering a HID function driver
 * with the Device Layer. While registering the function driver, an initialization
 * data structure must be specified. In this example, hidInit is the HID function
 * driver initialization data structure. */

/* This hid_rpt01 report descriptor describes a 3 button 2
 * axis mouse pointing device */
const uint8_t hid_rpt01[]=
{
    0x06, 0x00, 0xFF,    // Usage Page = 0xFF00 (Vendor Defined Page 1)
    0x09, 0x01,          // Usage (Vendor Usage 1)
    0xA1, 0x01,          // Collection (Application)
    0x19, 0x01,          // Usage Minimum
    0x29, 0x40,          // Usage Maximum     //64 input usages total (0x01 to 0x40)
    0x15, 0x01,          // Logical Minimum (data bytes in the report may have minimum value = 0x00)
    0x25, 0x40,          // Logical Maximum (data bytes in the report may have maximum value = 0x00FF =
unsigned 255)
    0x75, 0x08,          // Report Size: 8-bit field size
    0x95, 0x40,          // Report Count: Make sixty-four 8-bit fields (the next time the parser hits an
"Input", "Output",
                         // or "Feature" item)
    0x81, 0x00,          // Input (Data, Array, Abs): Instantiates input packet fields based on the
previous report size,
                         // count, logical min/max, and usage.
    0x19, 0x01,          // Usage Minimum
    0x29, 0x40,          // Usage Maximum     //64 output usages total (0x01 to 0x40)
    0x91, 0x00,          // Output (Data, Array, Abs): Instantiates output packet fields.  Uses same report
size and
                         // count as "Input" fields, since nothing new or different was specified to the
parser since
                         // the "Input" item.
    0xC0                 // End Collection
};

/* HID Function Driver Initialization data structure. This
 * contains the size of the report descriptor and a pointer
 * to the report descriptor. If there are multiple HID instances
 * each with different report descriptors, multiple such data
 * structures may be needed */

USB_DEVICE_HID_INITIALIZATION hidInit =
{
    sizeof(hid_rpt01), // Size of the report
    (uint8_t *)&hid_rpt01 // Pointer to the report
    1, // Send queue size is 1. We will not queue up reports.
    0 // Receive queue size 0. We will not receive reports.
};

/* The HID function driver instance is now registered with
 * device layer through the function driver registration
 * table. */

const USB_DEVICE_FUNCTION_REGISTRATION_TABLE funcRegistrationTable[1] =
{
    {
         .speed = USB_SPEED_FULL|USB_SPEED_HIGH,    // Supported speed
         .configurationValue = 1,                   // To be initialized for Configuration 1
         .interfaceNumber = 0,                      // Starting interface number
         .numberOfInterfaces = 1,                   // Number of Interfaces
         .funcDriverIndex = 0,                      // Function Driver instance index is 0
         .funcDriverInit = &hidInit,                // Function Driver Initialization
         .driver = USB_DEVICE_HID_FUNCTION_DRIVER   // Pointer to the function driver - Device Layer
Interface functions
     }
};
```

Event Handling

Describes HID Function Driver event handler registration and event handling.

Description

Registering a HID Function Driver Event Handler

While creating a USB HID Device-based application, an event handler must be registered with the Device Layer (the Device Layer Event Handler) and every HID Function Driver instance (HID Function Driver Event Handler). The HID Function Driver event handler receives HID events. This event handler should be registered before the USB Device Layer acknowledges the SET CONFIGURATION request from the USB Host. To ensure this, the event handler should be set in the USB_DEVICE_EVENT_CONFIGURED event that is generated by the device layer. While registering the HID Function Driver event handler, the HID Function Driver allows the application to also pass a data object in the event handler register function. This data object gets associated with the instance of the HID Function Driver and is returned by the driver when a HID Function Driver event occurs. The following code shows an example of how this can be done.

```
/* This is a sample Application Device Layer Event Handler
* Note how the HID Function Driver event handler APP_USBDeviceHIDEventHandler()
* is registered in the USB_DEVICE_EVENT_CONFIGURED event. The appData
* object that is passed in the USB_DEVICE_HID_EventHandlerSet()
* function will be returned as the userData parameter in the
* when the APP_USBDeviceHIDEventHandler() function is invoked */

   /* Application states */
    typedef enum
    {
        /* Application's state machine's initial state. */
        APP_STATE_INIT=0,
        APP_STATE_SERVICE_TASKS,
        APP_STATE_WAIT_FOR_CONFIGURATION,
    } APP_STATES;

    USB_DEVICE_HANDLE usbDeviceHandle;
    APP_STATES appState;

    /* This is the application device layer event handler function. */

    USB_DEVICE_EVENT_RESPONSE APP_USBDeviceEventHandler
    (
        USB_DEVICE_EVENT event,
        void * eventData,
        uintptr_t context
    )
    {
        uint8_t activeConfiguration;
        USB_SETUP_PACKET * setupPacket;
        switch(event)
        {
            case USB_DEVICE_EVENT_POWER_DETECTED:
                /* This event in generated when VBUS is detected. Attach the device */
                USB_DEVICE_Attach(usbDeviceHandle);
                break;

            case USB_DEVICE_EVENT_POWER_REMOVED:
                /* This event is generated when VBUS is removed. Detach the device */
                USB_DEVICE_Detach (usbDeviceHandle);
                break;

            case USB_DEVICE_EVENT_CONFIGURED:
                /* This event indicates that Host has set Configuration in the Device.*/
                /* Check the configuration */
                activeConfiguration = ((USB_DEVICE_EVENT_DATA_CONFIGURED *)pData)->configurationValue;
                if ( activeConfiguration == 1)
                {
                   /* Register the HID Device application event handler here.
                    * Note how the appData object pointer is passed as the
                    * user data */
                    USB_DEVICE_HID_EventHandlerSet(USB_DEVICE_HID_INDEX_0, APP_USBDeviceHIDEventHandler,
(uintptr_t)&appData);
```

```
                    /* Mark that set configuration is complete */
                    appData.isConfigured = true;
                }
                break;

            case USB_DEVICE_EVENT_CONTROL_TRANSFER_SETUP_REQUEST:
                /* This event indicates a Control transfer setup stage has been completed. */
                setupPacket = (USB_SETUP_PACKET *)eventData;

                /* Parse the setup packet and respond with a USB_DEVICE_ControlSend(),
                   USB_DEVICE_ControlReceive or USB_DEVICE_ControlStatus(). */

                break;

            case USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_SENT:
                /* This event indicates that a Control transfer Data has been sent to Host. */
                break;

            case USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_RECEIVED:
                /* This event indicates that a Control transfer Data has been received from Host. */
                break;

            case USB_DEVICE_EVENT_CONTROL_TRANSFER_ABORTED:
                /* This event indicates a control transfer was aborted. */
                break;

            case USB_DEVICE_EVENT_SUSPENDED:
                break;

            case USB_DEVICE_EVENT_RESUMED:
                break;

            case USB_DEVICE_EVENT_ERROR:
                break;

            case USB_DEVICE_EVENT_RESET:
                break;

            case USB_DEVICE_EVENT_SOF:
                /* This event indicates an SOF is detected on the bus. The USB_DEVICE_SOF_EVENT_ENABLE
                   macro should be defined to get this event. */
                break;
            default:
                break;
        }
    }
```

The HID Function Driver event handler executes in an interrupt context when the device stack is configured for Interrupt mode.

In Polled mode, the event handler is invoked in the context of the SYS_Tasks function. The application should not call computationally intensive functions, blocking functions, functions that are not interrupt safe, or functions that poll on hardware conditions from the event handler. Doing so will affect the ability of the USB device stack to respond to USB events and could potentially make the USB device non-compliant.

HID Function Driver Events:

The HID Function Driver generates events to which the application must respond. Some of these events are control requests communicated through control transfers. The application must therefore complete the control transfer. Based on the generated event, the application may be required to:

- Respond with a USB_DEVICE_ControlSend function, which completes the data stage of a Control Read Transfer
- Respond with a USB_DEVICE_ControlReceive function, which provisions the data stage of a Control Write Transfer
- Respond with a USB_DEVICE_ControlStatus function which completes the handshake stage of the Control Transfer. The application can either STALL or Acknowledge the handshake stage via the USB_DEVICE_HID_ControlStatus function.

The following table shows the HID Function Driver control transfer related events and the required application control transfer action.

HID Function Driver Control Transfer Event	Required Application Action
USB_DEVICE_HID_EVENT_GET_REPORT	Call USB_DEVICE_ControlSend function with a buffer containing the requested report.
USB_DEVICE_HID_EVENT_SET_REPORT	Call USB_DEVICE_ControlReceive function with a buffer to receive the report.

USB_DEVICE_HID_EVENT_SET_REPORT	Call the USB_DEVICE_ControlSend function with the pointer to the current USB_HID_PROTOCOL_CODE type data.
USB_DEVICE_HID_EVENT_SET_PROTOCOL	Acknowledge or stall using the USB_DEVICE_ControlStatus function.
USB_DEVICE_HID_EVENT_SET_IDLE	Acknowledge or stall using the USB_DEVICE_ControlStatus function.
USB_DEVICE_HID_EVENT_GET_IDLE	Call the USB_DEVICE_ControlSend function to send the current idle rate.
USB_DEVICE_HID_SET_DESCRIPTOR	Call the USB_DEVICE_ControlReceive function with a buffer to receive the report.
USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_SENT	No action required.
USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_RECEIVED	Acknowledge or stall using the USB_DEVICE_ControlStatus function.
USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_ABORTED	No action required.

The application can respond to HID Function Driver control transfer-related events in the function driver event handler. In a case where the data required for the response is not immediately available, the application can respond to the control transfer events after returning from the event handler. This defers the response to the control transfer event. However, please note that a USB host will typically wait for control transfer response for a finite time duration before timing out and canceling the transfer and associated transactions. Even when deferring response, the application must respond promptly if such timeouts have to be avoided.

The application should analyze the pData member of the event handler and check for event specific data. The following table shows the pData parameter data type for each HID function driver event.

Event Type	pData Parameter Data Type
USB_DEVICE_HID_EVENT_GET_REPORT	USB_DEVICE_HID_EVENT_DATA_GET_REPORT*
USB_DEVICE_HID_EVENT_SET_REPORT	USB_DEVICE_HID_EVENT_DATA_SET_REPORT *
USB_DEVICE_HID_EVENT_GET_IDLE	uint8_t*
USB_DEVICE_HID_EVENT_SET_IDLE	USB_DEVICE_HID_EVENT_DATA_SET_IDLE *
USB_DEVICE_HID_EVENT_SET_PROTOCOL	USB_HID_PROTOCOL_CODE*
USB_DEVICE_HID_EVENT_GET_PROTOCOL	NULL
USB_DEVICE_HID_EVENT_SET_DESCRIPTOR	USB_DEVICE_HID_EVENT_DATA_SET_DESCRIPTOR *
USB_DEVICE_HID_EVENT_REPORT_SENT	USB_DEVICE_HID_EVENT_DATA_REPORT_SENT *
USB_DEVICE_HID_EVENT_REPORT_RECEIVED	USB_DEVICE_HID_EVENT_DATA_REPORT_RECEIVED *

USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_RECEIVED	NULL
USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_ABORTED	NULL

The possible HID Function Driver events are described here along with the required application response, event specific data and likely follow up function driver event:

USB_DEVICE_HID_EVENT_GET_REPORT

Application Response: This event is generated when the USB HID Host is requesting a report over the control interface. The application must provide the report by calling the USB_DEVICE_HID_ControlSend function, either in the event handler, or in the application (after event handler function has exited). The application can use the USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_SENT event to track completion of the command.

Event Specific Data (eventData): The application must interpret the pData parameter as a pointer to a

USB_DEVICE_HID_EVENT_DATA_GET_REPORT data type, which contains details about the requested report.

Likely Follow-up event: This event will likely be followed by the USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_SENT event. This indicates that the data was sent to the Host successfully. The application must acknowledge the handshake stage of the control transfer by calling the USB_DEVICE_HID_ControlStatus function with the USB_DEVICE_HID_CONTROL_STATUS_OK flag.

USB_DEVICE_HID_EVENT_SET_REPORT

Application Response: This event is generated when the USB HID Host wants to send a report over the control interface. The application must provide a buffer to receive the report by calling the USB_DEVICE_HID_ControlReceive function either in the event handler or in the application (after the event handler function has exited). The application can use the USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_RECEIVED event to track completion of the command.

Event Specific Data (eventData): The application must interpret the pData parameter as a pointer to a

USB_DEVICE_HID_EVENT_DATA_SET_REPORT data type, which contains details about the report that the Host intends to send.

Likely Follow-up event: This event will likely be followed by the

USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_RECEIVED event. This indicates that the data was received successfully. The application must either acknowledge or stall the handshake stage of the control transfer by calling the USB_DEVICE_HID_ControlStatus function with the USB_DEVICE_HID_CONTROL_STATUS_OK or

USB_DEVICE_HID_CONTROL_STATUS_ERROR flag, respectively.

USB_DEVICE_HID_EVENT_GET_IDLE

Application Response: This event is generated when the USB HID Host wants to read the current idle rate for the specified report. The application must provide the idle rate through the USB_DEVICE_HID_ControlSend function, either in the event handler, or in the application (after the event handler function has exited). The application must use the controlTransferHandle parameter provided in the event while calling the USB_DEVICE_HID_ControlSend function. The application can use the USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_SENT event to track completion of the command.

Event Specific Data (eventData): The application must interpret the pData parameter as a pointer to a uint8_t data type, which contains a report ID of the report for which the idle rate is requested.

Likely Follow-up event: This event will likely be followed by the

USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_SENT event. This indicates that the data was sent to the Host successfully. The application must acknowledge the handshake stage of the control transfer by calling the USB_DEVICE_HID_ControlStatus function with the USB_DEVICE_HID_CONTROL_STATUS_OK flag.

USB_DEVICE_HID_EVENT_SET_IDLE

Application Response: This event is generated when the USB HID Host sends a Set Idle request to the device. The application must inspect the eventData and determine if the idle rate is to be supported. The application must either acknowledge (if the idle rate is supported) or stall the handshake stage of the control transfer (if the idle rate is not supported) by calling the USB_DEVICE_HID_ControlStatus function with the USB_DEVICE_HID_CONTROL_STATUS_OK or USB_DEVICE_HID_CONTROL_STATUS_ERROR flag, respectively.

Event Specific Data (eventData): The application must interpret the pData parameter as a pointer to a USB_DEVICE_HID_EVENT_DATA_SET_IDLE data type that contains details about the report ID and the idle duration.

Likely Follow-up event: None.

USB_DEVICE_HID_EVENT_SET_PROTOCOL

Application Response: This event is generated when the USB HID Host sends a Set Protocol request to the device . The application must inspect the eventData and determine if the protocol is to be supported. The application must either acknowledge (if the protocol is supported) or stall the handshake stage of the control transfer (if the protocol is not supported) by calling USB_DEVICE_HID_ControlStatus function with SB_DEVICE_HID_CONTROL_STATUS_OK or USB_DEVICE_HID_CONTROL_STATUS_ERROR flag, respectively.

Event Specific Data (eventData): The application must interpret the pData parameter as a pointer to a USB_HID_PROTOCOL_CODE data type that contains details about the protocol to be set.

Likely Follow-up event: None.

USB_DEVICE_HID_EVENT_GET_PROTOCOL

Application Response: This event is generated when the USB HID Host issues a Get Protocol Request. The application must provide the current protocol through the USB_DEVICE_HID_ControlSend function either in the event handler or in the application (after the event handler has exited). The application can use the USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_SENT event to track completion of the command.

Event Specific Data (eventData): None.

Likely Follow-up event: This event will likely be followed by the USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_SENT event. This indicates that the data was sent to the host successfully. The application must acknowledge the handshake stage of the control transfer by calling the USB_DEVICE_HID_ControlStatus function with the USB_DEVICE_HID_CONTROL_STATUS_OK flag.

USB_DEVICE_HID_EVENT_SET_DESCRIPTOR

Application Response: This event is generated when the HID Host issues a Set Descriptor request. The application must provide a buffer to receive the descriptor through the USB_DEVICE_HID_ControlReceive function, either in the event handler, or in the application (after the event handler has exited). The application can use the USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_RECEIVED event to track completion of the command.

Event Specific Data: None

Likely Follow-up event: This event will likely be followed by the USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_RECEIVED event. This indicates that the data was received successfully. The application must either acknowledge or stall the handshake stage of the control transfer by calling USB_DEVICE_HID_ControlStatus function with USB_DEVICE_HID_CONTROL_STATUS_OK or the USB_DEVICE_HID_CONTROL_STATUS_ERROR flag, respectively.

USB_DEVICE_HID_EVENT_REPORT_SENT

Application Response: This event occurs when a report send operation scheduled by calling the USB_DEVICE_HID_ReportSend function has completed. This event does not require the application to respond with any function calls.

Event Specific Data (pData): The application must interpret the pData parameter as a pointer to a

USB_DEVICE_HID_EVENT_DATA_REPORT_SENT data type that contains details about the report that was sent.

Likely Follow-up event: None.

USB_DEVICE_HID_EVENT_REPORT_RECEIVED

Application Response: This event occurs when a report receive operation scheduled by calling the USB_DEVICE_HID_ReportReceive function has completed. This event does not require the application to respond with any function calls.

Event Specific Data (pData): The application must interpret the pData parameter as a pointer to a USB_DEVICE_HID_EVENT_DATA_REPORT_RECEIVED data type that contains details about the report that was received.

Likely Follow-up event: None

USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_SENT

Application Response: This event occurs when the data stage of a control read transfer has completed in response to the USB_DEVICE_HID_ControlSend function. The application must acknowledge the handshake stage of the control transfer by calling the USB_DEVICE_HID_ControlStatus function with the USB_DEVICE_HID_CONTROL_STATUS_OK flag.

Event Specific Data (pData): None.

Likely Follow-up event: None.

USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_RECEIVED

Application Response: This event occurs when the data stage of a control write transfer has completed in response to the USB_DEVICE_HID_ControlReceive function. The application must either acknowledge or stall the handshake stage of the control transfer by calling USB_DEVICE_HID_ControlStatus function with the USB_DEVICE_HID_CONTROL_STATUS_OK or USB_DEVICE_HID_CONTROL_STATUS_ERROR flag, respectively.

Event Specific Data (pData): None

Likely Follow-up event: None.

USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_ABORTED

Application Response: This event occurs when the a control transfer request is aborted by the Host. The application can use this event to update its HID class-specific control transfer state machine.

Event Specific Data (pData): None

Likely Follow-up event: None. The following code shows an example HID Function Driver event handling scheme.

The following code shows an example HID Function Driver event handling scheme.

```
// This code example shows all USB HID Driver events and a possible
// scheme for handling these events. In this example event responses are not
// deferred.

   USB_DEVICE_HID_EVENT_RESPONSE USB_AppHIDEventHandler
   (
      USB_DEVICE_HID_INDEX instanceIndex,
      USB_DEVICE_HID_EVENT event,
      void * pData,
      uintptr_t userData
)
{

```

```
            // application can inspect that data and then stall the
            // handshake stage of the control transfer or accept it
            // (as shown here).
            USB_DEVICE_ControlStatus(deviceHandle, USB_DEVICE_CONTROL_STATUS_OK);

            break;

        case USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_SENT:

            // This means that control transfer data was sent. The
            // application would typically acknowledge the handshake
            // stage of the control transfer.

            USB_DEVICE_HID_ControlStatus(instanceIndex, controlTransferHandle,
                  USB_DEVICE_HID_CONTROL_STATUS_OK);

            break;

        case USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_ABORTED:

             // This means that control transfer data was sent. The
             // application would typically acknowledge the handshake
             // stage of the control transfer.

            break;

        case USB_DEVICE_HID_EVENT_REPORT_RECEIVED:

            // This means a HID report receive request has completed.
            // The pData member should be interpreted as a
            // USB_DEVICE_HID_EVENT_DATA_REPORT_RECEIVED pointer type.

            break;

        case USB_DEVICE_HID_EVENT_REPORT_SENT:

            // This means a HID report send request has completed.
            // The pData member should be interpreted as a
            // USB_DEVICE_HID_EVENT_DATA_REPORT_SENT pointer type.

            break;
    }
    return(USB_DEVICE_HID_EVENT_RESPONSE_NONE);
}
```

Sending a Report

Describes how to send a report.

Description

The USB HID Device sends data to the USB HID Host as reports. The USB HID Device application should use the USB_DEVICE_HID_ReportSend function to send the report. This function returns a transfer handler that allows the application to track the read request. The request is completed when the Host has requested the data. A report send request could fail if the driver instance transfer queue is full. The completion of the write transfer is indicated by a USB_DEVICE_HID_EVENT_REPORT_SENT event. The transfer handle and the amount of data sent is returned in the reportSent member of the eventData data structure along with the event.

The following code shows an example of how a USB HID Mouse application sends a report to the host.

```
/* In this code example, the application uses the
 * USB_HID_MOUSE_ReportCreate to create the mouse report
 * and then uses the USB_DEVICE_HID_ReportSend() function
 * to send the report */

USB_HID_MOUSE_ReportCreate(appData.xCoordinate, appData.yCoordinate,
    appData.mouseButton, &appData.mouseReport);

/* Send the mouse report. */
USB_DEVICE_HID_ReportSend(appData.hidInstance,
    &appData.reportTransferHandle, (uint8_t*)&appData.mouseReport,
    sizeof(USB_HID_MOUSE_REPORT));
```

Receiving a Report

Describes how to receive a report.

Description

The application can receive a report from the Host by using the USB_DEVICE_HID_ReportReceive function. This function returns a transfer handler that allows the application to track the read request. The request is completed when the Host sends the report. The application must make sure that it allocates a buffer size that is at least the size of the report. The return value of the function indicates the success of the request. A read request could fail if the driver transfer queue is full. The completion of the read transfer is indicated by a USB_DEVICE_HID_EVENT_REPORT_RECEIVED event. The reportReceived member of the eventData data structure contains details about the received report. The following code shows an example of how a USB HID Keyboard can schedule a receive report operation to get the keyboard LED status.

```
/* The following code shows how the
 * USB HID Keyboard application schedules a
 * receive report operation to receive the
 * keyboard output report from the host. This
 * report contains the keyboard LED status. The
 * size of the report is 1 byte */

result = USB_DEVICE_HID_ReportReceive(appData.hidInstance,
             &appData.receiveTransferHandle,
             (uint8_t *)&appData.keyboardOutputReport,1);

if(USB_DEVICE_HID_RESULT_OK != result)
{
    /* Do error handling here */
}
```

Configuring the Library

Describes how to configure the HID Function Driver.

Macros

	Name	Description
	USB_DEVICE_HID_INSTANCES_NUMBER	Specifies the number of HID instances.
	USB_DEVICE_HID_QUEUE_DEPTH_COMINED	DOM-IGONORE-BEGIN

Description

The following configuration parameters must be defined while using the HID Function Driver. The configuration macros that implement these parameters must be located in the `system_config.h` file in the application project and a compiler include path (to point to the folder that contains this file) should be specified.

USB_DEVICE_HID_INSTANCES_NUMBER Macro

Specifies the number of HID instances.

File

usb_device_hid_config_template.h

C

```
#define USB_DEVICE_HID_INSTANCES_NUMBER
```

Description

USB Device HID Maximum Number of Instances

This macro defines the number of instances of the HID Function Driver. For example, if the application needs to implement two instances of the HID Function Driver (to create composite device) on one USB Device, the macro should be set to 2. Note that implementing a USB Device that features multiple HID interfaces requires appropriate USB configuration descriptors.

Remarks

None.

USB_DEVICE_HID_QUEUE_DEPTH_COMINED Macro

File

usb_device_hid_config_template.h

C

```
#define USB_DEVICE_HID_QUEUE_DEPTH_COMINED
```

Description

DOM-IGONORE-BEGIN

Building the Library

Describes the files to be included in the project while using the HID Function Driver.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/usb`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`usb_device_hid.h`	This header file should be included in any `.c` file that accesses the USB Device HID Function Driver API.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/dynamic/usb_device_hid.c`	This file implements the HID Function driver interface and should be included in the project if the HID Device function is desired.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The USB HID Device Library depends on the following modules:

- USB Device Layer Library

Library Interface

a) Functions

	Name	Description
	USB_DEVICE_HID_EventHandlerSet	This function registers a event handler for the specified HID function driver instance.
	USB_DEVICE_HID_ReportReceive	This function submits the buffer to HID function driver library to receive a report from host to device.
	USB_DEVICE_HID_ReportSend	This function submits the buffer to HID function driver library to send a report from device to host.
	USB_DEVICE_HID_TransferCancel	This function cancels a scheduled HID Device data transfer.

b) Data Types and Constants

	Name	Description
	USB_DEVICE_HID_EVENT	USB Device HID Function Driver Events
	USB_DEVICE_HID_EVENT_DATA_GET_REPORT	USB Device HID Get Report Event Data Type.
	USB_DEVICE_HID_EVENT_DATA_REPORT_RECEIVED	USB Device HID Report Received Event Data Type.
	USB_DEVICE_HID_EVENT_DATA_REPORT_SENT	USB Device HID Report Sent Event Data Type.
	USB_DEVICE_HID_EVENT_DATA_SET_IDLE	USB Device HID Set Idle Event Data Type.
	USB_DEVICE_HID_EVENT_DATA_SET_REPORT	USB Device HID Set Report Event Data Type.
	USB_DEVICE_HID_INDEX	USB device HID Function Driver Index.
	USB_DEVICE_HID_EVENT_DATA_GET_IDLE	USB Device HID Get Idle Event Data Type.
	USB_DEVICE_HID_TRANSFER_HANDLE	USB Device HID Function Driver Transfer Handle Definition.
	USB_DEVICE_HID_EVENT_DATA_SET_PROTOCOL	USB Device HID Set Protocol Event Data Type.
	USB_DEVICE_HID_EVENT_HANDLER	USB Device HID Event Handler Function Pointer Type.
	USB_DEVICE_HID_EVENT_RESPONSE	USB Device HID Function Driver Event Callback Response Type
	USB_DEVICE_HID_INIT	USB Device HID Function Driver Initialization Data Structure
	USB_DEVICE_HID_RESULT	USB Device HID Function Driver USB Device HID Result enumeration.
	USB_DEVICE_HID_EVENT_RESPONSE_NONE	USB Device HID Function Driver Event Handler Response Type None.
	USB_DEVICE_HID_TRANSFER_HANDLE_INVALID	USB Device HID Function Driver Invalid Transfer Handle Definition.
	USB_DEVICE_HID_FUNCTION_DRIVER	This is a pointer to a group of HID Function Driver callback function pointers.
	USB_DEVICE_HID_INDEX_0	USB Device HID Function Driver Index Constants
	USB_DEVICE_HID_INDEX_1	This is macro USB_DEVICE_HID_INDEX_1.
	USB_DEVICE_HID_INDEX_2	This is macro USB_DEVICE_HID_INDEX_2.
	USB_DEVICE_HID_INDEX_3	This is macro USB_DEVICE_HID_INDEX_3.
	USB_DEVICE_HID_INDEX_4	This is macro USB_DEVICE_HID_INDEX_4.
	USB_DEVICE_HID_INDEX_5	This is macro USB_DEVICE_HID_INDEX_5.
	USB_DEVICE_HID_INDEX_6	This is macro USB_DEVICE_HID_INDEX_6.
	USB_DEVICE_HID_INDEX_7	This is macro USB_DEVICE_HID_INDEX_7.

Description

This section describes the Application Programming Interface (API) functions of the USB Device HID library.

Refer to each section for a detailed description.

a) Functions

USB_DEVICE_HID_EventHandlerSet Function

This function registers a event handler for the specified HID function driver instance.

File

usb_device_hid.h

C

```
USB_DEVICE_HID_RESULT USB_DEVICE_HID_EventHandlerSet(USB_DEVICE_HID_INDEX instanceIndex,
USB_DEVICE_HID_EVENT_HANDLER eventHandler, uintptr_t context);
```

Returns

USB_DEVICE_HID_RESULT_OK - The operation was successful

USB_DEVICE_HID_RESULT_ERROR_INSTANCE_INVALID - The specified instance does not exist.

USB_DEVICE_HID_RESULT_ERROR_PARAMETER_INVALID - The eventHandler parameter is NULL

Description

This function registers a event handler for the specified HID function driver instance. This function should be called by the client when it receives a SET CONFIGURATION event from the device layer. A event handler must be registered for function driver to respond to function driver specific commands. If the event handler is not registered, the device layer will stall function driver specific commands and the USB device may not function.

Remarks

None.

Preconditions

This function should be called when the function driver has been initialized as a result of a set configuration.

Example

```
// This code snippet shows an example registering an event handler. Here
// the application specifies the context parameter as a pointer to an
// application object (appObject) that should be associated with this
// instance of the HID function driver.

USB_DEVICE_HID_RESULT result;

USB_DEVICE_HID_EVENT_RESPONSE APP_USBDeviceHIDEventHandler
(
    USB_DEVICE_HID_INDEX instanceIndex,
    USB_DEVICE_HID_EVENT event,
    void * pData,
    uintptr_t context
)
{
    // Event Handling comes here

    switch(event)
    {
        ...
    }

    return(USB_DEVICE_HID_EVENT_RESPONSE_NONE);
}

result = USB_DEVICE_HID_EventHandlerSet (0, &APP_EventHandler, (uintptr_t) &appObject);

if(USB_DEVICE_HID_RESULT_OK != result)
{
    SYS_ASSERT ( false , "Error while registering event handler" );
}
```

Parameters

Parameters	Description
instance	Instance of the HID Function Driver.
eventHandler	A pointer to event handler function.
context	Application specific context that is returned in the event handler.

Function

USB_DEVICE_HID_RESULT USB_DEVICE_HID_EventHandlerSet

(

USB_DEVICE_HID_INDEX instance

USB_DEVICE_HID_EVENT_HANDLER eventHandler

uintptr_t context

);

USB_DEVICE_HID_ReportReceive Function

This function submits the buffer to HID function driver library to receive a report from host to device.

File

usb_device_hid.h

C

```
USB_DEVICE_HID_RESULT USB_DEVICE_HID_ReportReceive(USB_DEVICE_HID_INDEX instanceIndex,
USB_DEVICE_HID_TRANSFER_HANDLE * handle, void * buffer, size_t size);
```

Returns

USB_DEVICE_HID_RESULT_OK - The receive request was successful. transferHandle contains a valid transfer handle.

USB_DEVICE_HID_RESULT_ERROR_TRANSFER_QUEUE_FULL - internal request queue is full. The receive request could not be added.

USB_DEVICE_HID_RESULT_ERROR_INSTANCE_NOT_CONFIGURED - The specified instance is not configured yet.

USB_DEVICE_HID_RESULT_ERROR_INSTANCE_INVALID - The specified instance was not provisioned in the application and is invalid.

Description

This function submits the buffer to HID function driver library to receive a report from host to device. On completion of the transfer the library generates USB_DEVICE_HID_EVENT_REPORT_RECEIVED event to the application. A handle to the request is passed in the transferHandle parameter. The transfer handle expires when event handler for the USB_DEVICE_HID_EVENT_REPORT_RECEIVED exits. If the receive request could not be accepted, the function returns an error code and transferHandle will contain the value USB_DEVICE_HID_TRANSFER_HANDLE_INVALID.

Remarks

While the using the HID Function Driver with the PIC32MZ USB module, the report data buffer provided to the USB_DEVICE_HID_ReportReceive function should be placed in coherent memory and aligned at a 16 byte boundary. This can be done by declaring the buffer using the __attribute__((coherent, aligned(16))) attribute. An example is shown here

```
uint8_t data[256] __attribute__((coherent, aligned(16)));
```

Preconditions

USB device layer must be initialized.

Example

```
USB_DEVICE_HID_TRANSFER_HANDLE hidTransferHandle;
USB_DEVICE_HID_RESULT result;

// Register APP_HIDEventHandler function
USB_DEVICE_HID_EventHandlerSet( USB_DEVICE_HID_INDEX_0 ,
                                APP_HIDEventHandler );

// Prepare report and request HID to send the report.
result = USB_DEVICE_HID_ReportReceive( USB_DEVICE_HID_INDEX_0,
                           &hidTransferHandle ,
                           &appReport[0], sizeof(appReport));

if( result != USB_DEVICE_HID_RESULT_OK)
{
   //Handle error.

}

//Implementation of APP_HIDEventHandler

USB_DEVICE_HIDE_EVENT_RESPONSE APP_HIDEventHandler
{
  USB_DEVICE_HID_INDEX instanceIndex,
  USB_DEVICE_HID_EVENT event,
  void * pData,
  uintptr_t context
}
{
    USB_DEVICE_HID_EVENT_DATA_REPORT_RECEIVED reportReceivedEventData;
    // Handle HID events here.
    switch (event)
    {
        case USB_DEVICE_HID_EVENT_REPORT_RECEIVED:
           if( (reportReceivedEventData->reportSize == sizeof(appReport)
                && reportReceivedEventData->report == &appReport[0])
           {
              // Previous transfer was complete.
           }
           break;
        ....
    }
}
```

Parameters

Parameters	Description
instanceIndex	HID instance index.
transferHandle	HID transfer handle.
buffer	Pointer to buffer where the received report has to be received stored.
size	Buffer size.

Function

```
USB_DEVICE_HID_RESULT USB_DEVICE_HID_ReportReceive
(
    USB_DEVICE_HID_INDEX instanceIndex,
    USB_DEVICE_HID_TRANSFER_HANDLE * transferHandle,
void * buffer,
size_t size
);
```

USB_DEVICE_HID_ReportSend Function

This function submits the buffer to HID function driver library to send a report from device to host.

File

usb_device_hid.h

C

```
USB_DEVICE_HID_RESULT USB_DEVICE_HID_ReportSend(USB_DEVICE_HID_INDEX instanceIndex,
USB_DEVICE_HID_TRANSFER_HANDLE * handle, void * buffer, size_t size);
```

Returns

USB_DEVICE_HID_RESULT_OK - The send request was successful. transferHandle contains a valid transfer handle.

USB_DEVICE_HID_RESULT_ERROR_TRANSFER_QUEUE_FULL - Internal request queue is full. The send request could not be added.

USB_DEVICE_HID_RESULT_ERROR_INSTANCE_NOT_CONFIGURED - The specified instance is not configured yet.

USB_DEVICE_HID_RESULT_ERROR_INSTANCE_INVALID - The specified instance was not provisioned in the application and is invalid.

Description

This function places a request to send a HID report with the USB Device HID Function Driver Layer. The function places a requests with driver, the request will get serviced when report is requested by the USB Host. A handle to the request is returned in the transferHandle parameter. The termination of the request is indicated by the USB_DEVICE_HID_EVENT_REPORT_SENT event. The amount of data sent, a pointer to the report and the transfer handle associated with the request is returned along with the event in the pData parameter of the event handler. The transfer handle expires when event handler for the USB_DEVICE_HID_EVENT_REPORT_SENT exits. If the send request could not be accepted, the function returns an error code and transferHandle will contain the value USB_DEVICE_HID_TRANSFER_HANDLE_INVALID.

Remarks

While the using the HID Function Driver with the PIC32MZ USB module, the report data buffer provided to the USB_DEVICE_HID_ReportSend function should be placed in coherent memory and aligned at a 16 byte boundary. This can be done by declaring the buffer using the __attribute__((coherent, aligned(16))) attribute. An example is shown here

```
uint8_t data[256] __attribute__((coherent, aligned(16)));
```

Preconditions

USB device layer must be initialized.

Example

```
USB_DEVICE_HID_TRANSFER_HANDLE hidTransferHandle;
USB_DEVICE_HID_RESULT result;

// Register APP_HIDEventHandler function
USB_DEVICE_HID_EventHandlerSet( USB_DEVICE_HID_INDEX_0 ,
                                APP_HIDEventHandler );

// Prepare report and request HID to send the report.
result = USB_DEVICE_HID_ReportSend( USB_DEVICE_HID_INDEX_0,
                           &hidTransferHandle ,
```

```
                            &appReport[0], sizeof(appReport));

    if( result != USB_DEVICE_HID_RESULT_OK)
    {
       //Handle error.

    }

    //Implementation of APP_HIDEventHandler

    USB_DEVICE_HIDE_EVENT_RESPONSE APP_HIDEventHandler
    {
        USB_DEVICE_HID_INDEX instanceIndex,
        USB_DEVICE_HID_EVENT event,
        void * pData,
        uintptr_t context
    }
    {
        USB_DEVICE_HID_EVENT_DATA_REPORT_SENT * reportSentEventData;

        // Handle HID events here.
        switch (event)
        {
            case USB_DEVICE_HID_EVENT_REPORT_SENT:

                reportSentEventData = (USB_DEVICE_HID_EVENT_REPORT_SENT *)pData;
                if(reportSentEventData->reportSize == sizeof(appReport))
                {
                    // The report was sent completely.
                }
                break;

                ....

        }
        return(USB_DEVICE_HID_EVENT_RESPONSE_NONE);
    }
```

Parameters

Parameters	Description
instance	USB Device HID Function Driver instance.
transferHandle	Pointer to a USB_DEVICE_HID_TRANSFER_HANDLE type of variable. This variable will contain the transfer handle in case the send request was successful.
data	pointer to the data buffer containing the report to be sent.
size	Size (in bytes) of the report to be sent.

Function

USB_DEVICE_HID_RESULT USB_DEVICE_HID_ReportSend

(

USB_DEVICE_HID_INDEX instanceIndex,

USB_DEVICE_HID_TRANSFER_HANDLE * transferHandle,

void * buffer,

size_t size

)

USB_DEVICE_HID_TransferCancel Function

This function cancels a scheduled HID Device data transfer.

File

usb_device_hid.h

C

```
USB_DEVICE_HID_RESULT USB_DEVICE_HID_TransferCancel(USB_DEVICE_HID_INDEX usbDeviceHandle,
```

```
USB_DEVICE_HID_TRANSFER_HANDLE transferHandle);
```

Returns

USB_DEVICE_HID_RESULT_OK - The transfer will be canceled completely or partially.

USB_DEVICE_HID_RESULT_ERROR_PARAMETER_INVALID - Invalid transfer handle

USB_DEVICE_HID_RESULT_ERROR_INSTANCE_INVALID - Invalid HID instance index

USB_DEVICE_HID_RESULT_ERROR - The transfer could not be canceled because it has either completed, the transfer handle is invalid or the last transaction is in progress.

Description

This function cancels a scheduled HID Device data transfer. The transfer could have been scheduled using the USB_DEVICE_HID_ReportReceive, USB_DEVICE_HID_ReportSend function. If a transfer is still in the queue and its processing has not started, then the transfer is canceled completely. A transfer that is in progress may or may not get canceled depending on the transaction that is presently in progress. If the last transaction of the transfer is in progress, then the transfer will not be canceled. If it is not the last transaction in progress, the in-progress will be allowed to complete. Pending transactions will be canceled. The first transaction of an in progress transfer cannot be canceled.

Remarks

The buffer specific to the transfer handle should not be released unless the transfer abort event is notified through callback.

Preconditions

The USB Device should be in a configured state.

Example

```
// The following code snippet cancels a HID transfer.

USB_DEVICE_HID_TRANSFER_HANDLE transferHandle;
USB_DEVICE_HID_RESULT result;

result = USB_DEVICE_HID_TransferCancel(instanceIndex, transferHandle);

if(USB_DEVICE_HID_RESULT_OK == result)
{
    // The transfer cancellation was either completely or
    // partially successful.
}
```

Parameters

Parameters	Description
instanceIndex	HID Function Driver instance index.
transferHandle	Transfer handle of the transfer to be canceled.

Function

```
USB_DEVICE_HID_RESULT USB_DEVICE_HID_TransferCancel
(
    USB_DEVICE_HID_INDEX instanceIndex,
    USB_DEVICE_HID_TRANSFER_HANDLE transferHandle
);
```

b) Data Types and Constants

USB_DEVICE_HID_EVENT Enumeration

USB Device HID Function Driver Events

File

usb_device_hid.h

C

```
typedef enum {
  USB_DEVICE_HID_EVENT_GET_REPORT,
```

```
  USB_DEVICE_HID_EVENT_GET_IDLE,
  USB_DEVICE_HID_EVENT_GET_PROTOCOL,
  USB_DEVICE_HID_EVENT_SET_REPORT,
  USB_DEVICE_HID_EVENT_SET_IDLE,
  USB_DEVICE_HID_EVENT_SET_PROTOCOL,
  USB_DEVICE_HID_EVENT_REPORT_SENT,
  USB_DEVICE_HID_EVENT_REPORT_RECEIVED,
  USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_RECEIVED,
  USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_SENT,
  USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_ABORTED
} USB_DEVICE_HID_EVENT;
```

Members

Members	Description
USB_DEVICE_HID_EVENT_GET_REPORT	This event occurs when the host issues a GET REPORT command. This is a HID class specific control transfer related event. The application must interpret the pData parameter as USB_DEVICE_HID_EVENT_DATA_GET_REPORT pointer type. If the report request is supported, the application must send the report to the host by using the USB_DEVICE_ControlSend function either in the event handler or after the event handler routine has returned. The application can track the completion of the request by using the USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_SENT event. If the report request is not supported, the application must stall the request by calling the USB_DEVICE_ControlStatus function with a USB_DEVICE_CONTROL_STATUS_ERROR flag.
USB_DEVICE_HID_EVENT_GET_IDLE	This event occurs when the host issues a GET IDLE command. This is a HID class specific control transfer related event. The pData parameter will be a USB_DEVICE_HID_EVENT_DATA_GET_IDLE pointer type containing the ID of the report for which the idle parameter is requested. If the request is supported, the application must send the idle rate to the host by calling the USB_DEVICE_ControlSend function. This function can be called either in the event handler or after the event handler routine has returned. The application can track the completion of the request by using the USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_SENT event. If the request is not supported, the application must stall the request by calling the USB_DEVICE_ControlStatus function with a USB_DEVICE_CONTROL_STATUS_ERROR flag.
USB_DEVICE_HID_EVENT_GET_PROTOCOL	This event occurs when the host issues a GET PROTOCOL command. This is a HID class specific control transfer related event. The pData parameter will be NULL. If the request is supported, the application must send a USB_HID_PROTOCOL_CODE data type object, containing the current protocol, to the host by calling the USB_DEVICE_ControlSend function. This function can be called either in the event handler or after the event handler routine has returned. The application can track the completion of the request by using the USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_SENT event. If the request is not supported, the application must stall the request by calling the USB_DEVICE_ControlStatus function with a USB_DEVICE_CONTROL_STATUS_ERROR flag.
USB_DEVICE_HID_EVENT_SET_REPORT	This event occurs when the host issues a SET REPORT command. This is a HID class specific control transfer related event. The application must interpret the pData parameter as a USB_DEVICE_HID_EVENT_DATA_SET_REPORT pointer type. If the report request is supported, the application must provide a buffer, to receive the report, to the host by calling the USB_DEVICE_ControlReceive function either in the event handler or after the event handler routine has returned. The application can track the completion of the request by using the USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_RECEIVED event. If the report request is not supported, the application must stall the request by calling the USB_DEVICE_ControlStatus function with a USB_DEVICE_CONTROL_STATUS_ERROR flag.

USB_DEVICE_HID_EVENT_SET_IDLE	This event occurs when the host issues a SET IDLE command. This is a HID class specific control transfer related event. The pData parameter will be USB_DEVICE_HID_EVENT_DATA_SET_IDLE pointer type. The application can analyze the idle duration and acknowledge or reject the setting by calling the USB_DEVICE_ControlStatus function. This function can be called in the event handler or after the event handler exits. If application can reject the request by calling the USB_DEVICE_ControlStatus function with a USB_DEVICE_CONTROL_STATUS_ERROR flag. It can accept the request by calling this function with USB_DEVICE_CONTROL_STATUS_OK flag.
USB_DEVICE_HID_EVENT_SET_PROTOCOL	This event occurs when the host issues a SET PROTOCOL command. This is a HID class specific control transfer related event. The pData parameter will be a pointer to a USB_DEVICE_HID_EVENT_DATA_SET_PROTOCOL data type. If the request is supported, the application must acknowledge the request by calling the USB_DEVICE_ControlStatus function with a USB_DEVICE_CONTROL_STATUS_OK flag. If the request is not supported, the application must stall the request by calling the USB_DEVICE_ControlStatus function with a USB_DEVICE_CONTROL_STATUS_ERROR flag.
USB_DEVICE_HID_EVENT_REPORT_SENT	This event indicates that USB_DEVICE_HID_ReportSend function completed a report transfer on interrupt endpoint from host to device. The pData parameter will be a USB_DEVICE_HID_EVENT_DATA_REPORT_SENT type.
USB_DEVICE_HID_EVENT_REPORT_RECEIVED	This event indicates that USB_DEVICE_HID_ReportReceive function completed a report transfer on interrupt endpoint from device to host. The pData parameter will be a USB_DEVICE_HID_EVENT_DATA_REPORT_RECEIVED type
USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_RECEIVED	This event occurs when the data stage of a control write transfer has completed. This happens after the application uses the USB_DEVICE_ControlReceive function to respond to a HID Function Driver Control Transfer Event that requires data to be received from the host. The pData parameter will be NULL. The application should call the USB_DEVICE_ControlStatus function with the USB_DEVICE_CONTROL_STATUS_OK flag if the received data is acceptable or should call this function with USB_DEVICE_CONTROL_STATUS_ERROR flag if the received data needs to be rejected.
USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_SENT	This event occurs when the data stage of a control read transfer has completed. This happens after the application uses the USB_DEVICE_ControlSend function to respond to a HID Function Driver Control Transfer Event that requires data to be sent to the host. The pData parameter will be NULL
USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_ABORTED	This event occurs when an ongoing control transfer was aborted. The application must stop any pending control transfer related activities.

Description

USB Device HID Function Driver Events

These events are specific to the USB Device HID Function Driver instance. Each event description contains details about the parameters passed with event. The contents of pData depends on the generated event.

Events that are associated with the HID Function Driver Specific Control Transfers require application response. The application should respond to these events by using the USB_DEVICE_ControlReceive, USB_DEVICE_ControlSend and USB_DEVICE_ControlStatus functions.

Calling the USB_DEVICE_ControlStatus function with a USB_DEVICE_CONTROL_STATUS_ERROR will stall the control transfer request. The application would do this if the control transfer request is not supported. Calling the USB_DEVICE_ControlStatus function with a USB_DEVICE_CONTROL_STATUS_OK will complete the status stage of the control transfer request. The application would do this if the control transfer request is supported

The following code snippet shows an example of a possible event handling scheme.

```
// This code example shows all HID Function Driver events and a possible
// scheme for handling these events. In this example event responses are not
// deferred.

USB_DEVICE_HID_EVENT_RESPONSE USB_AppHIDEventHandler
(
    USB_DEVICE_HID_INDEX instanceIndex,
    USB_DEVICE_HID_EVENT event,
    void * pData,
    uintptr_t userData
)
```

```
{
    uint8_t currentIdleRate;
    uint8_t someHIDReport[128];
    uint8_t someHIDDescriptor[128];
    USB_DEVICE_HANDLE       usbDeviceHandle;
    USB_HID_PROTOCOL_CODE  currentProtocol;
    USB_DEVICE_HID_EVENT_DATA_GET_REPORT        * getReportEventData;
    USB_DEVICE_HID_EVENT_DATA_SET_IDLE          * setIdleEventData;
    USB_DEVICE_HID_EVENT_DATA_SET_DESCRIPTOR    * setDescriptorEventData;
    USB_DEVICE_HID_EVENT_DATA_SET_REPORT        * setReportEventData;

    switch(event)
    {
        case USB_DEVICE_HID_EVENT_GET_REPORT:

            // In this case, pData should be interpreted as a
            // USB_DEVICE_HID_EVENT_DATA_GET_REPORT pointer. The application
            // must send the requested report by using the
            // USB_DEVICE_ControlSend() function.

            getReportEventData = (USB_DEVICE_HID_EVENT_DATA_GET_REPORT *)pData;
            USB_DEVICE_ControlSend(usbDeviceHandle, someHIDReport, getReportEventData->reportLength);

            break;

        case USB_DEVICE_HID_EVENT_GET_PROTOCOL:

            // In this case, pData will be NULL. The application
            // must send the current protocol to the host by using
            // the USB_DEVICE_ControlSend() function.

           USB_DEVICE_ControlSend(usbDeviceHandle, &currentProtocol, sizeof(USB_HID_PROTOCOL_CODE));
           break;

        case USB_DEVICE_HID_EVENT_GET_IDLE:

            // In this case, pData will be a
            // USB_DEVICE_HID_EVENT_DATA_GET_IDLE pointer type containing the
            // ID of the report for which the idle rate is being requested.
            // The application must send the current idle rate to the host
            // by using the USB_DEVICE_ControlSend() function.

           USB_DEVICE_ControlSend(usbDeviceHandle, &currentIdleRate, 1);
           break;

        case USB_DEVICE_HID_EVENT_SET_REPORT:

            // In this case, pData should be interpreted as a
            // USB_DEVICE_HID_EVENT_DATA_SET_REPORT type pointer. The
            // application can analyze the request and then obtain the
            // report by using the USB_DEVICE_ControlReceive() function.

            setReportEventData = (USB_DEVICE_HID_EVENT_DATA_SET_REPORT *)pData;
            USB_DEVICE_ControlReceive(deviceHandle, someHIDReport, setReportEventData->reportLength);
            break;

        case USB_DEVICE_HID_EVENT_SET_PROTOCOL:

            // In this case, pData should be interpreted as a
            // USB_DEVICE_HID_EVENT_DATA_SET_PROTOCOL type pointer. The application can
            // analyze the data and decide to stall or accept the setting.
            // This shows an example of accepting the protocol setting.

            USB_DEVICE_ControlStatus(deviceHandle, USB_DEVICE_CONTROL_STATUS_OK);
            break;

        case USB_DEVICE_HID_EVENT_SET_IDLE:

            // In this case, pData should be interpreted as a
```

```
            // USB_DEVICE_HID_EVENT_DATA_SET_IDLE type pointer. The
            // application can analyze the data and decide to stall
            // or accept the setting. This shows an example of accepting
            // the protocol setting.

            setIdleEventData = (USB_DEVICE_HID_EVENT_DATA_SET_IDLE *)pData;
            USB_DEVICE_ControlStatus(deviceHandle, USB_DEVICE_CONTROL_STATUS_OK);
            break;

        case USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_RECEIVED:

            // In this case, control transfer data was received. The
            // application can inspect that data and then stall the
            // handshake stage of the control transfer or accept it
            // (as shown here).

            USB_DEVICE_ControlStatus(deviceHandle, USB_DEVICE_CONTROL_STATUS_OK);
            break;

        case USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_DATA_SENT:

            // This means that control transfer data was sent. The
            // application would typically acknowledge the handshake
            // stage of the control transfer.

            break;

        case USB_DEVICE_HID_EVENT_CONTROL_TRANSFER_ABORTED:

            // This is an indication only event. The application must
            // reset any HID control transfer related tasks when it receives
            // this event.

        break;

        case USB_DEVICE_HID_EVENT_REPORT_RECEIVED:

            // This means a HID report receive request has completed.
            // The pData member should be interpreted as a
            // USB_DEVICE_HID_EVENT_DATA_REPORT_RECEIVED pointer type.

            break;

        case USB_DEVICE_HID_EVENT_REPORT_SENT:

            // This means a HID report send request has completed.
            // The pData member should be interpreted as a
            // USB_DEVICE_HID_EVENT_DATA_REPORT_SENT pointer type.

            break;
    }

    return(USB_DEVICE_HID_EVENT_RESPONSE_NONE);
}
```

Remarks

Some of the events allow the application to defer responses. This allows the application some time to obtain the response data rather than having to respond to the event immediately. Note that a USB host will typically wait for event response for a finite time duration before timing out and canceling the event and associated transactions. Even when deferring response, the application must respond promptly if such timeouts have to be avoided.

```

Description

USB Device HID Event Handler Function Pointer Type.

This data type defines the required function signature of the USB Device HID Function Driver event handling callback function. The application must register a pointer to a HID Function Driver events handling function whose function signature (parameter and return value types) match the types specified by this function pointer in order to receive event call backs from the HID Function Driver. The function driver will invoke this function with event relevant parameters. The description of the event handler function parameters is given here.

instanceIndex - Instance index of the HID Function Driver that generated the event.

event - Type of event generated.

pData - This parameter should be type casted to a event specific pointer type based on the event that has occurred. Refer to the USB_DEVICE_HID_EVENT enumeration description for more details.

context - Value identifying the context of the application that registered the event handling function.

Remarks

None.

USB_DEVICE_HID_EVENT_RESPONSE Type

USB Device HID Function Driver Event Callback Response Type

File

usb_device_hid.h

C

```
typedef void USB_DEVICE_HID_EVENT_RESPONSE;
```

Description

USB Device HID Function Driver Event Handler Response Type

This is the return type of the HID Function Driver event handler.

Remarks

None.

USB_DEVICE_HID_INIT Structure

USB Device HID Function Driver Initialization Data Structure

File

usb_device_hid.h

C

```
typedef struct {
  size_t hidReportDescriptorSize;
  void * hidReportDescriptor;
  size_t queueSizeReportSend;
  size_t queueSizeReportReceive;
} USB_DEVICE_HID_INIT;
```

Members

Members	Description
size_t hidReportDescriptorSize;	Size of the HID report descriptor
void * hidReportDescriptor;	Pointer to HID report descriptor
size_t queueSizeReportSend;	Report send queue size
size_t queueSizeReportReceive;	Report receive queue size

Description

USB Device HID Function Driver Initialization Data Structure

This data structure must be defined for every instance of the HID function driver. It is passed to the HID function driver, by the Device Layer, at the time of initialization. The funcDriverInit member of the Device Layer Function Driver registration table entry must point to this data structure for an instance of the HID function driver.

Remarks

None.

USB_DEVICE_HID_RESULT Enumeration

USB Device HID Function Driver USB Device HID Result enumeration.

File

usb_device_hid.h

C

```
typedef enum {
  USB_DEVICE_HID_RESULT_OK,
  USB_DEVICE_HID_RESULT_ERROR_TRANSFER_QUEUE_FULL,
  USB_DEVICE_HID_RESULT_ERROR_INSTANCE_NOT_CONFIGURED,
  USB_DEVICE_HID_RESULT_ERROR_INSTANCE_INVALID,
  USB_DEVICE_HID_RESULT_ERROR_TERMINATED_BY_HOST,
  USB_DEVICE_HID_RESULT_ERROR
} USB_DEVICE_HID_RESULT;
```

Members

Members	Description
USB_DEVICE_HID_RESULT_OK	The operation was successful
USB_DEVICE_HID_RESULT_ERROR_TRANSFER_QUEUE_FULL	The transfer queue is full. No new transfers can be • scheduled
USB_DEVICE_HID_RESULT_ERROR_INSTANCE_NOT_CONFIGURED	The specified instance is not configured yet

USB_DEVICE_HID_RESULT_ERROR_INSTANCE_INVALID	The specified instance is not provisioned in the system
USB_DEVICE_HID_RESULT_ERROR_TERMINATED_BY_HOST	Transfer terminated by host because of a stall clear
USB_DEVICE_HID_RESULT_ERROR	General Error

Description

USB Device HID Function Driver USB Device HID Result enumeration.

This enumeration lists the possible USB Device HID Function Driver operation results. These values USB Device HID Library functions.

Remarks

None.

USB_DEVICE_HID_EVENT_RESPONSE_NONE Macro

USB Device HID Function Driver Event Handler Response Type None.

File

usb_device_hid.h

C

```
#define USB_DEVICE_HID_EVENT_RESPONSE_NONE
```

Description

USB Device HID Function Driver Event Handler Response None

This is the definition of the HID Function Driver Event Handler Response Type none.

Remarks

Intentionally defined to be empty.

USB_DEVICE_HID_TRANSFER_HANDLE_INVALID Macro

USB Device HID Function Driver Invalid Transfer Handle Definition.

File

usb_device_hid.h

C

```
#define USB_DEVICE_HID_TRANSFER_HANDLE_INVALID
```

Description

USB Device HID Function Driver Invalid Transfer Handle Definition

This definition defines a USB Device HID Function Driver Invalid Transfer Handle. A Invalid Transfer Handle is returned by the USB_DEVICE_HID_ReportReceive and USB_DEVICE_HID_ReportSend functions when the request was not successful.

Remarks

None.

USB_DEVICE_HID_FUNCTION_DRIVER Macro

This is a pointer to a group of HID Function Driver callback function pointers.

File

usb_device_hid.h

C

```
#define USB_DEVICE_HID_FUNCTION_DRIVER
```

Description

USB Device HID Function Driver Device Layer callback function pointer group

This is a pointer to a group of HID Function Driver callback function pointers. The application must use this pointer while registering an instance of the HID function driver with the Device Layer via the function driver registration table i.e. the driver member of the function driver registration object in the device layer function driver registration table should be set to this value.

Remarks

None.

USB_DEVICE_HID_INDEX_0 Macro

USB Device HID Function Driver Index Constants

File

usb_device_hid.h

C

```
#define USB_DEVICE_HID_INDEX_0 0
```

Description

USB Device HID Function Driver Index Constants

This constants can be used by the application to specify HID function driver instance indexes.

Remarks

None.

USB_DEVICE_HID_INDEX_1 Macro

File

usb_device_hid.h

C

```
#define USB_DEVICE_HID_INDEX_1 1
```

Description

This is macro USB_DEVICE_HID_INDEX_1.

USB_DEVICE_HID_INDEX_2 Macro

File

usb_device_hid.h

C

```
#define USB_DEVICE_HID_INDEX_2 2
```

Description

This is macro USB_DEVICE_HID_INDEX_2.

USB_DEVICE_HID_INDEX_3 Macro

File

usb_device_hid.h

C

```
#define USB_DEVICE_HID_INDEX_3 3
```

Description

This is macro USB_DEVICE_HID_INDEX_3.

USB_DEVICE_HID_INDEX_4 Macro

File

usb_device_hid.h

C

```
#define USB_DEVICE_HID_INDEX_4 4
```

Description

This is macro USB_DEVICE_HID_INDEX_4.

USB_DEVICE_HID_INDEX_5 Macro

File

usb_device_hid.h

C

```
#define USB_DEVICE_HID_INDEX_5 5
```

Description

This is macro USB_DEVICE_HID_INDEX_5.

USB_DEVICE_HID_INDEX_6 Macro

File

usb_device_hid.h

C

```
#define USB_DEVICE_HID_INDEX_6 6
```

Description

This is macro USB_DEVICE_HID_INDEX_6.

USB_DEVICE_HID_INDEX_7 Macro

File

usb_device_hid.h

C

```
#define USB_DEVICE_HID_INDEX_7 7
```

Description

This is macro USB_DEVICE_HID_INDEX_7.

USB MSD Device Library

This section describes the USB MSD Device Library.

Introduction

Introduces the MPLAB Harmony USB Mass Storage Device (MSD) Library.

Description

The USB Mass Storage Device Library (also referred to as the MSD Function Driver) allows applications to create USB Mass Storage device such as USB Pen Drives or USB-based SD Card readers. Applications can also leverage the ready support for Mass Storage Devices by popular Host personal computer operating systems by using the MSD Function Driver interfaces as a means to access the device functionality. The MSD Function Driver also features the following:

- Supports Bulk Only Transport (BOT) protocol
- Allows implementation of multiple Logical Unit Number (LUN) storage devices
- Uses the MPLAB Harmony Block Driver interface to connect to storage media drivers

Using the Library

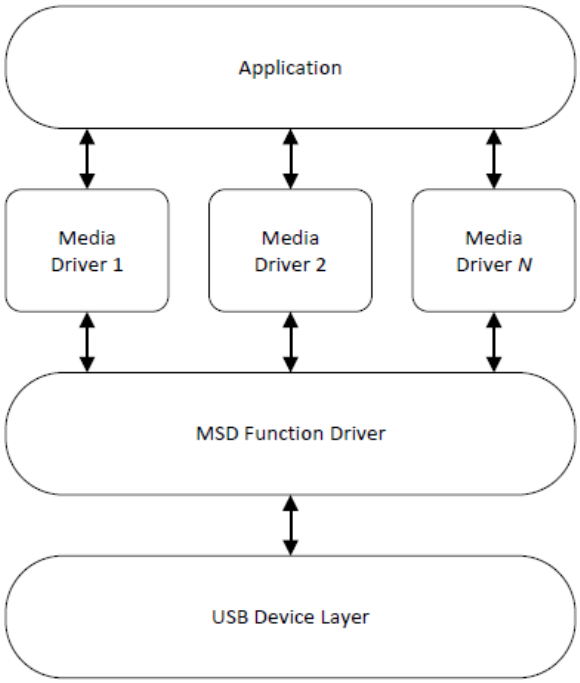
This topic describes the basic architecture of the USB MSD Device Library and provides information and examples on its use.

Abstraction Model

Provides an architectural overview of the USB MSD Device Library driver.

Description

The following diagram illustrates the functional interaction between the application, the MSD Function Driver, the media drivers, and the USB Device Layer.



As seen in the previous figure, the application does not have to interact with MSD function driver. Also, the MSD Function Driver does not have application functions that can be called. The media drivers control the storage media. The application interacts with the media drivers to update or access the information on the storage media. The MSD Function Driver interacts with the media drivers to process data read and write requests that it receives from the Host. This data is always accessed in blocks.

The MPLAB Harmony System module initializes the Device Layer and media drivers. A media driver is plugged into the MSD Function Driver by providing a media driver entry point in the MSD Function Driver initialization data structure. In the case of a multi-LUN storage, multiple media drivers can be plugged into the MSD Function Driver, with each one being capable of accessing different storage media types. The Device Layer initializes the MSD Function Driver when the Host sets the configuration that contains the Mass Storage interfaces. The MSD Function Driver Tasks routine is invoked in the context of the Device Layer Tasks routine. The MSD Function Driver interfaces should be registered in the USB Device Layer Function Driver Registration Table.

Library Overview

The USB MSD Device Library mainly interacts with the system, its clients and function drivers, as shown in the Abstraction Model.

The library interface routines are divided into sub-sections, which address one of the blocks or the overall operation of the USB MSD Device Library.

Library Interface Section	Description
System Configuration Functions	Provides event handler, report send/receive, and transfer cancellation functions.

How the Library Works

This section explains how the MSD Function Driver should be added to the USB Device application and how a media driver should be plugged into it. Considerations while creating new media drivers to operate with the MSD function driver are also discussed.

Library Initialization

Describes how to initialize the MSD Function Driver.

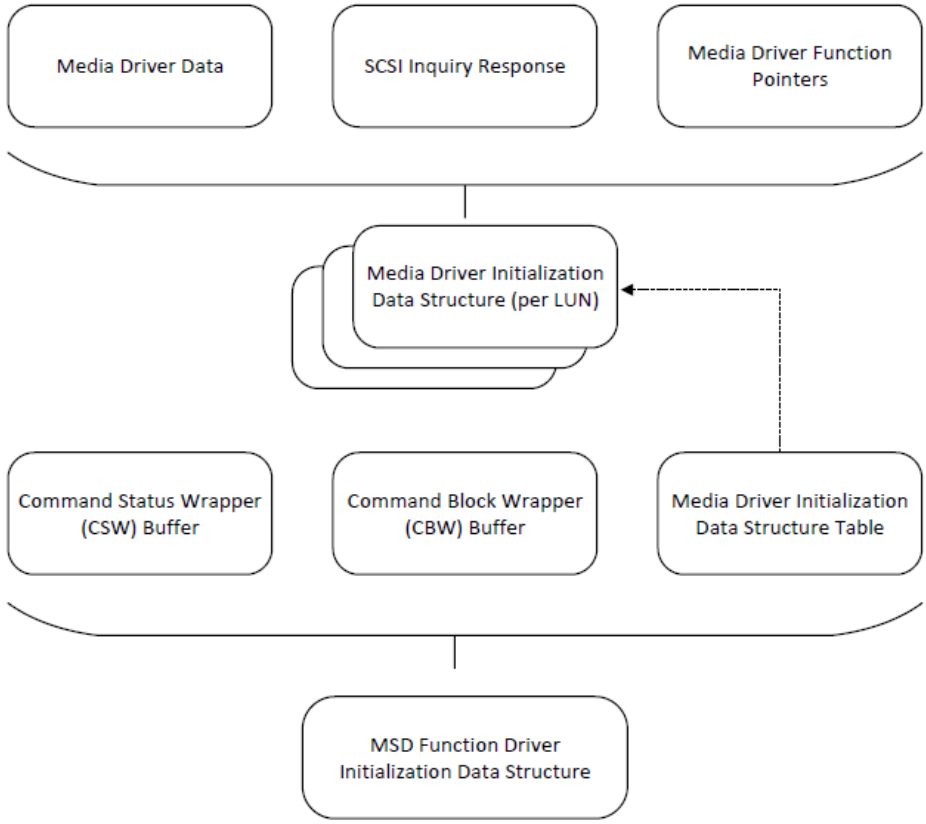
Description

The MSD Function Driver instance for a USB Device configuration is initialized by the USB Device Layer when the Host sets that configuration. This process does not require application intervention. Each instance of the MSD Function Driver should be registered with the USB Device Layer through the Device Layer Function Driver Registration Table. While registering the MSD Function Driver, the driver member of the Function Driver Registration Table entry should be set to USB_DEVICE_MSD_FUNCTION_DRIVER. This is an opaque function driver entry point provided by the MSD Function Driver for the Device Layer to use.

The MSD Function Driver requires an initialization data structure to be defined for each instance of the function driver. This initialization data structure should be of the type USB_DEVICE_MSD_INIT. This initialization data structure contains the following:

- The number of Logical Unit Numbers (LUNs) in this MSD Function Driver instance
- A pointer to the USB_MSD_CBW type data structure. This pointer is used by the MSD Function Driver to receive the Command Block Wrapper (CBW) from the Host. For a PIC32MZ device, this array should be placed in coherent memory and should be aligned on a 4-byte boundary.
- A pointer to the USB_MSD_CSW type data structure. This pointer is used by the MSD Function Driver to send the Command Status Wrapper (CSW) to the Host. For a PIC32MZ device, this array should be placed in coherent memory and should be aligned on a 4-byte boundary.
- A pointer to the array of media driver initialization data structure. There should be one structure for every LUN. This is a USB_DEVICE_MSD_MEDIA_INIT_DATA type of data structure. There exists a one-to-one mapping between the LUN and the media driver initialization data structure.

The following figure shows a pictorial representation of the MSD Function Driver initialization data structure.



The USB_DEVICE_MSD_MEDIA_INIT_DATA data structure allows a media driver to be plugged into the MSD Function Driver. Any media driver that needs to be plugged into the MSD Function Driver needs to implement the interface (function pointer signatures) specified by the USB_DEVICE_MSD_MEDIA_FUNCTIONS type. For every LUN, a SCSI Inquiry Response data structure needs to be made available.

Use the following guidelines while implementing the media driver:

- Read functions should be non-blocking
- Write functions should be non-blocking
- The media driver should provide an event to indicate when a block transfer has complete. It should allow the event handler to be registered.
- Where required, the write function should erase and write to the storage area in one operation. The MSD Function Driver does not explicitly call the erase operation.
- The media driver should provide a media geometry object when required. This media geometry object allows the MSD Function Driver to understand the media characteristics. This object is of the type, SYS_FS_MEDIA_GEOMETRY.

The following code shows an example of plugging the MPLAB Harmony NVM Driver into the MSD Function Driver. The coherency and alignment attributes that are applied to the sectorBuffer, msdCBW, and msdCBW data objects is needed for operation on PIC32MZ devices.

```
/*********************************************
 * Sector buffer needed by for the MSD LUN.
 *********************************************/
uint8_t sectorBuffer[512] __attribute__((coherent)) __attribute__((aligned(4)));

/*********************************************
 * CBW and CSW structure needed by the MSD
 * function driver instance.
 *********************************************/
USB_MSD_CBW msdCBW __attribute__((coherent)) __attribute__((aligned(4)));
USB_MSD_CSW msdCSW __attribute__((coherent)) __attribute__((aligned(4)));

/*********************************************
```

```
 * Because the PIC32MZ flash row size if 2048
 * and the media sector size if 512 bytes, we
 * have to allocate a buffer of size 2048
 * to backup the row. A pointer to this row
 * is passed in the media initialization data
 * structure.
 ********************************************/
uint8_t flashRowBackupBuffer [DRV_NVM_ROW_SIZE];
/*****************************************
 * MSD Function Driver initialization
 *****************************************/

USB_DEVICE_MSD_MEDIA_INIT_DATA msdMediaInit[1] =
{
    {
        DRV_NVM_INDEX_0,
        512,
        sectorBuffer,
        flashRowBackupBuffer,

        .configurationValue =  1,                   // Configuration value
        .interfaceNumber = 0,                       // Start interface number
        .numberOfInterfaces = 1,                    // Number of interfaces owned
        .funcDriverIndex = 0,                       // Function driver index
        .funcDriverInit = (void*)&msdInit,          // Pointer to initialization data structure
        .driver = USB_DEVICE_MSD_FUNCTION_DRIVER    // Pointer to function driver
    }
};
```

Data Transfer

Describes how the MSD Function Driver accesses the media.

Description

The MSD Function Driver opens the media drivers for read/write operations when the function driver is initialized by the Device Layer. This happens when the Host sets a configuration containing MSD interfaces. The Open operation is complete in the MSD Function Driver Tasks routines (called by the Device Layer).

The MSD Function Driver registers its own block operation event handler with the media drivers. Media Read and Write functions are called when the function driver receives a Sector Read or Sector Write request from the Host. The request will be tracked in the function driver Task routine. While the function driver waits for the media to complete the block operation, the function driver will NAK the data stage of the MSD data transfer request.

The MSD Function Driver does not provide any events to the application. It is possible that the application may also open the media driver while they are already opened by the MSD Function Driver. If the application and the MSD Function Driver try to write to the same media driver, the result could be unpredictable. It is recommended that the application restrict write access to the media driver while the USB device is plugged into the Host.

The application does not have to intervene in the functioning of the MSD Function Driver. Basically, the MSD Function Driver does provide any application callable functions.

Configuring the Library

Describes how to configure the MSD Function Driver.

Macros

	Name	Description
	USB_DEVICE_MSD_INSTANCES_NUMBER	Number of MSD function Driver instances required in the USB Device.
	USB_DEVICE_MSD_LUNS_NUMBER	Defines the number of LUNs per MSD function driver instance.

Description

The following configuration parameters must be defined while using the MSD Function Driver. The configuration macros that implement these parameters must be located in the `system_config.h` file in the application project and a compiler include path (to point to the folder that contains this file) should be specified.

USB_DEVICE_MSD_INSTANCES_NUMBER Macro

Number of MSD function Driver instances required in the USB Device.

File

usb_device_msd_config_template.h

C

```
#define USB_DEVICE_MSD_INSTANCES_NUMBER 1
```

Description

MSD Function Driver Instances Number

This configuration constant defines the number of MSD Function Driver instances in the USB Device. This value should be atleast 1 if the MSD function is required. In case where multiple MSD function drivers are required, it should be noted the MSD function driver supports multiple LUNs. This allows one MSD function driver instance to manage multiple media. Using multiple LUNs can be considered as an alternative to using multiple MSD function driver instances.

Remarks

None.

USB_DEVICE_MSD_LUNS_NUMBER Macro

Defines the number of LUNs per MSD function driver instance.

File

usb_device_msd_config_template.h

C

```
#define USB_DEVICE_MSD_LUNS_NUMBER 1
```

Description

Number of LUNs

This constant sets maximum possible number of Logical Unit (LUN) an instance of MSD can support. This value should be atleast 1. In cases where multiple MSD Function Driver instances are required, this constant should be set to the maximum number of LUNs required by any MSD Function Driver instanceThe following figure shows a pictorial representation of the MSD function driver initialization data structure.

Remarks

None.

Building the Library

Describes the files to be included in the project while using the MSD Function Driver.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/usb`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`usb_device_msd.h`	This header file should be included in any `.c` file that accesses the USB Device MSD Function Driver API.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/dynamic/usb_device_msd.c`	This file implements the MSD Function driver interface and should be included in the project if the MSD Device function is desired.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The USB CDC Device Library depends on the following modules:

- USB Device Layer Library

Based on application needs, the library may depend on the related storage media libraries, such as:

- Secure Digital (SD) Card Driver Library
- NVM Driver Library

Library Interface

Data Types and Constants

	Name	Description
	USB_DEVICE_MSD_MEDIA_FUNCTIONS	Pointer to the media driver functions for media instances to used with the the MSD function driver.
	USB_DEVICE_MSD_INIT	This structure contains required parameters for MSD function driver initialization.
	USB_DEVICE_MSD_MEDIA_INIT_DATA	This structure holds media related data of a particular logical unit.
	USB_DEVICE_MSD_FUNCTION_DRIVER	USB Device MSD Function Driver Function pointer

Description

This section describes the Application Programming Interface (API) functions of the USB MSD Device Library.

Refer to each section for a detailed description.

a) System Configuration Functions

Data Types and Constants

USB_DEVICE_MSD_MEDIA_FUNCTIONS Structure

Pointer to the media driver functions for media instances to used with the the MSD function driver.

File

usb_device_msd.h

C

```
struct USB_DEVICE_MSD_MEDIA_FUNCTIONS {
  bool (* isAttached)(const DRV_HANDLE handle);
  DRV_HANDLE (* open)(const SYS_MODULE_INDEX index, const DRV_IO_INTENT intent);
  void (* close)(DRV_HANDLE hClient);
  SYS_FS_MEDIA_GEOMETRY * (* geometryGet)(DRV_HANDLE hClient);
  void (* blockRead)(DRV_HANDLE handle, uintptr_t * blockOperationHandle, void * data, uint32_t blockStart,
uint32_t nBlocks);
  void (* blockWrite)(DRV_HANDLE handle, uintptr_t * blockOperationHandle, void * data, uint32_t
blockStart, uint32_t nBlocks);
  bool (* isWriteProtected)(DRV_HANDLE drvHandle);
  void (* blockEventHandlerSet)(const DRV_HANDLE drvHandle, const void * eventHandler, const uintptr_t
context);
  void (* blockStartAddressSet)(const DRV_HANDLE drvHandle, const void * addressOfStartBlock);
};
```

Members

Members	Description
bool (* isAttached)(const DRV_HANDLE handle);	In case of pluggable media, such as SD Card, this function returns true when the media is inserted, initialized and ready to be used. In case of non-pluggable media, such as Internal Flash memory, this function can return true when the media is ready to be used. The MSD host may not detect the media until this function returns true. This function pointer cannot be NULL
DRV_HANDLE (* open)(const SYS_MODULE_INDEX index, const DRV_IO_INTENT intent);	The MSD Function Driver calls this function to obtain a handle and gain access to functionality of the specified instance of the media driver. The MSD function driver will attempt to open the driver with DRV_IO_INTENT_READWRITE and DRV_IO_INTENT_NONBLOCKING. The MSD host may not detect the media until the MSD function driver obtains a valid driver handle. The function driver will use this handle in all other functions to communicate with the media driver. This function pointer cannot be NULL
void (* close)(DRV_HANDLE hClient);	The MSD function driver calls this function when the function driver gets deinitialized as result of device detach or a change in configuration. The MSD function driver will open the media driver again to obtain a fresh driver handle when it gets initialized again. This function pointer cannot be NULL.

SYS_FS_MEDIA_GEOMETRY * (* geometryGet)(DRV_HANDLE hClient);	The MSD function driver calls this function when the function driver needs to know the storage capacity of the media. The MSD function driver uses the size of read region and number of read blocks to report the media capacity to the MSD host. This function pointer cannot be NULL.
void (* blockRead)(DRV_HANDLE handle, uintptr_t * blockOperationHandle, void * data, uint32_t blockStart, uint32_t nBlocks);	The MSD function driver calls this function when it needs to read a block of data. This function pointer cannot be NULL.
void (* blockWrite)(DRV_HANDLE handle, uintptr_t * blockOperationHandle, void * data, uint32_t blockStart, uint32_t nBlocks);	The MSD function driver calls this function when it needs to write a block of data. This function pointer can be NULL if the media is write protected.
bool (* isWriteProtected)(DRV_HANDLE drvHandle);	The MSD function driver calls this function to find out if the media is write-protected. This function pointer cannot be NULL.
void (* blockEventHandlerSet)(const DRV_HANDLE drvHandle, const void * eventHandler, const uintptr_t context);	The MSD function driver calls this function to register an block event call back function with the media driver. This event call back will be called when a block related operation has completed. This function pointer should not be NULL.
void (* blockStartAddressSet)(const DRV_HANDLE drvHandle, const void * addressOfStartBlock);	If not NULL and if the blockStartAddress parameter in the USB_DEVICE_MSD_MEDIA_INIT_DATA data structure for this media is not 0, then the MSD function driver calls this function immediately after opening the media driver. For media such a NVM, where the storage media is a part of the program memory flash, this function sets the start of the storage area on the media. This function is not required for media such as SD Card.

Description

Media Driver Function Pointer Data Structure

This structure contains function pointers, pointing to the media driver functions. The MSD function driver calls these functions at run time to access the media. This data structure should be specified during compilation and is a part of the MSD function driver initialization data structure. It is processed by the function driver when the function driver is initialized by the Device Layer.

Remarks

None.

USB_DEVICE_MSD_INIT Structure

This structure contains required parameters for MSD function driver initialization.

File

usb_device_msd.h

C

```
typedef struct {
  uint8_t numberOfLogicalUnits;
  USB_MSD_CBW * msdCBW;
  USB_MSD_CSW * msdCSW;
  USB_DEVICE_MSD_MEDIA_INIT_DATA * mediaInit;
} USB_DEVICE_MSD_INIT;
```

Members

Members	Description
uint8_t numberOfLogicalUnits;	Number of logical units supported.
USB_MSD_CBW * msdCBW;	Pointer to a Command Block Wrapper structure allocated to this instance • of the MSD function driver. In case of PIC32MZ device, this should be • placed in non cacheable section of RAM and should be aligned at a 4 byte • boundary.
USB_MSD_CSW * msdCSW;	Pointer to a Command Status Wrapper structure allocated to this instance • of the MSD function driver. In case of PIC32MZ device, this should be • placed in non cacheable section of RAM and should be aligned at a 4 byte • boundary.
USB_DEVICE_MSD_MEDIA_INIT_DATA * mediaInit;	Pointer to a table of media initialization data. This should contain an entry for every logical unit.

Description

USB MSD init structure.

This structure contains interface number, bulk-IN and bulk-OUT endpoint addresses, endpointSize, number of logical units supported and pointer

to array of structure that contains media initialization.

Remarks

This structure must be configured by the user at compile time.

USB_DEVICE_MSD_MEDIA_INIT_DATA Structure

This structure holds media related data of a particular logical unit.

File

usb_device_msd.h

C

```
typedef struct {
  SYS_MODULE_INDEX instanceIndex;
  uint32_t sectorSize;
  uint8_t * sectorBuffer;
  uint8_t * blockBuffer;
  void * block0StartAddress;
  SCSI_INQUIRY_RESPONSE inquiryResponse;
  USB_DEVICE_MSD_MEDIA_FUNCTIONS mediaFunctions;
} USB_DEVICE_MSD_MEDIA_INIT_DATA;
```

Members

Members	Description
SYS_MODULE_INDEX instanceIndex;	Instance index of the media driver to opened for this LUN
uint32_t sectorSize;	Sector size for this LUN. If 0, means that sector size will be available from media geometry.
uint8_t * sectorBuffer;	Pointer to a bye buffer whose size if the size of the sector on this • media. In case of a PIC32MZ device, this buffer should be coherent and • should be aligned on a 16 byte boundary
uint8_t * blockBuffer;	In a case where the sector size of this media is less than the size of • the write block, a byte buffer of write block size should be provided to • the function driver. For example, the PIC32MZ NVM flash driver has a • flash program memory row size of 4096 bytes which is more than the • standard 512 byte sector. In such a case the application should set this • pointer to 4096 byte buffer
void * block0StartAddress;	Block 0 Start Address on this media. If non zero, then this address will be passed to blockStartAddressSet function. This should be set to start of the storage address on the media.
SCSI_INQUIRY_RESPONSE inquiryResponse;	Pointer to SCSI inquiry response for this LUN
USB_DEVICE_MSD_MEDIA_FUNCTIONS mediaFunctions;	Function pointers to the media driver functions

Description

USB Device MSD Media Initialization Data Member

It holds pointer to inquiry response, instance index and pointer to a structure that contains all media callback functions.

Remarks

An object of this structure must be configured by the user at compile time.

USB_DEVICE_MSD_FUNCTION_DRIVER Macro

USB Device MSD Function Driver Function pointer

File

usb_device_msd.h

C

```
#define USB_DEVICE_MSD_FUNCTION_DRIVER
```

Description

USB Device MSD Function Driver Function Pointer

This is the USB Device MSD Function Driver Function pointer. This should registered with the device layer in the function driver registration table.

Remarks

None.

Generic USB Device Library

This section describes the Generic USB Device Library.

Introduction

Introduces the MPLAB Harmony Generic USB Device Library.

Description

A USB Device that does not follow any of the standard USB device class specifications is referred to as Generic (or a Vendor) USB Device. Such a device may be needed in cases where a standard USB device class does not meet application requirements with respect to transfer type, throughput or available interfaces. Generic USB Devices also typically require custom USB Host drivers.

The MPLAB Harmony USB Device Layer API features Endpoint API and events that facilitate development of a Generic USB Device. These API and events allow the application to do the following:

- Configure, enable, and disable endpoints
- Schedule Bulk, Interrupt and, Isochronous transfers
- Respond to control transfers
- Receive control and other transfer type related events

Using the Library

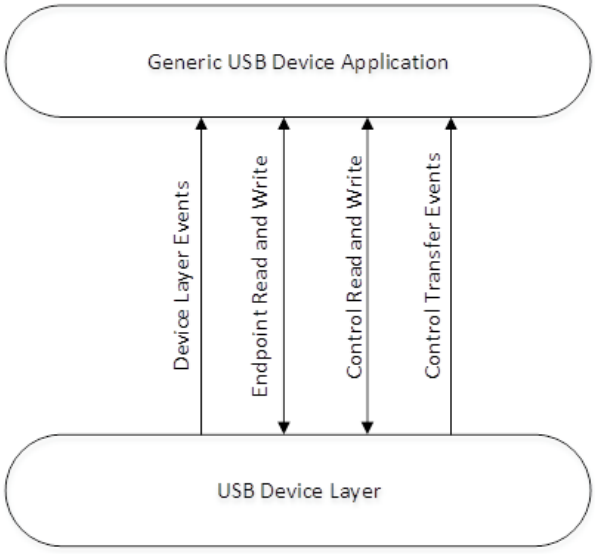
This topic describes the basic architecture of the Generic USB Device Library and provides information and examples on its use.

Abstraction Model

Provides an architectural overview of the Generic USB Device Driver.

Description

The Generic USB Device Library consists of USB Device Layer Endpoint API and events. The API allows the application to configure, enable, and disable endpoints. Endpoints can be configured for bulk, isochronous, and interrupt transfers. The events allow the application to track the completion of transfers and respond to control transfer events. It should be noted that the Generic USB Device Library in the MPLAB Harmony USB Device Stack does not have its own implementation, but rather, uses a subset of the Device Layer API to access the USB, as shown in the following diagram.



As seen in the figure, the application must implement the logic to implement the Generic USB Device behavior. It must respond to interface, class, and other control transfers. It must configure endpoints when the Host sets the configuration. Thus, the application implements the function driver for the Generic USB Function Driver.

The Generic USB Device Endpoint function and events provided by the Device Layer API abstract the details of configuring the USB peripheral. The Device Layer responds to standard USB requests as a part of the device enumeration process. The Device Layer control transfer functions and events allow the application to complete control transfers that are targeted to an endpoint, interface or others. The Device Layer endpoint read and write API provide a USB transaction or transfer level interface. Transactions or transfers can be queued.

Library Overview

Provides an overview of the Generic USB Device Driver.

Description

The Generic Function Driver features API to set application event handlers and transfer data over non-zero endpoints. The function driver is initialized by the Device Layer when a Set Configuration request is received by the device. This process does not require application intervention. As a part of this initialization process, all the endpoints belonging to the Generic Function Driver Interfaces will be enabled and configured. When the application receives the USB_DEVICE_EVENT_CONFIGURED, these endpoints are ready for data transfers.

The application design must ensure that the Generic Function Driver is registered in the Device Layer Function Driver Registration Table.

How the Library Works

This topic describes the basic architecture of the Generic USB Device Library and provides information and examples on its use.

Library Initialization

Describes how the Generic USB Device Library is initialized.

Description

Unlike the standard USB function drivers in the MPLAB Harmony USB Device Stack, in the case of a Generic USB Device, the USB Device Layer does not automatically enable or disable endpoints that belong to the Generic interface. This must be done by the application when the device is configured by the Host.

A USB Device can have multiple Generic interfaces. Each of these interfaces must have corresponding entries in the USB Device Layer function driver registration table. For Generic interfaces, the driver and funcDriverInit member of the function driver registration table entry should be set to NULL. The following code shows an example of how this is done.

```
/* This code shows an example function driver registration table entry
 * for a Generic USB Device Interface. Note that the function driver entry point
 * member is NULL. This instructs the Device Layer to pass all interface related
 * control transfers to the application. */
const USB_DEVICE_FUNCTION_REGISTRATION_TABLE funcRegistrationTable[1] =
{
    {
         .configurationValue = 1 ,      // Configuration descriptor index
         .driver = NULL,                // No APIs exposed to the device layer
         .funcDriverIndex = 0 ,         // Zero Instance index
         .funcDriverInit = NULL,        // No init data
         .interfaceNumber = 0 ,         // Start interface number of this instance
         .numberOfInterfaces = 1 ,      // Total number of interfaces contained in this instance
         .speed = USB_SPEED_FULL|USB_SPEED_HIGH         // USB Speed
    }
};
```

The endpoint read and endpoint write queue sizes are specified by the queueSizeEndpointRead and queueSizeEndpointWrite members of the USB_DEVICE_INIT device layer initialization data structure. These read and write queue sizes define the size of the read and write buffer object pools. Objects from these pools are then queued up at each read and write endpoint, when an endpoint read or write is requested. The total number of buffer objects is specified by the USB_DEVICE_ENDPOINT_QUEUE_DEPTH_COMBINED configuration constant.

Event Handling

This topic explains how the application should handle Generic USB Device events.

Description

The USB Device Layer generates two different types of events for a Generic USB Device.

- Control transfer events
- Endpoint data transfer events

While handing Device Layer events, it is recommended that computationally intensive operations or hardware access should not be performed with in the event handler. Doing so may affect the capability of the Device Stack to respond to changes on the USB and could cause the Device to become non-compliant.

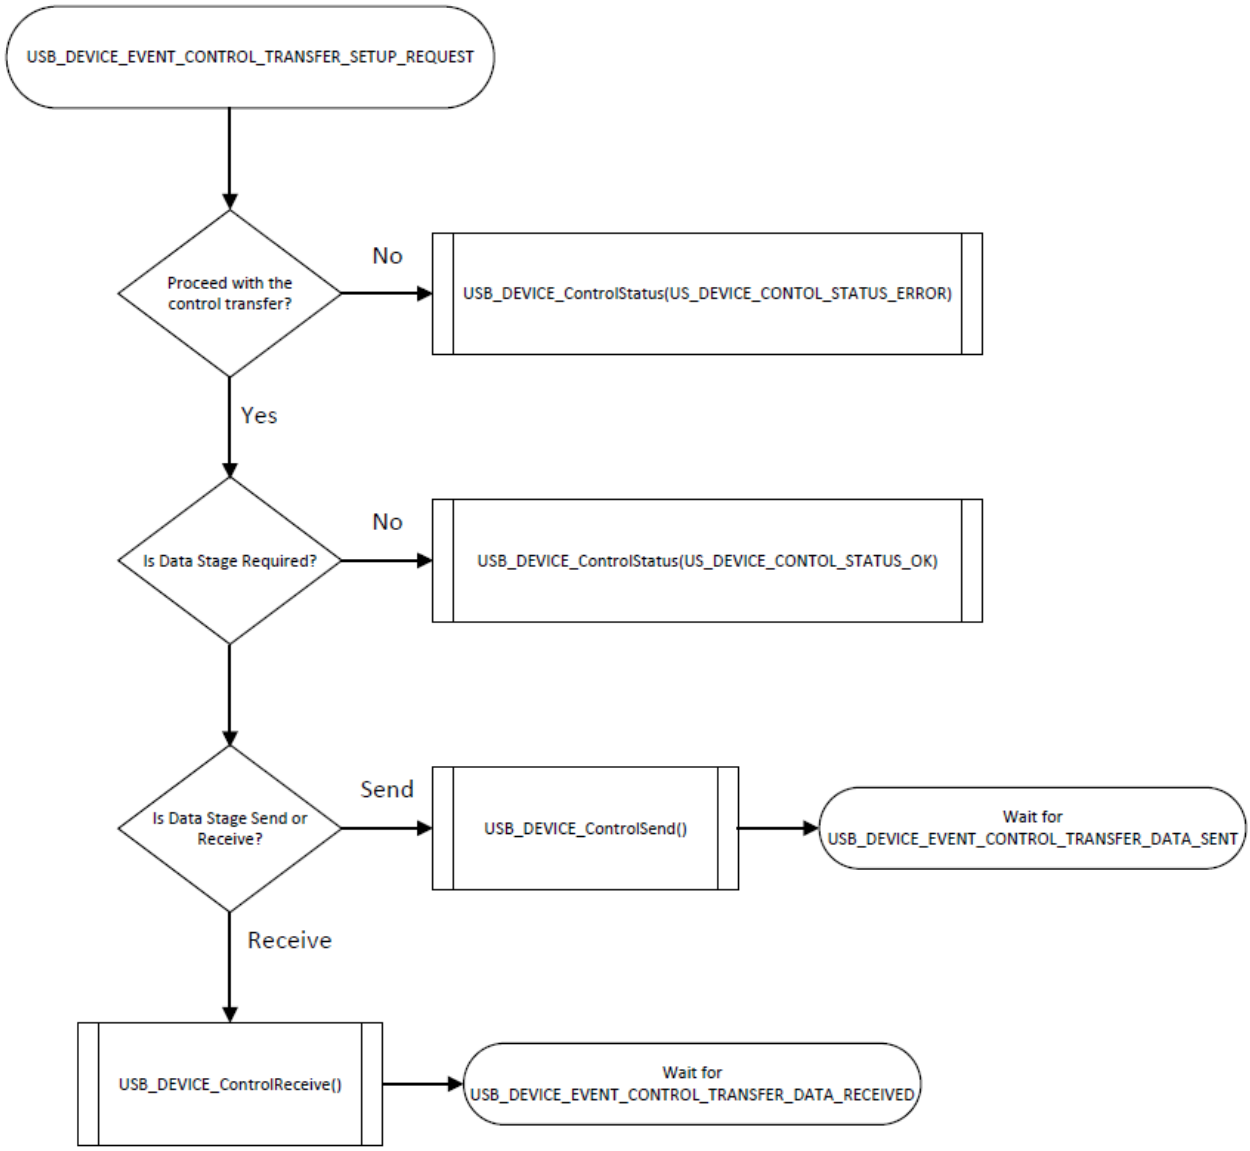
A Generic USB Device application must handle the above events along with the other Device Layer events.

Control Transfer Events

Describes control transfer events and provides a code example.

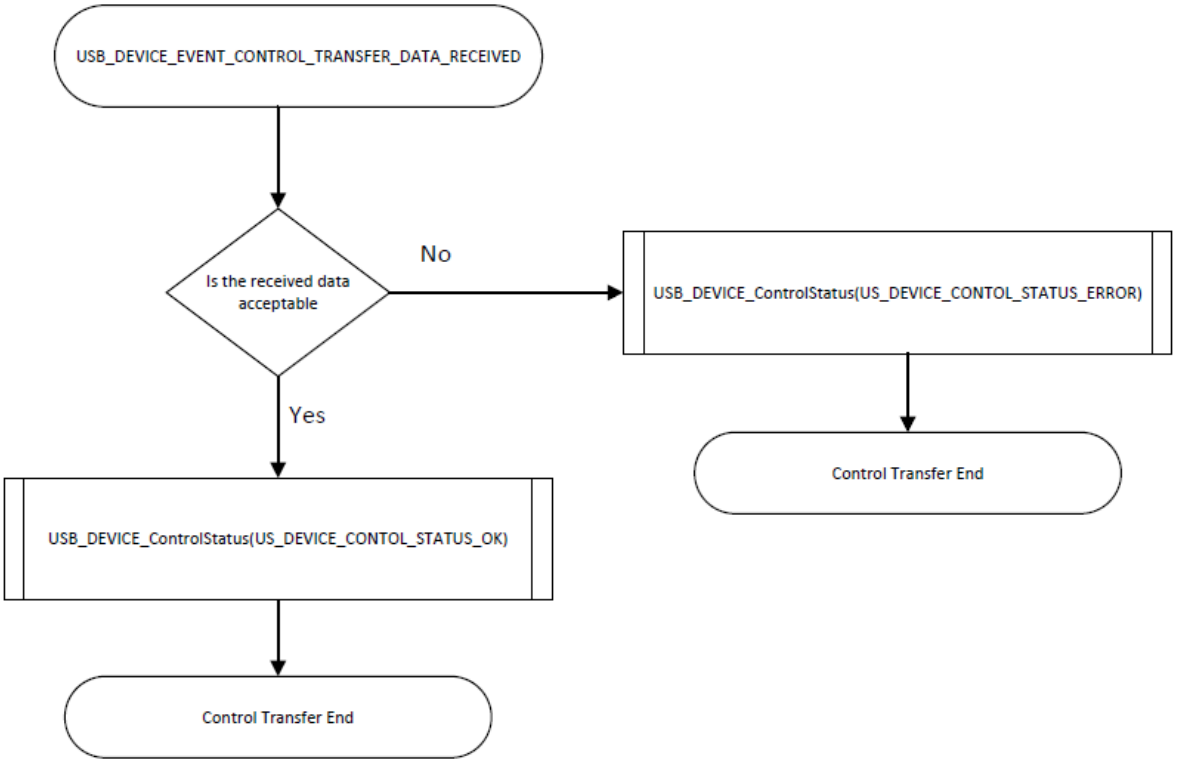
Description

These events occur when the Device Layer has received a control transfer that is targeted to an interface or an endpoint which is managed by the Generic USB Device Application. The USB_DEVICE_EVENT_CONTROL_TRANSFER_SETUP_REQUEST event is generated when the Setup stage of the control transfer has been received. The application must investigate the 8-byte setup command that accompanies this event. The following flowchart explains the interaction.



The application can then either choose to continue the control transfer or stall it. The control transfer is stalled by calling the USB_DEVICE_ControlStatus function with the USB_DEVICE_CONTROL_STATUS_ERROR flag. In case of zero data stage control transfers, the application can complete the control transfer by calling the USB_DEVICE_ControlStatus function with the USB_DEVICE_CONTROL_STATUS_OK flag. In case of control transfers that contain a data stage, the application must use the USB_DEVICE_ControlSend or the USB_DEVICE_ControlReceive function to send and receive data from the Host, respectively.

In a case where data is to be received from the host, the device layer generates USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_RECEIVED event when the data stage has completed. The application can analyze the received data and can then either choose to acknowledge or stall the control transfer by the calling the USB_DEVICE_ControlStatus function with the USB_DEVICE_CONTROL_STATUS_ERROR flag. This is shown in the following flow chart.



The following code shows an example of handling control transfer in a Generic USB Device. Note that the control transfer events are generated by the Device Layer.

```
/* This code shows an example of how the control transfer events
 * can be handled in a Generic USB Device. The example device will accepts the
 * Set Interface Control Request and replies to the Get Interface Control Request
 * with the current alternate setting. */
case USB_DEVICE_EVENT_CONTROL_TRANSFER_SETUP_REQUEST:
    /* This means we have received a setup packet */
       setupPacket = (USB_SETUP_PACKET *)eventData;
    if(setupPacket->bRequest == USB_REQUEST_SET_INTERFACE)
    {
        /* If we have got the SET_INTERFACE request, we just acknowledge
         * for now. In this example, there is one alternate setting which
         * is already active. */
        USB_DEVICE_ControlStatus(appData.usbDevHandle,USB_DEVICE_CONTROL_STATUS_OK);
    }
    else if(setupPacket->bRequest == USB_REQUEST_GET_INTERFACE)
    {
        /* We have only one alternate setting and this setting 0. So
        * we send this information to the host. */
        USB_DEVICE_ControlSend(appData.usbDevHandle, &appData.altSetting, 1);
    }
    else
    {
        /* We have received a request that we cannot handle. Stall it*/
        USB_DEVICE_ControlStatus(appData.usbDevHandle, USB_DEVICE_CONTROL_STATUS_ERROR);
    }
    break;
case USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_SENT:
    /* This is a notification event which the application can use to free
     * buffer that was used in a USB_DEVICE_ControlSend() function. */
    break;
case USB_DEVICE_EVENT_CONTROL_TRANSFER_DATA_RECEIVED:
    /* This event means that data has been received in the control transfer
     * and the application must either stall or acknowledge the data stage
     * by calling the USB_DEVICE_ControlStatus() function. Here we simply
     * acknowledge the received data. This is an example only. */
    USB_DEVICE_ControlStatus(appData.usbDevHandle, USB_DEVICE_CONTROL_STATUS_OK);
    break;
```

Endpoint Data Transfer Events

Describes endpoint data transfer events and provides a code example.

Description

The USB Device Layer provides notification events to indicate completion of transfers. These events are generated by the Device Layer and are made available in the Device Layer event handler. The USB_DEVICE_EVENT_ENDPOINT_READ_COMPLETE event occurs when a transfer scheduled by the USB_DEVICE_EndpointRead function has completed. The USB_DEVICE_EVENT_ENDPOINT_WRITE_COMPLETE event occurs when a transfer scheduled by the USB_DEVICE_EndpointWrite function has completed. The event data accompanying these events contains the transfer handle and number of bytes that were transferred.

The following code shows an example of handling these events.

```
/* The following code shows an example handling of the
 * endpoint transfer events. Here the code updates a transfer
 * pending flag indicating to the application that transfers have
 * completed. */
case USB_DEVICE_EVENT_ENDPOINT_READ_COMPLETE:
    /* Endpoint read is complete */
    appData.epDataReadPending = false;
    break;
case USB_DEVICE_EVENT_ENDPOINT_WRITE_COMPLETE:
    /* Endpoint write is complete */
    appData.epDataWritePending = false;
    break;
```

Endpoint Management

Describes how the application can enable and disable endpoints.

Description

Unlike standard USB function drivers, such as CDC, MSD, Audio, and HID, the Device Layer does not automatically manage endpoints for a Generic USB Device interface. This means that the application must maintain all endpoint that belong to a Generic USB Device Interface. Maintaining the endpoint involves the following:

- Enabling the endpoints for the desired transfer type when the host sets the configuration,
- Disabling the endpoint when the device receives a USB reset or when the Host changes the configuration
- Enabling and clearing endpoint stall conditions

Warning

The application should never access Endpoint 0 directly. Doing so may cause the Device Stack to malfunction, which could cause the USB device to be non-compliant.

Endpoints can be enabled or disabled with the USB_DEVICE_EndpointEnable and USB_DEVICE_EndpointDisable functions. The USB_DEVICE_EndpointIsEnabled function can be used to check if an endpoint is enabled. The application should enable the endpoint when host sets the configuration which contains interfaces that use the endpoint. The endpoints should otherwise be disabled. The endpoint function should not be called in the Device Layer event handler. Instead, they should be called in the application task routine. The following code shows an example of how an endpoint is enabled.

```
/* The following code shows an example of how the endpoint enable functions
 * are called to enabled a Receive and Transmit Bulk endpoints. Note that the size
 * of the endpoint must be specified and this size should match the endpoint size
 * mentioned in the endpoint descriptor */
if (USB_DEVICE_EndpointIsEnabled(appData.usbDevHandle, appData.endpointRx) == false )
{
    /* Enable Read Endpoint */
    USB_DEVICE_EndpointEnable(appData.usbDevHandle, 0, appData.endpointRx,
                              USB_TRANSFER_TYPE_BULK, sizeof(receivedDataBuffer));
}
if (USB_DEVICE_EndpointIsEnabled(appData.usbDevHandle, appData.endpointTx) == false )
{
    /* Enable Write Endpoint */
    USB_DEVICE_EndpointEnable(appData.usbDevHandle, 0, appData.endpointTx,
                             USB_TRANSFER_TYPE_BULK, sizeof(transmitDataBuffer));
}
```

An endpoint should be disabled when the host has changed the device configuration and the new configuration does not contain any interfaces that use this endpoint. The endpoint can also be disabled when the application receives USB_DEVICE_EVENT_RESET or when the USB_DEVICE_EVENT_DECONFIGURED event has occurred. The following code shows an example of disabling the endpoint.

```
/* In this example, the endpoints are disabled when
 * when the device has is not configured. This can happen
```

```
 * if the configuration set is 0 or if the device is reset. */
if(!appData.deviceIsConfigured)
{
    /* This means the device got deconfigured. Change the
     * application state back to waiting for configuration. */
    appData.state = APP_STATE_WAIT_FOR_CONFIGURATION;

    /* Disable the endpoint*/
    USB_DEVICE_EndpointDisable(appData.usbDevHandle, appData.endpointRx);
    USB_DEVICE_EndpointDisable(appData.usbDevHandle, appData.endpointTx);
    appData.epDataReadPending = false;
    appData.epDataWritePending = false;
}
```

The application can use the USB_DEVICE_EndpointStall and USB_DEVICE_EndpointStallClear functions to enable stall and clear the stall on endpoints. The USB_DEVICE_EndpointIsStalled function can be called to check stall status of the endpoint.

Endpoint Data Transfer

Describes how the application can transfer data over endpoints.

Description

The application should call the USB_DEVICE_EndpointRead and USB_DEVICE_EndpointWrite functions to transfer data over an enabled endpoint. Calling this function causes a USB transfer to be scheduled on the endpoint. The transfer is added to the endpoint queue and is serviced as the host schedules the transaction on the bus. The USB_DEVICE_EndpointRead and USB_DEVICE_EndpointWrite functions return a unique transfer handle which can be track the transfer. These transfer handles are returned along with the USB_DEVICE_EVENT_ENDPOINT_READ_COMPLETE (when a endpoint read transfer is complete) and USB_DEVICE_EVENT_ENDPOINT_WRITE_COMPLETE (when an endpoint write is complete) events.

The following code shows an example of sending data over an endpoint.

```
/* This code shows an example of using the USB_DEVICE_EndpointWrite
 * function to send data over the endpoint. The completion of the write is
 * indicated by the USB_DEVICE_EVENT_ENDPOINT_WRITE_COMPLETE event. The
 * transfer handle is returned in appData.writeTransferHandle */
USB_DEVICE_EndpointWrite ( appData.usbDevHandle, &appData.writeTranferHandle,
        appData.endpointTx, &transmitDataBuffer[0], sizeof(transmitDataBuffer),
        USB_DEVICE_TRANSFER_FLAGS_DATA_COMPLETE );

void APP_USBDeviceEventHandler(USB_DEVICE_EVENT event, void * eventData, uintptr_t context)
{
    /* This is the Device Layer event handler */
    case USB_DEVICE_EVENT_ENDPOINT_WRITE_COMPLETE:
        /* Endpoint write is complete */
        appData.epDataWritePending = false;
        break;
}
```

The USB_DEVICE_EndpointWrite function allows the application to send data to the host without ending the transfer. This is done by specifying USB_DEVICE_TRANSFER_FLAGS_DATA_PENDING as the transfer flag in the call to the USB_DEVICE_EndpointWrite function. The application can use this option when the data to be sent is not readily available or when the application is memory constrained. The combination of the transfer flag and the transfer size affects how the data is sent to the host:

- If size is a multiple of maxPacketSize (the IN endpoint size) and flag is set as USB_DEVICE_TRANSFER_FLAGS_DATA_COMPLETE, the write function will append a Zero Length Packet (ZLP) to complete the transfer
- If size is a multiple of maxPacketSize and flag is set as USB_DEVICE_TRANSFER_FLAGS_MORE_DATA_PENDING, the write function will not append a ZLP and therefore and hence will not complete the transfer
- If size is greater than but not a multiple of maxPacketSize and flags is set as USB_DEVICE_TRANSFER_FLAGS_DATA_COMPLETE, the write function schedules (length/maxPacketSize) packets and one packet for the residual data
- If size is greater than but not a multiple of maxPacketSize and flags is set as USB_DEVICE_TRANSFER_FLAGS_MORE_DATA_PENDING, the write function returns an error code and sets the transferHandle parameter to USB_DEVICE_TRANSFER_HANDLE_INVALID
- If size is less than maxPacketSize and flag is set USB_DEVICE_TRANSFER_FLAGS_DATA_COMPLETE, the write function schedules one packet
- If size is less than maxPacketSize and flag is set as USB_DEVICE_TRANSFER_FLAGS_MORE_DATA_PENDING, the write function returns an error code and sets the transferHandle parameter to USB_DEVICE_TRANSFER_HANDLE_INVALID

Refer to USB_DEVICE_EndpointWrite function API description for more details and code examples.

The application should use the USB_DEVICE_EndpointRead function to read data from an endpoint. The size of the buffer that is specified in this function should always be a multiple of the endpoint size. The following code shows an example of using the USB_DEVICE_EndpointRead function.

```
/* This code shows to use the USB_DEVICE_EndpointRead function
 * to read from an endpoint.  The transfer handle is returned in
```

```
 * appData.readTransferHandle. The size of receivedDataBuffer should
 * be a multiple of the receive endpoint size. */

USB_DEVICE_EndpointRead(appData.usbDevHandle, &appData.readTranferHandle,
             appData.endpointRx, &receivedDataBuffer[0], sizeof(receivedDataBuffer) );
void APP_USBDeviceEventHandler(USB_DEVICE_EVENT event, void * eventData, uintptr_t context)
{
    /* This is the Device Layer event handler */
    case USB_DEVICE_EVENT_ENDPOINT_READ_COMPLETE:
        /* Endpoint write is complete */
        appData.epDataReadPending = false;
        break;
}
```

In a case where a transfer is in progress, the USB_DEVICE_EndpointRead and USB_DEVICE_EndpointWrite functions can queue up transfers. The maximum number of read transfers that can queued (on any receive endpoint) is specified by the endpointQueueSizeRead member of the USB_DEVICE_INIT data structure. The maximum number of write transfers that can queued (on any transmit endpoint) is specified by the endpointQueueSizeWrite member of the USB_DEVICE_INIT data structure. The USB_DEVICE_ENDPOINT_QUEUE_DEPTH_COMBINED configuration macro should be set to total of read and write transfers that need to be queued.

For example, consider a Generic USB Device that contains two OUT (read) endpoint (EP1 and EP2) and one IN write endpoint (EP1). The application will queue a maximum of three read transfers on EP1, a maximum of five read transfers on EP2 and a maximum of four write transfers on EP1. Therefore, the total read transfer that will be queued in eight (3 + 5) and total write transfers that will be queued is four. The endpointQueueSizeRead member of the USB_DEVICE_INIT data structure should be set to eight. The endpointQueueSizeWrite member of the USB_DEVICE_INIT data structure should be set to four. The USB_DEVICE_ENDPOINT_QUEUE_DEPTH_COMBINED configuration macro should be set to 12 (8 + 4).

Configuring the Library

Describes how to configure the Generic USB Device Library.

Description

The application designer must specify the following configuration parameters while implementing the Generic USB Device. The configuration macros that implement these parameters must be located in the `system_config.h` file in the application project and a compiler include path (to point to the folder that contains this file) should be specified.

Configuration Macro Name	Description	Comments
USB_DEVICE_ENDPOINT_QUEUE_DEPTH_COMBINED	Size of buffer object pool for Endpoint Read and Endpoint Write functions.	This macro defines the total number of transfers that can be queued across all Generic USB Device endpoints. The number of read transfers that can be queued is specified by the endpointQueueSizeRead member of the USB_DEVICE_INIT data structure. The number of write transfers that can be queued is specified by the endpointQueueSizeWrite member of the USB_DEVICE_INIT data structure.

Building the Library

This section lists the files to be included in the project to implement a Generic USB Device Library.

Description

The Generic USB Device library does not have its own implementation. It is implemented using Device Layer API which are implemented in the Device Layer Files.

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/usb`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
usb_device.h	This header file should be included in any `.c` file that accesses the Device Layer API needed to implement the Generic USB Device.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/dynamic/usb_device.c	This file contains the Device Layer API implementation.
/src/dynamic/usb_device_endpoint_functions.c	This file contains the endpoint transfer and management routines that are needed to implement the Generic USB Device.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The Generic USB Device Library depends on the following modules:

- USB Device Layer Library

Library Interface

The API for implementing the Generic USB Device is contained the USB Device Library. Please refer to the Library Interface section in the USB Device Layer Library for more details.

USB Host Library

This section provides information on the USB Host libraries that are available in MPLAB Harmony.

USB Host Library - Getting Started

This section provides information for getting started with the USB Host Library.

Introduction

Provides an introduction to the MPLAB Harmony USB Host Library

Description

The MPLAB Harmony USB Host Library (referred to as the USB Host Library) provides embedded application developers with a framework to design and develop USB Host Support for a wide variety of USB Device Classes. Low-Speed and Full-Speed USB Devices can be supported with PIC32MX microcontrollers. High-Speed devices can be supported with PIC32MZ microcontrollers. The USB Host Library facilitates support of standard USB devices through client drivers that implement standard the USB Device class specification. The library is modular, thus allowing application developers to readily support composite USB devices.

The USB Host Library is a part of the MPLAB Harmony installation and is accompanied by demonstration applications that highlight library usage. These demonstration applications can also be modified or updated to build custom applications. The USB Host Library also features the following:

- Class Driver Support (CDC, Audio, HID, and MSD)
- Designed to support USB devices with multiple configurations at different speeds
- Supports low-speed, full-speed and high-speed operation
- Supports multiple USB peripherals (allows multiple host stacks)
- Modular and Layered architecture
- Completely non-blocking
- Supports both polled and interrupt operation
- Works readily in an RTOS environment
- Designed to readily integrate with other Harmony Middleware

This document serves as a getting started guide and provides information on the following:

- USB Host Stack Architecture
- USB Host Library - Application Interaction

Note: It is assumed that the reader is familiar with the USB 2.0 specification (available at www.usbif.org). While certain topics in USB may be discussed in this document, it is recommended that the reader refer to the specification documentation for a complete description.

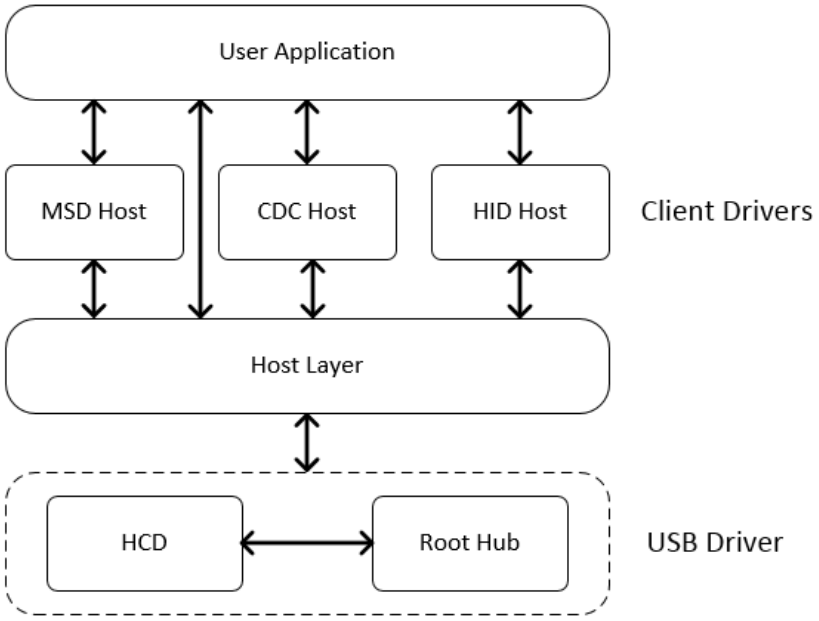
USB Host Library Architecture

Describes the USB Host Library Architecture.

Description

The USB Host Library Architecture features a modular and layered architecture as illustrated in the following figure.

USB Host Library Architecture



As seen in the figure, the USB Device Library consists of the following three major components.

Host Controller Driver (HCD)

The HCD manages the state of the USB peripheral and provides the Host Layer with structured methods to access data on the USB. The HCD is a MPLAB Harmony driver and uses the MPLAB Harmony framework components (USB Peripheral Library and the Interrupt System Service) of its operation. The HCD is initialized in the system initialization routine and its tasks routine is invoked in the system tasks routine. It is accessed exclusively by the Host layer. The HCD provides the following services to the host layer:

- Establish and manage communication pipes between the host layer and the attached devices
- Manage USB transfers

Root Hub Driver

The Root Hub Driver models the USB peripheral as a Hub. It then allows the Host Layer to perform the same actions on the Root Hub port that would be performed on an external Hub's port. The Root Hub Driver thus leads to an optimized implementation of Hub support in the Host Layer. The Root Hub Driver is hardware specific and is implemented as a part of the HCD. It provides the following services to the Host Layer

- Provides device attach and detach events
- Allows the Host to suspend, resume, and reset the port

The Root Hub Driver works in tandem with the HCD to provides the Host Layer with required USB protocol related means and methods to manage the attached USB device.

Host Layer

The Host Layer receives attach and detach events from the Root Hub Driver. It enumerates attached devices based on information contained in the Target Peripheral List (TPL). It allows client drivers to access the attached device through Host Layer methods. This includes allowing the client driver to set the device configuration. Where the client driver does not set the device configuration, the Host Layer will set the device configuration.

The Host layer opens the HCD, instantiates the Root Hub Driver, then controls and communicates with the attached device. The user application can call the Host Layer API to get information on attached devices. It can also register a Host Layer Event handler to get device related events. The user application can additionally suspend or resume a device. The Host Layer also provides bus level control where the application can

suspend or resume all devices connected to a USB.

Client Driver

The USB Host Stack Client Drivers implement the support for different device classes as per the class specifications. Along with Host Layer, the client drivers are designed to support multiple device of the same type (where multiple devices are connected to the host through a hub or is a single device with multiple interfaces). A client driver abstracts intricate details of the class specification and provides a high level command and data interface to the application. Completion of requests is indicated by events. The application must register an event handler to receive these events.

The Client Driver may manage devices whose functionality is specified by USB VID and PID. In such cases, the client driver can set the device configuration. The client driver may manage a device whose functionality is defined by an interface class, subclass and protocol. In such a case, the configuration is set by the Host layer. The client driver can also manage devices whose functionality is defined by a combination of VID PID and class, sub-class and protocol.

USB Host Library - Application Interaction

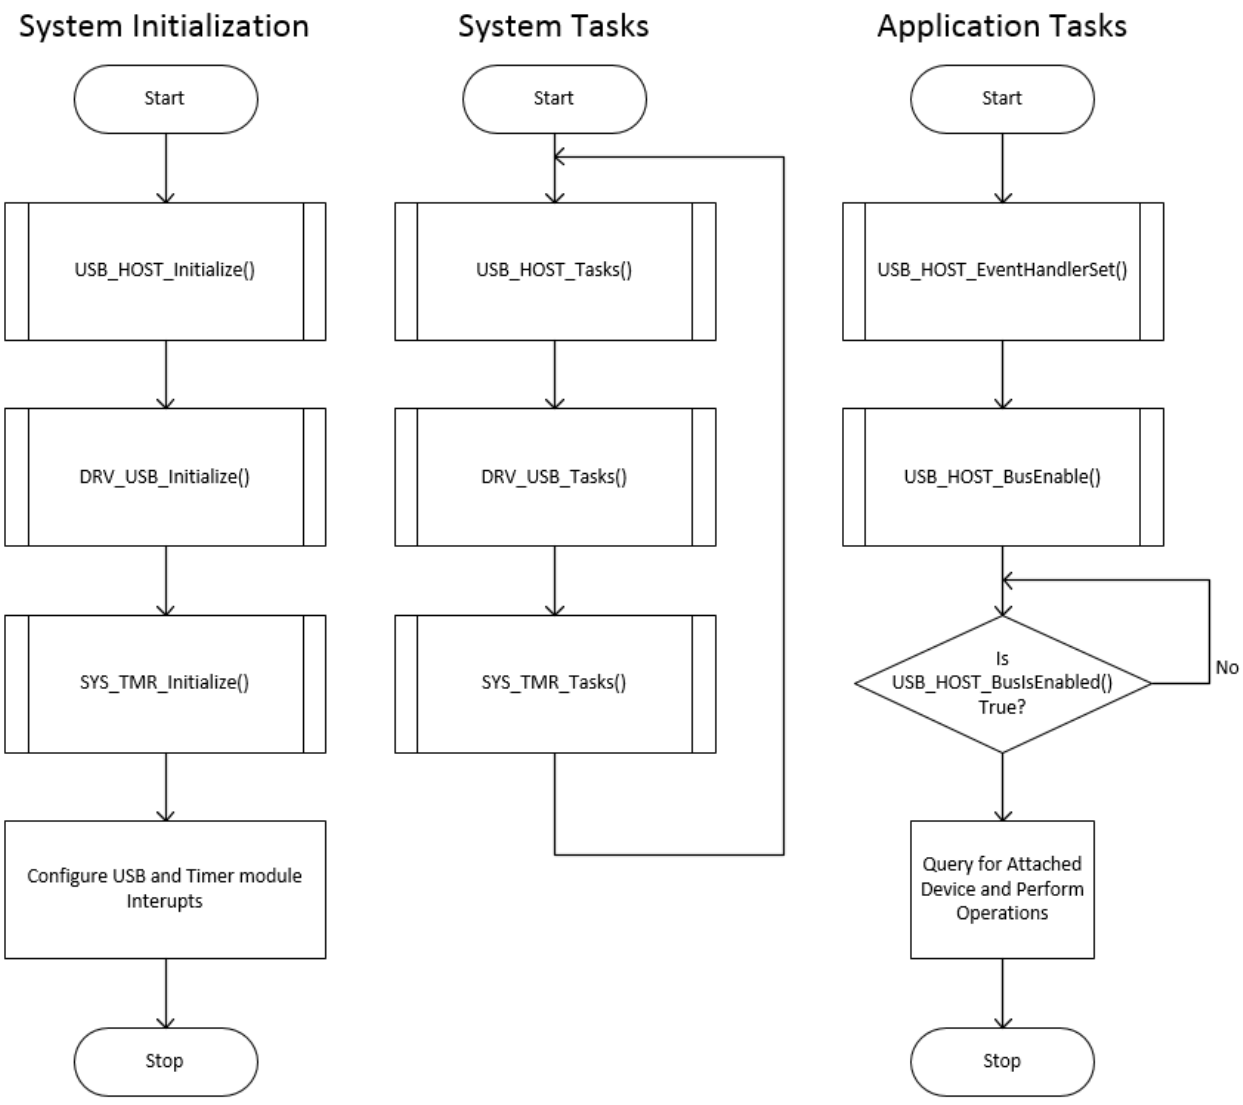
Describes how the application must interact with the USB Host Stack.

Description

Note: Additional information on the tests conducted on Flash devices (i.e., Pen Drives) and a list of USB application configurations is available in the USB Demonstrations section.

The following figure highlights the steps that the application must follow to use the USB Host Library.

Application Interaction with Host Layer



The USB Host stack is initialized in the MPLAB Harmony System Initialization function. The Host Stack requires the Timer System Service and

USB Driver. So these must be initialized as well. Note that the figure refers to a general USB Driver. The application may use the USBFS Driver (DRV_USBFS) for PIC32MX microcontroller or use the USBHS Driver (DRV_USBHS) for PIC32MZ microcontroller. The Timer and USB module interrupt priorities must be configured.

The USB Host layer, the USB Driver and the Timer System Service tasks must be called in the MPLAB Harmony System Tasks Routine. This ensures that the state machines of these module stays updated. If the USB Driver and the Timer driver have been configured for interrupt operation, then their corresponding interrupt tasks routines should be called in the corresponding module interrupt service routines.

The application state machine must first set the Host Layer event handler and then enable the bus. Enabling the bus will enable device detection and the Host Layer will enumerate attached devices. The application can query for attached devices and perform operations on attached devices.

USB Host Library Migration Guide

This section provides information on migrating from MPLAB Harmony v1.03.01 and earlier to the MPLAB Harmony USB Host Stack in MPLAB Harmony v1.04 and later.

Introduction

Provides an introduction to migrating from older versions to v1.04 and later versions of MPLAB Harmony.

Description

The USB Host Stack API in MPLAB Harmony v1.04 has changed from that of previous versions of MPLAB Harmony.

USB CDC and MSD Host applications that were developed using the MPLAB Harmony USB Host Stack v1.03.01 and earlier, will not build unless the application calls to the USB Host Stack API is updated. While the MHC utility provides an option to continue creating USB Host applications using the v1.03.01 and earlier USB Host Stack API, it is recommended that existing USB Host application migrate to the latest USB Host API to take advantage of the latest features in the USB Host Stack. The following sections describe the API changes and other considerations while updating the application for changes in the USB Host Stack.

Note: All USB Host Stack Demonstration Applications and USB Host Stack related documentation have been updated to the latest (new) USB Host API. The following sections do not discuss changes in the USB Host Stack configuration related code. This is updated automatically when the project is re-generated using MHC utility. Only the application related API changes are discussed.

USB Host Layer

Describes differences in the USB Host Library. Describes differences from earlier versions of MPLAB Harmony and the USB Host Layer Library in v1.04 of MPLAB Harmony.

Description

In MPLAB Harmony v1.03.01, the application was required to open the Host Layer to obtain a handle by calling the USB_HOST_Open function. This handle was then used along with other Host Layer API. Once opened, the application must enable Host Layer operation by calling the USB_HOST_OperationEnable function. The application must check the status of the enable operation function by calling the USB_HOST_OperationIsEnabled function. This is shown in the following code example.

Example:

```
/* This code shows an example application tasks that enabled Host
 * operation and waits for the enable operation to complete */

void APP_Tasks ( void )
{
    /* Check the application's current state. */
   USB_HOST_CDC_RESULT result;
    uint8_t  temp;

    switch (appData.state)
    {
        case APP_STATE_OPEN_HOST_LAYER:

            /* Open the host layer and then enable Host layer operation */
            appData.hostHandle = USB_HOST_Open(USB_HOST_INDEX_0, DRV_IO_INTENT_EXCLUSIVE);

            if (appData.hostHandle != USB_HOST_HANDLE_INVALID)
            {
                /* Host layer was opened successfully. Enable operation
                 * and then wait for operation to be enabled  */

                USB_HOST_OperationEnable(appData.hostHandle );
                appData.state = APP_STATE_WAIT_FOR_HOST_ENABLE;
```

```
            }
            break;

        case APP_STATE_WAIT_FOR_HOST_ENABLE:

            /* Check if the host operation has been enabled */
            if(USB_HOST_OperationIsEnabled(appData.hostHandle))
            {
                /* This means host operation is enabled. We can
                 * move on to the next state */
                appData.state = APP_STATE_WAIT_FOR_DEVICE_ATTACH;
            }

            break;

        default:
            break;
    }
}
```

In MPLAB Harmony v1.04, the application is not required to open the Host Layer. This is because the Host Layer by itself does not support multi-client operation. The application must first set the Host Layer event handler using the USB_HOST_EventHandlerSet function and then enable the desired bus using the USB_HOST_BusEnable function. The completion of the Bus Enable function can be checked by calling the USB_HOST_BusIsEnabled function. Once enabled, the application can perform operations on the bus, look for attached devices, and perform operations on the attached device. The following code shows an example of enabling the bus.

```
/* This code shows an example of how the bus is enabled in the MPLAB Harmony v1.04
 * USB Host Stack. The application state machine then waits for the bus enable
 * operation to complete */

void APP_Tasks ( void )
{
    switch (appData.state)
    {
        case APP_STATE_BUS_ENABLE:

            /* In this state the application enables the USB Host Bus. Note
             * how the Host event handler are registered before the bus
             * is enabled. */

            USB_HOST_EventHandlerSet(APP_USBHostEventHandler, (uintptr_t)0);
            USB_HOST_BusEnable(0);
            appData.state = APP_STATE_WAIT_FOR_BUS_ENABLE_COMPLETE;
            break;

        case APP_STATE_WAIT_FOR_BUS_ENABLE_COMPLETE:

            /* In this state we wait for the Bus enable to complete */
            if(USB_HOST_BusIsEnabled(0))
            {
                appData.state = APP_STATE_WAIT_FOR_DEVICE_ATTACH;
            }
            break;

        default:
            break;
    }
}
```

API Changes

The following table shows the legacy Host API and corresponding v1.04 MPLAB Harmony Host Stack API.

USB Host Layer API

MPLAB Harmony v1.03.01 and Earlier	MPLAB Harmony v1.04 and Later
USB_HOST_Open	N/A The USB Host Layer does not have to be opened.

USB_HOST_Close	N/A The USB Host Layer does not have to be closed.
USB_HOST_EventCallBackSet	USB_HOST_EventHandlerSet Events have changed.
USB_HOST_OperationEnable	USB_HOST_BusEnable Multiple busses can be managed.
USB_HOST_OperationDisable	N/A A bus disable function is not currently available and will be added in a future release of MPLAB Harmony.
USB_HOST_OperationIsEnabled	USB_HOST_BusIsEnabled
USB_HOST_DeviceSuspend	USB_HOST_DeviceSuspend Function parameters have changed.
USB_HOST_DeviceResume	USB_HOST_DeviceResume Function parameters have changed.
N/A	USB_HOST_BusSuspend Provides multiple bus support.
N/A	USB_HOST_BusResume Provides multiple bus support.
N/A	USB_HOST_DeviceGetFirst Provides multiple bus support.
N/A	USB_HOST_DeviceGetNext Provides multiple bus support.
N/A	USB_HOST_DeviceSpeedGet
N/A	USB_HOST_DeviceIsSuspended
N/A	USB_HOST_DeviceStringDescriptorGet

Event Changes

The type of events that the Host Layer generates in earlier versions of MPLAB Harmony and v1.04 of the MPLAB Harmony USB Host Stack have changed. The following table shows a comparison.

USB Host Layer Events

MPLAB Harmony v1.03.01 and Earlier	MPLAB Harmony v1.04 and Later
N/A	USB_HOST_EVENT_DEVICE_REJECTED_INSUFFICIENT_POWER
USB_HOST_EVENT_UNSUPPORTED_DEVICE	USB_HOST_EVENT_DEVICE_UNSUPPORTED
USB_HOST_EVENT_CANNOT_ENUMERATE	This event is not needed and is the same as an unsupported device.
USB_HOST_EVENT_CONFIGURATION_FAILED	This event is not needed and is the same as an unsupported device.
USB_HOST_EVENT_DEVICE_SUSPENDED	This event is not needed. A polling based function is available.
USB_HOST_EVENT_DEVICE_RESUMED	This event is not needed. A polling based function is available.
N/A	USB_HOST_EVENT_HUB_TIER_LEVEL_EXCEEDED
N/A	USB_HOST_EVENT_PORT_OVERCURRENT_DETECTED

USB MSD Host Client Driver and SCSI Block Storage Driver

Provides migration information for the MSD Host Client Driver and the SCSI Block Storage Driver.

Description

The application would use the MSD Host Client Driver and SCSI Block Storage Driver for accessing USB Storage Devices, such as USB Pen Drives. The key difference between the MSD Host Client Drivers in previous versions of the MPLAB Harmony USB Host Stack and the v1.04 MPLAB Harmony USB Host Stack MSD Host Client Drivers is the way the storage device attach and detach events are handled.

In previous versions (i.e., v1.03.01 or earlier) of USB Host Stack MSD Host Client Driver an application would have to register an event handler using the USB_HOST_MSDEventHandlerSet) function after Host operation has been enabled. When the application would receive an event, USB_HOST_MSD_EVENT_ATTACH would be detected, and the application would then try to mount the drive in this event. This is shown in the following code example.

Example:

```
/* In a v1.03.01 or earlier MSD Host Client Driver implementation, the driver will send an
 * attach detach event to the application. The application must use this to mount or unmount
 * the drive in its main state machine */

bool APP_USBHostMSDEventHandler
(
    USB_HOST_MSD_INDEX index,
    USB_HOST_MSD_EVENT event,
    void* pData
)
{
    switch ( event)
    {
        case USB_HOST_MSD_EVENT_ATTACH:

            /* This means a USB storage device was plugged in. Update the
             * application state */
            appData.state =  APP_STATE_DEVICE_CONNECTED;

            break;

        case USB_HOST_MSD_EVENT_DETACH:

            /* This means the USB storage was unplugged. Update the application
             * state */
            appData.state = APP_STATE_UNMOUNT_DISK;
            break;

        default:
            break;
    }

    return 0;
}

/* In the main application task routine, the host layer is opened and the host
 * operation is enabled. A MSD Host Client Driver event handler is registered
 * and disk is mounted when an attach event has been detected */

void APP_Tasks ( void )
{
    /* The application task state machine */

    switch(appData.state)
    {
        case APP_STATE_OPEN_HOST_LAYER:

            /* Open the host layer and then enable Host layer operation */
            appData.hostHandle = USB_HOST_Open(USB_HOST_INDEX_0, DRV_IO_INTENT_EXCLUSIVE);

            if (appData.hostHandle != USB_HOST_HANDLE_INVALID)
            {
                /* Host layer was opened successfully. Enable operation
                 * and then wait for operation to be enabled  */

                USB_HOST_OperationEnable(appData.hostHandle );
                appData.state = APP_STATE_WAIT_FOR_HOST_ENABLE;

            }
            break;

        case APP_STATE_WAIT_FOR_HOST_ENABLE:

            /* Check if the host operation has been enabled */
            if(USB_HOST_OperationIsEnabled(appData.hostHandle))
            {
                /* This means host operation is enabled. We can
```

```
                 * move on to the next state */

                USB_HOST_EventCallBackSet(appData.hostHandle,APP_USBHostEventHandler , 0 );
                USB_HOST_MSD_EventHandlerSet (APP_USBHostMSDEventHandler );
                appData.state = APP_STATE_WAIT_FOR_DEVICE_ATTACH;
            }

            break;

        case APP_STATE_WAIT_FOR_DEVICE_ATTACH:

            /* Wait for device attach. The state machine will move
             * to the next state when the attach event
             * is received.  */

            break;

        case APP_STATE_DEVICE_CONNECTED:

            /* Device was connected. We can try mounting the disk */
            appData.state = APP_STATE_MOUNT_DISK;
            break;

        case  APP_STATE_MOUNT_DISK:

            /* The application gets into this state when the drive is attached
             * */

            if(SYS_FS_Mount("/dev/sda1", "/mnt/myDrive", FAT, 0, NULL) != 0)
            {
                /* The disk could not be mounted. Try
                 * mounting again until success. */

                appData.state = APP_STATE_MOUNT_DISK;
            }
            else
            {
                /* Mount was successful. Try opening the file */
                appData.state = APP_STATE_OPEN_FILE;
            }
            break;

        case APP_STATE_UNMOUNT_DISK:

            /* The application gets into this state when the drive is detached
             * */

            if(SYS_FS_Unmount("/mnt/myDrive") != 0)
            {
                /* The disk could not be unmounted. Try
                 * unmounting again until success. */

                appData.state = APP_STATE_UNMOUNT_DISK;
            }
            else
            {
                /* Unmount was successful. Wait for device attach */
                appData.state =  APP_STATE_WAIT_FOR_DEVICE_ATTACH;

            }
            break;

        default:
            break;
    }
}
```

In the v1.04 USB Host Stack MSD Host Client Driver, the application must use the auto mount feature of the MPLAB Harmony File System. This feature should be enabled when the project is generated via MHC. The application then uses the MPLAB Harmony File System event handler to know when the File System has mounted the attached USB Storage Device. The application does not have to explicitly mount or unmount the

drive. This is shown in the following code example.

Example:

```
/* In v1.04 USB MSD Host Client Driver, the driver uses the auto mount feature
 * of the MPLAB Harmony File System. The application must make sure that this
 * feature is enabled when the project is generated using MHC. Note that unlike
 * previous implement, here the USB Storage device attach detach event appears
 * as a File System Event. */

void APP_SYSFSEventHandler(SYS_FS_EVENT event, void * eventData, uintptr_t context)
{
    switch(event)
    {
        case SYS_FS_EVENT_MOUNT:

            /* The file system generates this event when the drive is mounted.
             * This happens when the USB storage device is connected */
            appData.deviceIsConnected = true;
            break;

        case SYS_FS_EVENT_UNMOUNT:

            /* The file system generates this event when the drive is unmounted.
             * This happens when the USB storage device is disconnected */
            appData.deviceIsConnected = false;

            break;

        default:
            break;
    }
}

/* This is the application state machine. Note how the application register the
 * event handler with the File System before enabling the bus */

void APP_Tasks ( void )
{
    switch(appData.state)
    {
        case APP_STATE_BUS_ENABLE:

            /* Set the event handler and enable the bus */
            SYS_FS_EventHandlerSet(APP_SYSFSEventHandler, (uintptr_t)NULL);
            USB_HOST_EventHandlerSet(APP_USBHostEventHandler, 0);
            USB_HOST_BusEnable(0);
            appData.state = APP_STATE_WAIT_FOR_BUS_ENABLE_COMPLETE;
            break;

        case APP_STATE_WAIT_FOR_BUS_ENABLE_COMPLETE:
            if(USB_HOST_BusIsEnabled(0))
            {
                appData.state = APP_STATE_WAIT_FOR_DEVICE_ATTACH;
            }
            break;

        case APP_STATE_WAIT_FOR_DEVICE_ATTACH:

            /* Wait for device attach. The state machine will move
             * to the next state when the attach event
             * is received.  */
            if(appData.deviceIsConnected)
            {
                appData.state = APP_STATE_DEVICE_CONNECTED;
            }

            break;

        case APP_STATE_DEVICE_CONNECTED:
```

```
            /* Device was connected. We can try mounting the disk */
            appData.state = APP_STATE_OPEN_FILE;
            break;

        case APP_STATE_IDLE:

            /* The application reaches here after completing operation and waits
             * for device detach and if detached, wait for attach. */
            if(appData.deviceIsConnected == false)
            {
                appData.state = APP_STATE_WAIT_FOR_DEVICE_ATTACH;
            }
            break;

        default:
            break;
    }
}
```

USB CDC Host Client Driver

Describes differences from earlier versions of MPLAB Harmony and the USB CDC Host Client Driver API in v1.04 of MPLAB Harmony.

Description

The key differences between the USB CDC Host Client Driver API in earlier versions of MPLAB Harmony and MPLAB Harmony v1.04 are:

- In the v1.04 release, the Device Attach event handler must be registered before enabling the bus and the General CDC Host Client Driver Event Handler is registered after the attached CDC device has been opened. In v1.03.01 and earlier, there was only one event handler which received all events and this event handler was to be registered after the Host Operation was enabled.
- In the v1.04 release, the application must open the attached CDC device. In v1.03.01 and earlier, the application does not have to open the attached CDC Device.

Registering Events

In v1.03.01 and earlier versions of the USB CDC Host Client Driver, the application registers the CDC Event Handler after the Host Operation was enabled. Only one event handler could be registered for all attached CDC Devices. The CDC Host Client Driver would specify the instance of the CDC Device generating the event when the event handler was invoked. The following code shows an example of this.

```
/* This code shows how a single CDC event handler is registered for all
 * instances of the CDC Host Client Driver. The instance of the client driver
 * generating this event is available in the index parameter of the event
 * handler. This code example is applicable to pre-v1.04 releases of the client
 * driver */

USB_HOST_CDC_EVENT_RESPONSE APP_USBHostCDCEventHandler
(
    USB_HOST_CDC_INDEX index,
    USB_HOST_CDC_EVENT event,
    void * eventData,
    uintptr_t context
)
{
    /* Get the application context */
    uint8_t deviceAddress;

    switch(event)
    {
        case USB_HOST_CDC_EVENT_ATTACH:

            /* The event data in this case is the address of the
             * attached device. */

            appData.state = APP_STATE_DEVICE_CONNECTED;
            deviceAddress = *((uint8_t *)eventData);
            break;

        case USB_HOST_CDC_EVENT_DETACH:

            /* This means the device was detached. There is no event data
             * associated with this event.*/
```

```
            appData.state = APP_STATE_WAIT_FOR_DEVICE_ATTACH;
            break;

            /* Other events not shown here for the sake of brevity */

        default:
            break;
    }

    return USB_HOST_CDC_EVENT_RESPONSE_NONE;
}

/* This is a pre v1.04 release application tasks for a CDC host client driver.
 * Note that application does not open the client driver and hence when
 * registering an event handler, is registering it all CDC Host Client Driver
 * instances. */

void APP_Tasks ( void )

        case APP_STATE_WAIT_FOR_DEVICE_ATTACH:

            /* Wait for device attach. The state machine will move
             * to the next state when the USB_HOST_CDC_EVENT_ATTACH
             * is received. The application state is update in the
             * CDC Host event handler */

            break;

        default:
            break;
    }
}
```

In the v1.04 released version of the USB CDC Host Client Driver, the application must register an Attach Event Handler before enabling the bus operation. This one Attach Event handler will be invoked when even a CDC Device is attached. The application must use the CDC object returned in the attach event handler to open the device. The application can then register an event handler using the handle returned by the open function. This is shown in the code snippet here.

```
/* This code how event handling is performed in the v1.04 release of the
 * CDC Host Client Driver. The application must register a listener function
 * that check if the CDC Device is attached. When the attached device is opened
 * the application must then register event handler to register other CDC Host
 * Client Driver events */

void APP_USBHostCDCAttachEventListener(USB_HOST_CDC_OBJ cdcObj, uintptr_t context)
{
    /* This function gets called when the CDC device is attached. Update the
     * application data structure to let the application know that this device
     * is attached */

    appData.deviceIsAttached = true;
    appData.cdcObj = cdcObj;
}

USB_HOST_CDC_EVENT_RESPONSE APP_USBHostCDCEventHandler

API Differences

The following table shows the difference in API names between the pre v1.04 release and the v1.04 release versions of the CDC Host Client Driver.

MPLAB Harmony v1.03.01 and Earlier	MPLAB Harmony v1.04 and Later
USB_HOST_CDC_EventHandlerSet	USB_HOST_CDC_EventHandlerSet
USB_HOST_CDC_Read	USB_HOST_CDC_Read
USB_HOST_CDC_Write	USB_HOST_CDC_Write
USB_HOST_CDC_SerialStateNotificationGet	USB_HOST_CDC_SerialStateNotificationGet
USB_HOST_CDC_LineCodingGet	USB_HOST_CDC_ACM_LineCodingGet
USB_HOST_CDC_ControlLinetStateSet	USB_HOST_CDC_ACM_ControlLineStateSet
USB_HOST_CDC_BreakSend	USB_HOST_CDC_ACM_BreakSend
Not needed.	USB_HOST_CDC_EventHandlerSet The attach event requires a separate event handler in v1.04.
Not available.	USB_HOST_CDC_DeviceObjHandleGet
Not available.	USB_HOST_CDC_Open The driver needs to be opened in v1.04.
Not available.	USB_HOST_CDC_Close

Event Name Differences

The following table shows the difference in event names between earlier versions and the MPLAB Harmony v1.04 release of the CDC Host Client Driver.

MPLAB Harmony v1.03.01 and Earlier	MPLAB Harmony v1.04 and Later
USB_HOST_CDC_EVENT_READ_COMPLETE	USB_HOST_CDC_EVENT_READ_COMPLETE
USB_HOST_CDC_EVENT_WRITE_COMPLETE	USB_HOST_CDC_EVENT_WRITE_COMPLETE
USB_HOST_CDC_EVENT_SERIAL_STATE_NOTIFICATION_RECEIVED	USB_HOST_CDC_EVENT_SERIAL_STATE_NOTIFICATION_RECEIVED
USB_HOST_CDC_EVENT_GET_LINE_CODING_COMPLETE	USB_HOST_CDC_EVENT_ACM_GET_LINE_CODING_COMPLETE
USB_HOST_CDC_EVENT_SET_LINE_CODING_COMPLETE	USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE
USB_HOST_CDC_EVENT_SET_CONTROL_LINE_STATE_COMPLETE	USB_HOST_CDC_EVENT_ACM_SET_CONTROL_LINE_STATE_COMPLETE
USB_HOST_CDC_EVENT_SEND_BREAK_COMPLETE	USB_HOST_CDC_EVENT_ACM_SEND_BREAK_COMPLETE
USB_HOST_CDC_EVENT_DETACH	USB_HOST_CDC_EVENT_DEVICE_DETACHED
USB_HOST_CDC_EVENT_ATTACH	Not needed. Refer to the USB_HOST_AttachEventHandlerSet function.

USB Host Layer Library

This section describes the USB Host Layer Library.

Introduction

Introduces the MPLAB Harmony USB Host Layer Library.

Description

The USB Host Layer in the MPLAB Harmony USB Host Stack performs the tasks of enumerating an attached device and interfacing the HCD. The following are the key features of the MPLAB Harmony USB Host Layer:

- Supports multi-configuration and composite USB Devices

- Supports VID PID and class, subclass, and protocol devices
- Can manage multiple USB devices through the Root Hub
- Concise API simplifies application development
- Modular architecture allows support for multiple (and different) USB controller in one application. Can operate multiple USB segments.
- Supports Low-Speed, Full-Speed, and Hi-Speed USB devices

Using the Library

This topic describes the basic architecture of the USB Host Layer and provides information and examples on its use.

Abstraction Model

Describes the abstraction model of the USB Host Layer.

Description

The USB Host Layer abstracts USB HCD hardware interaction details and presents an easy-to-use interface to the application and the client drivers. The Host Layer provides the application with a device object handle, which the application can use to suspend or resume the device. The Host Layer provides client drivers with device client handles and interface handles. These handles allow the client drivers to interact with the device and its interfaces. The Host Layer allows the client drivers to

- Open control pipes and schedule control transfers
- Open bulk, isochronous, and interrupt pipes
- Perform data transfers
- Claim and release ownership of the device and device interfaces
- Perform standard device operations.

The Host Layer has exclusive access to the HCD and the Root Hub. It opens the HCD and presents an abstracted interface to the application and client drivers.

Library Overview

The USB Host layer API is grouped functionally, as shown in the following table.

Library Interface Section	Description
System Interface Functions	These functions make the USB Host Layer compatible with MPLAB Harmony.
Bus Control Functions	These functions allow the application to enable, disable, suspend and resume the USB.
Device Related Functions	These functions allow the application to suspend and resume the USB. Attached devices can be queried and their string descriptors can be obtained.
Event Handling	Allows the application to register an event handler.
Client Driver Routines	These functions are exclusive to the client drivers and should not be accessed by the application.

How the Library Works

Describes how the Library works and how it should be used.

Description

The Host Layer in the MPLAB Harmony USB Host Stack plays the key role of enumerating an attached device and facilitating the communication between the USB Host Client Driver and the attached devices. The following sections describe the steps and methods that the user application must follow to use the Host Layer (and the USB Host stack). The following topics are discusses:

- Host Layer Initialization
- Operating the Host layer
- Host Layer Application Events

Host Layer Initialization

This topic describes how to initialize the Host Layer and includes code examples.

Description

The Host Layer must be initialized with relevant data to enable correct operation. This initialization must be performed in the SYS_Initialize function of the MPLAB Harmony application. The Host Layer will require the USB Controller Peripheral driver to be initialized for host mode operation (and

hence operate as a HCD). This initialization must be performed in the SYS_Initialize function. The order in which the Host Layer and the USB Peripheral Driver are initialized does not affect the Host Layer operation. The Host Layer could be initialized before or after the USB Controller Peripheral Driver initialization.

The Host Layer requires the following information for initialization:

- The HCD interface for each bus
- The Target Peripheral List (TPL)

The Host Layer is capable of operating more than one USB device. This is possible on PIC32 microcontrollers that feature multiple USB Controller Peripherals. The one instance of the Host Layer manages multiple HCDs. The interface to each to every instance of the HCD that the Host Layer must operate must be specified in the Host Layer initialization. The total number of USB devices the Host Layer should manage is defined statically by the USB_HOST_CONTROLLERS_NUMBER configuration macro in the `system_config.h` file. The following code shows an example initialization of a PIC32MX USB HCD.

Example: PIC32MZ USB HCD Initialization

```
/* This code shows an example of how to initialize the PIC32MX USB
 * Driver for host mode operation. For more details on the PIC32MX Full-Speed
 * USB Driver, please refer to the Driver Libraries documentation. */

/* Include the full-speed USB driver header file */
#include "driver/usb/usbfs/drv_usbfs.h"

/* Create a driver initialization data structure */
DRV_USBFS_INIT drvUSBFSInit;

/* The PIC32MX Full-Speed USB Driver when operating in host mode requires an
 * endpoint table (a byte array) whose size should be 32 bytes. This table should
 * be aligned at 512 byte address boundary */
uint8_t __attribute__((aligned(512))) endpointTable[32];

/* Configure the driver initialization data structure */
DRV_USBFS_INIT drvUSBFSInit =
{
    /* This parameter should be set to SYS_MODULE_POWER_RUN_FULL. */
    .moduleInit = {SYS_MODULE_POWER_RUN_FULL},

    /* Driver operates in Host mode */
    .operationMode = USB_OPMODE_HOST,

    /* USB module interrupt source */
    .interruptSource = INT_SOURCE_USB_1,

    /* Continue operation when CPU is in Idle mode */
    .stopInIdle = false,

    /* Do not suspend operation when CPU enters Sleep mode */
    .suspendInSleep = false,

    /* The USB module index */
    .usbID = USB_ID_1,

    /* The maximum current that the VBUS supply can provide */
    .rootHubAvailableCurrent = 500,

    /* Pointer to the endpoint table */
    .endpointTable = endpointTable,

    /* Pointer to the Port Power Enable function. Driver will cause this
     * function when the port power must be enabled */
    .portPowerEnable = PortPowerEnable,

    /* Pointer to the Port Over Current Detect function. Driver will cause this
     * function periodically to check if the port current has exceeded limit */
    .portOverCurrentDetect = PortOverCurrentDetect,

    /* Pointer to the Port LED indication function. The driver will call this
     * function to update the Port LED status */
    .portIndication = PortIndication

};
```

```
/* USB Driver system module object */
SYS_MODULE_OBJ drvUSBObj = SYS_MODULE_OBJ_INVALID;

void SYS_Initialize(void * data)
{
    /* Initialize the driver */
    drvUSBObj = DRV_USBFS_Initialize(DRV_USBFS_INDEX_0, (SYS_MODULE_INIT *)(&drvUSBFSInit));
}

void SYS_Tasks(void)
{
    /* Call the driver tasks routine in SYS_Tasks() function *//
    DRV_USBFS_Tasks(drvUSBObj);
}

void __ISR(_USB_1_VECTOR, ipl4AUTO) _IntHandlerUSBInstance0(void)
{
    /* Call the driver interrupt tasks routine in the USB module ISR */
    DRV_USBFS_Tasks_ISR(sysObj.drvUSBModuleObj);
}
```

The Host Layer Initialization requires a USB_HOST_HCD data structure. This data structure specifies the HCD module index and the HCD Host Layer Interface for each bus. The following code shows the USB_HOST_HCD data structure is initialized for a single USB Controller Peripheral PIC32MX microcontroller device.

Example: Data Structure Initialized for a Single USB Controller Peripheral PIC32MX MCU

```
/* This code shows an example of setting up the USB_HOST_HCD data
 * structure for the PIC32MX USB controller */

USB_HOST_HCD usbHostHCD =
{
    /* This is the driver instance index that the USB Host Layer will use */
    .drvIndex = DRV_USBFS_INDEX_0,

    /* This is the interface to the PIC32MX USB HCD. The
     * DRV_USBHS_HOST_INTERFACE pointer is exported by the PIC32MX Host Mode USB
     * Driver. */
    .hcdInterface = DRV_USBHS_HOST_INTERFACE
};
```

The other important component required for USB Host Layer initialization is the Target Peripheral List (TPL). Embedded USB Hosts unlike standard USB Host are not expected to support all USB Device Types. The device types to be supported are specified in the TPL. The TPL contains an entry for every device type that the Embedded USB host must support. If the attached device matches the criteria specified in the TPL entry , the Host Layer attaches the driver corresponding to that entry to the manage device. A device may match multiple entries in the TPL. This happens in the case of composite devices.

An entry in the TPL contains the following information:

- Device Type: This specifies whether the Host must inspect the VID, PID field or Class, Subclass and Protocol fields while matching the attached device to the entry
- Flags: These flags provide the system designer with various options while matching the attached device to a driver. For example, a flag can be specified to ignore the device PID and only consider the VID while matching VID PID device.
- PID Mask: This is a PID mask that can be applied to the PID before matching the PID to the attached device PID
- Driver: This is the pointer to the interface of the client driver that should manage the device if the matching criteria is met

The following code shows an example TPL table.

Example: TPL Table

```
    /* This code shows some examples of configuring the USB Host Layer
     * TPL Table. In this example, the USB Host layer is configured to support
     * three different types of devices. */

    USB_HOST_TARGET_PERIPHERAL_LIST usbHostTPL[4] =
    {

        /* Catch every device with the exact Vendor ID = 0x04D9 and Product ID = 0x0001.
         * Every other device will not load this driver. */
        TPL_DEVICE_VID_PID( 0x04D9, 0x0001, &driverInitData, &DEVICE_DRIVER_EXAMPLE1_Driver ),

        /* This driver will catch any device with the Vendor ID of 0x04D9 and any
         * product ID = 0x0000 or 0x0002-0x00FF.  The entry in the TPL before this
         * caught the Product ID = 0x0001 case so that is why it is not caught by
         * this entry.  Those devices have already been caught. */
        TPL_DEVICE_VID_PID_MASKED( 0x04D9, 0x0002, 0xFF00, &driverInitData, &DEVICE_DRIVER_EXAMPLE2_Driver
```

```
),

        /* This entry will catch all other devices. */
        TPL_DEVICE_ANY( &driverInitData, &DEVICE_DRIVER_EXAMPLE3_Driver ),

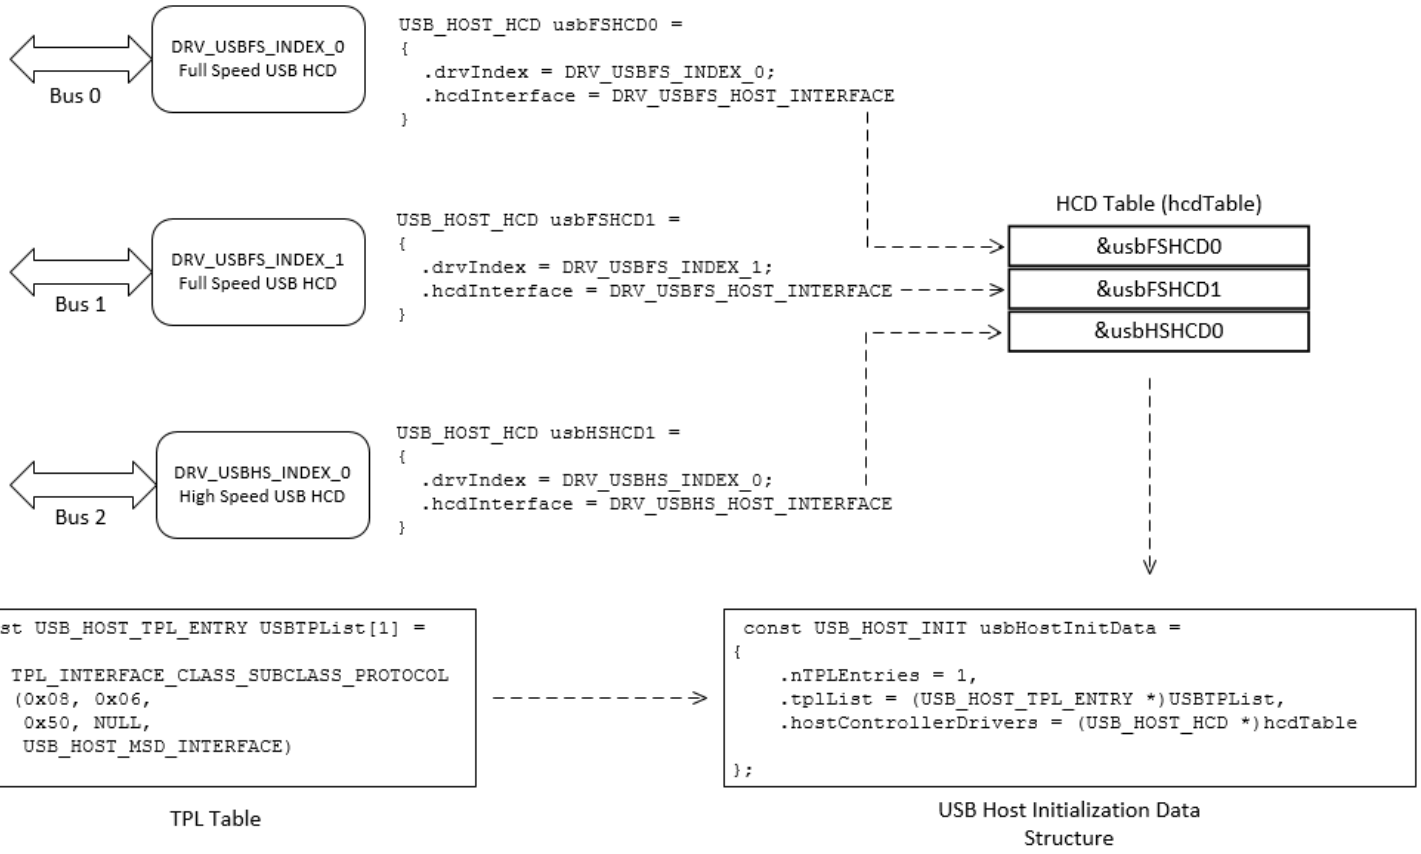
        /* This entry will catch only a HID boot keyboard.  All other devices,
         * including other HID keyboards that are non-boot, will be skipped by this
         * entry. This driver will handle only this specific case. */
        TPL_INTERFACE_CLASS_SUBCLASS_PROTOCOL( USB_HID_CLASS_CODE, USB_HID_SUBCLASS_CODE_BOOT_INTERFACE,
                                               USB_HID_PROTOCOL_CODE_KEYBOARD, &hidDriverInitData,
                                               USB_HOST_HID_BOOT_KEYBOARD_DRIVER ),

        /* This entry will catch all CDC-ACM devices.  It filters on the class and
         * subclass but ignores the protocol since the driver will handle all
         * possible protocol options. */
        TPL_INTERFACE_CLASS_SUBCLASS( USB_CDC_CLASS_CODE, USB_CDC_SUBCLASS_CODE_ABSTRACT_CONTROL_MODEL,
                                      &cdcDriverInitData, USB_HOST_CDC_ACM_DRIVER ),

        /* This will catch all instances of the MSD class regardless subclass or
         * protocol.  In this case the driver will sort out if it supports the
         * device or not. */
        TPL_INTERFACE_CLASS( USB_MSD_CLASS_CODE, &msdDriverInitData, USB_HOST_MSD_DRIVER ),

        /* Any unclaimed interfaces can be sent to a particular driver if desired.
         * This can be used to create a similar mechanism that libUSB or WinUSB
         * provides on a PC where any unused interface can be opened and utilized by
         * these drivers. */
        TPL_INTERFACE_ANY( &driverInitData, USB_HOST_VENDOR_DRIVER )
    }
```

The Host Layer can now be initialized. The following code shows how the USB_HOST_HCD and the TPL table are specified in the USB_HOST_INIT (the Host Layer Initialization) data structure. In addition, the following figure illustrates the various initialization inputs needed by the Host Layer.



The USB_HOST_Initialize function is called to initialize the Host Layer. The initialization process may not complete when the USB_HOST_Initialization function exits. This will complete in subsequent calls to the USB_HOST_Tasks function.

Example: Specifying the TPL Table

```
/* This code shows an example of the USB Host Layer Initialization data
```

```
 * structure. In this case the number of TPL entries is one and there is only
 * one HCD (and hence only one USB bus) in the application */

const USB_HOST_TPL_ENTRY USBTPList[1] =
{
    /* This is the TPL */
    TPL_INTERFACE_CLASS_SUBCLASS_PROTOCOL(0x08, 0x06, 0x50, NULL,  USB_HOST_MSD_INTERFACE)

};

const USB_HOST_HCD hcdTable =
{
    /* The HCD table only contains one entry */
    .drvIndex = DRV_USBFS_INDEX_0,
    .hcdInterface = DRV_USBFS_HOST_INTERFACE
};

const USB_HOST_INIT usbHostInitData =
{
    /* This is the Host Layer Initialization data structure */
    .nTPLEntries = 1,
    .tplList = (USB_HOST_TPL_ENTRY *)USBTPList,
    .hostControllerDrivers = (USB_HOST_HCD *)&hcdTable

};
```

Host Layer - Application Interaction

This topic describes application interaction with the USB Host Layer.

Description

The Host Layer in the MPLAB Harmony USB Host stack provides the user application with API methods to operate the USB Host. The following sections discuss these API methods.

Registering the Event Handler

The application must register an event handler to receive device related USB Host events. The application sets the events handler by using the USB_HOST_EventHandlerSet function. An application defined context can also be provided. This context is returned along with the event handler and helps the application to identify the context in case of a dynamic application use cases. The host layer provides events when a connected device requires more current than can be provided or when a unsupported device was attached. The following code shows an example of registering the event handler.

```
/* This code shows an example of registering an event handler with the
 * Host Layer */

USB_HOST_EVENT_RESPONSE APP_USBHostEventHandler
(
    USB_HOST_EVENT event,
    void * eventData,
    uintptr_t context
)
{
    /* This is the event handler implementation */
    switch (event)
    {
        case USB_HOST_EVENT_DEVICE_UNSUPPORTED:
            break;
        case USB_HOST_EVENT_DEVICE_REJECTED_INSUFFICIENT_POWER:
            break;
        case USB_HOST_EVENT_HUB_TIER_LEVEL_EXCEEDED:
            break;
        case USB_HOST_EVENT_PORT_OVERCURRENT_DETECTED:
            break;
        default:
            break;
    }

    return(USB_HOST_EVENT_RESPONSE_NONE);
}
```

```
void APP_Tasks(void)
{
    /* This shows an example app state machine implementation in which the event
     * handler is set and the bus is then enabled. */

    switch(appData.state)
    {
        case APP_STATE_BUS_ENABLE:

            /* Set the event handler and enable the bus */
            USB_HOST_EventHandlerSet(APP_USBHostEventHandler, 0);
            USB_HOST_BusEnable(0);
            appData.state = APP_STATE_WAIT_FOR_BUS_ENABLE_COMPLETE;
            break;

        default:
            break;
    }
}
```

Enabling the Bus

The user application must call the USB_HOST_BusEnable function to enable the bus. This function enables the 5V VBUS supply to root hub port thus powering up the bus powered device that are attached to the bus. The attached devices will then indicate attach. The root hub will provide these attach events to the Host layer which in turn starts the enumeration process. The application can call other Host Layer functions only after the bus has been enabled. The USB_HOST_BusIsEnabled function must be called to check if the enable process has completed. The following code shows an example application state machine that enables the bus.

```
void APP_Tasks ( void )
{
   /* The application shows an example of how the USB bus is enabled and how the
    * application must wait for the bus to enabled */

    switch(appData.state)
    {
        case APP_STATE_BUS_ENABLE:

           /* Set the event handler and enable the bus */
            USB_HOST_EventHandlerSet(APP_USBHostEventHandler, 0);
            USB_HOST_BusEnable(0);
            appData.state = APP_STATE_WAIT_FOR_BUS_ENABLE_COMPLETE;
            break;

        case APP_STATE_WAIT_FOR_BUS_ENABLE_COMPLETE:
            /* Check if the bus is enabled */
            if(USB_HOST_BusIsEnabled(0))
            {
                appData.state = APP_STATE_WAIT_FOR_DEVICE_ATTACH;
            }
            break;

        default:
            break;
    }
}
```

Attached Device Information

The application can use the USB_HOST_DeviceFirstGet and the USB_HOST_DeviceNextGet function to query for attached devices. The USB_HOST_DeviceFirstGet function will provide information on the first device that was attached to the bus. Information is returned in application specified USB_HOST_DEVICE_INFO object. The USB_HOST_DeviceFirstGet function will return the following information in the USB_HOST_DEVICE_INFO object:

- A Device Object Handle of the type USB_HOST_DEVICE_OBJ_HANDLE. The application can use this device object handle to perform operations on the device.
- The address of the device on the USB
- The bus to which this device belongs

The application can access the contents of the USB_HOST_DEVICE_INFO object but should not alter it contents. The same object is passed to the USB_HOST_DeviceNextGet function to get the information about the next device attached on the bus. Each call to this function defines the point at which the USB_HOST_DeviceNextGet function will start searching. If the device that is represented by the USB_HOST_DEVICE_INFO

object has been disconnected, calling the USB_HOST_DeviceNextGet function will return an error. The search must be reset by calling the USB_HOST_DeviceFirstGet function. The application can define multiple USB_HOST_DEVICE_INFO objects to search on different busses or maintain different search points.

```
void APP_Tasks(void)
{
    USB_HOST_DEVICE_INFO deviceInfo;
    USB_HOST_RESULT result;

    /* Get information about the first device on Bus 0 */
    result = USB_HOST_DeviceGetFirst(0, &deviceInfo);

    while(result != USB_HOST_RESULT_END_OF_DEVICE_LIST)
    {
        /* deviceInfo.address has the address of the bus */
        /* deviceInfo.deviceObjHandle will have the device object handle */

        /* Now we can get the information about the next device on the bus. */
        result = USB_HOST_DeviceGetNext(&deviceInfo);
    }
}
```

Suspend and Resume

The USB Host Layer allows the application to suspend and resume a device. The USB_HOST_DeviceSuspend and the USB_HOST_DeviceResume function are provided for this purpose. The application must use the device object handles, obtained from the USB_HOST_DeviceFirstGet or USB_HOST_DeviceNextGet function, to specify the device to suspend or resume when calling USB_HOST_DeviceSuspend and the USB_HOST_DeviceResume() function. The USB_HOST_DeviceIsSuspended function can be called to check the suspend status of the device.

In a case where the entire bus (and hence all device connected on the bus) need to be suspended or resumed, the application must call USB_HOST_BusSuspend and USB_HOST_BusResume functions to suspend or resume the entire bus. The USB_HOST_BusIsSuspended function can be called to check the suspend status of the bus.

Device String Descriptors

The application may want to obtain the string descriptors of a device. Sting descriptors are optionally provided by the USB device manufacturer and provide device information. The USB_HOST_DeviceStringDescriptorGet function is available to read the string descriptors. Calling this function will cause the Host Layer to invoke a control transfer request to read the string descriptor. The string descriptor will be available when the control transfer completes. The host layer calls the USB_HOST_STRING_REQUEST_COMPLETE_CALLBACK type callback function, that is provided in the USB_HOST_DeviceStringDescriptorGet function, when the control transfer has completed. The completion status of the request and the size of the string descriptor are available in the callback.

The function allows the application to obtain the supported string language IDs. The language ID of the string can be specified or a default can be used.

```
typedef struct
{
    /* This is an application specific data structure */
    char string[APP_STRING_SIZE];
    USB_HOST_REQUEST_HANDLE requestHandle;
    uintptr_t context;

} APP_DATA;

APP_DATA appData;

void APP_USBHostSringDescriptorGetCallBack
(
    USB_HOST_REQUEST_HANDLE requestHandle,
    size_t size,
    uintptr_t context
)
{
    /* This function is called when the string descriptor get function has
     * completed. */

    if(size != 0)
    {
        /* This means the function executed successfully and we have a string.
         * An application function prints the string to the console. */
        APP_PrintStringToConsole(appData.string, size);
    }
```

```
}

void APP_Tasks(void)
{
    USB_HOST_DEVICE_INFO deviceInfo;
    USB_HOST_RESULT result;

    /* Get information about the first device on Bus 0 */
    result = USB_HOST_DeviceGetFirst(0, &deviceInfo);

    if(result != USB_HOST_RESULT_END_OF_DEVICE_LIST)
    {
        /* deviceInfo.deviceObjHandle will have the device object handle. Use
         * this device object handle along with the
         * USB_HOST_DeviceStringDescriptorGet() function to read the product
         * string ID using the default Language ID. */

        USB_HOST_DeviceStringDescriptorGet(deviceInfo.deviceObjHandle, USB_HOST_DEVICE_STRING_PRODUCT,
                USB_HOST_DEVICE_STRING_LANG_ID_DEFAULT, appData.string, APP_STRING_SIZE,
                &appData.requestHandle, APP_USBHostSringDescriptorGetCallBack, appData.context );
    }
}
```

Event Handling

This topic describes event handling.

Description

The USB Host Layer provides general device related events to the application. The application must register an event handling function by using the USB_HOST_EventHandlerSet function. A context specified at the time of calling this function, is returned in the event handler. The event handler must be registered before the bus is enabled. Refer to the description of USB_HOST_DEVICE_EVENT events for details on the available events.

Configuring the Library

Describes how to configure the USB Host Layer.

Macros

	Name	Description
	USB_HOST_CONTROLLERS_NUMBER	Defines the number of USB Host Controllers that this Host Layer must manage.
	USB_HOST_DEVICE_INTERFACES_NUMBER	Defines the maximum number of interface that the attached device can contain in order for the USB Host Layer to process the device.
	USB_HOST_DEVICES_NUMBER	Defines the maximum number of devices to support.
	USB_HOST_HUB_SUPPORT_ENABLE	Defines if this USB Host application must support a Hub.
	USB_HOST_HUB_TIER_LEVEL	Defines the maximum tier of connected hubs to be supported.
	USB_HOST_PIPES_NUMBER	Defines the maximum number of pipes that the application will need.
	USB_HOST_TRANSFERS_NUMBER	Defines the maximum number of transfers that host layer should handle.

Description

The following configuration parameters must be defined while using the USB Host Layer. The configuration macros that implement these parameters must be located in the `system_config.h` file in the application project and a compiler include path (to point to the folder that contains this file) should be specified.

USB_HOST_CONTROLLERS_NUMBER Macro

Defines the number of USB Host Controllers that this Host Layer must manage.

File

usb_host_config_template.h

C

```
#define USB_HOST_CONTROLLERS_NUMBER
```

Description

USB Host Layer Controller Numbers

This constant defines the number of USB Host Controllers that this Host Layer must manage. The value of this constant should be atleast 1. Typical embedded applicatons contains only 1 USB host controller and hence only 1 USB. A microcontroller that features multiple USB modules can support multiple USB Host controllers and multipel USBs. USB contollers can also be interfaced to the microcontroller through common communication peripherals such as SPI.

This constant also defines the number of entries in the Host Controller Driver interface table, a pointer to which is passed in the hostContollerDrivers member of the USB_HOST_INIT data structure.

Remarks

None.

USB_HOST_DEVICE_INTERFACES_NUMBER Macro

Defines the maximum number of interface that the attached device can contain in order for the USB Host Layer to process the device.

File

usb_host_config_template.h

C

```
#define USB_HOST_DEVICE_INTERFACES_NUMBER
```

Description

USB Host Device Interface Numbers

This constant defines the maximum number of interface that the attached device can contain in order for the USB Host Layer to process the device. The device will be processed if it only contains less interfaces than the value of this constant.

Remarks

Supporting more interface per device required more processing time and data memory.

Example

An attached device contains a configuration that contains 10 interfaces, but the USB_HOST_DEVICE_INTERFACES_NUMBER is set to 5. The device will not be processed by the Host Layer. A dual CDC device needs to be supported. This device will have 4 interfaces. The USB_HOST_DEVICE_INTERFACES_NUMBER constant should be atleast 4.

USB_HOST_DEVICES_NUMBER Macro

Defines the maximum number of devices to support.

File

usb_host_config_template.h

C

```
#define USB_HOST_DEVICES_NUMBER
```

Description

USB Host Layer Devices Number

This configuration constant defines the maximum number of devices that this USB Host application must support. The value of this constant should be atleast 1. Multiple devices can be supported if Hub support is enabled. See USB_HOST_HUB_SUPPORT_ENABLE. The Hub itself will be treated as a device.

Remarks

Supporting multiple devices requires more data memory and processing time.

Example

If the USB Host application must support one USB Pen Drive and one USB Serial COM port (CDC Device), then this constant should be set to 3 (one additional device will be the Hub).

USB_HOST_HUB_SUPPORT_ENABLE Macro

Defines if this USB Host application must support a Hub.

File

usb_host_config_template.h

C

```
#define USB_HOST_HUB_SUPPORT_ENABLE
```

Description

USB Host Layer Hub Support

Specifying this macro will enable Hub Support. The HUB tier level to be supported is then specified by USB_HOST_HUB_TIER_LEVEL constant. If this macro is specified, the file usb_host_hub.c must be included in the application.

Remarks

Not specifying this macro will disable Hub support.

USB_HOST_HUB_TIER_LEVEL Macro

Defines the maximum tier of connected hubs to be supported.

File

usb_host_config_template.h

C

```
#define USB_HOST_HUB_TIER_LEVEL
```

Description

USB Host Hub Tier Level

This constant defines the maximum hub tiers to be supported by the USB Host application. This constant is considered only if the USB_HOST_HUB_SUPPORT_ENABLE option in specified. If specified, the value should be atleast 1. This means that one hub should be supported. In a case where another hub will be be connected to the hub which is connected to the USB Host, the value should be 2. As per the USB specification the maximum number of non-root hub tiers can be 5. Hence the value of this configuration constant should not exceed 5.

Remarks

None.

USB_HOST_PIPES_NUMBER Macro

Defines the maximum number of pipes that the application will need.

File

usb_host_config_template.h

C

```
#define USB_HOST_PIPES_NUMBER
```

Description

USB Host Layer Pipes Number

This configuration constant defines the maximum number of device communication pipes that Host Layer would need in the application. Every attached device requires atleast one pipe. This pipe is the control transfer pipe. Additional pipes are needed based on the type of device. For example, a standard Mass Storage Class device will need 2 pipes, a Communication Class Device will need 3 pipes, a HID device will need atleast 1 pipe. Vendor device will need communication pipe based on the device implementation. The number of pipes must also take into account the number of devices to support.

Remarks

This number should match the number of pipes configured in the HCD that this application will use, that is DRV_USBHS_HOST_PIPES_NUMBER or DRV_USBFS_HOST_PIPES_NUMBER.

Example

If a USB Host application must support 2 devices, either 2 USB pen driver or 2 CDC devices or a mix of both, then the pipes number should be set to

8. This is because the 2 CDC devices connected to the host will pose larger pipe

requirement. Two such devices will requires 2 control pipes, 2 interrupt pipes, 2 Bulk IN and 2 Bulk OUT pipes.

USB_HOST_TRANSFERS_NUMBER Macro

Defines the maximum number of transfers that host layer should handle.

File

usb_host_config_template.h

C

```
#define USB_HOST_TRANSFERS_NUMBER
```

Description

USB Host Layer Transfers Number

This constant defines the maximum number of transfers that the host layer should handle. The choice of this constant depends on the nature of devices that the USB Host application must support. Atleast two transfers are needed per pipe in the system. If the number of transfers provisioned in the system are insufficient, the USB Host will decline transfer request citing a busy status. This will affect the speed performance of the system.

Remarks

None.

Example

A USB Host application will support an MSD device and a CDC Device. The total number of pipes needed in the system are 7. The USB_HOST_TRANSFERS_NUMBER constant should be atleast 14 (2 per pipe). Specifying a larger number will enable more transfers to be queued but will also require more data memory.

Building the Library

Describes the files to be included in the project while using the USB Host Layer Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/usb`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`usb_host.h`	This header file should be included in any `.c` file that accesses the USB Host Layer API.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/dynamic/usb_host.c`	This file implements the USB Host Layer interface and should be included in the project if USB Host mode operation is desired.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The USB Host Layer Library depends on the following modules:

- USB Driver Library (Host mode files)
- Timer System Service Library

Library Interface

a) Functions

	Name	Description
	USB_HOST_Deinitialize	Deinitializes the specified instance of the USB Host Layer.
	USB_HOST_Status	Gets the current status of the USB Host Layer.
	USB_HOST_Tasks	Maintains the USB Host Layer state machine.
	USB_HOST_BusEnable	Starts host operations.
	USB_HOST_BusIsEnabled	Checks if the bus is enabled.
	USB_HOST_BusIsSuspended	Returns the suspend status of the bus.
	USB_HOST_BusResume	Resumes the bus.
	USB_HOST_BusSuspend	Suspends the bus.
	USB_HOST_DeviceGetFirst	Returns information about the first attached device on the bus.
	USB_HOST_DeviceGetNext	Returns information about the next device on the bus.
	USB_HOST_DeviceIsSuspended	Returns the suspend state of the device is suspended.
	USB_HOST_DeviceResume	Resumes the selected device
	USB_HOST_DeviceSpeedGet	Returns the speed at which this device is operating.
	USB_HOST_DeviceStringDescriptorGet	Retrieves specified string descriptor from the device
	USB_HOST_DeviceSuspend	Suspends the specified device.
	USB_HOST_EventHandlerSet	USB Host Layer Event Handler Callback Function set function.
	USB_HOST_Initialize	Initializes the USB Host layer instance specified by the index.

b) Data Types and Constants

	Name	Description
	USB_HOST_INIT	Defines the data required to initialize a USB Host Layer instance.
	USB_HOST_EVENT_RESPONSE	Host Layer Events Handler Function Response Type.
	\ .tplFlags.driverType = (TPL_FLAG_CLASS_SUBCLASS_PROTOCOL)	USB Host Layer TPL Table Entry Matching Criteria flag
	\ .tplFlags.driverType = (TPL_FLAG_VID_PID)	USB Host Layer TPL Table Entry Matching Criteria flag
	0	USB Host Layer TPL Table Entry Matching Criteria flag
	0x0000	USB Host Layer TPL Table Entry Matching Criteria flag
	0xFF	USB Host Layer TPL Table Entry Matching Criteria flag
	0xFF }	USB Host Layer TPL Table Entry Matching Criteria flag
	0xFFFF	USB Host Layer TPL Table Entry Matching Criteria flag
	0xFFFF }	USB Host Layer TPL Table Entry Matching Criteria flag
	1	USB Host Layer TPL Table Entry Matching Criteria flag
	classCode	USB Host Layer TPL Table Entry Matching Criteria flag
	false	USB Host Layer TPL Table Entry Matching Criteria flag
	initData	USB Host Layer TPL Table Entry Matching Criteria flag
	mask	USB Host Layer TPL Table Entry Matching Criteria flag
	pid	USB Host Layer TPL Table Entry Matching Criteria flag
	pid }	USB Host Layer TPL Table Entry Matching Criteria flag
	subClassCode	USB Host Layer TPL Table Entry Matching Criteria flag
	true	USB Host Layer TPL Table Entry Matching Criteria flag
	USB_HOST_BUS	Defines a USB Bus Data Type.
	USB_HOST_DEVICE_INFO	Defines the data type that is used by the USB_HOST_DeviceGetFirst() and USB_HOST_DeviceGetNext() functions.
	USB_HOST_DEVICE_OBJ_HANDLE	Handle to an attached USB Device.
	USB_HOST_DEVICE_STRING	Defines a defines types of strings that can be request through the USB_HOST_DeviceStringDescriptorGet() function.
	USB_HOST_EVENT	Defines the different events that the USB Host Layer can generate.
	USB_HOST_EVENT_HANDLER	USB Host Layer Event Handler Function Pointer Type
	USB_HOST_HCD	Defines the USB Host HCD Information object that is provided to the host layer.

	USB_HOST_REQUEST_HANDLE	USB Host Request Handle Type
	USB_HOST_RESULT	USB Host Results.
	USB_HOST_STRING_REQUEST_COMPLETE_CALLBACK	USB Host Device String Descriptor Request Complete Callback Function Type
	USB_HOST_TARGET_PERIPHERAL_LIST_ENTRY	USB Host Layer TPL Table Entry Matching Criteria flag
	USB_HOST_TPL_ENTRY	USB Host Layer TPL Table Entry Matching Criteria flag
	vid	USB Host Layer TPL Table Entry Matching Criteria flag
	USB_HOST_BUS_ALL	USB Host Bus All
	USB_HOST_DEVICE_OBJ_HANDLE_INVALID	Defines an invalid USB Device Object Handle.
	USB_HOST_DEVICE_STRING_LANG_ID_DEFAULT	Defines the default Lang ID to be used while obtaining the string.
	USB_HOST_REQUEST_HANDLE_INVALID	USB Host Request Invalid Handle
	USB_HOST_RESULT_MIN	USB Host Result Minimum Constant.

Description

This section describes the Application Programming Interface (API) functions of the USB Host Layer Library.

Refer to each section for a detailed description.

a) Functions

USB_HOST_Deinitialize Function

Deinitializes the specified instance of the USB Host Layer.

File

usb_host.h

C

```
void USB_HOST_Deinitialize(SYS_MODULE_OBJ hostLayerObject);
```

Returns

None.

Description

Deinitializes the USB Host Layer. All internal data structures will be reset.

Remarks

Once the Initialize operation has been called, the Deinitialize operation must be called before the Initialize operation can be called again. This routine will NEVER block waiting for hardware.

Preconditions

Function USB_HOST_Initialize should have been called before calling this function.

Example

```
SYS_MODULE_OBJ      object;     //  Returned from USB_HOST_Initialize
SYS_STATUS          status;

USB_HOST_Deinitialize(object);

status = USB_HOST_Status(object);
if (SYS_MODULE_DEINITIALIZED != status)
{
    // Can check again later if you need to know
    // when the driver is deinitialized.
}
```

Parameters

Parameters	Description
object	USB Host layer object handle, returned from the USB_HOST_Initialize routine

Function

void USB_HOST_Deinitialize(SYS_MODULE_OBJ object)

USB_HOST_Status Function

Gets the current status of the USB Host Layer.

File

usb_host.h

C

```
SYS_STATUS USB_HOST_Status(SYS_MODULE_OBJ hostLayerObject);
```

Returns

SYS_STATUS_READY - Indicates that the USB Host layer is ready for operations.

SYS_STATUS_BUSY - The initialization is in progress.

SYS_STATUS_DEINITIALIZED - Indicates that the driver has been deinitialized

Description

This routine provides the current status of the USB Host Layer.

Remarks

This function is typically called by the MPLAB Harmony System to check the system status of the USB Host Layer. This function is not intended to be called directly by the application tasks routine.

Preconditions

Function USB_HOST_Initialize should have been called before calling this function.

Example

```
SYS_MODULE_OBJ      object;     // Returned from USB_HOST_Initialize
SYS_STATUS          status;

status = USB_HOST_Status(object);
if (SYS_STATUS_READY == status)
{
    // The USB Host system is ready and is running.
}
```

Parameters

Parameters	Description
object	USB Host Layer object handle, returned from the USB_HOST_Initialize routine

Function

SYS_STATUS USB_HOST_Status(SYS_MODULE_OBJ object)

USB_HOST_Tasks Function

Maintains the USB Host Layer state machine.

File

usb_host.h

C

```
void USB_HOST_Tasks(SYS_MODULE_OBJ hostLayerObject);
```

Returns

None.

Description

This routine maintains the USB Host layer's state machine. It must be called frequently to ensure proper operation of the USB. This function should be called from the SYS_Tasks function.

Remarks

This routine is not intended to be called directly by an application. It is called by the MPLAB Harmony System Tasks function.

Preconditions

The USB_HOST_Initialize routine must have been called for the specified USB Host Layer instance.

Example

```
SYS_MODULE_OBJ      object;     // Returned from USB_HOST_Initialize

void SYS_Tasks(void)
{
    USB_HOST_Tasks (object);

    // Do other tasks
}
```

Parameters

Parameters	Description
object	Object handle for the specified driver instance (returned from USB_HOST_Initialize)

Function

void USB_HOST_Tasks (SYS_MODULE_OBJ object);

USB_HOST_BusEnable Function

Starts host operations.

File

usb_host.h

C

```
USB_HOST_RESULT USB_HOST_BusEnable(USB_HOST_BUS bus);
```

Returns

USB_HOST_RESULT_SUCCESS if the request was accepted. USB_HOST_RESULT_BUS_UNKNOWN if the specified bus is invalid (it does not exist in the system). USB_HOST_RESULT_FAILURE if an unknown failure occurred.

Description

The function starts the operation of the USB Host Bus. It enables the root hub associated with specified bus and starts the process of detecting attached devices and enumerating them. The USB_HOST_EventHandlerSet() function should have been called to register an application host layer event handler before the bus is enabled (before the USB_HOST_BusEnable() function is called). This will ensure that the application does not miss any events.

Remarks

The Host Layer may generate events after the USB_HOST_BusEnable() function is called. The application should have registered an event handler using the USB_HOST_EventHandlerSet() function to handle these events. The USB_HOST_EventHandlerSet() function should have been called before the USB_HOST_BusEnable() function is called.

Preconditions

The USB_HOST_Initialize() function should have been called before calling this function.

Example

```
TBD.
```

Parameters

Parameters	Description
bus	the bus to be enabled. If this is set to USB_HOST_BUS_ALL, all buses will be enabled.

Function

USB_HOST_RESULT USB_HOST_BusEnable(USB_HOST_BUS bus)

USB_HOST_BusIsEnabled Function

Checks if the bus is enabled.

File

usb_host.h

C

```
USB_HOST_RESULT USB_HOST_BusIsEnabled(USB_HOST_BUS bus);
```

Returns

USB_HOST_RESULT_TRUE if the bus is enabled. USB_HOST_RESULT_FALSE if the bus is not enabled..
USB_HOST_RESULT_BUS_UNKNOWN if the specified bus is invalid (it does not exist in the system). USB_HOST_RESULT_FAILURE if an unknown failure occurred.

Description

The function returns the enable status of the bus. It can be called after the USB_HOST_BusEnable() function is called, to check if the bus has been enabled yet. If the bus parameter is set to USB_HOST_BUS_ALL, then the function will check the enable status of all the busses and will return true only if all the busses are enabled.

Remarks

None.

Preconditions

The USB_HOST_Initialize() function should have been called before calling this function.

Example

TBD.

Parameters

Parameters	Description
bus	the bus that needs to checked for enable status. If this is set to USB_HOST_BUS_ALL, all buses will be checked.

Function

USB_HOST_RESULT USB_HOST_BusIsEnabled(USB_HOST_BUS bus)

USB_HOST_BusIsSuspended Function

Returns the suspend status of the bus.

File

usb_host.h

C

```
USB_HOST_RESULT USB_HOST_BusIsSuspended(USB_HOST_BUS bus);
```

Returns

USB_HOST_RESULT_TRUE - if the bus is suspended. USB_HOST_RESULT_FALSE - if the bus is not suspended.
USB_HOST_RESULT_BUS_NOT_ENABLED - if the bus was not enabled. USB_HOST_RESULT_BUS_UNKNOWN - if the specified bus does not exist in the system. USB_HOST_RESULT_FAILURE - an unknown error occurred.

Description

This function returns suspend status of the specified USB bus. This function can be used to check the completion of the Suspend operation started by using the USB_HOST_BusSuspend() function. The function would return USB_HOST_RESULT_FALSE if the bus is not suspended. Calling the USB_HOST_BusIsSuspended() with bus specified as USB_HOST_BUS_ALL returns the suspend status of the all USB segments that are managed by the host layer. The function would return USB_HOST_RESULT_TRUE only if all the bus are in a suspended state.

Remarks

None.

Preconditions

The USB_HOST_BusEnable() function should have been called to enable the bus.

Example

TBD.

Parameters

Parameters	Description
bus	the bus whose suspend status is to be queried.

Function

USB_HOST_RESULT USB_HOST_BusIsSuspended (USB_HOST_BUS bus)

USB_HOST_BusResume Function

Resumes the bus.

File

usb_host.h

C

```
USB_HOST_RESULT USB_HOST_BusResume(USB_HOST_BUS bus);
```

Returns

USB_HOST_RESULT_SUCCESS - if the request was successful or if the bus was already resumed. USB_HOST_RESULT_BUS_UNKNOWN - the request failed because the bus does not exist in the system. USB_HOST_RESULT_BUS_NOT_ENABLED - the bus was not enabled. USB_HOST_RESULT_FAILURE - An unknown error occurred.

Description

The function resumes the bus. All devices on the bus will be receive resume signaling. If bus is specified as USB_HOST_BUS_ALL, all the buses managed by this host will be resumed.

Remarks

None.

Preconditions

The USB_HOST_BusEnable() function should have been called to enable the bus.

Example

```
// Resume bus 0
USB_HOST_BusResume(0);

// Resume all buses
USB_HOST_BusSuspend(USB_HOST_BUS_ALL);
```

Parameters

Parameters	Description
bus	The bus to be resume or USB_HOST_BUS_ALL to resume all buses.

Function

USB_HOST_RESULT USB_HOST_BusResume (USB_HOST_BUS bus);

USB_HOST_BusSuspend Function

Suspends the bus.

File

usb_host.h

C

```
USB_HOST_RESULT USB_HOST_BusSuspend(USB_HOST_BUS bus);
```

Returns

USB_HOST_RESULT_SUCCESS - if the request was successful. USB_HOST_RESULT_BUS_NOT_ENABLED - if the bus was not enabled. USB_HOST_RESULT_FAILURE - An unknown error has occurred. USB_HOST_RESULT_BUS_UNKNOWN - if the specified bus does not exist in the system.

Description

The function suspends the bus. All devices on the bus will be suspended. If bus is specified as USB_HOST_BUS_ALL, all the buses managed by this host will be suspended.

Remarks

None.

Preconditions

The USB_HOST_BusEnable() function should have been called to enable the bus.

Example

```
// Suspend the bus 0
USB_HOST_BusSuspend(0);

// Suspend all buses
USB_HOST_BusSuspend(USB_HOST_BUS_ALL);
```

Parameters

Parameters	Description
bus	The bus to be suspended or USB_HOST_BUS_ALL to suspend all buses.

Function

USB_HOST_RESULT USB_HOST_BusSuspend (USB_HOST_BUS bus);

USB_HOST_DeviceGetFirst Function

Returns information about the first attached device on the bus.

File

usb_host.h

C

```
USB_HOST_RESULT USB_HOST_DeviceGetFirst(USB_HOST_BUS bus, USB_HOST_DEVICE_INFO * deviceInfo);
```

Returns

USB_HOST_RESULT_SUCCESS - The function executed successfully. USB_HOST_RESULT_END_OF_DEVICE_LIST - There are no attached devices on the bus. USB_HOST_RESULT_BUS_UNKNOWN - The specified bus does not exist in the system.
USB_HOST_RESULT_BUS_NOT_ENABLED - The specified bus is not enabled. USB_HOST_RESULT_PARAMETER_INVALID - the deviceInfo parameter is NULL. USB_HOST_RESULT_FAILURE - an unknown failure occurred.

Description

This function returns information about the first attached device on the specified bus. The USB_HOST_DeviceGetNext() function can be used to get the reference to the next attached device on the bus. The USB_HOST_DEVICE_INFO object is provided by the application.The device information will be populated into this object. If there are no devices attached on the bus, the function will set the deviceObjHandle parameter, in the USB_HOST_DEVICE_INFO object, to USB_HOST_DEVICE_OBJ_HANDLE INVALID.

Remarks

None.

Preconditions

The USB_HOST_BusEnable function should have been called to enable detection of attached devices.

Example

TBD.

Parameters

Parameters	Description
bus	the bus to be queried for attached devices.
deviceInfo	output parameter. Will contain device information when the function returns. If the deviceObjHandle member of the structure contains USB_HOST_DEVICE_OBJ_HANDLE INVALID, then there are no attached devices on the bus and the deviceAddress and the bus member of the info object will contain indeterminate values.

Function

```
USB_HOST_RESULT USB_HOST_DeviceGetFirst
(
    USB_HOST_BUS bus,
    USB_HOST_DEVICE_INFO * deviceInfo
);
```

USB_HOST_DeviceGetNext Function

Returns information about the next device on the bus.

File

usb_host.h

C

```
USB_HOST_RESULT USB_HOST_DeviceGetNext(USB_HOST_DEVICE_INFO * deviceInfo);
```

Returns

USB_HOST_RESULT_SUCCESS - The function executed successfully. USB_HOST_RESULT_END_OF_DEVICE_LIST - There are no attached devices on the bus. USB_HOST_RESULT_PARAMETER_INVALID - the deviceInfo parameter is NULL.
USB_HOST_RESULT_DEVICE_UNKNOWN - the device specified in deviceInfo does not exist in the system. The search should be restarted.
USB_HOST_RESULT_FAILURE - an unknown failure occurred. Application can restart the search by calling the USB_HOST_DeviceGetFirst() function.

Description

This function returns information of the next device attached on the bus. The USB_HOST_DeviceGetFirst() function should have been called at least once on the deviceInfo object. Then calling this function repeatedly on the deviceInfo object will return information about the next attached device on the bus. When there are no more attached devices to report, the function returns USB_HOST_RESULT_END_OF_DEVICE_LIST.

Calling the USB_HOST_DeviceGetFirst() function on the deviceInfo object after the USB_HOST_DeviceGetNext() function has been called will cause the host to reset the deviceInfo object to point to the first attached device.

Remarks

None.

Preconditions

The USB_HOST_DeviceGetFirst() function must have been called before calling this function.

Example

```
TBD.
```

Parameters

Parameters	Description
deviceInfo	pointer to the USB_HOST_DEVICE_INFO object.

Function

```
USB_HOST_RESULT USB_HOST_DeviceGetNext (USB_HOST_DEVICE_INFO * deviceInfo);
```

USB_HOST_DeviceIsSuspended Function

Returns the suspend state of the device is suspended.

File

usb_host.h

C

```
USB_HOST_RESULT USB_HOST_DeviceIsSuspended(USB_HOST_DEVICE_OBJ_HANDLE deviceObjHandle);
```

Returns

USB_HOST_RESULT_TRUE - if the device is suspended. USB_HOST_RESULT_FALSE - if the device is not suspended. USB_HOST_RESULT_DEVICE_UNKNOWN - the specified device does not exist in the system. USB_HOST_RESULT_FAILURE - An unknown failure occurred.

Description

This function returns the suspend state of the specified USB device. This function can be used to check the completion of the Resume operation started by using the USB_HOST_Resume() function. If the Resume signaling has completed, the USB_HOST_IsSuspended() function would return USB_HOST_RESULT_TRUE.

Remarks

None.

Preconditions

The USB_HOST_BusEnable() function should have been called.

Example

TBD.

Parameters

Parameters	Description
deviceObjHandle	handle to the device that needs to be checked for suspend status.

Function

```
USB_HOST_RESULT USB_HOST_DeviceIsSuspended
(
    USB_HOST_DEVICE_OBJ_HANDLE deviceObjHandle
);
```

USB_HOST_DeviceResume Function

Resumes the selected device

File

usb_host.h

C

```
USB_HOST_RESULT USB_HOST_DeviceResume(USB_HOST_DEVICE_OBJ_HANDLE deviceObjHandle);
```

Returns

USB_HOST_RESULT_SUCCESS - The request was accepted and the device will be resumed or the device was already resumed. USB_HOST_RESULT_DEVICE_UNKNOWN - The request failed. The device may have been detached. USB_HOST_RESULT_FAILURE - An unknown failure occurred.

Description

The function resumes the selected device. A device can be resumed only if it was suspended.

Remarks

None.

Preconditions

None.

Example

TBD.

Parameters

Parameters	Description
deviceObjHandle	handle to the device to be resumed.

Function

```
USB_HOST_RESULT USB_HOST_DeviceResume
(
    USB_HOST_DEVICE_OBJ_HANDLE deviceObjHandle
);
```

USB_HOST_DeviceSpeedGet Function

Returns the speed at which this device is operating.

File

usb_host.h

C

```
USB_HOST_RESULT USB_HOST_DeviceSpeedGet(USB_HOST_DEVICE_OBJ_HANDLE deviceHandle, USB_SPEED * speed);
```

Returns

USB_HOST_RESULT_SUCCESS - The function was successful. speed will contain the speed of the device.
USB_HOST_RESULT_DEVICE_UNKNOWN - The device does not exist in the system. speed will contain USB_SPEED_ERROR.
USB_HOST_RESULT_FAILURE - an unknown error occurred.

Description

This function returns the speed at which this device is operating.

Remarks

None.

Preconditions

The USB_HOST_Initialize() function should have been called.

Example

Parameters

Parameters	Description
deviceObjHandle	handle to the device whose speed is required.
speed	output parameter. Will contain the speed of the device if the function was successful.

Function

```
USB_HOST_RESULT USB_HOST_DeviceSpeedGet
(
    USB_HOST_DEVICE_OBJ_HANDLE deviceObjHandle,
    USB_SPEED * speed
)
```

USB_HOST_DeviceStringDescriptorGet Function

Retrieves specified string descriptor from the device

File

usb_host.h

C

```
USB_HOST_RESULT USB_HOST_DeviceStringDescriptorGet(USB_HOST_DEVICE_OBJ_HANDLE deviceObjHandle,
USB_HOST_DEVICE_STRING stringType, uint16_t languageID, void * stringDescriptor, size_t length,
USB_HOST_REQUEST_HANDLE * requestHandle, USB_HOST_STRING_REQUEST_COMPLETE_CALLBACK callback, uintptr_t
context);
```

Returns

USB_HOST_RESULT_SUCCESS - The request was scheduled successfully. requestHandle will contain a valid request handle. USB_HOST_RESULT_DEVICE_UNKNOWN - The request failed because the device was detached. USB_HOST_RESULT_FAILURE - An unknown error occurred. USB_HOST_RESULT_REQUEST_BUSY - The host layer cannot take more requests at this point. The application should try later. USB_HOST_RESULT_STRING_DESCRIPTOR_UNSUPPORTED - The device does not support the specified string descriptor type.

Description

This function retrieves the specified string descriptor from the device. This function will cause the host layer to issue a control transfer to the device. When the string descriptor is available, the host layer will call the callback function to let the application know that the request has completed.

The function will return a valid request handle in requestHandle, if the request was successful. This request handle will be returned in the callback function. The size of the stringDescriptor buffer is specified by the length parameter. Only length number of bytes will be retrieved. The type of device string descriptor to be retrieved is specified by the stringType parameter. The supported language IDs, manufacturer, product and serial number strings can be obtained. While obtaining the supported language IDs, the languageID parameter will be ignored.

Remarks

None.

Preconditions

The USB_HOST_BusEnable() function should have been called.

Example

Parameters

Parameters	Description
deviceObjHandle	handle to the device whose string descriptor is to be retrieved.
stringType	type of string descriptor to be retrieved
languageID	the language ID of the string descriptor
stringDescriptor	output buffer for the descriptor
length	size of the specified output buffer
requestHandle	This is an output parameter. It will contain a valid request handle if the request was successful. It will contain USB_HOST_REQUEST_HANDLE_INVALID is the request was not successful.
callback	Function that will be called when this request completes. If this is NULL, then the application will not receive indication of completion.
context	Calling application context to be returned in the callback function.

Function

```
  USB_HOST_RESULT USB_HOST_DeviceStringDescriptorGet
(
    USB_HOST_DEVICE_OBJ_HANDLE deviceObjHandle,
    USB_HOST_DEVICE_STRING stringType,
uint16_t languageID,
void * stringDescriptor,
size_t length,
    USB_HOST_REQUEST_HANDLE * requestHandle,
    USB_HOST_STRING_REQUEST_COMPLETE_CALLBACK callback,
uintptr_t context
);
```

USB_HOST_DeviceSuspend Function

Suspends the specified device.

File

usb_host.h

C

```
USB_HOST_RESULT USB_HOST_DeviceSuspend(USB_HOST_DEVICE_OBJ_HANDLE deviceObjHandle);
```

Returns

USB_HOST_RESULT_SUCCESS - The request was accepted and the device will be suspended. USB_HOST_RESULT_DEVICE_UNKNOWN - The request failed. The device may have been detached. USB_HOST_RESULT_FAILURE - An unknown failure occurred.

Description

The function suspends the specified device.

Remarks

None.

Preconditions

The USB_HOST_BusEnable() function should have been called.

Example

TBD.

Parameters

Parameters	Description
deviceObjHandle	handle to the device to suspend.

Function

```
USB_HOST_RESULT USB_HOST_DeviceSuspend
(
    USB_HOST_DEVICE_OBJ_HANDLE deviceObjHandle
);
```

USB_HOST_EventHandlerSet Function

USB Host Layer Event Handler Callback Function set function.

File

usb_host.h

C

```
USB_HOST_RESULT USB_HOST_EventHandlerSet(USB_HOST_EVENT_HANDLER eventHandler, uintptr_t context);
```

Returns

USB_HOST_RESULT_SUCCESS - The function was successful. USB_HOST_RESULT_FAILURE - An unknown failure occurred.

Description

This is the USB Host Layer Event Handler Callback Set function. An application can receive USB Host Layer events by using this function to register and event handler callback function. The application can additionally specify a specific context which will returned with the event handler callback function. The event handler must be set (this function must be called) before any of the USB buses are enabled.

Remarks

None.

Preconditions

The host layer should have been initialized.

Example

TBD.

Parameters

Parameters	Description
eventHandler	Pointer to the call back function. The host layer notifies the application about host layer events by calling this function. If this is NULL, then events will not be generated.
context	application specific context.

Function

```
USB_HOST_RESULT USB_HOST_EventHandlerSet
```

(
USB_HOST_EVENT_HANDLER * eventHandler,
uintptr_t context
)

USB_HOST_Initialize Function

Initializes the USB Host layer instance specified by the index.

File

usb_host.h

C

```
SYS_MODULE_OBJ USB_HOST_Initialize(const SYS_MODULE_INIT * init);
```

Returns

Return a SYS_MODULE_OBJ_INVALID if the initialization failed.

Description

This routine initializes the USB Host Layer. This function must be called before any other Host layer function can be called. The initialization data is specified by the init parameter. This function is typically called in the SYS_Initialize() function. The initialization completion may require the USB_HOST_Tasks() routine to execute. The initialization function does not start the operation of the Host on the USB. This must be done explicitly via the USB_HOST_BusEnable() function. This function will initialize all client drivers listed in the TPL.

Remarks

This routine must be called before any other USB Host routine is called. This routine should only be called once during system initialization unless USB_HOST_Deinitialize is called to deinitialize the Host Layer instance. This routine will NEVER block for hardware access. The USB_HOST_Tasks() function should be called to complete the initialization.

Preconditions

The USB Host Controller driver initialization should be called somewhere in the SYS_Initialize() function.

Example

TBD.

Parameters

Parameters	Description
init	Pointer to a USB_HOST_INIT data structure containing data necessary to initialize the driver.

Function

SYS_MODULE_OBJ USB_HOST_Initialize
(
const SYS_MODULE_INIT * const init
)

b) Data Types and Constants

USB_HOST_INIT Structure

Defines the data required to initialize a USB Host Layer instance.

File

usb_host.h

C

```
typedef struct {
  size_t nTPLEntries;
  USB_HOST_TPL_ENTRY * tplList;
  USB_HOST_HCD * hostControllerDrivers;
} USB_HOST_INIT;
```

Members

Members	Description
size_t nTPLEntries;	Size of the TPL table
USB_HOST_TPL_ENTRY * tplList;	Pointer to the TPL table for this host layer implementation.
USB_HOST_HCD * hostControllerDrivers;	This is a pointer to a table of host controller drivers that the host layer will operate on. The number of entries in this table is specified via the USB_HOST_CONTROLLERS_NUMBER configuration macro in system_config.h

Description

USB Host Initialization Data Structure

This data type defines the data required to initialize the host layer. A pointer to a structure of this type is required by the USB_HOST_Initialize() function.

Remarks

This data structure is specific to the PIC32MX implementation of the USB Host layer.

USB_HOST_EVENT_RESPONSE Enumeration

Host Layer Events Handler Function Response Type.

File

usb_host.h

C

```
typedef enum {
  USB_HOST_EVENT_RESPONSE_NONE = 0
} USB_HOST_EVENT_RESPONSE;
```

Members

Members	Description
USB_HOST_EVENT_RESPONSE_NONE = 0	Returning this value indicates no application response to the host event

Description

Host Layer Events Handler Function Response Type.

This is the definition of the Host Layer Event Handler Response Type.

Remarks

None.

```

Description

USB Host Layer TPL Table Entry Matching Criteria flag

This enumeration defines the possible matching criteria flag that can be specified for a Host TPL table entry. The tplFlag member of the TPL table entry should be set to one or more of these flags. These flags define the criteria that the Host layer will use while matching the attached device to the TPL table entry. For example, if a device is specified by class, subclass and protocol specifying the TPL_FLAG_IGNORE_SUBCLASS flag will cause the Host layer to ignore the subclass while comparing the class, subclass and protocol of the attached device.

Multiple flags can be specified as a logically OR'ed combination. While combining multiple flags, VID and PID criteria flags cannot be combined with the Class, Subclass, Protocol flags. For example, the TPL_FLAG_VID_PID flag cannot be combined with TPL_FLAG_IGNORE_SUBCLASS.

Remarks

None.

Description

USB Host Layer TPL Table Entry Matching Criteria flag

This enumeration defines the possible matching criteria flag that can be specified for a Host TPL table entry. The tplFlag member of the TPL table entry should be set to one or more of these flags. These flags define the criteria that the Host layer will use while matching the attached device to the TPL table entry. For example, if a device is specified by class, subclass and protocol specifying the TPL_FLAG_IGNORE_SUBCLASS flag will cause the Host layer to ignore the subclass while comparing the class, subclass and protocol of the attached device.

Multiple flags can be specified as a logically OR'ed combination. While combining multiple flags, VID and PID criteria flags cannot be combined with the Class, Subclass, Protocol flags. For example, the TPL_FLAG_VID_PID flag cannot be combined with TPL_FLAG_IGNORE_SUBCLASS.

Remarks

None.

```

Description

USB Host Layer TPL Table Entry Matching Criteria flag

This enumeration defines the possible matching criteria flag that can be specified for a Host TPL table entry. The tplFlag member of the TPL table entry should be set to one or more of these flags. These flags define the criteria that the Host layer will use while matching the attached device to the TPL table entry. For example, if a device is specified by class, subclass and protocol specifying the TPL_FLAG_IGNORE_SUBCLASS flag will

cause the Host layer to ignore the subclass while comparing the class, subclass and protocol of the attached device.

Multiple flags can be specified as a logically OR'ed combination. While combining multiple flags, VID and PID criteria flags cannot be combined with the Class, Subclass, Protocol flags. For example, the TPL_FLAG_VID_PID flag cannot be combined with TPL_FLAG_IGNORE_SUBCLASS.

Remarks

None.

Description

USB Host Layer TPL Table Entry Matching Criteria flag

This enumeration defines the possible matching criteria flag that can be specified for a Host TPL table entry. The tplFlag member of the TPL table entry should be set to one or more of these flags. These flags define the criteria that the Host layer will use while matching the attached device to the TPL table entry. For example, if a device is specified by class, subclass and protocol specifying the TPL_FLAG_IGNORE_SUBCLASS flag will cause the Host layer to ignore the subclass while comparing the class, subclass and protocol of the attached device.

Multiple flags can be specified as a logically OR'ed combination. While combining multiple flags, VID and PID criteria flags cannot be combined with the Class, Subclass, Protocol flags. For example, the TPL_FLAG_VID_PID flag cannot be combined with TPL_FLAG_IGNORE_SUBCLASS.

Remarks

None.

USB_HOST_BUS Type

Defines a USB Bus Data Type.

File

usb_host.h

C

```
typedef uint8_t USB_HOST_BUS;
```

Description

USB Bus Data Type

This data type defines a USB Bus. In microcontroller devices, that may have multiple USB peripherals, this type identifies the USB bus associated with each peripheral. Bus numbers start from 0 and counts up to include all the busses in the system. The total number of busses and the mapping

between a bus and the USB controller is specified in the Host Layer initialization data structure.

Remarks

None.

USB_HOST_DEVICE_INFO Structure

Defines the data type that is used by the USB_HOST_DeviceGetFirst() and USB_HOST_DeviceGetNext() functions.

File

usb_host.h

C

```
typedef struct {
  USB_HOST_DEVICE_OBJ_HANDLE deviceObjHandle;
  uint8_t deviceAddress;
  USB_HOST_BUS bus;
} USB_HOST_DEVICE_INFO;
```

Members

Members	Description
USB_HOST_DEVICE_OBJ_HANDLE deviceObjHandle;	USB Host Device Object Handle
uint8_t deviceAddress;	Address of the device on the USB
USB_HOST_BUS bus;	The bus to which this device is connected

Description

USB Host Device Info Type

This data type defines the type of data that is used by the USB_HOST_DeviceGetFirst() and USB_HOST_DeviceGetNext() functions. The application must provide an object of this type to these functions to obtain information about the devices attached on the USB.

Remarks

The application must only instantiate this data structure and should not modify it's contents. Multiple objects can be instantiated and used.

USB_HOST_DEVICE_OBJ_HANDLE Type

Handle to an attached USB Device.

File

usb_host.h

C

```
typedef uintptr_t USB_HOST_DEVICE_OBJ_HANDLE;
```

Description

USB Host Device Object Handle

This data type defines the type of handle to an attached USB Device. This handle uniquely identifies the attached device. A handle of this type is returned in the deviceObjHandle member of the USB_HOST_DEVICE_INFO structure when the USB_HOST_DeviceGetFirst() and the USB_HOST_DeviceGetNext() functions are called.

Remarks

None.

USB_HOST_DEVICE_STRING Enumeration

Defines a defines types of strings that can be request through the USB_HOST_DeviceStringDescriptorGet() function.

File

usb_host.h

C

```
typedef enum {
  USB_HOST_DEVICE_STRING_LANG_ID = 0,
```

```
  USB_HOST_DEVICE_STRING_MANUFACTURER,
  USB_HOST_DEVICE_STRING_PRODUCT,
  USB_HOST_DEVICE_STRING_SERIAL_NUMBER
} USB_HOST_DEVICE_STRING;
```

Members

Members	Description
USB_HOST_DEVICE_STRING_LANG_ID = 0	Specifies the language ID string
USB_HOST_DEVICE_STRING_MANUFACTURER	Specifies the manufacturer string
USB_HOST_DEVICE_STRING_PRODUCT	Specifies the product string
USB_HOST_DEVICE_STRING_SERIAL_NUMBER	Specifies the serial number string

Description

USB Host Device String Type

This type defines the types of strings that can be request through the USB_HOST_DeviceStringDescriptorGet() function. The stringType parameter in the function call can be set any one of these types.

Remarks

None.

USB_HOST_EVENT Enumeration

Defines the different events that the USB Host Layer can generate.

File

usb_host.h

C

```
typedef enum {
  USB_HOST_EVENT_DEVICE_REJECTED_INSUFFICIENT_POWER,
  USB_HOST_EVENT_DEVICE_UNSUPPORTED,
  USB_HOST_EVENT_HUB_TIER_LEVEL_EXCEEDED,
  USB_HOST_EVENT_PORT_OVERCURRENT_DETECTED
} USB_HOST_EVENT;
```

Members

Members	Description
USB_HOST_EVENT_DEVICE_REJECTED_INSUFFICIENT_POWER	This event occurs when device needs more current than what the host can supply.
USB_HOST_EVENT_DEVICE_UNSUPPORTED	This event occurs when a host layer could not attach any drivers to the attached device or when an error has occurred. There is no event data associated with this event.
USB_HOST_EVENT_HUB_TIER_LEVEL_EXCEEDED	This event occurs when the number of hubs connected to the host exceeds the configured maximum number of hubs USB_HOST_HUB_TIER_LEVEL. There is no event data associated with this event.
USB_HOST_EVENT_PORT_OVERCURRENT_DETECTED	This event occurs when an over-current condition is detected at the root • hub or an external hub port.

Description

USB Host Events

This data type defines the different events that USB Host Layer can generate. The application is intended recipient of these events. Some events return event related data. The application must register an event handler with the host layer (via the USB_HOST_EventHandlerSet() function) before enabling any of the buses.

Remarks

None.

USB_HOST_EVENT_HANDLER Type

USB Host Layer Event Handler Function Pointer Type

File

usb_host.h

C

```
typedef USB_HOST_EVENT_RESPONSE (* USB_HOST_EVENT_HANDLER)(USB_HOST_EVENT event, void * eventData,
uintptr_t context);
```

Description

USB Host Layer Event Handler Function Pointer Type

This data type defines the required function signature of the USB Host Layer Event handling callback function. The application must register a pointer to a Host Layer Event handling function who's function signature (parameter and return value types) match the types specified by this function pointer in order to receive event call backs from the Host Layer. The Host Layer will invoke this function with event relevant parameters. The description of the event handler function parameters is given here.

event - Type of event generated.

pData - This parameter should be type cast to an event specific pointer type based on the event that has occurred. Refer to the USB_HOST_EVENT enumeration description for more details.

context - Value identifying the context of the application that was registered along with the event handling function.

Remarks

None.

USB_HOST_HCD Structure

Defines the USB Host HCD Information object that is provided to the host layer.

File

usb_host.h

C

```
typedef struct {
  SYS_MODULE_INDEX drvIndex;
  void * hcdInterface;
} USB_HOST_HCD;
```

Members

Members	Description
SYS_MODULE_INDEX drvIndex;	Index of the USB Host Controller driver that the host layer should open and use.
void * hcdInterface;	USB Host Controller Driver function pointers

Description

USB Host Controller Driver Information

This data type defines the data required to connect a Host Controller Driver to the host layer. The USB Host layer used the HCD routines to access the root hub and the USB.

Remarks

This data structure is specific to the PIC32 implementation of the USB Host layer.

USB_HOST_REQUEST_HANDLE Type

USB Host Request Handle Type

File

usb_host.h

C

```
typedef uintptr_t USB_HOST_REQUEST_HANDLE;
```

Description

USB Host Request Handle Type

This type defines the USB Host Request Handle. This type of handle is returned by the USB_HOST_DeviceStringDescriptorGet() function. Each request will generate a unique handle. This handle will be returned in the event associated with the completion of the string descriptor request.

Remarks

None.

USB_HOST_RESULT Enumeration

USB Host Results.

File

usb_host.h

C

```
typedef enum {
  USB_HOST_RESULT_REQUEST_BUSY = USB_HOST_RESULT_MIN,
  USB_HOST_RESULT_STRING_DESCRIPTOR_UNSUPPORTED,
  USB_HOST_RESULT_TRANSFER_ABORTED,
  USB_HOST_RESULT_REQUEST_STALLED,
  USB_HOST_RESULT_PIPE_HANDLE_INVALID,
  USB_HOST_RESULT_END_OF_DEVICE_LIST,
  USB_HOST_RESULT_INTERFACE_UNKNOWN,
  USB_HOST_RESULT_PARAMETER_INVALID,
  USB_HOST_RESULT_CONFIGURATION_UNKNOWN,
  USB_HOST_RESULT_BUS_NOT_ENABLED,
  USB_HOST_RESULT_BUS_UNKNOWN,
  USB_HOST_RESULT_DEVICE_UNKNOWN,
  USB_HOST_RESULT_FAILURE,
  USB_HOST_RESULT_FALSE = 0,
  USB_HOST_RESULT_TRUE = 1,
  USB_HOST_RESULT_SUCCESS = USB_HOST_RESULT_TRUE
} USB_HOST_RESULT;
```

Members

Members	Description
USB_HOST_RESULT_REQUEST_BUSY = USB_HOST_RESULT_MIN	Indicates that the Host Layer cannot accept any requests at this point
USB_HOST_RESULT_STRING_DESCRIPTOR_UNSUPPORTED	The device does not support the request string descriptor
USB_HOST_RESULT_TRANSFER_ABORTED	Request was aborted
USB_HOST_RESULT_REQUEST_STALLED	Request was stalled
USB_HOST_RESULT_PIPE_HANDLE_INVALID	The specified pipe is not valid
USB_HOST_RESULT_END_OF_DEVICE_LIST	The end of the device list was reached.
USB_HOST_RESULT_INTERFACE_UNKNOWN	The specified interface is not available
USB_HOST_RESULT_PARAMETER_INVALID	A NULL parameter was passed to the function
USB_HOST_RESULT_CONFIGURATION_UNKNOWN	The specified configuration does not exist on this device.
USB_HOST_RESULT_BUS_NOT_ENABLED	A bus operation was requested but the bus was not operated
USB_HOST_RESULT_BUS_UNKNOWN	The specified bus does not exist in the system
USB_HOST_RESULT_DEVICE_UNKNOWN	The specified device does not exist in the system
USB_HOST_RESULT_FAILURE	An unknown failure has occurred
USB_HOST_RESULT_FALSE = 0	Indicates a false condition
USB_HOST_RESULT_TRUE = 1	Indicate a true condition
USB_HOST_RESULT_SUCCESS = USB_HOST_RESULT_TRUE	Indicates that the operation succeeded or the request was accepted and will be processed.

Description

USB Host Result

This enumeration defines the possible returns values of USB Host Layer API. A function may only return some of the values in this enumeration. Refer to function description for details on which values will be returned.

Remarks

None.

USB_HOST_STRING_REQUEST_COMPLETE_CALLBACK Type

USB Host Device String Descriptor Request Complete Callback Function Type

File

usb_host.h

C

```
typedef void (* USB_HOST_STRING_REQUEST_COMPLETE_CALLBACK)(USB_HOST_REQUEST_HANDLE requestHandle, size_t
size, uintptr_t context);
```

Description

USB Host Device String Descriptor Request Complete Callback Function Type

This data type defines the required function signature of the USB Host Device String Descriptor Request Complete Callback Function. The application must specify a pointer to a function who's function signature (parameter and return value types) matches the type specified by this function pointer in order to a call backs from the Host Layer when the USB_HOST_DeviceStringDescriptorGet() function has completed its operation. The description of the callback function parameters is given here.

requestHandle - a handle that is unique to this request. This will match the handle that was returned by the USB_HOST_DeviceStringDescriptorGet() function.

size - size of the returned string descriptor. If the string descriptor could not be obtained, the size will be zero.

context - Value identifying the context of the application that was registered along with the event handling function.

Remarks

None.

USB_HOST_TARGET_PERIPHERAL_LIST_ENTRY Enumeration

USB Host Layer TPL Table Entry Matching Criteria flag

File

usb_host.h

C

```
typedef enum {

```

Description

USB Host Layer TPL Table Entry Matching Criteria flag

This enumeration defines the possible matching criteria flag that can be specified for a Host TPL table entry. The tplFlag member of the TPL table entry should be set to one or more of these flags. These flags define the criteria that the Host layer will use while matching the attached device to the TPL table entry. For example, if a device is specified by class, subclass and protocol specifying the TPL_FLAG_IGNORE_SUBCLASS flag will

cause the Host layer to ignore the subclass while comparing the class, subclass and protocol of the attached device.

Multiple flags can be specified as a logically OR'ed combination. While combining multiple flags, VID and PID criteria flags cannot be combined with the Class, Subclass, Protocol flags. For example, the TPL_FLAG_VID_PID flag cannot be combined with TPL_FLAG_IGNORE_SUBCLASS.

Remarks

None.

USB_HOST_BUS_ALL Macro

USB Host Bus All

File

usb_host.h

C

```
#define USB_HOST_BUS_ALL ((USB_HOST_BUS)(0xFF))
```

Description

USB Host Bus All

This constant defines the value that should be passed to the USB_HOST_BusSuspend(), USB_HOST_BusResume() and USB_HOST_IsBusSuspended() function if all the USB segments must be addressed. Passing this constant to these functions will cause Suspend and Resume operation to affect all the USB segments and hence affect all connected devices.

Remarks

None.

USB_HOST_DEVICE_OBJ_HANDLE_INVALID Macro

Defines an invalid USB Device Object Handle.

File

usb_host.h

C

```
#define USB_HOST_DEVICE_OBJ_HANDLE_INVALID ((USB_HOST_DEVICE_OBJ_HANDLE)(-1))
```

Description

USB Host Invalid Device Object Handle

This constant defines an invalid USB Device Object Handle. The USB_HOST_DeviceGetFirst() and the USB_HOST_DeviceGetNext() functions return this value in the deviceObjHandle member of the USB_HOST_DEVICE_INFO object when there are no attached devices to report.

Remarks

None.

USB_HOST_DEVICE_STRING_LANG_ID_DEFAULT Macro

Defines the default Lang ID to be used while obtaining the string.

File

usb_host.h

C

```
#define USB_HOST_DEVICE_STRING_LANG_ID_DEFAULT (0)
```

Description

USB Host Device String Default Lang ID

This constant defines the default Lang ID. When then languageID parameter in the USB_HOST_DeviceStringDescriptorGet() function is set to this value, the function will specify the default Lang ID while requesting the string from the device.

Remarks

None.

USB_HOST_REQUEST_HANDLE_INVALID Macro

USB Host Request Invalid Handle

File

usb_host.h

C

```
#define USB_HOST_REQUEST_HANDLE_INVALID ((USB_HOST_REQUEST_HANDLE)(-1))
```

Description

USB Host Request Invalid Handle

This constant defines an Invalid USB Host Request Handle. This handle is returned by the USB_HOST_DeviceStringDescriptorGet() function when the request was not accepted.

Remarks

None.

USB_HOST_RESULT_MIN Macro

USB Host Result Minimum Constant.

File

usb_host.h

C

```
#define USB_HOST_RESULT_MIN -100
```

Description

USB Host Result Minimum Constant

Constant identifying the USB Host Result Minimum Value. This constant is used in the USB_HOST_RESULT enumeration.

Remarks

None.

Functions

	Name	Description
	USB_HOST_BusEnable	Starts host operations.

	USB_HOST_BusIsEnabled	Checks if the bus is enabled.
	USB_HOST_BusIsSuspended	Returns the suspend status of the bus.
	USB_HOST_BusResume	Resumes the bus.
	USB_HOST_BusSuspend	Suspends the bus.
	USB_HOST_Deinitialize	Deinitializes the specified instance of the USB Host Layer.
	USB_HOST_DeviceGetFirst	Returns information about the first attached device on the bus.
	USB_HOST_DeviceGetNext	Returns information about the next device on the bus.
	USB_HOST_DeviceIsSuspended	Returns the suspend state of the device is suspended.
	USB_HOST_DeviceResume	Resumes the selected device
	USB_HOST_DeviceSpeedGet	Returns the speed at which this device is operating.
	USB_HOST_DeviceStringDescriptorGet	Retrieves specified string descriptor from the device
	USB_HOST_DeviceSuspend	Suspends the specified device.
	USB_HOST_EventHandlerSet	USB Host Layer Event Handler Callback Function set function.
	USB_HOST_Initialize	Initializes the USB Host layer instance specified by the index.
	USB_HOST_Status	Gets the current status of the USB Host Layer.
	USB_HOST_Tasks	Maintains the USB Host Layer state machine.

Macros

	Name	Description
	USB_HOST_BUS_ALL	USB Host Bus All
	USB_HOST_DEVICE_OBJ_HANDLE_INVALID	Defines an invalid USB Device Object Handle.
	USB_HOST_DEVICE_STRING_LANG_ID_DEFAULT	Defines the default Lang ID to be used while obtaining the string.
	USB_HOST_REQUEST_HANDLE_INVALID	USB Host Request Invalid Handle
	USB_HOST_RESULT_MIN	USB Host Result Minimum Constant.

Structures

	Name	Description
	USB_HOST_DEVICE_INFO	Defines the data type that is used by the USB_HOST_DeviceGetFirst() and USB_HOST_DeviceGetNext() functions.
	USB_HOST_HCD	Defines the USB Host HCD Information object that is provided to the host layer.
	USB_HOST_INIT	Defines the data required to initialize a USB Host Layer instance.

Types

	Name	Description
	USB_HOST_BUS	Defines a USB Bus Data Type.
	USB_HOST_DEVICE_OBJ_HANDLE	Handle to an attached USB Device.

	USB_HOST_REQUEST_HANDLE	USB Host Request Handle Type
	USB_HOST_STRING_REQUEST_COMPLETE_CALLBACK	USB Host Device String Descriptor Request Complete Callback Function Type

Description

USB Host Layer Interface Definition

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the USB HOST layer.

File Name

usb_host.h

Company

Microchip Technology Inc.

usb_host_config_template.h

USB host configuration template header file.

Macros

	Name	Description
	USB_HOST_CONTROLLERS_NUMBER	Defines the number of USB Host Controllers that this Host Layer must manage.
	USB_HOST_DEVICE_INTERFACES_NUMBER	Defines the maximum number of interface that the attached device can contain in order for the USB Host Layer to process the device.
	USB_HOST_DEVICES_NUMBER	Defines the maximum number of devices to support.
	USB_HOST_HUB_SUPPORT_ENABLE	Defines if this USB Host application must support a Hub.
	USB_HOST_HUB_TIER_LEVEL	Defines the maximum tier of connected hubs to be supported.
	USB_HOST_PIPES_NUMBER	Defines the maximum number of pipes that the application will need.
	USB_HOST_TRANSFERS_NUMBER	Defines the maximum number of transfers that host layer should handle.

Description

USB Host Layer Configuration constants

This file contains USB host layer compile time options (macros) that are to be configured by the user. This file is a template file and must be used as an example only. This file must not be directly included in the project.

USB Audio v1.0 Host Client Driver Library

This section describes the USB Audio v1.0 Host Client Driver Library.

Introduction

Introduces the MPLAB Harmony USB Audio v1.0 Host Client Driver Library.

Description

The USB Audio v1.0 Host Client Driver in the MPLAB Harmony USB Host Stack allows USB Host applications to support and interact with Audio v1.0 USB devices. The USB Audio v1.0 Host Client Driver has the following features:

- Supports Audio v1.0 device with multiple streaming interfaces
- Designed to support multi-client operation
- RTOS ready
- Features an event driver non-clocking application interaction model
- Supports queuing of read and write data transfers

Using the Library

This topic describes the basic architecture of the USB Audio v1.0 Host Client Driver Library and provides information and examples on its use.

Abstraction Model

Describes the Abstraction Model of the USB Audio v1.0 Host Client Driver Library.

Description

The USB Audio v1.0 Host Client Driver interacts with Host Layer to control the attached Audio v1.0 device. The USB Host Layer attaches the Audio v1.0 Host Client Driver to the Audio v1.0 device when it meets the matching criteria specified in the USB Host TPL table. The Audio v1.0 Host Client Driver abstracts the details of sending Audio v1.0 class specific control transfer commands by providing easy to use non-blocking API to send these command. A command when issued is assigned a request handle. This request handle is returned in the event that is generated when the command has been processed, and can be used by the application to track the command.

While transferring data Audio Stream Data over the USB Audio v1.0 Host Client Driver abstracts details such as the Audio Streaming interface, endpoints and endpoint size. The USB Audio v1.0 Host Client Driver internally (and without application intervention) validates the Audio v1.0 class specific device descriptors and opens isochronous pipes. While transferring data, multiple read and write requests can be queued. Each such request gets assigned a transfer handle. The transfer handle for a transfer request is returned along with the completion event for that transfer request. The data transfer routines are implemented in `usb_host_audio_v1_0.c`.

Library Overview

The USB Audio v1.0 Host Client Driver can be grouped functionally as shown in the following table.

Library Interface Section	Description
Audio Device access Functions	These functions allow application clients to perform audio control transfers, register event handlers and get the number of stream groups and the details of each audio stream. These functions are implemented in the `usb_host_audio_v1_0.c` file.
Audio Stream Access Functions	These functions allow the application client to open audio streams, set parameters of an audio stream, and perform data transfer operations on an audio stream. These functions are implemented in the `usb_host_audio_v1_0.c` file.

How the Library Works

Describes how the library works and how it should be used.

Description

The USB Audio v1.0 Host Client Driver provides the user application with an easy-to-use interface to the attached Audio v1.0 device. The USB Host Layer initializes the USB Audio v1.0 Host Client Driver when a device is attached. This process does not require application intervention. The following sections describe the steps and methods required for the user application to interact with the attached devices.

TPL Table Configuration for Audio v1.0 Devices

Describes how to configure TPL table options, which includes a code example.

Description

The Host Layer attaches the Audio v1.0 Host Client Driver to a device when the device class in the Interface descriptor matches the entry in the TPL table. When specifying the entry for the Audio v1.0 device, the entry for the Audio v1.0 device, the driver interface must be set to USB_HOST_AUDIO_V1_0_INTERFACE. This will attach the Audio v1.0 Host Client Driver to the device when the USB Host matches the TPL entry to the device. The following code shows possible TPL table options for matching Audio v1.0 Devices.

```
/* This code shows an example of TPL table entries for supporting Audio v1.0
 * devices. Note the driver interface is set to USB_HOST_AUDIO_V1_0_INTERFACE. This
 * will load the Audio v1.0 Host Client Driver when there is TPL match */

const USB_HOST_TPL_ENTRY USBTPList[1] =
{
    /* This entry looks for any Audio v1.0 device. The Audio v1.0 Host Client Driver will
     * check if this is an Audio Streaming Device and will then load itself */
    TPL_INTERFACE_CLASS(USB_AUDIO_CLASS_CODE, NULL, USB_HOST_AUDIO_V1_0_INTERFACE),

};
```

Detecting Device Attach

Describes how to detect when a Audio v1.0 Device is attached, which includes a code example.

Description

The application will need to know when a Audio v1.0 Device is attached. To receive this attach event from the Audio v1.0 Host Client Driver, the application must register an Attach Event Handler by calling the USB_HOST_AUDIO_V1_0_AttachEventHandlerSet function. This function should be called before the USB_HOST_BusEnable function is called, else the application may miss Audio v1.0 attach events. It can be called multiple times to register multiple event handlers, each for different application clients that need to know about Audio v1.0 Device Attach events.

The total number of event handlers that can be registered is defined by USB_HOST_AUDIO_V1_0_ATTACH_LISTENERS_NUMBER configuration option in `system_config.h`. When a device is attached, the Audio v1.0 Host Client Driver will send the attach event to all the registered event handlers. In this event handler, the USB Audio v1.0 Host Client Driver will pass a USB_HOST_AUDIO V1_0_OBJ that can be opened to gain access to the device. The following code shows an example of how to register attach event handlers.

```
/* This code shows an example of Audio v1.0 Attach Event Handler and how this
 * attach event handler can be registered with the Audio v1.0 Host Client Driver */
bool isAudioDeviceAttached = false;
USB_HOST_AUDIO_V1_0_OBJ audioDeviceObj;

/* Audio attach event listener function */
void APP_USBHostAudioAttachEventListener
```

```
(
    USB_HOST_AUDIO_V1_0_OBJ audioObj,
    USB_HOST_AUDIO_V1_0_EVENT event,
    uintptr_t context
)
{
    /* This function gets called when the Audio v1.0 device is attached/detached. In this
     * example we let the application know that a device is attached and we
     * store the Audio v1.0 device object. This object will be required to open the
     * device. */
    switch (event)
    {
        case USB_HOST_AUDIO_V1_0_EVENT_ATTACH:
            if (isAudioDeviceAttached == false)
            {
                isAudioDeviceAttached = true;
                audioDeviceObj = audioObj;
            }
            else
            {
                /* This application supports only one Audio Device . Handle Error Here.*/
            }
        break;
        case USB_HOST_AUDIO_V1_0_EVENT_DETACH:
            if (isAudioDeviceAttached == true)
            {
                /* This means the device was detached. There is no event data
                 * associated with this event.*/
                isAudioDeviceAttached = false;
                break;
            }
        break;
    }
}

void APP_Tasks(void)
{
    switch (appData.state)
    {
        case APP_STATE_BUS_ENABLE:

            /* In this state the application enables the USB Host Bus. Note
             * how the Audio v1.0 Attach event handler is registered before the bus
             * is enabled. */

            USB_HOST_AUDIO_V1_0_AttachEventHandlerSet(APP_USBHostAudioAttachEventListener, (uintptr_t) 0);
            USB_HOST_BusEnable(0);
            appData.state = APP_STATE_WAIT_FOR_BUS_ENABLE_COMPLETE;
            break;

        case APP_STATE_WAIT_FOR_BUS_ENABLE_COMPLETE:
            /* Here we wait for the bus enable operation to complete. */
            break;
    }
}
```

Obtaining Audio v1.0 Device Audio Stream Details

Describes how to obtain audio stream details, which includes a code example.

Description

The application will need to know more details about an attached audio device like Number of Audio Stream Groups and audio format details of each audio stream in audio stream group. Application will need to search through all of the audio streams and find if a suitable audio stream is available before it can open a stream and start communicating.

USB_HOST_AUDIO_V1_0_NumberOfStreamGroupsGet function can be used to know how many stream groups are available in the attached Audio device. This function takes USB_HOST_AUDIO_V1_0_OBJ as an argument and returns uint8_t value as number of stream groups.

USB_HOST_AUDIO_V1_0_StreamGetFirst function can be used to find out audio format details of first audio stream in a Stream Groups. This function takes USB_HOST_AUDIO_V1_0_OBJ, stream group index and pointer to the USB_HOST_AUDIO_V1_0_STREAM_INFO as arguments. The stream index can any number between zero to number of stream groups returned by USB_HOST_AUDIO_V1_0_NumberOfStreamGroupsGet function. The audio stream object returned as part of USB_HOST_AUDIO_V1_0_STREAM_OBJ structure.

USB_HOST_AUDIO_V1_0_StreamGetNext function can be used to find details about subsequent audio streams. When there are no more audio streams available in the specified audio stream group this function return USB_HOST_AUDIO_V1_0_RESULT_END_OF_STREAM_LIST error. It is application's responsibility to map and Audio Stream group and an audio stream.

If the application is looking for a audio stream with certain properties, application need compare audio stream properties with members of the USB_HOST_AUDIO_V1_0_STREAM_INFO structure returned by USB_HOST_AUDIO_V1_0_StreamGetFirst and USB_HOST_AUDIO_V1_0_StreamGetNext functions.

```
/* This code shows an example of getting details about audio stream
   in an attached Audio v1.0 device.*/

/* Specify the Audio Stream format details that this application supports */
const APP_USB_HOST_AUDIO_STREAM_FORTMAT audioSpeakerStreamFormat =
{

    .streamDirection = USB_HOST_AUDIO_V1_0_DIRECTION_OUT,
    .format = USB_AUDIO_FORMAT_PCM,
    .nChannels = 2,
    .bitResolution = 16,
    .subFrameSize = 2,
    .samplingRate = 48000
};

bool isAudioDeviceAttached = false;

        default:
            break;
    }
}
```

Obtaining an Audio Stream

Describes how to open an audio stream, which includes a code example.

Description

Once application has identified which audio stream to use, application must open that audio stream by using USB_HOST_AUDIO_V1_0_StreamOpen function. This function takes audio stream object USB_HOST_AUDIO_V1_0_STREAM_OBJ as an argument which obtained by USB_HOST_AUDIO_V1_0_StreamGetFirst and USB_HOST_AUDIO_V1_0_StreamGetNext functions and returns audio stream handle USB_HOST_AUDIO_V1_0_STREAM_HANDLE. If the open function fails, it returns an invalid handle (USB_HOST_AUDIO_V1_0_STREAM_HANDLE _INVALID). Once opened successfully, a valid handle tracks the relationship between the client and the Audio Stream. This handle should be used with other Audio Stream functions.

An audio stream can be opened multiple times by different application clients. In an RTOS based application each client could running its own thread. Multiple clients can read write data to the one Audio stream. In such a case, the read and write requests are queued. The following code shows an example of how an Audio Stream is opened.

```
/* This code shows an example of opening an audio stream */

/* Specify the Audio Stream format details that this application supports */
const APP_USB_HOST_AUDIO_STREAM_FORTMAT audioSpeakerStreamFormat =
{

    .streamDirection = USB_HOST_AUDIO_V1_0_DIRECTION_OUT,
    .format = USB_AUDIO_FORMAT_PCM,
    .nChannels = 2,
    .bitResolution = 16,
    .subFrameSize = 2,
    .samplingRate = 48000
};

bool isAudioDeviceAttached = false;
USB_HOST_AUDIO_V1_0_OBJ audioDeviceObj;

Audio Stream Event Handling

Describes audio stream event handling, which includes a code example.

Description

The Audio v1.0 streams presents an event driven interface to the application. The USB Audio v1.0 Host Client Driver requires the application client to set an event handler against each audio stream for meaningful operation.

A request to send a command or transfer data typically completes after the command request or transfer function has exited. The application must then use the Audio stream event to track the completion of this command or data transfer request. In a case where multiple data transfers are queued, the transfer handles can be used to identify the transfer requests.

The application must use the USB_HOST_AUDIO_V1_0_StreamEventHandlerSet function to register an audio stream handler. This event handler will be called when a command or data transfer event has occurred and should be registered before the request for command or a data transfer. The following code shows an example of registering an audio stream event handler.

```
/* This code shows an example of Audio stream event handling */

/* Specify the Audio Stream format details that this application supports */
const APP_USB_HOST_AUDIO_STREAM_FORTMAT audioSpeakerStreamFormat =
{

    .streamDirection = USB_HOST_AUDIO_V1_0_DIRECTION_OUT,
    .format = USB_AUDIO_FORMAT_PCM,
    .nChannels = 2,
    .bitResolution = 16,
    .subFrameSize = 2,
    .samplingRate = 48000
};

bool isAudioDeviceAttached = false;
USB_HOST_AUDIO_V1_0_OBJ audioDeviceObj;

```

Enabling Audio Stream

Describes how to enable an audio stream, which includes a code example.

Description

An audio stream must be enabled before doing any data transfer operation. An audio stream enable or disable can be scheduled by using USB_HOST_AUDIO_V1_0_StreamEnable or USB_HOST_AUDIO_V1_0_StreamEnable functions. Return values of these function indicates if the request has been placed successfully or failed. When the audio stream enable request is completed, stream event handler generates an event USB_HOST_AUDIO_V1_0_STREAM_EVENT_ENABLE_COMPLETE. Similarly it generates an event USB_HOST_AUDIO_V1_0_STREAM_EVENT_DISABLE_COMPLETE when stream disable is complete. The event data USB_HOST_AUDIO_V1_0_STREAM_EVENT_ENABLE_COMPLETE_DATA has details like request handle and termination status. The requestStatus member of the USB_HOST_AUDIO_V1_0_STREAM_EVENT_ENABLE_COMPLETE_DATA indicates if the request was success or failed. When audio stream multiple audio streams with an audio stream group cannot be enabled at the same time. The following code shows an example of how an Audio Stream is enabled.

```
/* This code shows an example of enabling an audio stream */

/* Specify the Audio Stream format details that this application supports */
const APP_USB_HOST_AUDIO_STREAM_FORTMAT audioSpeakerStreamFormat =
{

    .streamDirection = USB_HOST_AUDIO_V1_0_DIRECTION_OUT,
    .format = USB_AUDIO_FORMAT_PCM,
    .nChannels = 2,
    .bitResolution = 16,
    .subFrameSize = 2,
    .samplingRate = 48000
};

Setting the Desired Audio Stream Sampling Rate

Describes how to set the desired audio stream sampling rate, which includes a code example.

Description

Sampling rate of an audio stream can be set using USB_HOST_AUDIO_V1_0_StreamSamplingRateSet function. Supported sampling rates for an audio stream is returned as part of USB_HOST_AUDIO_V1_0_STREAM_INFO by the USB_HOST_AUDIO_V1_0_StreamGetFirst and USB_HOST_AUDIO_V1_0_StreamGetNextfunctions. Return values of these function indicates if the request has been placed successfully or failed. When the set sampling rate request is completed the stream event handler generates an event USB_HOST_AUDIO_V1_0_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE. The event data USB_HOST_AUDIO_V1_0_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE_DATA has request handle and the requestStatus which indicates the set sampling request was accepted by the device or failed. The following code shows an example of how sampling rates can be set in an audio stream.

```
/* This code shows an example of Set sampling rate to an audio stream */

/* Specify the Audio Stream format details that this application supports */
const APP_USB_HOST_AUDIO_STREAM_FORTMAT audioSpeakerStreamFormat =
{

    .streamDirection = USB_HOST_AUDIO_V1_0_DIRECTION_OUT,
    .format = USB_AUDIO_FORMAT_PCM,
    .nChannels = 2,
    .bitResolution = 16,
    .subFrameSize = 2,
    .samplingRate = 48000
};

bool isAudioDeviceAttached = false;
bool isStreamEnabled = false;
bool isSampleRateSetComplete = false;
USB_HOST_AUDIO_V1_0_OBJ audioDeviceObj;

```

Audio Data Streaming

Describes how to transfer data to an audio stream, which includes a code example.

Description

The application can use the USB_HOST_AUDIO_V1_0_StreamRead and USB_HOST_AUDIO_V1_0_StreamWrite functions to transfer data to an Audio Stream. While calling these functions, the stream handle specifies the target Audio stream and the event handler function to which the events should be sent. It is possible for multiple clients to open the same audio stream and transfer data to the stream.

Calling the USB_HOST_AUDIO_V1_0_StreamRead and USB_HOST_AUDIO_V1_0_StreamWrite functions while a read/write transfer is already in progress will cause the transfer result to be queued. If the transfer was successfully queued or scheduled, the USB_HOST_AUDIO_V1_0_StreamRead and USB_HOST_AUDIO_V1_0_StreamWrite functions will return a valid transfer handle. This transfer handle identifies the transfer request. The application clients can use the transfer handles to keep track of multiple queued transfers. When a transfer completes, the Audio stream handler generates an event. The following table shows the event and the event data associated with the event.

Table 1: Read

Function	USB_HOST_AUDIO_V1_0_StreamRead
Event	USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE
Event Data Type	USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE _DATA

Table 2: Write

Function	USB_HOST_AUDIO_V1_0_StreamWrite
Event	USB_HOST_AUDIO_V1_0_STREAM_EVENT_WRITE_COMPLETE
Event Data Type	USB_HOST_AUDIO_V1_0_STREAM_EVENT_WRITE_COMPLETE _DATA

The event data contains information on the amount of data transferred, completion status and the transfer handle of the transfer. The following code shows an example of reading and writing data.

```
/* This code  shows an example of audio data streaming */

/* PCM16 samples for 1Khz Sine Wave at 48 kHz Sample Rate */
uint16_t audioSamples[96] =  {

Sending Class Specific Control Transfers

Describes how to send class-specific control transfers to the connected device, which includes a code example.

Description

The Audio v1.0 Host Client Driver allows the application client to send Audio v1.0 Class specific commands to the connected device. These commands can be send using USB_HOST_AUDIO_V1_0_ControlRequest function.

This function is non-blocking. The functions will return before the actual command execution is complete. The return value indicates if the command was scheduled successfully, or if the driver is busy and cannot accept commands, or if the command failed due to an unknown reason. If the command failed because the driver was busy, it can be retried. If scheduled successfully, the function will return a valid request handle. This request handle is unique and tracks the requested command.

When the command related control transfer has completed, the Audio v1.0 Host Client Driver generates a callback function. The call back function is one of the argument to the USB_HOST_AUDIO_V1_0_ControlRequest function.

The following code shows an example of sending a Audio v1.0 class specific commands.

```
/* This code shows an example for Audio Control transfer */
bool isAudioDeviceAttached = false;
USB_HOST_AUDIO_V1_0_OBJ audioDeviceObj;

Configuring the Library

Describes how to configure the USB Audio v1.0 Host Client Driver.

Macros

	Name	Description
	USB_HOST_AUDIO_V1_ATTACH_LISTENERS_NUMBER	Defines the number of attach event listeners that can be registered with Audio v1.0 Host Client Driver.
	USB_HOST_AUDIO_V1_INSTANCES_NUMBER	Specifies the number of Audio v1.0 instances.
	USB_HOST_AUDIO_V1_STREAMING_INTERFACE_ALTERNATE_SETTINGS_NUMBER	Defines maximum number of alternate settings per Streaming interface provided by any Device that will be connected to this Audio Host.
	USB_HOST_AUDIO_V1_STREAMING_INTERFACES_NUMBER	Defines the maximum number of streaming interfaces could be present in an Audio v1.0 device that this Audio v1.0 Host Client Driver can support.

Description

The USB Audio v1.0 Host Client Driver requires configuration constants to be specified in `system_config.h` file. These constants define the build time configuration (functionality and static resources) of the USB Audio v1.0 Host Client Driver.

USB_HOST_AUDIO_V1_ATTACH_LISTENERS_NUMBER Macro

Defines the number of attach event listeners that can be registered with Audio v1.0 Host Client Driver.

File

usb_host_audio_v1_0_config_template.h

C

```
#define USB_HOST_AUDIO_V1_ATTACH_LISTENERS_NUMBER
```

Description

USB Host Audio v1.0 Attach Listeners Number

The USB Audio v1.0 Host Client Driver provides attach notification to listeners who have registered with the client driver via the USB_HOST_AUDIO_V1_0_AttachEventHandlerSet() function. The USB_HOST_AUDIO_V1_0_ATTACH_LISTENERS_NUMBER configuration constant defines the maximum number of event handlers that can be set. This number should be set to equal the number of entities that interested in knowing when a Audio v1.0 device is attached.

Remarks

None.

USB_HOST_AUDIO_V1_INSTANCES_NUMBER Macro

Specifies the number of Audio v1.0 instances.

File

usb_host_audio_v1_0_config_template.h

C

```
#define USB_HOST_AUDIO_V1_INSTANCES_NUMBER
```

Description

USB Host Audio v1.0 Maximum Number of Instances

This macro defines the number of instances of the Audio v1.0 host Driver. For example, if the application needs to implement two instances of the Audio v1.0 host Driver should be set to 2.

Remarks

None.

USB_HOST_AUDIO_V1_STREAMING_INTERFACE_ALTERNATE_SETTINGS_NUMBER Macro

Defines maximum number of alternate settings per Streaming interface provided by any Device that will be connected to this Audio Host.

File

usb_host_audio_v1_0_config_template.h

C

```
#define USB_HOST_AUDIO_V1_STREAMING_INTERFACE_ALTERNATE_SETTINGS_NUMBER
```

Description

USB Host Audio v1.0 Streaming interface alternate setting number

This configuration constant defines maximum number of Streaming interface alternate settings provided by any Device that will be connected to this Audio Host. The value of this constant should be at-least 1.

Remarks

Supporting multiple alternate settings per streaming interfaces requires more data memory and processing time.

Example

If the USB Audio v1.0 Host application must support a USB Audio Device with 2 alternate settings including Alternate Setting 0 then this constant should be defined to 3.

USB_HOST_AUDIO_V1_STREAMING_INTERFACES_NUMBER Macro

Defines the maximum number of streaming interfaces could be present in an Audio v1.0 device that this Audio v1.0 Host Client Driver can support.

File

usb_host_audio_v1_0_config_template.h

C

```
#define USB_HOST_AUDIO_V1_STREAMING_INTERFACES_NUMBER
```

Description

USB Host Audio v1.0 Streaming Interfaces Number

This configuration constant defines maximum number of streaming interfaces could be present in an Audio v1.0 device that this Audio v1.0 Host Client Driver can support. The value of this constant should be atleast 1.

Example 1 - If the USB Audio v1.0 Host application must support a USB Headset, this constant should be set 2 as an Audio Headset will have atleast 2 Audio Streaming interfaces, one for Host to Device streaming and one for Device to Host streaming.

Example 2 - If the USB Audio v1.0 Hos t application must support a USB Speaker, this constant should be set 1 as an Audio Speaker will have atleast 1 Audio Streaming interface.

Remarks

Supporting multiple streaming interfaces requires more data memory and processing time.

Building the Library

Describes the files to be included in the project while using the USB Audio v1.0 Host Client Driver.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/usb`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
usb_host_audio_v1_0.h	This header file should be included in any `.c` file that accesses the USB Audio v1.0 Host Client Driver API.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/dynamic/usb_host_audio_v1_0.c	This file implements the USB Audio v1.0 Host Client Driver interface and should be included in the project if the USB Audio v1.0 Host Client Driver operation is desired.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The USB Audio v1.0 Host Client Driver Library depends on the following modules:

- USB Host Layer Library

Library Interface

a) Audio Device Access Functions

	Name	Description
	USB_HOST_AUDIO_V1_AttachEventHandlerSet	Sets an attach/detach event handler.
	USB_HOST_AUDIO_V1_0_ControlRequest	Schedules an Audio v1.0 control transfer.
	USB_HOST_AUDIO_V1_ControlEntityGetFirst	Retrieves the handle to the first audio control entity
	USB_HOST_AUDIO_V1_ControlEntityGetNext	Retrieves the handle to the next audio control entity.
	USB_HOST_AUDIO_V1_DeviceObjHandleGet	Returns the device object handle for this Audio v1.0 Device.
	USB_HOST_AUDIO_V1_EntityObjectGet	Retrieves the entity object for the entity ID.
	USB_HOST_AUDIO_V1_EntityRequestCallbackSet	Registers an audio entity request callback function with the Audio v1.0 Client Driver.
	USB_HOST_AUDIO_V1_EntityTypeGet	Returns the entity type of the audio control entity.
	USB_HOST_AUDIO_V1_FeatureUnitChannelMuteExists	Returns "true" if mute control exists for the specified channel of the feature unit.
	USB_HOST_AUDIO_V1_FeatureUnitChannelMuteGet	Schedules a get mute control request to the specified channel.
	USB_HOST_AUDIO_V1_FeatureUnitChannelMuteSet	Schedules a set mute control request to the specified channel.
	USB_HOST_AUDIO_V1_FeatureUnitChannelNumbersGet	Returns the number of channels.
	USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeExists	Returns "true" if volume control exists for the specified channel of the feature unit.
	USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeGet	Schedules a get current volume control request to the specified channel.
	USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeSet	Schedules a set current volume control request to the specified channel.
	USB_HOST_AUDIO_V1_FeatureUnitIDGet	Returns ID of the Feature Unit.
	USB_HOST_AUDIO_V1_FeatureUnitSourceIDGet	Returns the ID of the unit or terminal to which this feature unit is connected.
	USB_HOST_AUDIO_V1_TerminalAssociationGet	Returns the associated terminal ID of the audio control terminal.
	USB_HOST_AUDIO_V1_TerminalIDGet	Returns the terminal ID of the audio control entity.
	USB_HOST_AUDIO_V1_TerminalInputChannelNumbersGet	Returns the number of logical output channels in the terminal's output audio channel cluster.
	USB_HOST_AUDIO_V1_TerminalSourceIDGet	Returns the ID of the unit or terminal to which this terminal is connected.
	USB_HOST_AUDIO_V1_TerminalTypeGet	Returns the terminal type of the audio control entity.

b) Audio Stream Access Functions

	Name	Description
	USB_HOST_AUDIO_V1_0_NumberOfStreamGroupsGet	Gets the number of stream groups present in the attached Audio v1.0 Device.
	USB_HOST_AUDIO_V1_StreamClose	Closes the audio stream.
	USB_HOST_AUDIO_V1_StreamEventHandlerSet	Registers an event handler with the Audio v1.0 Client Driver stream.

	USB_HOST_AUDIO_V1_0_StreamDisable	Schedules an audio stream disable request for the specified audio stream.
	USB_HOST_AUDIO_V1_StreamingInterfaceGetFirst	Gets the first streaming interface object from the attached Audio Device.
	USB_HOST_AUDIO_V1_0_StreamEnable	Schedules an audio stream enable request for the specified audio stream.
	USB_HOST_AUDIO_V1_StreamingInterfaceGetNext	Gets the next streaming interface object from the attached Audio Device.
	USB_HOST_AUDIO_V1_0_StreamEventHandlerSet	Registers an event handler with the Audio v1.0 Client Driver stream.
	USB_HOST_AUDIO_V1_StreamingInterfaceSet	Schedules a SET_INTERFACE request to the specified audio stream.
	USB_HOST_AUDIO_V1_0_StreamGetFirst	Returns information about first audio stream in the specified audio stream group.
	USB_HOST_AUDIO_V1_StreamingInterfaceSettingGetFirst	Gets the first streaming interface setting object within an audio streaming interface.
	USB_HOST_AUDIO_V1_0_StreamGetNext	Returns information about the next audio stream in the specified audio stream group.
	USB_HOST_AUDIO_V1_StreamingInterfaceSettingGetNext	Gets the next streaming interface setting object within an audio streaming interface.
	USB_HOST_AUDIO_V1_0_StreamSamplingRateSet	Schedules an audio stream set sampling rate request for the specified audio stream.
	USB_HOST_AUDIO_V1_StreamOpen	Opens the specified audio stream.
	USB_HOST_AUDIO_V1_StreamRead	Schedules an audio stream read request for the specified audio stream.
	USB_HOST_AUDIO_V1_StreamWrite	Schedules an audio stream write request for the specified audio stream.
	USB_HOST_AUDIO_V1_StreamingInterfaceBitResolutionGet	Returns the bit resolution of the specified streaming interface setting.
	USB_HOST_AUDIO_V1_StreamingInterfaceChannelNumbersGet	Returns the number of channels of the specified streaming interface setting.
	USB_HOST_AUDIO_V1_StreamingInterfaceDirectionGet	Returns the direction of the specified streaming interface setting.
	USB_HOST_AUDIO_V1_StreamingInterfaceFormatTagGet	Returns the format tag of the specified streaming interface setting.
	USB_HOST_AUDIO_V1_StreamingInterfaceSamplingFrequenciesGet	Returns the sampling frequencies supported by the specified streaming interface setting.
	USB_HOST_AUDIO_V1_StreamingInterfaceSamplingFrequencyTypeGet	Returns the sampling frequency type of the specified streaming interface setting.
	USB_HOST_AUDIO_V1_StreamingInterfaceSubFrameSizeGet	Returns the sub-frame size of the specified streaming interface setting.
	USB_HOST_AUDIO_V1_StreamingInterfaceTerminalLinkGet	Returns the terminal link of the specified streaming interface setting.
	USB_HOST_AUDIO_V1_StreamSamplingFrequencyGet	Schedules an audio stream get sampling rate request for the specified audio stream.
	USB_HOST_AUDIO_V1_StreamSamplingFrequencySet	Schedules an audio stream set sampling rate request for the specified audio stream.
	USB_HOST_AUDIO_V1_0_StreamRead	Schedules an audio stream read request for the specified audio stream.
	USB_HOST_AUDIO_V1_0_StreamWrite	Schedules an audio stream write request for the specified audio stream.

c) Other Functions

	Name	Description
	USB_HOST_AUDIO_V1_TerminalInputChannelConfigGet	Returns a structure that describes the spatial location of the logical channels of in the terminal's output audio channel cluster.
	USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeRangeGet	Schedules a control request to the Audio Device feature unit to get the range supported by the volume control on the specified channel.
	USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeSubRangeNumbersGet	Schedules a control request to an Audio Device feature unit to get the number of sub-ranges supported by the volume control on the specified channel.

d) Data Types and Constants

	Name	Description
	USB_HOST_AUDIO_V1_ATTACH_EVENT_HANDLER	USB Host Audio v1.0 Client Driver attach event handler function pointer type.
	USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ	Defines the type of the Audio v1.0 Host control entity object.
	USB_HOST_AUDIO_V1_ENTITY_REQUEST_CALLBACK	USB Host Audio v1.0 class driver control transfer complete callback function pointer type.
	USB_HOST_AUDIO_V1_EVENT	Identifies the possible events that the Audio v1.0 Class Driver attach event handler can generate.
	USB_HOST_AUDIO_V1_OBJ	Defines the type of the Audio v1.0 Host client object.
	USB_HOST_AUDIO_V1_REQUEST_HANDLE	USB Host Audio v1.0 Client Driver request handle.
	USB_HOST_AUDIO_V1_RESULT	USB Host Audio v1.0 Class Driver result enumeration.
	USB_HOST_AUDIO_V1_0_ATTACH_EVENT_HANDLER	USB Host Audio v1.0 Client Driver attach event handler function pointer type.
	USB_HOST_AUDIO_V1_STREAM_DIRECTION	USB Host Audio v1.0 Class Driver stream direction.
	USB_HOST_AUDIO_V1_STREAM_EVENT	Identifies the possible events that the Audio v1.0 Stream can generate.
	USB_HOST_AUDIO_V1_STREAM_EVENT_HANDLER	USB Host Audio v1.0 Class Driver stream event handler function pointer type.
	USB_HOST_AUDIO_V1_STREAM_EVENT_INTERFACE_SET_COMPLETE_DATA	USB Host Audio v1.0 class stream control event data.
	USB_HOST_AUDIO_V1_0_CONTROL_CALLBACK	USB Host Audio v1.0 Class Driver control transfer complete callback function pointer type.
	USB_HOST_AUDIO_V1_STREAM_EVENT_READ_COMPLETE_DATA	USB Host Audio v1.0 class stream data transfer event data.
	USB_HOST_AUDIO_V1_0_EVENT	Identifies the possible events that the Audio v1.0 Class Driver can generate.
	USB_HOST_AUDIO_V1_STREAM_EVENT_RESPONSE	Returns the type of the USB Host Audio v1.0 stream event handler.
	USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE_DATA	USB Host Audio v1.0 class stream control event data.
	USB_HOST_AUDIO_V1_0_OBJ	Defines the type of the Audio v1.0 Host client object.
	USB_HOST_AUDIO_V1_STREAM_EVENT_WRITE_COMPLETE_DATA	USB Host Audio v1.0 class stream data transfer event data.
	USB_HOST_AUDIO_V1_0_REQUEST_HANDLE	USB Host Audio v1.0 Client Driver request handle.
	USB_HOST_AUDIO_V1_STREAM_HANDLE	Defines the type of the Audio v1.0 Host stream handle.
	USB_HOST_AUDIO_V1_0_RESULT	USB Host Audio v1.0 Class Driver audio result enumeration.
	USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE	USB Host Audio v1.0 Class Driver stream data transfer handle.
	USB_HOST_AUDIO_V1_0_STREAM_DIRECTION	USB Host Audio v1.0 Class Driver stream direction.
	USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ	Defines the type of the Audio v1.0 Host streaming interface object.
	USB_HOST_AUDIO_V1_0_STREAM_EVENT	Identifies the possible events that the Audio v1.0 stream can generate.
	USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ	Defines the type of the Audio v1.0 Host streaming interface setting object.

	USB_HOST_AUDIO_V1_0_STREAM_EVENT_DISABLE_COMPLETE_DATA	USB Host Audio v1.0 class stream control event data.
	USB_HOST_AUDIO_V1_0_STREAM_EVENT_ENABLE_COMPLETE_DATA	USB Host Audio v1.0 class stream control event data.
	USB_HOST_AUDIO_V1_0_STREAM_EVENT_HANDLER	USB Host Audio v1.0 Class Driver stream event handler function pointer type.
	USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE_DATA	This is macro USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE_DATA.
	USB_HOST_AUDIO_V1_0_STREAM_EVENT_RESPONSE	Returns the type of the USB Audio v1.0 Host Client Driver event handler.
	USB_HOST_AUDIO_V1_0_STREAM_EVENT_WRITE_COMPLETE_DATA	USB Host Audio v1.0 class stream transfer event data.
	USB_HOST_AUDIO_V1_0_STREAM_HANDLE	Defines the type of the Audio v1.0 Host stream handle.
	USB_HOST_AUDIO_V1_INTERFACE	USB HOST Audio v1.0 Client Driver interface.
	USB_HOST_AUDIO_V1_0_STREAM_INFO	This is type USB_HOST_AUDIO_V1_0_STREAM_INFO.
	USB_HOST_AUDIO_V1_REQUEST_HANDLE_INVALID	USB Host Audio v1.0 Client Driver invalid request handle.
	USB_HOST_AUDIO_V1_0_STREAM_OBJ	Defines the type of the Audio v1.0 Host stream object.
	USB_HOST_AUDIO_V1_STREAM_HANDLE_INVALID	Defines Audio v1.0 Host stream invalid handle.
	USB_HOST_AUDIO_V1_0_STREAM_RESULT	USB Host Audio v1.0 stream result enumeration.
	USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE_INVALID	USB Host Audio v1.0 Class Driver invalid stream data transfer handle.
	USB_HOST_AUDIO_V1_0_STREAM_TRANSFER_HANDLE	USB Host Audio v1.0 Class Driver transfer handle.
	USB_HOST_AUDIO_V1_0_INTERFACE	USB HOST Audio Client Driver interface.
	USB_HOST_AUDIO_V1_0_REQUEST_HANDLE_INVALID	USB Host Audio v1.0 Client Driver invalid request handle.
	USB_HOST_AUDIO_V1_0_STREAM_HANDLE_INVALID	Defines the type of the Audio v1.0 Host stream invalid handle.
	USB_HOST_AUDIO_V1_0_STREAM_TRANSFER_HANDLE_INVALID	USB Host Audio v1.0 Class Driver invalid transfer handle definition.
	USB_HOST_AUDIO_V1_0_AttachEventHandlerSet	Sets an attach/detach event handler.
	USB_HOST_AUDIO_V1_0_DeviceObjHandleGet	Returns the device object handle for this Audio v1.0 Device.
	USB_HOST_AUDIO_V1_0_DIRECTION_IN	This is macro USB_HOST_AUDIO_V1_0_DIRECTION_IN.
	USB_HOST_AUDIO_V1_0_DIRECTION_OUT	This is macro USB_HOST_AUDIO_V1_0_DIRECTION_OUT.
	USB_HOST_AUDIO_V1_0_EVENT_ATTACH	This is macro USB_HOST_AUDIO_V1_0_EVENT_ATTACH.
	USB_HOST_AUDIO_V1_0_EVENT_DETACH	This is macro USB_HOST_AUDIO_V1_0_EVENT_DETACH.
	USB_HOST_AUDIO_V1_0_STREAM_EVENT_RESPONSE_NONE	Returns the type of the USB Host Audio v1.0 stream event handler.
	USB_HOST_AUDIO_V1_0_StreamClose	Closes the audio stream.
	USB_HOST_AUDIO_V1_0_StreamOpen	Opens the specified audio stream.
	USB_HOST_AUDIO_V1_SAMPLING_FREQUENCIES_NUMBER	This structure defines USB Host audio stream information structure.
	USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_RATE_GET_COMPLETE_DATA	USB Host Audio v1.0 class stream control event data.

Description

This section describes the Application Programming Interface (API) functions of the USB Audio v1.0 Host Client Driver Library.

Refer to each section for a detailed description.

a) Audio Device Access Functions

USB_HOST_AUDIO_V1_AttachEventHandlerSet Function

Sets an attach/detach event handler.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_AttachEventHandlerSet(USB_HOST_AUDIO_V1_ATTACH_EVENT_HANDLER
eventHandler, uintptr_t context);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - If the attach event handler was registered successfully
- USB_HOST_AUDIO_V1_RESULT_FAILURE - If the number of registered event handlers has exceeded USB_HOST_AUDIO_V1_ATTACH_LISTENERS_NUMBER

Description

This function will set an attach event handler. The attach event handler will be called when a Audio v1.0 Device has been attached or detached. The context will be returned in the event handler. This function should be called before the bus has been enabled.

Remarks

This function should be called before the USB_HOST_BusEnable function is called.

Preconditions

None.

Parameters

Parameters	Description
eventHandler	Pointer to the attach event handler.
context	An application defined context that will be returned in the event handler.

Function

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_AttachEventHandlerSet
(
    USB_HOST_AUDIO_V1_ATTACH_EVENT_HANDLER eventHandler,
uintptr_t context
);
```

USB_HOST_AUDIO_V1_0_ControlRequest Function

Schedules an Audio v1.0 control transfer.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_0_RESULT USB_HOST_AUDIO_V1_0_ControlRequest(USB_HOST_AUDIO_V1_0_OBJ OBJ,
USB_HOST_AUDIO_V1_0_REQUEST_HANDLE * transferHandle, USB_SETUP_PACKET * setupPacket, void * data,
USB_HOST_AUDIO_V1_0_CONTROL_CALLBACK callback, uintptr_t context);
```

Returns

- USB_HOST_AUDIO_V1_0_RESULT_SUCCESS - The transfer was scheduled successfully. requestHandle will contain a valid transfer handle.
- USB_HOST_AUDIO_V1_0_RESULT_FAILURE - An unknown failure occurred. requestHandle will contain USB_HOST_AUDIO_V1_0_REQUEST_HANDLE_INVALID.

- USB_HOST_AUDIO_V1_0_RESULT_PARAMETER_INVALID - The data pointer or requestHandle pointer is NULL

Description

This function schedules an Audio v1.0 control transfer. The audioObj parameter is an object of the Audio v1.0 Class Driver to which the audio control transfer is to be scheduled. The setupPacket parameter points to the SETUP command to be sent in the setup state of the control transfer. The size and the direction of the data stage is indicated by the SETUP packet. For control transfers where there is no data stage, data is ignored and can be NULL. In all other instances, data should point to the data to data be transferred in the data stage of the control transfer.

If the transfer was scheduled successfully, requestHandle will contain a transfer handle that uniquely identifies this transfer. If the transfer could not be scheduled successfully, requestHandle will contain USB_HOST_AUDIO_V1_0_REQUEST_HANDLE_INVALID.

When the control transfer completes, the Audio v1.0 Client Driver will call the specified callback function. The context parameter specified here will be returned in the callback.

Remarks

None.

Preconditions

The Audio v1.0 Device should be attached.

Parameters

Parameters	Description
audioObj	Audio v1.0 client driver object
requestHandle	Output parameter that will contain the handle to this transfer
setupPacket	Pointer to the SETUP packet to sent to the device in the SETUP stage of the control transfer
data	For control transfer with a data stage, this should point to data to be sent to the device (for a control write transfer) or point to the buffer that will receive data from the device (for a control read transfer). For control transfers that do not require a data stage, this parameter is ignored and can be NULL.
callback	Pointer to the callback function that will be called when the control transfer completes. If the callback function is NULL, there will be no notification of when the control transfer will complete.
context	User-defined context that is returned with the callback function

Function

```
USB_HOST_AUDIO_V1_0_RESULT USB_HOST_AUDIO_V1_0_ControlRequest
(
    USB_HOST_AUDIO_V1_0_OBJ audioObj,
    USB_HOST_AUDIO_V1_0_REQUEST_HANDLE * requestHandle,
USB_SETUP_PACKET *setupPacket,
void * data,
    USB_HOST_AUDIO_V1_0_CONTROL_CALLBACK callback,
uintptr_t context
);
```

USB_HOST_AUDIO_V1_ControlEntityGetFirst Function

Retrieves the handle to the first audio control entity

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_ControlEntityGetFirst(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ * pEntityObject);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_RESULT_END_OF_CONTROL_ENTITY - No more audio control entities are available
- USB_HOST_AUDIO_V1_RESULT_OBJ_INVALID - The specified audio stream does not exist
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An unknown failure occurred

Description

This function retrieves the handle to the first audio control entity.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 device object.
pEntityObject	pointer to the Audio control entity handle.

Function

USB_HOST_AUDIO_V1_REESULT USB_HOST_AUDIO_V1_ControlEntityGetFirst

(

USB_HOST_AUDIO_V1_OBJ audioObj,

USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ * pEntityObject

);

USB_HOST_AUDIO_V1_ControlEntityGetNext Function

Retrieves the handle to the next audio control entity.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_ControlEntityGetNext(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObjectCurrent, USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ *
pEntityObject);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_RESULT_END_OF_CONTROL_ENTITY - No more audio control entities are available
- USB_HOST_AUDIO_V1_RESULT_OBJ_INVALID - The specified audio stream does not exist
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An unknown failure occurred

Description

This function retrieves the handle to the next audio control entity.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 device object.
entityObjectCurrent	Handle to current audio control entity.
pEntityObject	pointer to audio control entity handle.

Function

USB_HOST_AUDIO_V1_REESULT USB_HOST_AUDIO_V1_ControlEntityGetNext

(

USB_HOST_AUDIO_V1_OBJ audioObj,

USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObjectCurrent

USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ * pEntityObject
);

USB_HOST_AUDIO_V1_DeviceObjHandleGet Function

Returns the device object handle for this Audio v1.0 Device.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_DEVICE_OBJ_HANDLE USB_HOST_AUDIO_V1_DeviceObjHandleGet(USB_HOST_AUDIO_V1_OBJ audioDeviceObj);
```

Returns

Will return a valid device object handle if the device is still connected to the system. Otherwise, the function will return USB_HOST_DEVICE_OBJ_HANDLE_INVALID.

Description

This function returns the device object handle for this Audio v1.0 Device. This returned handle can be used by the application to perform device-level operations, such as obtaining the string descriptors.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
audioDeviceObj	Audio V1.0 device object handle returned in the USB_HOST_AUDIO_V1_ATTACH_EVENT_HANDLER function.

Function

USB_HOST_DEVICE_OBJ_HANDLE USB_HOST_AUDIO_V1_DeviceObjHandleGet
(
USB_HOST_AUDIO_V1_OBJ audioDeviceObj
);

USB_HOST_AUDIO_V1_EntityObjectGet Function

Retrieves the entity object for the entity ID.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_EntityObjectGet(USB_HOST_AUDIO_V1_OBJ audioObj, uint8_t
entityId, USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ* entityObj);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_RESULT_FAILURE - The entity Id could not be found or an unknown failure occurred

Description

This function retrieves the entity object for the entity ID.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 Device object
entityId	Entity ID
entityObject	Audio control entity object

Function

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_EntityObjectGet
(
    USB_HOST_AUDIO_V1_OBJ  audioObj,
uint8_t entityId,
    USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ* entityObj
);
```

USB_HOST_AUDIO_V1_EntityRequestCallbackSet Function

Registers an audio entity request callback function with the Audio v1.0 Client Driver.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_EntityRequestCallbackSet(USB_HOST_AUDIO_V1_OBJ audioDeviceObj,
USB_HOST_AUDIO_V1_ENTITY_REQUEST_CALLBACK appAudioEntityRequestCallback, uintptr_t context);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_RESULT_OBJ_INVALID - The specified audio object does not exist
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An unknown failure occurred

Description

This function registers a callback function for the Audio v1.0 control entity requests. The Audio v1.0 Host Client Driver will call this callback function when an audio entity control request is completed.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
audioDeviceObj	Audio v1.0 device object.
appAudioEntityRequestCallback	A pointer to event handler function. If NULL, events will not be generated.
context	Application specific context that is returned in the event handler.

Function

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_EntityRequestCallbackSet
(
    USB_HOST_AUDIO_V1_OBJ audioDeviceObj,
USB_HOST_AUDIO_V1_CONTROL_EVENT_HANDLER appAudioEntityRequestCallback,
uintptr_t context
);
```

USB_HOST_AUDIO_V1_EntityTypeGet Function

Returns the entity type of the audio control entity.

File

usb_host_audio_v1_0.h

C

```
USB_AUDIO_V1_ENTITY_TYPE USB_HOST_AUDIO_V1_EntityTypeGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject);
```

Returns

USB_AUDIO_V1_ENTITY_TYPE.

Description

This function returns the entity type of the audio control entity. Prior to calling this function the entity object should be obtained by calling USB_HOST_AUDIO_V1_ControlEntityGetFirst, USB_HOST_AUDIO_V1_ControlEntityGetNext, or USB_HOST_AUDIO_V1_EntityObjectGet.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 Device object
entityObject	Audio control entity object

Function

USB_AUDIO_V1_ENTITY_TYPE USB_HOST_AUDIO_V1_EntityTypeGet

(

USB_HOST_AUDIO_V1_OBJ audioObj,

USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject

);

USB_HOST_AUDIO_V1_FeatureUnitChannelMuteExists Function

Returns "true" if mute control exists for the specified channel of the feature unit.

File

usb_host_audio_v1_0.h

C

```
bool USB_HOST_AUDIO_V1_FeatureUnitChannelMuteExists(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject, uint8_t channel);
```

Returns

- true - Mute control exists on the specified channel
- false - Mute control does not exist on the specified channel

Description

This function returns "true" if mute control exists on the specified channel of the feature unit. Channel 0 indicates Master mute control. This function is only applicable to a feature unit. Prior to calling this function the entity object should be obtained by calling USB_HOST_AUDIO_V1_ControlEntityGetFirst, USB_HOST_AUDIO_V1_ControlEntityGetNext, or USB_HOST_AUDIO_V1_EntityObjectGet.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 Device object
entityObject	Audio control entity object
channel	Channel number

Function

bool USB_HOST_AUDIO_V1_FeatureUnitChannelMuteExists

(
USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject,
uint8_t channel
);

USB_HOST_AUDIO_V1_FeatureUnitChannelMuteGet Function

Schedules a get mute control request to the specified channel.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_FeatureUnitChannelMuteGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject, USB_HOST_AUDIO_V1_REQUEST_HANDLE * requestHandle,
uint8_t channelNumber, bool * muteStatus);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The request was scheduled successfully. requestHandle will contain a valid request handle.
- USB_HOST_AUDIO_V1_RESULT_BUSY - The control request mechanism is currently busy. Retry the request.
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An unknown failure occurred. requestHandle will contain USB_HOST_AUDIO_V1_0_REQUEST_HANDLE_INVALID.
- USB_HOST_AUDIO_V1_RESULT_PARAMETER_INVALID - The data pointer or requestHandle pointer is NULL

Description

This function schedules a get mute control request to the specified channel. Prior to calling this function the user should check if mute control exists on the specified channel by calling the USB_HOST_AUDIO_V1_FeatureUnitChannelMuteExists function.

If the request was scheduled successfully, the requestHandle parameter will contain a request handle that uniquely identifies this request. If the transfer could not be scheduled successfully, requestHandle will contain USB_HOST_AUDIO_V1_REQUEST_HANDLE_INVALID.

When the control request completes, the Audio v1.0 Client Driver will call the callback function that was set using the USB_HOST_AUDIO_V1_EntityRequestCallbackSet function. The context parameter specified here will be returned in the callback.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 Device object
entityObject	Audio control entity object
requestHandle	Output parameter that will contain the handle to this request
channelNumber	Channel number
muteStatus	Output parameter that will contain Current Mute status when the request is completed and a callback is received

Function

USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_FeatureUnitChannelMuteGet
(
USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject,
USB_HOST_AUDIO_V1_REQUEST_HANDLE * requestHandle,
uint8_t channelNumber,
bool *muteStatus
);

USB_HOST_AUDIO_V1_FeatureUnitChannelMuteSet Function

Schedules a set mute control request to the specified channel.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_FeatureUnitChannelMuteSet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject, USB_HOST_AUDIO_V1_REQUEST_HANDLE * requestHandle,
uint8_t channelNumber, bool * muteStatus);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The request was scheduled successfully. requestHandle will contain a valid request handle.
- USB_HOST_AUDIO_V1_RESULT_BUSY - The control request mechanism is currently busy. Retry the request.
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An unknown failure occurred. requestHandle will contain USB_HOST_AUDIO_V1_0_REQUEST_HANDLE_INVALID.
- USB_HOST_AUDIO_V1_RESULT_PARAMETER_INVALID - The data pointer or requestHandle pointer is NULL

Description

This function schedules a set mute control request to the specified channel. Prior to calling this function the user should check if mute control exists on the specified channel by calling the USB_HOST_AUDIO_V1_FeatureUnitChannelMuteExists function.

If the request was scheduled successfully, the requestHandle parameter will contain a request handle that uniquely identifies this transfer. If the transfer could not be scheduled successfully, requestHandle will contain USB_HOST_AUDIO_V1_REQUEST_HANDLE_INVALID.

When the control request completes, the Audio v1.0 Client Driver will call the callback function that was set using the USB_HOST_AUDIO_V1_EntityRequestCallbackSet function. The context parameter specified here will be returned in the callback.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 Device object
entityObject	Audio control entity object
requestHandle	Output parameter that will contain the handle to this request
channelNumber	Channel Number
muteStatus	Value of mute control, where 1 mutes the channel and 0 removes unmutes

Function

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_FeatureUnitChannelMuteSet
(
    USB_HOST_AUDIO_V1_OBJ  audioObj,
    USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject,
    USB_HOST_AUDIO_V1_REQUEST_HANDLE * requestHandle,
uint8_t channelNumber,
bool *muteStatus
);
```

USB_HOST_AUDIO_V1_FeatureUnitChannelNumbersGet Function

Returns the number of channels.

File

usb_host_audio_v1_0.h

C

```
uint8_t USB_HOST_AUDIO_V1_FeatureUnitChannelNumbersGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject);
```

Returns

The number of channels.

Description

This function returns the number of channels. This function is only applicable to a feature unit. Prior to calling this function the entity object should

be obtained by calling USB_HOST_AUDIO_V1_ControlEntityGetFirst, USB_HOST_AUDIO_V1_ControlEntityGetNext, or USB_HOST_AUDIO_V1_EntityObjectGet.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 Device object
entityObject	Audio control entity object

Function

uint8_t USB_HOST_AUDIO_V1_FeatureUnitChannelNumbersGet

(

USB_HOST_AUDIO_V1_OBJ audioObj,

USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject

);

USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeExists Function

Returns "true" if volume control exists for the specified channel of the feature unit.

File

usb_host_audio_v1_0.h

C

```
bool USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeExists(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject, uint8_t channel);
```

Returns

- true - Volume control exists on the specified channel
- false - Volume control does not exist on the specified channel

Description

This function returns "true" if volume control exists on the specified channel of the feature unit. Channel 0 indicates master volume control. This function is only applicable to a feature unit. Prior to calling this function the entity object should be obtained by calling USB_HOST_AUDIO_V1_ControlEntityGetFirst, USB_HOST_AUDIO_V1_ControlEntityGetNext, or USB_HOST_AUDIO_V1_EntityObjectGet.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 Device object
entityObject	Audio control entity object
channel	Channel number

Function

bool USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeExists

(

USB_HOST_AUDIO_V1_OBJ audioObj,

USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject,

uint8_t channel

);

USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeGet Function

Schedules a get current volume control request to the specified channel.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject, USB_HOST_AUDIO_V1_REQUEST_HANDLE * requestHandle,
uint8_t channelNumber, uint16_t * volume);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The request was scheduled successfully. requestHandle will contain a valid request handle.
- USB_HOST_AUDIO_V1_RESULT_BUSY - The control request mechanism is currently busy. Retry the request.
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An unknown failure occurred. requestHandle will contain USB_HOST_AUDIO_V1_0_REQUEST_HANDLE_INVALID
- USB_HOST_AUDIO_V1_RESULT_PARAMETER_INVALID - The data pointer or requestHandle pointer is NULL

Description

This function schedules a get current volume control request to the specified channel. Prior to calling this function the user should check if volume control exists on the specified channel by calling the USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeExists function.

If the request was scheduled successfully, the requestHandle parameter will contain a request handle that uniquely identifies this request. If the request could not be scheduled successfully, requestHandle will contain USB_HOST_AUDIO_V1_REQUEST_HANDLE_INVALID.

When the control request completes, the Audio v1.0 Client Driver will call the callback function that was set using the USB_HOST_AUDIO_V1_EntityRequestCallbackSet function. The context parameter specified here will be returned in the callback.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 Device object
entityObject	Audio control entity object
requestHandle	Output parameter that will contain the handle to this request
channelNumber	Channel number to which the volume control is addressed
volume	Output parameter that will contain the current volume when a request is completed and a callback is received

Function

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeGet
(
    USB_HOST_AUDIO_V1_OBJ  audioObj,
    USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject,
    USB_HOST_AUDIO_V1_REQUEST_HANDLE * requestHandle,
uint8_t channelNumber,
uint16_t *volume
);
```

USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeSet Function

Schedules a set current volume control request to the specified channel.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeSet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject, USB_HOST_AUDIO_V1_REQUEST_HANDLE * requestHandle,
uint8_t channelNumber, uint16_t * volume);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The request was scheduled successfully. requestHandle will contain a valid request handle.
- USB_HOST_AUDIO_V1_RESULT_BUSY - The control request mechanism is currently busy. Retry the request.

- USB_HOST_AUDIO_V1_RESULT_FAILURE - An unknown failure occurred. requestHandle will contain USB_HOST_AUDIO_V1_0_REQUEST_HANDLE_INVALID.
- USB_HOST_AUDIO_V1_RESULT_PARAMETER_INVALID - The data pointer or requestHandle pointer is NULL

Description

This function schedules a set current volume request to the specified channel. Prior to calling this function the user should check if volume control exists on the specified channel by calling the USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeExists function.

If the request was scheduled successfully, the requestHandle parameter will contain a request handle that uniquely identifies this request. If the request could not be scheduled successfully, requestHandle will contain USB_HOST_AUDIO_V1_REQUEST_HANDLE_INVALID.

When the control request completes, the Audio v1.0 Client Driver will call the callback function that was set using the USB_HOST_AUDIO_V1_EntityRequestCallbackSet function. The context parameter specified here will be returned in the callback.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 Device object
entityObject	Audio control entity object
requestHandle	Output parameter that will contain the handle to this request
channelNumber	Channel number to which the volume control is addressed
volume	Current volume control value that should be set in the Audio Device

Function

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeSet
(
    USB_HOST_AUDIO_V1_OBJ  audioObj,
    USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject,
    USB_HOST_AUDIO_V1_REQUEST_HANDLE * requestHandle,
uint8_t channelNumber,
uint16_t *volume
);
```

USB_HOST_AUDIO_V1_FeatureUnitIDGet Function

Returns ID of the Feature Unit.

File

usb_host_audio_v1_0.h

C

```
uint8_t USB_HOST_AUDIO_V1_FeatureUnitIDGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject);
```

Returns

The ID of the feature unit.

Description

This function returns the ID of the D of the Feature Unit. This function is only applicable to Feature Unit. Prior to calling this function Entity Object should be obtained by calling the USB_HOST_AUDIO_V1_ControlEntityGetFirst, USB_HOST_AUDIO_V1_ControlEntityGetNext, or USB_HOST_AUDIO_V1_EntityObjectGet function.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 device object.
entityObject	Audio control entity Object

Function

uint8_t USB_HOST_AUDIO_V1_FeatureUnitIDGet
(
USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject
);

USB_HOST_AUDIO_V1_FeatureUnitSourceIDGet Function

Returns the ID of the unit or terminal to which this feature unit is connected.

File

usb_host_audio_v1_0.h

C

```
uint8_t USB_HOST_AUDIO_V1_FeatureUnitSourceIDGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject);
```

Returns

The ID of the unit or terminal to which this feature unit is connected.

Description

This function returns the ID of the Unit or Terminal to which this feature unit is connected. This function is only applicable to a feature unit. Prior to calling this function the entity object should be obtained by calling USB_HOST_AUDIO_V1_ControlEntityGetFirst, USB_HOST_AUDIO_V1_ControlEntityGetNext, or USB_HOST_AUDIO_V1_EntityObjectGet.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 Device object
entityObject	Audio control entity object

Function

uint8_t USB_HOST_AUDIO_V1_FeatureUnitSourceIDGet
(
USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject
);

USB_HOST_AUDIO_V1_TerminalAssociationGet Function

Returns the associated terminal ID of the audio control terminal.

File

usb_host_audio_v1_0.h

C

```
uint8_t USB_HOST_AUDIO_V1_TerminalAssociationGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject);
```

Returns

The ID of the associated terminal.

Description

This function returns the ID of the associated terminal type of the audio control terminal. Prior to calling this function the entity object should be obtained by calling USB_HOST_AUDIO_V1_ControlEntityGetFirst, USB_HOST_AUDIO_V1_ControlEntityGetNext, or USB_HOST_AUDIO_V1_EntityObjectGet.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 Device object
entityObject	Audio control entity object

Function

uint8_t USB_HOST_AUDIO_V1_TerminalAssociationGet
(
    USB_HOST_AUDIO_V1_OBJ audioObj,
    USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject
);

USB_HOST_AUDIO_V1_TerminalIDGet Function

Returns the terminal ID of the audio control entity.

File

usb_host_audio_v1_0.h

C

```
uint8_t USB_HOST_AUDIO_V1_TerminalIDGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject);
```

Returns

The terminal ID of the audio control entity object.

Description

This function returns the Terminal ID of the Audio Control entity. Prior to calling this function the entity object should be obtained by calling USB_HOST_AUDIO_V1_ControlEntityGetFirst, USB_HOST_AUDIO_V1_ControlEntityGetNext, or USB_HOST_AUDIO_V1_EntityObjectGet.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 Device object
entityObject	Audio control entity object

Function

uint8_t USB_HOST_AUDIO_V1_TerminalIDGet
(
    USB_HOST_AUDIO_V1_OBJ audioObj,
    USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject
);

USB_HOST_AUDIO_V1_TerminalInputChannelNumbersGet Function

Returns the number of logical output channels in the terminal's output audio channel cluster.

File

usb_host_audio_v1_0.h

C

```
uint8_t USB_HOST_AUDIO_V1_TerminalInputChannelNumbersGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject);
```

Returns

The number of logical output channels in the terminal's output audio channel cluster.

Description

This function returns the number of logical output channels in the terminal's output audio channel cluster. This function is only applicable to an input terminal. Prior to calling this function the entity object should be obtained by calling USB_HOST_AUDIO_V1_ControlEntityGetFirst, USB_HOST_AUDIO_V1_ControlEntityGetNext, or USB_HOST_AUDIO_V1_EntityObjectGet.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 device object.
entityObject	Audio control entity object

Function

uint8_t USB_HOST_AUDIO_V1_TerminalInputChannelNumbersGet

(

USB_HOST_AUDIO_V1_OBJ audioObj,

USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject

);

USB_HOST_AUDIO_V1_TerminalSourceIDGet Function

Returns the ID of the unit or terminal to which this terminal is connected.

File

usb_host_audio_v1_0.h

C

```
uint8_t USB_HOST_AUDIO_V1_TerminalSourceIDGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject);
```

Returns

The ID of the unit or terminal to which this terminal is connected.

Description

This function returns the ID of the unit or terminal to which this terminal is connected. This function is only applicable to an output terminal. Prior to calling this function the entity object should be obtained by calling USB_HOST_AUDIO_V1_ControlEntityGetFirst, USB_HOST_AUDIO_V1_ControlEntityGetNext, or USB_HOST_AUDIO_V1_EntityObjectGet.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 Device object
entityObject	Audio control entity object

Function

uint8_t USB_HOST_AUDIO_V1_TerminalSourceIDGet

(

USB_HOST_AUDIO_V1_OBJ audioObj,

USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject

);

USB_HOST_AUDIO_V1_TerminalTypeGet Function

Returns the terminal type of the audio control entity.

File

usb_host_audio_v1_0.h

C

```
USB_AUDIO_V1_TERMINAL_TYPE USB_HOST_AUDIO_V1_TerminalTypeGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject);
```

Returns

The terminal type.

Description

This function returns the Terminal type of the audio control entity. Prior to calling this function Entity Object should be obtained by calling the USB_HOST_AUDIO_V1_ControlEntityGetFirst, USB_HOST_AUDIO_V1_ControlEntityGetNext, or USB_HOST_AUDIO_V1_EntityObjectGet function.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 device object
entityObject	Audio control entity Object

Function

USB_AUDIO_V1_TERMINAL_TYPE USB_HOST_AUDIO_V1_TerminalTypeGet

(

USB_HOST_AUDIO_V1_OBJ audioObj,

USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject

);

b) Audio Stream Access Functions

USB_HOST_AUDIO_V1_0_NumberOfStreamGroupsGet Function

Gets the number of stream groups present in the attached Audio v1.0 Device.

File

usb_host_audio_v1_0.h

C

```
uint8_t USB_HOST_AUDIO_V1_0_NumberOfStreamGroupsGet(USB_HOST_AUDIO_V1_0_OBJ audioObj);
```

Returns

A returned uint8_t indicates the number of audio stream groups present in the attached Audio v1.0 Device.

Description

This function will get number of stream groups present in the attached Audio v1.0 Device. The audio stream within an audio stream cannot be enabled at the same time.

Remarks

None.

Preconditions

The Audio v1.0 Device should have been attached.

Parameters

Parameters	Description
audioObj	Audio v1.0 Client Driver object

Function

uint8_t USB_HOST_AUDIO_V1_0_NumberOfStreamGroupsGet
(
    USB_HOST_AUDIO_V1_0_OBJ audioObj
);

USB_HOST_AUDIO_V1_StreamClose Function

Closes the audio stream.

File

usb_host_audio_v1_0.h

C

```
void USB_HOST_AUDIO_V1_StreamClose(USB_HOST_AUDIO_V1_STREAM_HANDLE audioStreamHandle);
```

Returns

None.

Description

This function will close the open audio stream. This closes the association between the application entity that opened the audio stream and the audio stream. The audio stream handle becomes invalid.

Remarks

The device handle becomes invalid after calling this function.

Preconditions

None.

Parameters

Parameters	Description
audioSteamHandle	handle to the audio stream obtained from the USB_HOST_AUDIO_V1_StreamOpen function.

Function

void USB_HOST_AUDIO_V1_StreamClose
(
    USB_HOST_AUDIO_V1_STREAM_HANDLE audioSteamHandle
);

USB_HOST_AUDIO_V1_StreamEventHandlerSet Function

Registers an event handler with the Audio v1.0 Client Driver stream.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamEventHandlerSet(USB_HOST_AUDIO_V1_STREAM_HANDLE handle,
USB_HOST_AUDIO_V1_STREAM_EVENT_HANDLER appAudioHandler, uintptr_t context);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_RESULT_HANDLE_INVALID - The specified audio stream does not exist
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An unknown failure occurred

Description

This function registers a client specific Audio v1.0 stream event handler. The Audio v1.0 Host Client Driver will call the appAudioHandler function specified as the second argument with relevant event and associated event data in response to audio stream data transfers that have been scheduled by the client.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
handle	The handle to the Audio v1.0 stream
eventHandler	A pointer to event handler function. If NULL, events will not be generated.
context	The application specific context that is returned in the event handler

Function

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamEventHandlerSet
(
    USB_HOST_AUDIO_V1_STREAM_HANDLE handle,
    USB_HOST_AUDIO_V1_STREAM_EVENT_HANDLER appAudioHandler,
uintptr_t context
);
```

USB_HOST_AUDIO_V1_0_StreamDisable Function

Schedules an audio stream disable request for the specified audio stream.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_0_STREAM_RESULT USB_HOST_AUDIO_V1_0_StreamDisable(USB_HOST_AUDIO_V1_0_STREAM_HANDLE
streamHandle, USB_HOST_AUDIO_V1_0_REQUEST_HANDLE * requestHandle);
```

Returns

- USB_HOST_AUDIO_V1_0_STREAM_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_0_STREAM_RESULT_HANDLE_INVALID - The specified audio stream does not exist
- USB_HOST_AUDIO_V1_0_STREAM_RESULT_FAILURE - An unknown failure occurred

Description

This function schedules an audio stream disable request for the specified audio stream. A USB_HOST_AUDIO_V1_0_STREAM_EVENT_DISABLE_COMPLETE event is generated when this request is completed. USB_HOST_AUDIO_V1_0_STREAM_EVENT_DISABLE_COMPLETE_DATA returns the status and request handle of the request.

Remarks

None.

Preconditions

The audio stream should have been opened.

Parameters

Parameters	Description
streamHandle	Handle to the Audio v1.0 stream
requestHandle	Handle to the stream disable request

Function

```
USB_HOST_AUDIO_V1_0_STREAM_RESULT USB_HOST_AUDIO_V1_0_StreamDisable
(
```

```
    USB_HOST_AUDIO_V1_0_STREAM_HANDLE streamHandle,
    USB_HOST_AUDIO_V1_0_REQUEST_HANDLE * requestHandle
);
```

USB_HOST_AUDIO_V1_StreamingInterfaceGetFirst Function

Gets the first streaming interface object from the attached Audio Device.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamingInterfaceGetFirst(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ* streamingInterfaceObj);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The request completed successfully
- USB_HOST_AUDIO_V1_RESULT_END_OF_STREAMING_INTERFACE - No more streaming interfaces are available
- USB_HOST_AUDIO_V1_RESULT_DEVICE_UNKNOWN - Device is not attached
- USB_HOST_AUDIO_V1_RESULT_OBJ_INVALID - Audio Device object is invalid
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An error has occurred

Description

This function will get the first streaming interface object from the attached Audio Device.

Remarks

None.

Preconditions

The Audio v1.0 Device should have been attached.

Parameters

Parameters	Description
audioObj	Audio v1.0 client driver object.
streamingInterfaceObj	Pointer to an audio streaming interface object.

Function

```
    USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamingInterfaceGetFirst
(
    USB_HOST_AUDIO_V1_OBJ audioObj,
    USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ* streamingInterfaceObj
);
```

USB_HOST_AUDIO_V1_0_StreamEnable Function

Schedules an audio stream enable request for the specified audio stream.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_0_STREAM_RESULT USB_HOST_AUDIO_V1_0_StreamEnable(USB_HOST_AUDIO_V1_0_STREAM_HANDLE
streamHandle, USB_HOST_AUDIO_V1_0_REQUEST_HANDLE * requestHandle);
```

Returns

- USB_HOST_AUDIO_V1_0_STREAM_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_0_STREAM_RESULT_HANDLE_INVALID - The specified audio stream does not exist
- USB_HOST_AUDIO_V1_0_STREAM_RESULT_FAILURE - An unknown failure occurred

Description

This function schedules an audio stream enable request for the specified audio stream. An audio stream must be enable before scheduling any

data transfer with the stream. A USB_HOST_AUDIO_V1_0_STREAM_EVENT_ENABLE_COMPLETE event is generated when this request is completed. USB_HOST_AUDIO_V1_0_STREAM_EVENT_ENABLE_COMPLETE_DATA returns the status and request handle of the request.

Remarks

None.

Preconditions

The audio stream should have been opened. Only one audio stream from an audio stream group can be enabled at a time.

Parameters

Parameters	Description
streamHandle	Handle to the audio v1.0 stream
requestHandle	Handle to the stream enable request

Function

```
USB_HOST_AUDIO_V1_0_STREAM_RESULT USB_HOST_AUDIO_V1_0_StreamEnable
(
    USB_HOST_AUDIO_V1_0_STREAM_HANDLE streamHandle,
    USB_HOST_AUDIO_V1_0_REQUEST_HANDLE * requestHandle
);
```

USB_HOST_AUDIO_V1_StreamingInterfaceGetNext Function

Gets the next streaming interface object from the attached Audio Device.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamingInterfaceGetNext(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObjCurrent,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ* streamingInterfaceObjNext);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The request completed successfully
- USB_HOST_AUDIO_V1_RESULT_END_OF_STREAMING_INTERFACE - No more streaming interfaces are available
- USB_HOST_AUDIO_V1_RESULT_DEVICE_UNKNOWN - Device is not attached
- USB_HOST_AUDIO_V1_RESULT_OBJ_INVALID - Audio Device object is invalid
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An error has occurred

Description

This function will get the next streaming interface object from the attached Audio Device.

Remarks

None.

Preconditions

The Audio v1.0 Device should have been attached.

Parameters

Parameters	Description
audioObj	Audio Device object.
streamingInterfaceObjCurrent	Current audio streaming interface object.
streamingInterfaceObj	Pointer to audio streaming interface object.

Function

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamingInterfaceGetNext
(
    USB_HOST_AUDIO_V1_OBJ audioObj,
    USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObjCurrent
```

USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ* streamingInterfaceObjNext
);

USB_HOST_AUDIO_V1_0_StreamEventHandlerSet Function

Registers an event handler with the Audio v1.0 Client Driver stream.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_0_STREAM_RESULT
USB_HOST_AUDIO_V1_0_StreamEventHandlerSet(USB_HOST_AUDIO_V1_0_STREAM_HANDLE handle,
USB_HOST_AUDIO_V1_0_STREAM_EVENT_HANDLER appAudioHandler, uintptr_t context);
```

Returns

- USB_HOST_AUDIO_V1_0_STREAM_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_0_STREAM_RESULT_HANDLE_INVALID - The specified audio stream does not exist
- USB_HOST_AUDIO_V1_0_STREAM_RESULT_FAILURE - An unknown failure occurred

Description

This function registers a client specific Audio v1.0 stream event handler. The Audio v1.0 Host Client Driver will call appAudioHandler function specified as 2nd argument with relevant event and associate event data, in response to audio stream data transfers that have been scheduled by the client.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
handle	A handle to the Audio v1.0 stream
eventHandler	A pointer to event handler function. If NULL, events will not be generated.
context	The application specific context that is returned in the event handler

Function

USB_HOST_AUDIO_V1_0_STREAM_RESULT USB_HOST_AUDIO_V1_0_StreamEventHandlerSet
(
USB_HOST_AUDIO_V1_0_STREAM_HANDLE handle,
USB_HOST_AUDIO_V1_0_STREAM_EVENT_HANDLER appAudioHandler,
uintptr_t context
);

USB_HOST_AUDIO_V1_StreamingInterfaceSet Function

Schedules a SET_INTERFACE request to the specified audio stream.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamingInterfaceSet(USB_HOST_AUDIO_V1_STREAM_HANDLE
streamHandle, USB_HOST_AUDIO_V1_REQUEST_HANDLE * requestHandle,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_RESULT_HANDLE_INVALID - The specified audio stream does not exist
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An unknown failure occurred

Description

This function schedules an audio stream enable request for the specified audio stream. An audio stream must be enable before scheduling any data transfer with the stream. A USB_HOST_AUDIO_V1_STREAM_EVENT_ENABLE_COMPLETE event is generated when this request is completed. USB_HOST_AUDIO_V1_STREAM_EVENT_ENABLE_COMPLETE_DATA returns the status and request handle of the request.

Remarks

None.

Preconditions

The audio stream should have been opened. Only one audio stream from an audio stream group can be enabled at a time.

Parameters

Parameters	Description
streamHandle	Handle to the Audio v1.0 stream.
requestHandle	Handle to the stream enable request.

Function

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamingInterfaceSet
(
    USB_HOST_AUDIO_V1_STREAM_HANDLE streamHandle,
USB_INTERFACE_DESCRIPTOR* pInterfaceDesc,
    USB_HOST_AUDIO_V1_REQUEST_HANDLE * requestHandle
);
```

USB_HOST_AUDIO_V1_0_StreamGetFirst Function

Returns information about first audio stream in the specified audio stream group.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_0_RESULT USB_HOST_AUDIO_V1_0_StreamGetFirst(USB_HOST_AUDIO_V1_0_OBJ audioDeviceObj,
uint8_t streamGroupIndex, USB_HOST_AUDIO_V1_0_STREAM_INFO * streamInfo);
```

Returns

- USB_HOST_AUDIO_V1_0_STREAM_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_0_RESULT_OBJ_INVALID - The specified Audio v1.0 client driver object does not exist
- USB_HOST_AUDIO_V1_0_STREAM_RESULT_FAILURE - An unknown failure occurred

Description

This function returns information about the first audio stream in the specified audio stream group. The stream group index is parameter to this function and it can be any value starting from zero to the number of stream groups minus one. Number of stream groups can be obtained by using the USB_HOST_AUDIO_V1_0_NumberOfStreamGroupsGet function.

The streamInfo object is an out parameter to this function.

Remarks

None.

Preconditions

The Audio v1.0 Device should have been attached to the Host.

Parameters

Parameters	Description
audioDeviceObj	Audio v1.0 Client Driver object
streamGroupIndex	Stream group index
streamInfo	Pointer to the streamInfo object

Function

```
USB_HOST_AUDIO_V1_0_RESULT USB_HOST_AUDIO_V1_0_StreamGetFirst
```

```
(
    USB_HOST_AUDIO_V1_0_OBJ audioDeviceObj,
uint8_t streamGroupIndex,
    USB_HOST_AUDIO_V1_0_STREAM_INFO * streamInfo
);
```

USB_HOST_AUDIO_V1_StreamingInterfaceSettingGetFirst Function

Gets the first streaming interface setting object within an audio streaming interface.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamingInterfaceSettingGetFirst(USB_HOST_AUDIO_V1_OBJ
audioObj, USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ * interfaceSettingObj);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The request completed successfully
- USB_HOST_AUDIO_V1_RESULT_END_OF_INTERFACE_SETTINGS - No more streaming interface settings are available
- USB_HOST_AUDIO_V1_RESULT_DEVICE_UNKNOWN - Device is not attached
- USB_HOST_AUDIO_V1_RESULT_OBJ_INVALID - Audio Device object is invalid
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An error has occurred

Description

This function gets the first streaming interface setting object within an audio streaming interface.

Remarks

None.

Preconditions

The Audio v1.0 Device should have been attached.

Parameters

Parameters	Description
audioObj	Audio device object.
streamingInterfaceObj	Audio streaming interface object.
interfaceSettingObj	Pointer to the audio streaming interface setting object.

Function

```
  USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamingInterfaceSettingGetFirst
(
    USB_HOST_AUDIO_V1_OBJ audioObj,
    USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,
    USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ *interfaceSettingObj
);
```

USB_HOST_AUDIO_V1_0_StreamGetNext Function

Returns information about the next audio stream in the specified audio stream group.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_0_RESULT USB_HOST_AUDIO_V1_0_StreamGetNext(USB_HOST_AUDIO_V1_0_STREAM_OBJ audioStreamObj,
USB_HOST_AUDIO_V1_0_STREAM_INFO * streamInfo);
```

Returns

- USB_HOST_AUDIO_V1_0_STREAM_RESULT_SUCCESS - The operation was successful

- USB_HOST_AUDIO_V1_0_RESULT_OBJ_INVALID - The specified Audio v1.0 client driver object does not exist
- USB_HOST_AUDIO_V1_0_STREAM_RESULT_FAILURE - An unknown failure occurred
- USB_HOST_AUDIO_V1_0_RESULT_END_OF_STREAM_LIST - There are no more audio streams in the stream group

Description

This function returns information about next audio stream in the specified Audio stream group. The USB_HOST_AUDIO_V1_0_StreamGetFirst function should have been called at least once on the same audio stream group before calling this function. Then, calling this function repeatedly on the stream group will return information about the next audio stream in the stream group. When there are no more audio streams to report, the function returns USB_HOST_AUDIO_V1_0_RESULT_END_OF_STREAM_LIST.

Calling the USB_HOST_AUDIO_V1_0_StreamGetFirst function on the stream group index after the USB_HOST_AUDIO_V1_0_StreamGetNext function has been called will cause the Audio v1.0 Client Driver to reset the audio stream group to point to the first stream in the stream group.

Remarks

None.

Preconditions

The USB_HOST_AUDIO_V1_0_StreamGetFirst function must have been called before calling this function.

Parameters

Parameters	Description
audioStreamObj	Present audio stream object
streamInfo	Pointer to the streamInfo object

Function

```
USB_HOST_AUDIO_V1_0_RESULT USB_HOST_AUDIO_V1_0_StreamGetNext
(
    USB_HOST_AUDIO_V1_0_STREAM_OBJ audioStreamObj,
    USB_HOST_AUDIO_V1_0_STREAM_INFO * streamInfo
);
```

USB_HOST_AUDIO_V1_StreamingInterfaceSettingGetNext Function

Gets the next streaming interface setting object within an audio streaming interface.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamingInterfaceSettingGetNext(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObjCurrent,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ * interfaceSettingObjNext);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The request completed successfully
- USB_HOST_AUDIO_V1_RESULT_END_OF_INTERFACE_SETTINGS - No more streaming interface settings are available
- USB_HOST_AUDIO_V1_RESULT_DEVICE_UNKNOWN - Device is not attached
- USB_HOST_AUDIO_V1_RESULT_OBJ_INVALID - Audio Device object is invalid
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An error has occurred

Description

This function gets the next streaming interface setting object within an audio streaming interface.

Remarks

None.

Preconditions

The Audio v1.0 Device should have been attached.

Parameters

Parameters	Description
audioObj	Audio Device object
streamingInterfaceObj	Audio streaming interface object
interfaceSettingObjCurrent	Current audio streaming interface setting object
interfaceSettingObjNext	Pointer to the next audio streaming interface setting object

Function

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamingInterfaceSettingGetNext
(
    USB_HOST_AUDIO_V1_OBJ audioObj,
    USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,
    USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObjCurrent,
    USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ *interfaceSettingObjNext
);
```

USB_HOST_AUDIO_V1_0_StreamSamplingRateSet Function

Schedules an audio stream set sampling rate request for the specified audio stream.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_0_STREAM_RESULT
USB_HOST_AUDIO_V1_0_StreamSamplingRateSet(USB_HOST_AUDIO_V1_0_STREAM_HANDLE streamHandle,
USB_HOST_AUDIO_V1_0_REQUEST_HANDLE * requestHandle, uint32_t * samplingRate);
```

Returns

- USB_HOST_AUDIO_V1_0_STREAM_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_0_STREAM_RESULT_HANDLE_INVALID - The specified audio stream does not exist
- USB_HOST_AUDIO_V1_0_STREAM_RESULT_FAILURE - An unknown failure occurred

Description

This function schedules an audio stream set sampling rate request for the specified audio stream. A USB_HOST_AUDIO_V1_0_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE event is generated when this request is completed. USB_HOST_AUDIO_V1_0_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE_DATA returns the status and request handle of the request.

Remarks

None.

Preconditions

The audio stream should have been opened.

Parameters

Parameters	Description
streamHandle	Handle to the Audio v1.0 stream
requestHandle	Handle to the stream set sampling rate request
samplingRate	Pointer to the sampling rate

Function

```
USB_HOST_AUDIO_V1_0_STREAM_RESULT USB_HOST_AUDIO_V1_0_StreamSamplingRateSet
(
    USB_HOST_AUDIO_V1_0_STREAM_HANDLE streamHandle,
    USB_HOST_AUDIO_V1_0_REQUEST_HANDLE requestHandle,
uint32_t* samplingRate
);
```

USB_HOST_AUDIO_V1_StreamOpen Function

Opens the specified audio stream.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_STREAM_HANDLE USB_HOST_AUDIO_V1_StreamOpen(USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ
audiostreamingInterfaceObj);
```

Returns

Will return a valid handle if the audio stream could be opened successfully. Otherwise, USB_HOST_AUDIO_V1_RESULT_HANDLE_INVALID is returned. The function will return a valid handle if the stream is ready to be opened.

Description

This function will open the specified audio stream. Once opened, the audio stream can be accessed via the handle that this function returns. The audiostreamingInterfaceObj parameter is the value returned in the USB_HOST_AUDIO_V1_StreamingInterfaceGetFirst or USB_HOST_AUDIO_V1_StreamingInterfaceGetNext functions.

Remarks

None.

Preconditions

The audio streaming interface object should be valid.

Parameters

Parameters	Description
audiostreamingInterfaceObj	Audio streaming interface object

Function

```
USB_HOST_AUDIO_V1_STREAM_HANDLE USB_HOST_AUDIO_V1_StreamOpen
(
    USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ audiostreamingInterfaceObj
);
```

USB_HOST_AUDIO_V1_StreamRead Function

Schedules an audio stream read request for the specified audio stream.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamRead(USB_HOST_AUDIO_V1_STREAM_HANDLE streamHandle,
USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE * transferHandle, void * source, size_t length);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_RESULT_HANDLE_INVALID - The specified audio stream does not exist
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An unknown failure occurred

Description

This function schedules an audio stream read request for the specified audio stream. A USB_HOST_AUDIO_V1_STREAM_EVENT_READ_COMPLETE event is generated when this request is completed. USB_HOST_AUDIO_V1_STREAM_EVENT_READ_COMPLETE_DATA returns the status and request handle of the request.

Remarks

None.

Preconditions

The audio stream should have been opened and enabled. The direction of the audio stream should be USB_HOST_AUDIO_V1_DIRECTION_IN.

Parameters

Parameters	Description
streamHandle	Handle to the Audio v1.0 stream
transferHandle	Handle to the stream read transfer request
source	Pointer to the buffer containing data to be read from the device
length	Amount of data to read (in bytes)

Function

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamRead
(
    USB_HOST_AUDIO_V1_STREAM_HANDLE streamHandle,
    USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE * transferHandle,
void * source,
size_t length
);
```

USB_HOST_AUDIO_V1_StreamWrite Function

Schedules an audio stream write request for the specified audio stream.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamWrite(USB_HOST_AUDIO_V1_STREAM_HANDLE streamHandle,
USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE * transferHandle, void * source, size_t length);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_RESULT_HANDLE_INVALID - The specified audio stream does not exist
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An unknown failure occurred

Description

This function schedules an audio stream write request for the specified audio stream. A USB_HOST_AUDIO_V1_STREAM_EVENT_WRITE_COMPLETE event is generated when this request is completed. USB_HOST_AUDIO_V1_STREAM_EVENT_WRITE_COMPLETE_DATA returns the status and request handle of the request.

Remarks

None.

Preconditions

The audio stream should have been opened and enabled. The direction of the audio stream should be USB_HOST_AUDIO_V1_DIRECTION_OUT.

Parameters

Parameters	Description
streamHandle	Handle to the Audio v1.0 stream
transferHandle	Handle to the stream write transfer request
source	Pointer to the buffer containing data to be written to the device
length	Amount of data to write (in bytes)

Function

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamWrite
(
    USB_HOST_AUDIO_V1_STREAM_HANDLE streamHandle,
    USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE * transferHandle,
```

void * source,
size_t length
);

USB_HOST_AUDIO_V1_StreamingInterfaceBitResolutionGet Function

Returns the bit resolution of the specified streaming interface setting.

File

usb_host_audio_v1_0.h

C

```
uint8_t USB_HOST_AUDIO_V1_StreamingInterfaceBitResolutionGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj);
```

Returns

The bit resolution size of the audio streaming interface setting.

Description

This function returns the bit resolution size of the specified streaming interface setting.

Remarks

None.

Preconditions

The Audio v1.0 Device should have been attached.

Parameters

Parameters	Description
audioObj	Audio Device object
streamingInterfaceObj	Audio streaming interface object
interfaceSettingObj	Audio streaming interface setting object

Function

uint8_t USB_HOST_AUDIO_V1_StreamingInterfaceBitResolutionGet
(
USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj
);

USB_HOST_AUDIO_V1_StreamingInterfaceChannelNumbersGet Function

Returns the number of channels of the specified streaming interface setting.

File

usb_host_audio_v1_0.h

C

```
uint8_t USB_HOST_AUDIO_V1_StreamingInterfaceChannelNumbersGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj);
```

Returns

The number of channels present in the audio streaming interface setting.

Description

This function returns the number of channels of the specified streaming interface setting.

Remarks

None.

Preconditions

The Audio v1.0 Device should have been attached.

Parameters

Parameters	Description
audioObj	Audio Device object
streamingInterfaceObj	Audio streaming interface object
interfaceSettingObj	Audio streaming interface setting object

Function

uint8_t USB_HOST_AUDIO_V1_StreamingInterfaceChannelNumbersGet

(

USB_HOST_AUDIO_V1_OBJ audioObj,

USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,

USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj

);

USB_HOST_AUDIO_V1_StreamingInterfaceDirectionGet Function

Returns the direction of the specified streaming interface setting.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_STREAM_DIRECTION USB_HOST_AUDIO_V1_StreamingInterfaceDirectionGet(USB_HOST_AUDIO_V1_OBJ audioObj, USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj);
```

Returns

- USB_HOST_AUDIO_V1_DIRECTION_OUT - Host to Device
- USB_HOST_AUDIO_V1_DIRECTION_IN - Device to Host

Description

This function returns the direction of the specified streaming interface setting.

Remarks

None.

Preconditions

The Audio v1.0 Device should have been attached.

Parameters

Parameters	Description
audioObj	Audio Device object
streamingInterfaceObj	Audio streaming interface object
interfaceSettingObj	Audio streaming interface setting object

Function

USB_HOST_AUDIO_V1_STREAM_DIRECTION USB_HOST_AUDIO_V1_StreamingInterfaceDirectionGet

(

USB_HOST_AUDIO_V1_OBJ audioObj,

USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,

USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj

);

USB_HOST_AUDIO_V1_StreamingInterfaceFormatTagGet Function

Returns the format tag of the specified streaming interface setting.

File

usb_host_audio_v1_0.h

C

```
USB_AUDIO_V1_FORMAT_TAG USB_HOST_AUDIO_V1_StreamingInterfaceFormatTagGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj);
```

Returns

The format tag of the audio streaming interface setting.

Description

This function returns the format tag link of the specified streaming interface setting.

Remarks

None.

Preconditions

The Audio v1.0 Device should have been attached.

Parameters

Parameters	Description
audioObj	Audio Device object
streamingInterfaceObj	Audio streaming interface object
interfaceSettingObj	Audio streaming interface setting object

Function

uint8_t USB_HOST_AUDIO_V1_StreamingInterfaceFormatTagGet

(

USB_HOST_AUDIO_V1_OBJ audioObj,

USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,

USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj

);

USB_HOST_AUDIO_V1_StreamingInterfaceSamplingFrequenciesGet Function

Returns the sampling frequencies supported by the specified streaming interface setting.

File

usb_host_audio_v1_0.h

C

```
uint8_t* USB_HOST_AUDIO_V1_StreamingInterfaceSamplingFrequenciesGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj);
```

Returns

A pointer to the sampling frequencies supported by the audio streaming interface setting.

Description

This function returns the sampling frequencies supported by the specified streaming interface setting.

Remarks

None.

Preconditions

The Audio v1.0 Device should have been attached.

Parameters

Parameters	Description
audioObj	Audio Device object
streamingInterfaceObj	Audio streaming interface object
interfaceSettingObj	Audio streaming interface setting object

Function

uint8_t* USB_HOST_AUDIO_V1_StreamingInterfaceSamplingFrequenciesGet
(
USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj
);

USB_HOST_AUDIO_V1_StreamingInterfaceSamplingFrequencyTypeGet Function

Returns the sampling frequency type of the specified streaming interface setting.

File

usb_host_audio_v1_0.h

C

```
uint8_t USB_HOST_AUDIO_V1_StreamingInterfaceSamplingFrequencyTypeGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj);
```

Returns

The sampling frequency type of the audio streaming interface setting.

- 0 - Continuous Sampling frequency is supported
- 1 to 255 - The number of discrete sampling frequencies supported by the audio streaming interface

Description

This function returns the sampling frequency type of the specified streaming interface setting.

Remarks

None.

Preconditions

The Audio v1.0 Device should have been attached.

Parameters

Parameters	Description
audioObj	Audio Device object
streamingInterfaceObj	Audio streaming interface object
interfaceSettingObj	Audio streaming interface setting object

Function

uint8_t USB_HOST_AUDIO_V1_StreamingInterfaceSamplingFrequencyTypeGet
(
USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj
);

USB_HOST_AUDIO_V1_StreamingInterfaceSubFrameSizeGet Function

Returns the sub-frame size of the specified streaming interface setting.

File

usb_host_audio_v1_0.h

C

```
uint8_t USB_HOST_AUDIO_V1_StreamingInterfaceSubFrameSizeGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj);
```

Returns

The sub-frame size of the audio streaming interface setting.

Description

This function returns the sub-frame size of the specified streaming interface setting.

Remarks

None.

Preconditions

The Audio v1.0 Device should have been attached.

Parameters

Parameters	Description
audioObj	Audio Device object
streamingInterfaceObj	Audio streaming interface object
interfaceSettingObj	Audio streaming interface setting object

Function

uint8_t USB_HOST_AUDIO_V1_StreamingInterfaceSubFrameSizeGet

(

USB_HOST_AUDIO_V1_OBJ audioObj,

USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,

USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj

);

USB_HOST_AUDIO_V1_StreamingInterfaceTerminalLinkGet Function

Returns the terminal link of the specified streaming interface setting.

File

usb_host_audio_v1_0.h

C

```
uint8_t USB_HOST_AUDIO_V1_StreamingInterfaceTerminalLinkGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,
USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj);
```

Returns

The terminal link of the audio streaming interface setting.

Description

This function returns the terminal link of the specified streaming interface setting.

Remarks

None.

Preconditions

The Audio v1.0 Device should have been attached.

Parameters

Parameters	Description
audioObj	Audio Device object
streamingInterfaceObj	Audio streaming interface object
interfaceSettingObj	Audio streaming interface setting object

Function

```
uint8_t USB_HOST_AUDIO_V1_StreamingInterfaceTerminalLinkGet
(
    USB_HOST_AUDIO_V1_OBJ audioObj,
    USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ streamingInterfaceObj,
    USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ interfaceSettingObj
);
```

USB_HOST_AUDIO_V1_StreamSamplingFrequencyGet Function

Schedules an audio stream get sampling rate request for the specified audio stream.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamSamplingFrequencyGet(USB_HOST_AUDIO_V1_STREAM_HANDLE
streamHandle, USB_HOST_AUDIO_V1_REQUEST_HANDLE * requestHandle, uint32_t * samplingFrequency);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_RESULT_HANDLE_INVALID - The specified audio stream does not exist
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An unknown failure occurred

Description

This function schedules an audio stream set sampling rate request for the specified audio stream. A USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE event is generated when this request is completed. USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE_DATA returns the status and request handle of the request.

Remarks

None.

Preconditions

The audio stream should have been opened.

Parameters

Parameters	Description
streamHandle	Handle to the Audio v1.0 stream
requestHandle	Handle to the stream set sampling rate request
samplingRate	Pointer to the sampling rate

Function

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamSamplingFrequencyGet
(
    USB_HOST_AUDIO_V1_STREAM_HANDLE streamHandle,
    USB_HOST_AUDIO_V1_REQUEST_HANDLE requestHandle,
uint32_t *samplingFrequency
)
```

USB_HOST_AUDIO_V1_StreamSamplingFrequencySet Function

Schedules an audio stream set sampling rate request for the specified audio stream.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamSamplingFrequencySet(USB_HOST_AUDIO_V1_STREAM_HANDLE
streamHandle, USB_HOST_AUDIO_V1_REQUEST_HANDLE * requestHandle, uint32_t * samplingFrequency);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_RESULT_HANDLE_INVALID - The specified audio stream does not exist
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An unknown failure occurred

Description

This function schedules an audio stream set sampling rate request for the specified audio stream. A USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE event is generated when this request is completed. USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE_DATA returns the status and request handle of the request.

Remarks

None.

Preconditions

The audio stream should have been opened.

Parameters

Parameters	Description
streamHandle	Handle to the Audio v1.0 stream
requestHandle	Handle to the stream set sampling rate request
samplingRate	Pointer to the sampling rate

Function

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_StreamSamplingFrequencySet
(
    USB_HOST_AUDIO_V1_STREAM_HANDLE streamHandle,
    USB_HOST_AUDIO_V1_REQUEST_HANDLE requestHandle,
uint32_t *samplingFrequency
)
```

USB_HOST_AUDIO_V1_0_StreamRead Function

Schedules an audio stream read request for the specified audio stream.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_0_StreamRead(USB_HOST_AUDIO_V1_STREAM_HANDLE streamHandle,
USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE * transferHandle, void * source, size_t length);
```

Returns

- USB_HOST_AUDIO_V1_0_STREAM_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_0_STREAM_RESULT_HANDLE_INVALID - The specified audio stream does not exist
- USB_HOST_AUDIO_V1_0_STREAM_RESULT_FAILURE - An unknown failure occurred

Description

This function schedules an audio stream read request for the specified audio stream. A USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE event is generated when this request is completed. USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE_DATA returns the status and request handle of the request.

Remarks

None.

Preconditions

The audio stream should have been opened and enabled. The direction of the audio stream should be USB_HOST_AUDIO_V1_0_DIRECTION_IN.

Parameters

Parameters	Description
streamHandle	Handle to the Audio v1.0 stream
transferHandle	Handle to the stream read transfer request
source	Pointer to the buffer containing data to be read from the device
length	Amount of data to read (in bytes)

Function

```
USB_HOST_AUDIO_V1_0_STREAM_RESULT USB_HOST_AUDIO_V1_0_StreamRead
(
    USB_HOST_AUDIO_V1_0_STREAM_HANDLE streamHandle,
    USB_HOST_AUDIO_V1_0_STREAM_TRANSFER_HANDLE * transferHandle,
void * source,
size_t length
);
```

USB_HOST_AUDIO_V1_0_StreamWrite Function

Schedules an audio stream write request for the specified audio stream.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_0_StreamWrite(USB_HOST_AUDIO_V1_STREAM_HANDLE streamHandle,
USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE * transferHandle, void * source, size_t length);
```

Returns

- USB_HOST_AUDIO_V1_0_STREAM_RESULT_SUCCESS - The operation was successful
- USB_HOST_AUDIO_V1_0_STREAM_RESULT_HANDLE_INVALID - The specified audio stream does not exist
- USB_HOST_AUDIO_V1_0_STREAM_RESULT_FAILURE - An unknown failure occurred

Description

This function schedules an audio stream write request for the specified audio stream. A USB_HOST_AUDIO_V1_0_STREAM_EVENT_WRITE_COMPLETE event is generated when this request is completed. USB_HOST_AUDIO_V1_0_STREAM_EVENT_WRITE_COMPLETE_DATA returns the status and request handle of the request.

Remarks

None.

Preconditions

The audio stream should have been opened and enabled. The direction of the audio stream should be USB_HOST_AUDIO_V1_0_DIRECTION_OUT.

Parameters

Parameters	Description
streamHandle	Handle to the Audio v1.0 stream
transferHandle	Handle to the stream write transfer request
source	Pointer to the buffer containing data to be written to the device
length	Amount of data to write (in bytes)

Function

```
USB_HOST_AUDIO_V1_0_STREAM_RESULT USB_HOST_AUDIO_V1_0_StreamWrite
(
```

USB_HOST_AUDIO_V1_0_STREAM_HANDLE streamHandle,
USB_HOST_AUDIO_V1_0_STREAM_TRANSFER_HANDLE * transferHandle,
void * source,
size_t length
);

c) Other Functions

USB_HOST_AUDIO_V1_TerminalInputChannelConfigGet Function

Returns a structure that describes the spatial location of the logical channels of in the terminal's output audio channel cluster.

File

usb_host_audio_v1_0.h

C

```
USB_AUDIO_CHANNEL_CONFIG USB_HOST_AUDIO_V1_TerminalInputChannelConfigGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject);
```

Returns

The structure that describes the spatial location of the logical channels.

Description

This function returns a structure that describes the spatial location of the logical channels of in the terminal's output audio channel cluster. This function is only applicable to an input terminal. Prior to calling this function the entity object should be obtained by calling USB_HOST_AUDIO_V1_ControlEntityGetFirst, USB_HOST_AUDIO_V1_ControlEntityGetNext, or USB_HOST_AUDIO_V1_EntityObjectGet.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 device object
entityObject	Audio control entity object

Function

USB_AUDIO_CHANNEL_CONFIG USB_HOST_AUDIO_V1_TerminalInputChannelConfigGet
(
USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject
);

USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeRangeGet Function

Schedules a control request to the Audio Device feature unit to get the range supported by the volume control on the specified channel.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeRangeGet(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject, USB_HOST_AUDIO_V1_REQUEST_HANDLE * requestHandle,
uint8_t channelNumber, void * data, size_t size);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The request was scheduled successfully. requestHandle will contain a valid request handle.
- USB_HOST_AUDIO_V1_RESULT_BUSY - The control request mechanism is currently busy. Retry the request.
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An unknown failure occurred. requestHandle will contain USB_HOST_AUDIO_V1_0_REQUEST_HANDLE_INVALID.
- USB_HOST_AUDIO_V1_RESULT_PARAMETER_INVALID - The data pointer or requestHandle pointer is NULL

Description

This function schedules a control request to the Audio Device feature unit to get the range supported by the volume control on the specified channel.

Prior to calling this function the user should call the USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeSubRangeNumbersGet function to know how many sub-ranges are supported.

Users should calculate the 'size' parameter of this function, as follows:

```
size = Size of number of ranges + nSubRanges * (Size (MIN) + Size (MAX) + Size of (RES))
```

If the request was scheduled successfully, the requestHandle parameter will contain a request handle that uniquely identifies this request. If the request could not be scheduled successfully, requestHandle will contain USB_HOST_AUDIO_V1_REQUEST_HANDLE_INVALID.

When the control request completes, the Audio v1.0 Client Driver will call the callback function that was set using the USB_HOST_AUDIO_V1_EntityRequestCallbackSet function. The context parameter specified here will be returned in the callback.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 Device object
entityObject	Audio control entity object
requestHandle	Output parameter that will contain the handle to this request
channelNumber	Channel number to which the volume control is addressed
nSubRanges	Output parameter that will contain the number of sub-ranges when the request is completed and a callback is received

Function

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeRangeGet
(
    USB_HOST_AUDIO_V1_OBJ  audioObj,
    USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject,
    USB_HOST_AUDIO_V1_REQUEST_HANDLE * requestHandle,
uint8_t channelNumber,
void * data,
size_t size
);
```

USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeSubRangeNumbersGet Function

Schedules a control request to an Audio Device feature unit to get the number of sub-ranges supported by the volume control on the specified channel.

File

usb_host_audio_v1_0.h

C

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeSubRangeNumbersGet(USB_HOST_AUDIO_V1_OBJ audioObj, USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject, USB_HOST_AUDIO_V1_REQUEST_HANDLE * requestHandle, uint8_t channelNumber, uint16_t * nSubRanges);
```

Returns

- USB_HOST_AUDIO_V1_RESULT_SUCCESS - The request was scheduled successfully. requestHandle will contain a valid request handle.
- USB_HOST_AUDIO_V1_RESULT_BUSY - The control request mechanism is currently busy. Retry the request.
- USB_HOST_AUDIO_V1_RESULT_FAILURE - An unknown failure occurred. requestHandle will contain USB_HOST_AUDIO_V1_0_REQUEST_HANDLE_INVALID.
- USB_HOST_AUDIO_V1_RESULT_PARAMETER_INVALID - The data pointer or requestHandle pointer is NULL

Description

This function schedules a control request to the Audio Device feature unit to get the number of sub-ranges supported by the volume control on the specified channel. Prior to calling this function the user should check if volume control exists on the specified channel by calling the USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeExists function.

If the request was scheduled successfully, the requestHandle parameter will contain a request handle that uniquely identifies this request. If the request could not be scheduled successfully, requestHandle will contain USB_HOST_AUDIO_V1_REQUEST_HANDLE_INVALID.

When the control request completes, the Audio v1.0 Client Driver will call the callback function that was set using the USB_HOST_AUDIO_V1_EntityRequestCallbackSet function. The context parameter specified here will be returned in the callback.

Remarks

None.

Parameters

Parameters	Description
audioObj	USB Host Audio v1.0 Device object
entityObject	Audio control entity object
requestHandle	Output parameter that will contain the handle to this request
channelNumber	Channel number to which the volume control is addressed
nSubRanges	Output parameter that will contain the number of sub-ranges when the request is completed and a callback is received

Function

```
USB_HOST_AUDIO_V1_RESULT USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeSubRangeNumbersGet
(
    USB_HOST_AUDIO_V1_OBJ  audioObj,
    USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ entityObject,
    USB_HOST_AUDIO_V1_REQUEST_HANDLE * requestHandle,
uint8_t channelNumber,
uint16_t *nSubRanges
);
```

d) Data Types and Constants

USB_HOST_AUDIO_V1_ATTACH_EVENT_HANDLER Type

USB Host Audio v1.0 Client Driver attach event handler function pointer type.

File

usb_host_audio_v1_0.h

C

```
typedef void (* USB_HOST_AUDIO_V1_ATTACH_EVENT_HANDLER)(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_EVENT event, uintptr_t context);
```

Description

USB Host Audio v1.0 Client Driver Attach Event Handler Function Pointer Type.

This data type defines the required function signature of the USB Host Audio v1.0 Client Driver attach event handling callback function. The application must register a pointer to the Audio v1.0 Client Driver attach events handling function whose function signature (parameter and return value types) match the types specified by this function pointer to receive attach and detach events callbacks from the Audio v1.0 Client Driver. The application should use the USB_HOST_AUDIO_V1_AttachEventHandlerSet function to register an attach event handler. The client driver will call this function with the relevant event parameters. The descriptions of the event handler function parameters are as follows:

- audioObj - Audio Device object to which this event is directed
- event - Event indicates if it is an Attach or Detach
- context - Value identifying the context of the application that was registered with the event handling function

Remarks

None.

USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ Type

Defines the type of the Audio v1.0 Host control entity object.

File

usb_host_audio_v1_0.h

C

```
typedef uintptr_t USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ;
```

Description

USB Host Audio v1.0 Control Entity Object

This data type defines the type of the object returned by the USB_HOST_AUDIO_V1_ControlEntityGetFirst or USB_HOST_AUDIO_V1_ControlEntityGetNext functions. This application uses this object to get more information about that audio control entity.

Remarks

None.

USB_HOST_AUDIO_V1_ENTITY_REQUEST_CALLBACK Type

USB Host Audio v1.0 class driver control transfer complete callback function pointer type.

File

usb_host_audio_v1_0.h

C

```
typedef void (* USB_HOST_AUDIO_V1_ENTITY_REQUEST_CALLBACK)(USB_HOST_AUDIO_V1_OBJ audioObj,
USB_HOST_AUDIO_V1_REQUEST_HANDLE requestHandle, USB_HOST_AUDIO_V1_RESULT result, size_t size, uintptr_t
context);
```

Description

USB Host Audio v1.0 Class driver Control Transfer Complete Callback Function Pointer type

This data type defines the required function signature of the USB Host Audio v1.0 class driver control transfer complete callback function. The client must provide a pointer to a control transfer complete callback function whose function signature (parameter and return value types) must match the types specified by this function pointer to receive notification when a control transfer has completed. The application should use the USB_HOST_AUDIO_V1_EntityRequestCallbackSet function to register an entity control request callback. The Audio v1.0 client driver will call this function with the relevant event parameters. The descriptions of the event handler function parameters are as follows:

- audioObj - Audio v1.0 client driver object associated with this event
- requestHandle - Request handle of the control transfer request that caused this event
- result - Completion result of the control transfer. This will be USB_HOST_AUDIO_V1_RESULT_SUCCESS if the control transfer completed successfully, USB_HOST_AUDIO_V1_RESULT_FAILURE if an unknown failure occurred, or USB_HOST_AUDIO_V1_RESULT_REQUEST_STALLED if the request was stalled.
- size - Size of the data stage that was transferred
- context - Value identifying the context of the application that was provided when the USB_HOST_AUDIO_V1_ControlRequest function was called

Remarks

None.

USB_HOST_AUDIO_V1_EVENT Enumeration

Identifies the possible events that the Audio v1.0 Class Driver attach event handler can generate.

File

usb_host_audio_v1_0.h

C

```
typedef enum {
  USB_HOST_AUDIO_V1_EVENT_ATTACH,
  USB_HOST_AUDIO_V1_EVENT_DETACH
} USB_HOST_AUDIO_V1_EVENT;
```

Members

Members	Description
USB_HOST_AUDIO_V1_EVENT_ATTACH	This event occurs when the Host layer has detected the Audio v1.0 Class Driver instance from a USB Audio v1.0 Device. There is no event data associated with this event.

USB_HOST_AUDIO_V1_EVENT_DETACH	This event occurs when host layer has detached the Audio v1.0 Class Driver instance from a USB Audio v1.0 Device. This can happen if the device itself was detached or if the device configuration was changed. There is no event data associated with this event.

Description

Audio v1.0 Class Driver Events

This enumeration identifies the possible events that the Audio v1.0 Class Driver attach event handler can generate. The application should register an event handler using the USB_HOST_AUDIO_V1_AttachEventHandlerSet function to receive Audio v1.0 Class Driver Attach events.

USB_HOST_AUDIO_V1_OBJ Type

Defines the type of the Audio v1.0 Host client object.

File

usb_host_audio_v1_0.h

C

```
typedef uintptr_t USB_HOST_AUDIO_V1_OBJ;
```

Description

USB Host Audio v1.0 Object

This data type defines the type of the Audio Host client object. This type is returned by the client driver attach event handler and is used by the application to open the attached Audio v1.0 Device.

Remarks

None.

USB_HOST_AUDIO_V1_REQUEST_HANDLE Type

USB Host Audio v1.0 Client Driver request handle.

File

usb_host_audio_v1_0.h

C

```
typedef uintptr_t USB_HOST_AUDIO_V1_REQUEST_HANDLE;
```

Description

USB Host Audio v1.0 Client Driver Request Handle

This handle is returned by the Audio v1.0 Host client driver entity control functions and audio stream control request functions. Applications should use this handle to track a request.

Remarks

None.

USB_HOST_AUDIO_V1_RESULT Enumeration

USB Host Audio v1.0 Class Driver result enumeration.

File

usb_host_audio_v1_0.h

C

```
typedef enum {
  USB_HOST_AUDIO_V1_RESULT_FAILURE,
  USB_HOST_AUDIO_V1_RESULT_BUSY,
  USB_HOST_AUDIO_V1_RESULT_REQUEST_STALLED,
  USB_HOST_AUDIO_V1_RESULT_INVALID_PARAMETER,
  USB_HOST_AUDIO_V1_RESULT_DEVICE_UNKNOWN,
  USB_HOST_AUDIO_V1_RESULT_HANDLE_INVALID,
  USB_HOST_AUDIO_V1_RESULT_TRANSFER_ABORTED,
  USB_HOST_AUDIO_V1_RESULT_OBJ_INVALID,
  USB_HOST_AUDIO_V1_RESULT_END_OF_CONTROL_ENTITY,
  USB_HOST_AUDIO_V1_RESULT_END_OF_STREAMING_INTERFACE,
```

```
  USB_HOST_AUDIO_V1_RESULT_END_OF_INTERFACE_SETTINGS,
  USB_HOST_AUDIO_V1_RESULT_SUCCESS
} USB_HOST_AUDIO_V1_RESULT;
```

Members

Members	Description
USB_HOST_AUDIO_V1_RESULT_FAILURE	An unknown failure has occurred
USB_HOST_AUDIO_V1_RESULT_BUSY	The transfer or request could not be scheduled because internal queues are full. The request or transfer should be retried
USB_HOST_AUDIO_V1_RESULT_REQUEST_STALLED	The request was stalled
USB_HOST_AUDIO_V1_RESULT_INVALID_PARAMETER	A required parameter was invalid
USB_HOST_AUDIO_V1_RESULT_DEVICE_UNKNOWN	The associated device does not exist in the system.
USB_HOST_AUDIO_V1_RESULT_HANDLE_INVALID	The specified handle is not valid
USB_HOST_AUDIO_V1_RESULT_TRANSFER_ABORTED	The transfer or requested was aborted
USB_HOST_AUDIO_V1_RESULT_OBJ_INVALID	The specified Audio v1.0 object is invalid
USB_HOST_AUDIO_V1_RESULT_END_OF_CONTROL_ENTITY	No more audio control entity
USB_HOST_AUDIO_V1_RESULT_END_OF_STREAMING_INTERFACE	No more streaming interface settings present in the audio device
USB_HOST_AUDIO_V1_RESULT_END_OF_INTERFACE_SETTINGS	No more interface alternate settings are present in the audio streaming interface
USB_HOST_AUDIO_V1_RESULT_SUCCESS	Indicates that the operation succeeded or the request was accepted and will be processed.

Description

USB Host Audio v1.0 Class Driver Result enumeration.

This enumeration lists the possible USB Host Audio v1.0 Class Driver operation results. These values are returned by Audio v1.0 Class Driver functions.

Remarks

None.

USB_HOST_AUDIO_V1_0_ATTACH_EVENT_HANDLER Type

USB Host Audio v1.0 Client Driver attach event handler function pointer type.

File

usb_host_audio_v1_0.h

C

```
typedef void (* USB_HOST_AUDIO_V1_0_ATTACH_EVENT_HANDLER)(USB_HOST_AUDIO_V1_0_OBJ audioObj,
USB_HOST_AUDIO_V1_0_EVENT event, uintptr_t context);
```

Description

USB Host Audio v1.0 Client Driver Attach Event Handler Function Pointer Type.

This data type defines the required function signature of the USB Host Audio v1.0 Client Driver attach event handling callback function. The application must register a pointer to a Audio v1.0 Client Driver attach events handling function whose function signature (parameter and return value types) match the types specified by this function pointer in order to receive attach and detach events call backs from the Audio v1.0 Client Driver. The client driver will invoke this function with event relevant parameters. The descriptions of the event handler function parameters are as follows:

- audioObj - Handle of the client to which this event is directed
- event - Event indicates if it is an attach or detach
- context - Value identifying the context of the application that was registered with the event handling function

Remarks

None.

USB_HOST_AUDIO_V1_STREAM_DIRECTION Enumeration

USB Host Audio v1.0 Class Driver stream direction.

File

usb_host_audio_v1_0.h

C

```
typedef enum {
  USB_HOST_AUDIO_V1_DIRECTION_OUT,
  USB_HOST_AUDIO_V1_DIRECTION_IN
} USB_HOST_AUDIO_V1_STREAM_DIRECTION;
```

Members

Members	Description
USB_HOST_AUDIO_V1_DIRECTION_OUT	Stream Direction Host to Device
USB_HOST_AUDIO_V1_DIRECTION_IN	Stream Direction Device to Host

Description

USB Host Audio v1.0 Class Driver Stream Direction

This enumeration lists the possible audio stream directions.

Remarks

None.

USB_HOST_AUDIO_V1_STREAM_EVENT Enumeration

Identifies the possible events that the Audio v1.0 Stream can generate.

File

usb_host_audio_v1_0.h

C

```
typedef enum {
  USB_HOST_AUDIO_V1_STREAM_EVENT_READ_COMPLETE,
  USB_HOST_AUDIO_V1_STREAM_EVENT_WRITE_COMPLETE,
  USB_HOST_AUDIO_V1_STREAM_EVENT_INTERFACE_SET_COMPLETE,
  USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_FREQUENCY_SET_COMPLETE,
  USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_FREQUENCY_GET_COMPLETE,
  USB_HOST_AUDIO_V1_STREAM_EVENT_DETACH
} USB_HOST_AUDIO_V1_STREAM_EVENT;
```

Members

Members	Description
USB_HOST_AUDIO_V1_STREAM_EVENT_READ_COMPLETE	This event occurs when a Audio v1.0 stream read operation has completed (i.e., when the data has been received from the connected Audio v1.0 stream). This event is generated after the application calls the USB_HOST_AUDIO_V1_StreamRead function. The eventData parameter in the event callback function will be of a pointer to a USB_HOST_AUDIO_V1_STREAM_EVENT_READ_COMPLETE_DATA structure. This contains details about the transfer handle associated with this read request, the amount of data read and the termination status of the read request.
USB_HOST_AUDIO_V1_STREAM_EVENT_WRITE_COMPLETE	This event occurs when an Audio v1.0 stream write operation has completed (i.e., when the data has been written to the connected Audio v1.0 stream). This event is generated after the application calls the USB_HOST_AUDIO_V1_StreamWrite function. The eventData parameter in the event callback function will be of a pointer to a USB_HOST_AUDIO_V1_STREAM_EVENT_WRITE_COMPLETE_DATA structure. This contains details about the transfer handle associated with this write request, the amount of data written and the termination status of the write request.

USB_HOST_AUDIO_V1_STREAM_EVENT_INTERFACE_SET_COMPLETE	This event occurs when an audio streaming set interface request has been completed. This event is generated after the application calls the USB_HOST_AUDIO_V1_StreamingInterfaceSet function. The eventData parameter in the event callback function will be of a pointer to a USB_HOST_AUDIO_V1_STREAM_EVENT_INTERFACE_SET_COMPLETE_DATA. This contains details about the request handle associated with the interface set request and the termination status of the request.
USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_FREQUENCY_SET_COMPLETE	This event occurs when an Audio v1.0 sampling frequency set request has been completed. This event is generated after the application calls the USB_HOST_AUDIO_V1_StreamSamplingFrequencySet function. The eventData parameter in the event callback function will be of a pointer to a USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_FREQUENCY_SET_COMPLETE_DATA. This contains details about the request handle associated with this sampling frequency set request and the termination status of the request.
USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_FREQUENCY_GET_COMPLETE	This event occurs when an Audio v1.0 sampling frequency get request has been completed. This event is generated after the application calls the USB_HOST_AUDIO_V1_StreamSamplingFrequencyGet function. The eventData parameter in the event call back function will be of a pointer to a USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_FREQUENCY_GET_COMPLETE_DATA. This contains details about the request handle associated with this sampling frequency get request and the termination status of the request.
USB_HOST_AUDIO_V1_STREAM_EVENT_DETACH	This event occurs when an audio stream is detached from the Host.This can happen if the Audio device itself was detached, or if the Audio device configuration was changed. There is no event data associated with this event.

Description

Audio v1.0 Stream Events

This enumeration identifies the possible events that the Audio v1.0 Stream can generate. The application should register an event handler using the USB_HOST_AUDIO_V1_StreamEventHandlerSet function to receive Audio v1.0 stream events.

An event may have data associated with it. Events that are generated due to a transfer of data between the host and device are accompanied by data structures that provide the status of the transfer termination. For example, the USB_HOST_AUDIO_V1_STREAM_EVENT_READ_COMPLETE event is accompanied by a pointer to a USB_HOST_AUDIO_V1_STREAM_EVENT_READ_COMPLETE_DATA data structure. The transferStatus member of this data structure indicates the success or failure of the transfer. A transfer may fail due to the device not responding on the bus, or if the device stalls any stages of the transfer. The event description provides details on the nature of the event and the data that is associated with the event.

USB_HOST_AUDIO_V1_STREAM_EVENT_HANDLER Type

USB Host Audio v1.0 Class Driver stream event handler function pointer type.

File

usb_host_audio_v1_0.h

C

```
typedef USB_HOST_AUDIO_V1_STREAM_EVENT_RESPONSE (*
USB_HOST_AUDIO_V1_STREAM_EVENT_HANDLER)(USB_HOST_AUDIO_V1_STREAM_HANDLE handle,
USB_HOST_AUDIO_V1_STREAM_EVENT event, void * eventData, uintptr_t context);
```

Description

USB Host Audio v1.0 Class Driver Stream Event Handler Function Pointer Type.

This data type defines the required function signature of the USB Host Audio v1.0 Class Driver Stream event handling callback function. The application must register a pointer to the Audio v1.0 Class Driver stream events handling function whose function signature (parameter and return

value types) match the types specified by this function pointer to receive event callbacks from the Audio v1.0 Class Driver. The application should use the USB_HOST_AUDIO_V1_StreamEventHandlerSet function to register an audio stream event handler. The class driver will call this function with the relevant event parameters. The descriptions of the stream event handler function parameters are as follows:

- handle - Handle to the Audio v1.0 stream
- event - Type of event generated
- eventData - This parameter should be type casted to an event specific pointer type based on the event that has occurred. Refer to the USB_HOST_AUDIO_V1_STREAM_EVENT enumeration description for more information.
- context - Value identifying the context of the application that was registered with the event handling function

Remarks

None.

USB_HOST_AUDIO_V1_STREAM_EVENT_INTERFACE_SET_COMPLETE_DATA Structure

USB Host Audio v1.0 class stream control event data.

File

usb_host_audio_v1_0.h

C

```
typedef struct {
  USB_HOST_AUDIO_V1_REQUEST_HANDLE requestHandle;
  USB_HOST_AUDIO_V1_RESULT requestStatus;
} USB_HOST_AUDIO_V1_STREAM_EVENT_INTERFACE_SET_COMPLETE_DATA,
USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE_DATA,
USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_RATE_GET_COMPLETE_DATA;
```

Members

Members	Description
USB_HOST_AUDIO_V1_REQUEST_HANDLE requestHandle;	Transfer handle of this transfer
USB_HOST_AUDIO_V1_RESULT requestStatus;	Transfer termination status

Description

USB Host Audio v1.0 Class Stream Control Event Data.

This data type defines the data structure returned by the Audio V1.0 stream in conjunction with the following events:

- USB_HOST_AUDIO_V1_STREAM_EVENT_INTERFACE_SET_COMPLETE
- USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_FREQUENCY_SET_COMPLETE
- USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_FREQUENCY_GET_COMPLETE

Remarks

None.

USB_HOST_AUDIO_V1_0_CONTROL_CALLBACK Type

USB Host Audio v1.0 Class Driver control transfer complete callback function pointer type.

File

usb_host_audio_v1_0.h

C

```
typedef void (* USB_HOST_AUDIO_V1_0_CONTROL_CALLBACK)(USB_HOST_AUDIO_V1_0_OBJ audioObj,
USB_HOST_AUDIO_V1_0_REQUEST_HANDLE requestHandle, USB_HOST_AUDIO_V1_0_RESULT result, size_t size, uintptr_t
context);
```

Description

USB Host Audio v1.0 Class driver Control Transfer Complete Callback Function Pointer type

This data type defines the required function signature of the USB Host Audio v1.0 Class Driver control transfer complete callback function. The client must provide a pointer to a control transfer complete callback function whose function signature (parameter and return value types) must match the types specified by this function pointer to receive notification when a control transfer has completed. The pointer to the callback function must be specified in USB_HOST_AUDIO_V1_0_ControlRequest function. The Audio v1.0 client driver will invoke this function with event relevant parameters. The descriptions of the event handler function parameters are as follows:

- audioObj - Audio v1.0 client driver object associated with this event

- requestHandle - Request handle of the control transfer request that caused this event
- result - Completion result of the control transfer. This will be USB_HOST_AUDIO_V1_0_RESULT_SUCCESS if the control transfer completed successfully, USB_HOST_AUDIO_V1_0_RESULT_FAILURE if an unknown failure occurred, or USB_HOST_AUDIO_V1_0_RESULT_REQUEST_STALLED if the request was stalled.

size - Size of the data stage that was transferred context - Value identifying the context of the application that was provided when the USB_HOST_AUDIO_V1_0_ControlRequest function was called.

Remarks

None.

USB_HOST_AUDIO_V1_STREAM_EVENT_READ_COMPLETE_DATA Structure

USB Host Audio v1.0 class stream data transfer event data.

File

usb_host_audio_v1_0.h

C

```
typedef struct {
  USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE transferHandle;
  size_t length;
  USB_HOST_AUDIO_V1_RESULT result;
} USB_HOST_AUDIO_V1_STREAM_EVENT_READ_COMPLETE_DATA, USB_HOST_AUDIO_V1_STREAM_EVENT_WRITE_COMPLETE_DATA;
```

Members

Members	Description
USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE transferHandle;	Transfer handle of this transfer
size_t length;	Amount of data transferred
USB_HOST_AUDIO_V1_RESULT result;	Transfer termination status

Description

USB Host Audio v1.0 Class Stream Data Transfer Event Data.

This data type defines the data structure returned by the Audio V1.0 stream in conjunction with the following events:

- USB_HOST_AUDIO_V1_STREAM_EVENT_READ_COMPLETE_DATA
- USB_HOST_AUDIO_V1_STREAM_EVENT_WRITE_COMPLETE_DATA

Remarks

None.

USB_HOST_AUDIO_V1_0_EVENT Macro

Identifies the possible events that the Audio v1.0 Class Driver can generate.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_EVENT USB_HOST_AUDIO_V1_EVENT
```

Description

Audio v1.0 Class Driver Events

This enumeration identifies the possible events that the Audio v1.0 Class Driver can generate. The application should register an event handler using the USB_HOST_AUDIO_V1_0_AttachEventHandlerSet function to receive Audio v1.0 Class Driver events.

USB_HOST_AUDIO_V1_STREAM_EVENT_RESPONSE Enumeration

Returns the type of the USB Host Audio v1.0 stream event handler.

File

usb_host_audio_v1_0.h

C

```
typedef enum {
  USB_HOST_AUDIO_V1_STREAM_EVENT_RESPONSE_NONE
} USB_HOST_AUDIO_V1_STREAM_EVENT_RESPONSE;
```

Members

Members	Description
USB_HOST_AUDIO_V1_STREAM_EVENT_RESPONSE_NONE	This means no response is required

Description

USB Host Audio v1.0 Stream Event Handler Return Type

This enumeration lists the possible return values of the USB Host Audio v1.0 stream event handler.

Remarks

None.

USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE_DATA Structure

USB Host Audio v1.0 class stream control event data.

File

usb_host_audio_v1_0.h

C

```
typedef struct {
  USB_HOST_AUDIO_V1_REQUEST_HANDLE requestHandle;
  USB_HOST_AUDIO_V1_RESULT requestStatus;
} USB_HOST_AUDIO_V1_STREAM_EVENT_INTERFACE_SET_COMPLETE_DATA,
USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE_DATA,
USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_RATE_GET_COMPLETE_DATA;
```

Members

Members	Description
USB_HOST_AUDIO_V1_REQUEST_HANDLE requestHandle;	Transfer handle of this transfer
USB_HOST_AUDIO_V1_RESULT requestStatus;	Transfer termination status

Description

USB Host Audio v1.0 Class Stream Control Event Data.

This data type defines the data structure returned by the Audio V1.0 stream in conjunction with the following events:

- USB_HOST_AUDIO_V1_STREAM_EVENT_INTERFACE_SET_COMPLETE
- USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_FREQUENCY_SET_COMPLETE
- USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_FREQUENCY_GET_COMPLETE

Remarks

None.

USB_HOST_AUDIO_V1_0_OBJ Macro

Defines the type of the Audio v1.0 Host client object.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_OBJ USB_HOST_AUDIO_V1_OBJ
```

Description

USB Host Audio v1.0 Object

This type defines the type of the Audio Host client object. This type is returned by the attach event handler and is used by the application to open the attached Audio v1.0 Device.

Remarks

None.

USB_HOST_AUDIO_V1_STREAM_EVENT_WRITE_COMPLETE_DATA Structure

USB Host Audio v1.0 class stream data transfer event data.

File

usb_host_audio_v1_0.h

C

```
typedef struct {
  USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE transferHandle;
  size_t length;
  USB_HOST_AUDIO_V1_RESULT result;
} USB_HOST_AUDIO_V1_STREAM_EVENT_READ_COMPLETE_DATA, USB_HOST_AUDIO_V1_STREAM_EVENT_WRITE_COMPLETE_DATA;
```

Members

Members	Description
USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE transferHandle;	Transfer handle of this transfer
size_t length;	Amount of data transferred
USB_HOST_AUDIO_V1_RESULT result;	Transfer termination status

Description

USB Host Audio v1.0 Class Stream Data Transfer Event Data.

This data type defines the data structure returned by the Audio V1.0 stream in conjunction with the following events:

- USB_HOST_AUDIO_V1_STREAM_EVENT_READ_COMPLETE_DATA
- USB_HOST_AUDIO_V1_STREAM_EVENT_WRITE_COMPLETE_DATA

Remarks

None.

USB_HOST_AUDIO_V1_0_REQUEST_HANDLE Macro

USB Host Audio v1.0 Client Driver request handle.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_REQUEST_HANDLE USB_HOST_AUDIO_V1_REQUEST_HANDLE
```

Description

USB Host Audio v1.0 Client Driver Request Handle

This is returned by the Audio v1.0 Client Driver command routines and should be used by the application to track the command especially in cases where transfers are queued.

Remarks

None.

USB_HOST_AUDIO_V1_STREAM_HANDLE Type

Defines the type of the Audio v1.0 Host stream handle.

File

usb_host_audio_v1_0.h

C

```
typedef uintptr_t USB_HOST_AUDIO_V1_STREAM_HANDLE;
```

Description

USB Host Audio stream handle

This data type defines the type of the handle returned by USB_HOST_AUDIO_V1_StreamOpen function. The application uses this handle to interact with an Audio Stream.

Remarks

None.

USB_HOST_AUDIO_V1_0_RESULT Enumeration

USB Host Audio v1.0 Class Driver audio result enumeration.

File

usb_host_audio_v1_0.h

C

```
typedef enum {
  USB_HOST_AUDIO_V1_0_RESULT_BUSY = USB_HOST_AUDIO_V1_0_RESULT_TRANSFER_ABORTED,
  USB_HOST_AUDIO_V1_0_RESULT_REQUEST_STALLED,
  USB_HOST_AUDIO_V1_0_RESULT_OBJ_INVALID,
  USB_HOST_AUDIO_V1_0_RESULT_END_OF_STREAM_LIST,
  USB_HOST_AUDIO_V1_0_RESULT_PARAMETER_INVALID,
  USB_HOST_AUDIO_V1_0_RESULT_DEVICE_UNKNOWN,
  USB_HOST_AUDIO_V1_0_RESULT_FAILURE,
  USB_HOST_AUDIO_V1_0_RESULT_FALSE = 0,
  USB_HOST_AUDIO_V1_0_RESULT_TRUE = 1,
  USB_HOST_AUDIO_V1_0_RESULT_SUCCESS = USB_HOST_RESULT_TRUE
} USB_HOST_AUDIO_V1_0_RESULT;
```

Members

Members	Description
USB_HOST_AUDIO_V1_0_RESULT_BUSY = USB_HOST_AUDIO_V1_0_RESULT_TRANSFER_ABORTED	The transfer or request could not be scheduled because internal • queues are full. The request or transfer should be retried
USB_HOST_AUDIO_V1_0_RESULT_REQUEST_STALLED	The request was stalled
USB_HOST_AUDIO_V1_0_RESULT_OBJ_INVALID	The specified Audio v1.0 Object is Invalid
USB_HOST_AUDIO_V1_0_RESULT_END_OF_STREAM_LIST	No more audio stream present in the Device
USB_HOST_AUDIO_V1_0_RESULT_PARAMETER_INVALID	A required parameter was invalid
USB_HOST_AUDIO_V1_0_RESULT_DEVICE_UNKNOWN	The specified device does not exist in the system
USB_HOST_AUDIO_V1_0_RESULT_FAILURE	An unknown failure has occurred
USB_HOST_AUDIO_V1_0_RESULT_FALSE = 0	Indicates a false condition
USB_HOST_AUDIO_V1_0_RESULT_TRUE = 1	Indicate a true condition
USB_HOST_AUDIO_V1_0_RESULT_SUCCESS = USB_HOST_RESULT_TRUE	Indicates that the operation succeeded or the request was accepted and will be processed.

Description

USB Host Audio v1.0 Class Driver Result enumeration.

This enumeration lists the possible USB Host Audio v1.0 Class Driver operation results. These values are returned by Audio v1.0 Class Driver functions.

Remarks

None.

USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE Type

USB Host Audio v1.0 Class Driver stream data transfer handle.

File

usb_host_audio_v1_0.h

C

```
typedef uintptr_t USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE;
```

Description

USB Host Audio v1.0 Class Driver Stream Data Transfer Handle

This handle is returned by the Audio v1.0 Class driver stream data transfer functions and should be used by the application to track the transfer, especially in cases where transfers are queued.

Remarks

None.

USB_HOST_AUDIO_V1_0_STREAM_DIRECTION Macro

USB Host Audio v1.0 Class Driver stream direction.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_STREAM_DIRECTION USB_HOST_AUDIO_V1_STREAM_DIRECTION
```

Description

USB Host Audio v1.0 Class Driver Stream Direction

This macro defines the stream direction of the USB Host Audio v1.0 Class Driver.

Remarks

None.

USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ Type

Defines the type of the Audio v1.0 Host streaming interface object.

File

usb_host_audio_v1_0.h

C

```
typedef uintptr_t USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ;
```

Description

USB Host Audio v1.0 Streaming interface Object

This data type defines the type of the Audio v1.0 Host streaming interface object. This type is returned by the USB_AUDIO_V1_StreamingInterfaceGetFirst and USB_AUDIO_V1_StreamingInterfaceGetNext functions.

Remarks

None.

USB_HOST_AUDIO_V1_0_STREAM_EVENT Enumeration

Identifies the possible events that the Audio v1.0 stream can generate.

File

usb_host_audio_v1_0.h

C

```
typedef enum {
  USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE,
  USB_HOST_AUDIO_V1_0_STREAM_EVENT_WRITE_COMPLETE,
  USB_HOST_AUDIO_V1_0_STREAM_EVENT_ENABLE_COMPLETE,
  USB_HOST_AUDIO_V1_0_STREAM_EVENT_DISABLE_COMPLETE,
  USB_HOST_AUDIO_V1_0_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE
} USB_HOST_AUDIO_V1_0_STREAM_EVENT;
```

Members

Members	Description
USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE	This event occurs when a Audio v1.0 stream read operation has completed (i.e., when the data has been received from the connected Audio v1.0 stream). This event is generated after the application calls the USB_HOST_AUDIO_V1_0_StreamRead function. The eventData parameter in the event callback function will be of a pointer to a USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE_DATA structure. This contains details about the transfer handle associated with this read request, the amount of data read and the termination status of the read request.
USB_HOST_AUDIO_V1_0_STREAM_EVENT_WRITE_COMPLETE	This event occurs when an Audio v1.0 stream write operation has completed (i.e., when the data has been written to the connected Audio v1.0 stream). This event is generated after the application calls the USB_HOST_AUDIO_V1_0_StreamWrte function. The eventData parameter in the event callback function will be of a pointer to a USB_HOST_AUDIO_V1_0_STREAM_EVENT_WRITE_COMPLETE_DATA structure. This contains details about the transfer handle associated with this write request, the amount of data written and the termination status of the write request.
USB_HOST_AUDIO_V1_0_STREAM_EVENT_ENABLE_COMPLETE	This event occurs when an Audio v1.0 stream enable request has been completed. This event is generated after the application calls the USB_HOST_AUDIO_V1_0_StreamEnable function. The eventData parameter in the event callback function will be of a pointer to a USB_HOST_AUDIO_V1_0_STREAM_EVENT_ENABLE_COMPLETE_DATA. This contains details about the request handle associated with this stream enable request and the termination status of the Stream Enable request.
USB_HOST_AUDIO_V1_0_STREAM_EVENT_DISABLE_COMPLETE	This event occurs when an Audio v1.0 stream disable request has been completed. This event is generated after the application calls the USB_HOST_AUDIO_V1_0_StreamDisable function. The eventData parameter in the event callback function will be of a pointer to a USB_HOST_AUDIO_V1_0_STREAM_EVENT_DISABLE_COMPLETE_DATA. This contains details about the request handle associated with this stream disable request and the termination status of the Stream Disable request.
USB_HOST_AUDIO_V1_0_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE	This event occurs when an Audio v1.0 sampling rate set request has been completed. This event is generated after the application calls the USB_HOST_AUDIO_V1_0_StreamSamplingRateSet function. The eventData parameter in the event callback function will be of a pointer to a USB_HOST_AUDIO_V1_0_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE_DATA. This contains details about the request handle associated with this Sampling Rate Set request and the termination status of the stream disable request.

Description

Audio v1.0 Stream Events

This enumeration identifies the possible events that the Audio v1.0 stream can generate. The application should register an event handler using the USB_HOST_AUDIO_V1_0_StreamEventHandlerSet function to receive Audio v1.0 stream events.

An event may have data associated with it. Events that are generated due to a transfer of data between the Host and Device are accompanied by data structures that provide the status of the transfer termination. For example, the USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE event is accompanied by a pointer to a USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE_DATA data structure. The transferStatus member of this data structure indicates the success or failure of the transfer. A transfer may fail due to the Device not responding on the bus if the Device stalls any stages of the transfer or due to NAK time-outs. The event description provides details on the nature of the event and the data that is associated with the event.

USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ Type

Defines the type of the Audio v1.0 Host streaming interface setting object.

File

usb_host_audio_v1_0.h

C

```
typedef uintptr_t USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ;
```

Description

USB Host Audio v1.0 Streaming Interface Setting Object

This data type defines the type of the Audio v1.0 Host streaming interface setting object. This type is returned by the USB_AUDIO_V1_StreamingInterfaceSettingGetFirst and USB_AUDIO_V1_StreamingInterfaceSettingGetNext functions.

Remarks

None.

USB_HOST_AUDIO_V1_0_STREAM_EVENT_DISABLE_COMPLETE_DATA Structure

USB Host Audio v1.0 class stream control event data.

File

usb_host_audio_v1_0.h

C

```
typedef struct {
  USB_HOST_AUDIO_V1_0_REQUEST_HANDLE requestHandle;
  USB_HOST_AUDIO_V1_0_RESULT requestStatus;
} USB_HOST_AUDIO_V1_0_STREAM_EVENT_ENABLE_COMPLETE_DATA,
USB_HOST_AUDIO_V1_0_STREAM_EVENT_DISABLE_COMPLETE_DATA;
```

Members

Members	Description
USB_HOST_AUDIO_V1_0_REQUEST_HANDLE requestHandle;	Transfer handle of this transfer
USB_HOST_AUDIO_V1_0_RESULT requestStatus;	Transfer termination status

Description

USB Host Audio v1.0 Class Stream Control Event Data.

This data type defines the data structure returned by the Audio V1.0 Client Driver in conjunction with the following events:

- USB_HOST_AUDIO_V1_0_STREAM_EVENT_ENABLE_COMPLETE_DATA
- USB_HOST_AUDIO_V1_0_STREAM_EVENT_DISABLE_COMPLETE_DATA

Remarks

None.

USB_HOST_AUDIO_V1_0_STREAM_EVENT_ENABLE_COMPLETE_DATA Structure

USB Host Audio v1.0 class stream control event data.

File

usb_host_audio_v1_0.h

C

```
typedef struct {
  USB_HOST_AUDIO_V1_0_REQUEST_HANDLE requestHandle;
  USB_HOST_AUDIO_V1_0_RESULT requestStatus;
} USB_HOST_AUDIO_V1_0_STREAM_EVENT_ENABLE_COMPLETE_DATA,
USB_HOST_AUDIO_V1_0_STREAM_EVENT_DISABLE_COMPLETE_DATA;
```

Members

Members	Description
USB_HOST_AUDIO_V1_0_REQUEST_HANDLE requestHandle;	Transfer handle of this transfer
USB_HOST_AUDIO_V1_0_RESULT requestStatus;	Transfer termination status

Description

USB Host Audio v1.0 Class Stream Control Event Data.

This data type defines the data structure returned by the Audio V1.0 Client Driver in conjunction with the following events:

- USB_HOST_AUDIO_V1_0_STREAM_EVENT_ENABLE_COMPLETE_DATA
- USB_HOST_AUDIO_V1_0_STREAM_EVENT_DISABLE_COMPLETE_DATA

Remarks

None.

USB_HOST_AUDIO_V1_0_STREAM_EVENT_HANDLER Type

USB Host Audio v1.0 Class Driver stream event handler function pointer type.

File

usb_host_audio_v1_0.h

C

```
typedef USB_HOST_AUDIO_V1_0_STREAM_EVENT_RESPONSE (*
USB_HOST_AUDIO_V1_0_STREAM_EVENT_HANDLER)(USB_HOST_AUDIO_V1_0_STREAM_HANDLE handle,
USB_HOST_AUDIO_V1_0_STREAM_EVENT event, void * eventData, uintptr_t context);
```

Description

USB Host Audio v1.0 Class Driver Stream Event Handler Function Pointer Type.

This data type defines the required function signature of the USB Host Audio v1.0 Class Driver stream event handling callback function. The application must register a pointer to a Audio v1.0 Class Driver stream events handling function whose function signature (parameter and return value types) match the types specified by this function pointer to receive event call backs from the Audio v1.0 Class Driver. The class driver will call this function with relevant event parameters. The descriptions of the event handler function parameters are as follows:

- handle - Handle to the Audio v1.0 stream
- event - Type of event generated
- eventData - This parameter should be type casted to an event specific pointer type based on the event that has occurred. Refer to the USB_HOST_AUDIO_V1_0_STREAM_EVENT enumeration description for more information.
- context - Value identifying the context of the application that was registered with the event handling function

Remarks

None.

USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE_DATA Macro

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE_DATA
USB_HOST_AUDIO_V1_STREAM_EVENT_READ_COMPLETE_DATA
```

Description

This is macro USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE_DATA.

USB_HOST_AUDIO_V1_0_STREAM_EVENT_RESPONSE Macro

Returns the type of the USB Audio v1.0 Host Client Driver event handler.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_STREAM_EVENT_RESPONSE USB_HOST_AUDIO_V1_STREAM_EVENT_RESPONSE
```

Description

USB Host Audio v1.0 Event Handler Return Type

This enumeration lists the possible return values of the USB Audio v1.0 Host Client Driver event handler.

Remarks

None.

USB_HOST_AUDIO_V1_0_STREAM_EVENT_WRITE_COMPLETE_DATA Macro

USB Host Audio v1.0 class stream transfer event data.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_STREAM_EVENT_WRITE_COMPLETE_DATA
USB_HOST_AUDIO_V1_STREAM_EVENT_WRITE_COMPLETE_DATA
```

Description

USB Host Audio v1.0 Class Stream Transfer Event Data.

This data type defines the data structure returned by the Audio V1.0 Client Driver in conjunction with the following events:

- USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE_DATA
- USB_HOST_AUDIO_V1_0_STREAM_EVENT_WRITE_COMPLETE_DATA

Remarks

None.

USB_HOST_AUDIO_V1_0_STREAM_HANDLE Macro

Defines the type of the Audio v1.0 Host stream handle.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_STREAM_HANDLE USB_HOST_AUDIO_V1_STREAM_HANDLE
```

Description

USB Host Audio stream handle

This type defines the type of the handle returned by the USB_HOST_AUDIO_V1_0_StreamOpen function. This application uses this handle to interact with an audio stream.

Remarks

None.

USB_HOST_AUDIO_V1_INTERFACE Macro

USB HOST Audio v1.0 Client Driver interface.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_INTERFACE
```

Description

USB HOST Audio V1 Client Driver Interface

This macro should be used by the application in the TPL table while adding support for the USB Audio v1.0 Host Client Driver.

Remarks

None.

USB_HOST_AUDIO_V1_0_STREAM_INFO Structure

File

usb_host_audio_v1_0.h

C

```
typedef struct {
  USB_HOST_AUDIO_V1_0_STREAM_OBJ streamObj;
  USB_AUDIO_FORMAT_CODE format;
  USB_HOST_AUDIO_V1_0_STREAM_DIRECTION streamDirection;
  uint8_t nChannels;
  uint8_t subFrameSize;
  uint8_t bitResolution;
  uint8_t nSamplingRates;
  uint32_t tSamFreq[USB_HOST_AUDIO_V1_SAMPLING_FREQUENCIES_NUMBER];
} USB_HOST_AUDIO_V1_0_STREAM_INFO;
```

Members

Members	Description
USB_HOST_AUDIO_V1_0_STREAM_OBJ streamObj;	Audio Stream Object. Clients need to pass this object when opening this audio stream using USB_HOST_AUDIO_V1_0_StreamOpen function.
USB_AUDIO_FORMAT_CODE format;	Audio Format code for this Stream
USB_HOST_AUDIO_V1_0_STREAM_DIRECTION streamDirection;	Stream direction
uint8_t nChannels;	Number of physical channels in the audio stream
uint8_t subFrameSize;	Number of bytes occupied by one audio sub-frame
uint8_t bitResolution;	Number of effectively used bits from the available bits in an audio sub-frame
uint8_t nSamplingRates;	Indicates how the sampling frequency can be programmed: 0: Continuous sampling frequency 1..255: Number of discrete sampling frequencies supported by Audio stream
uint32_t tSamFreq[USB_HOST_AUDIO_V1_SAMPLING_FREQUENCIES_NUMBER];	Supported sampling Frequencies

Description

This is type USB_HOST_AUDIO_V1_0_STREAM_INFO.

USB_HOST_AUDIO_V1_REQUEST_HANDLE_INVALID Macro

USB Host Audio v1.0 Client Driver invalid request handle.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_REQUEST_HANDLE_INVALID ((USB_HOST_AUDIO_V1_REQUEST_HANDLE)(-1))
```

Description

USB Host Audio v1.0 Client Driver Invalid Request Handle

This handle is returned by the Audio v1.0 Client driver command routines when the request could not be scheduled.

Remarks

None.

USB_HOST_AUDIO_V1_0_STREAM_OBJ Type

Defines the type of the Audio v1.0 Host stream object.

File

usb_host_audio_v1_0.h

C

```
typedef uintptr_t USB_HOST_AUDIO_V1_0_STREAM_OBJ;
```

Description

USB Host Audio v1.0 Stream Object

This type defines the type of the Audio v1.0 Host stream object. This type is returned by USB_AUDIO_V1_0_StreamGetFirst and USB_AUDIO_V1_0_StreamGetNext as part of USB_HOST_AUDIO_V1_0_STREAM_INFO structure.

Remarks

None.

USB_HOST_AUDIO_V1_STREAM_HANDLE_INVALID Macro

Defines Audio v1.0 Host stream invalid handle.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_STREAM_HANDLE_INVALID ((USB_HOST_AUDIO_V1_STREAM_HANDLE)(-1))
```

Description

USB Host Audio stream Invalid handle

This handle is returned by the USB_HOST_AUDIO_V1_StreamOpen function when a stream open has failed.

Remarks

None.

USB_HOST_AUDIO_V1_0_STREAM_RESULT Enumeration

USB Host Audio v1.0 stream result enumeration.

File

usb_host_audio_v1_0.h

C

```
typedef enum {
  USB_HOST_AUDIO_V1_0_STREAM_RESULT_REQUEST_BUSY = USB_HOST_RESULT_REQUEST_BUSY,
  USB_HOST_AUDIO_V1_0_STREAM_RESULT_TRANSFER_ABORTED,

  USB_HOST_AUDIO_V1_0_STREAM_RESULT_HANDLE_INVALID,
  USB_HOST_AUDIO_V1_0_STREAM_RESULT_END_OF_DEVICE_LIST,
  USB_HOST_AUDIO_V1_0_STREAM_RESULT_INTERFACE_UNKNOWN,
  USB_HOST_AUDIO_V1_0_STREAM_RESULT_PARAMETER_INVALID,
  USB_HOST_AUDIO_V1_0_STREAM_RESULT_CONFIGURATION_UNKNOWN,
  USB_HOST_AUDIO_V1_0_STREAM_RESULT_BUS_NOT_ENABLED,
  USB_HOST_AUDIO_V1_0_STREAM_RESULT_BUS_UNKNOWN,
  USB_HOST_AUDIO_V1_0_STREAM_RESULT_UNKNOWN,
  USB_HOST_AUDIO_V1_0_STREAM_RESULT_FAILURE,
  USB_HOST_AUDIO_V1_0_STREAM_RESULT_FALSE = 0,
  USB_HOST_AUDIO_V1_0_STREAM_RESULT_TRUE = 1,
  USB_HOST_AUDIO_V1_0_STREAM_SUCCESS = USB_HOST_RESULT_TRUE
} USB_HOST_AUDIO_V1_0_STREAM_RESULT;
```

Members

Members	Description
USB_HOST_AUDIO_V1_0_STREAM_RESULT_REQUEST_BUSY = USB_HOST_RESULT_REQUEST_BUSY	The transfer or request could not be scheduled because internal • queues are full. The request or transfer should be retried
USB_HOST_AUDIO_V1_0_STREAM_RESULT_TRANSFER_ABORTED	Request was aborted

USB_HOST_AUDIO_V1_0_STREAM_RESULT_REQUEST_STALLED	Request was stalled
USB_HOST_AUDIO_V1_0_STREAM_RESULT_HANDLE_INVALID	The specified Stream Handle is not valid
USB_HOST_AUDIO_V1_0_STREAM_RESULT_END_OF_DEVICE_LIST	The end of the device list was reached.
USB_HOST_AUDIO_V1_0_STREAM_RESULT_INTERFACE_UNKNOWN	The specified interface is not available
USB_HOST_AUDIO_V1_0_STREAM_RESULT_PARAMETER_INVALID	A NULL parameter was passed to the function
USB_HOST_AUDIO_V1_0_STREAM_RESULT_CONFIGURATION_UNKNOWN	The specified configuration does not exist on this device.
USB_HOST_AUDIO_V1_0_STREAM_RESULT_BUS_NOT_ENABLED	A bus operation was requested but the bus was not operated
USB_HOST_AUDIO_V1_0_STREAM_RESULT_BUS_UNKNOWN	The specified bus does not exist in the system
USB_HOST_AUDIO_V1_0_STREAM_RESULT_UNKNOWN	The specified audio stream does not exist in the system
USB_HOST_AUDIO_V1_0_STREAM_RESULT_FAILURE	An unknown failure has occurred
USB_HOST_AUDIO_V1_0_STREAM_RESULT_FALSE = 0	Indicates a false condition
USB_HOST_AUDIO_V1_0_STREAM_RESULT_TRUE = 1	Indicate a true condition
USB_HOST_AUDIO_V1_0_STREAM_SUCCESS = USB_HOST_RESULT_TRUE	Indicates that the operation succeeded or the request was accepted and will be processed.

Description

USB Host Audio v1.0 Stream Result enumeration.

This enumeration lists the possible USB Host Audio v1.0 stream operation results. These values are returned by Audio v1.0 stream functions.

Remarks

None.

USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE_INVALID Macro

USB Host Audio v1.0 Class Driver invalid stream data transfer handle.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE_INVALID ((USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE)(-1))
```

Description

USB Host Audio v1.0 Class Driver Invalid Stream Data Transfer Handle Definition

This macro defines a USB Host Audio v1.0 Class Driver invalid stream data transfer handle. An invalid transfer handle is returned by the Audio v1.0 Class Driver stream data transfer routines when the request was not successful.

Remarks

None.

USB_HOST_AUDIO_V1_0_STREAM_TRANSFER_HANDLE Macro

USB Host Audio v1.0 Class Driver transfer handle.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_STREAM_TRANSFER_HANDLE USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE
```

Description

USB Host Audio v1.0 Class Driver Transfer Handle

This is returned by the Audio v1.0 Class Driver command and data transfer routines and should be used by the application to track the transfer especially in cases where transfers are queued.

Remarks

None.

USB_HOST_AUDIO_V1_0_INTERFACE Macro

USB HOST Audio Client Driver interface.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_INTERFACE (void*)USB_HOST_AUDIO_V1_INTERFACE
```

Description

USB HOST Audio Client Driver Interface

This macro should be used by the application in the TPL table while adding support for the USB Audio Host Client Driver.

Remarks

None.

USB_HOST_AUDIO_V1_0_REQUEST_HANDLE_INVALID Macro

USB Host Audio v1.0 Client Driver invalid request handle.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_REQUEST_HANDLE_INVALID ((USB_HOST_AUDIO_V1_0_REQUEST_HANDLE)(-1))
```

Description

USB Host Audio v1.0 Client Driver Invalid Request Handle

This is returned by the Audio v1.0 Client Driver command routines when the request could not be scheduled.

Remarks

None.

USB_HOST_AUDIO_V1_0_STREAM_HANDLE_INVALID Macro

Defines the type of the Audio v1.0 Host stream invalid handle.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_STREAM_HANDLE_INVALID USB_HOST_AUDIO_V1_STREAM_HANDLE_INVALID
```

Description

USB Host Audio stream Invalid handle

This is returned by the USB_HOST_AUDIO_V1_0_StreamOpen function when a stream open request has failed.

Remarks

None.

USB_HOST_AUDIO_V1_0_STREAM_TRANSFER_HANDLE_INVALID Macro

USB Host Audio v1.0 Class Driver invalid transfer handle definition.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_STREAM_TRANSFER_HANDLE_INVALID USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE_INVALID
```

Description

USB Host Audio v1.0 Class Driver Invalid Transfer Handle Definition

This macro defines a USB Host Audio v1.0 Class Driver invalid transfer handle. A invalid transfer handle is returned by the Audio v1.0 Class Driver data and command transfer routines when the request was not successful.

Remarks

None.

USB_HOST_AUDIO_V1_0_AttachEventHandlerSet Macro

Sets an attach/detach event handler.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_AttachEventHandlerSet USB_HOST_AUDIO_V1_AttachEventHandlerSet
```

Returns

- USB_HOST_AUDIO_V1_0_RESULT_SUCCESS - if the attach event handler was registered

successfully

- USB_HOST_AUDIO_V1_0_RESULT_FAILURE - if the number of registered event

handlers has exceeded USB_HOST_AUDIO_V1_0_ATTACH_LISTENERS_NUMBER

Description

This function will set an attach event handler. The attach event handler will be called when a Audio v1.0 device has been attached or detached. The context will be returned in the event handler. This function should be called before the bus has been enabled.

Remarks

This function should be called before the USB_HOST_BusEnable function is called.

Preconditions

None.

Parameters

Parameters	Description
eventHandler	Pointer to the attach event handler
context	An application defined context that will be returned in the event handler

Function

```
USB_HOST_AUDIO_V1_0_RESULT USB_HOST_AUDIO_V1_0_AttachEventHandlerSet
(
    USB_HOST_AUDIO_V1_0_ATTACH_EVENT_HANDLER eventHandler,
uintptr_t context
);
```

USB_HOST_AUDIO_V1_0_DeviceObjHandleGet Macro

Returns the device object handle for this Audio v1.0 Device.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_DeviceObjHandleGet USB_HOST_AUDIO_V1_DeviceObjHandleGet
```

Returns

This function will return a valid device object handle if the device is still connected to the system. Otherwise, USB_HOST_DEVICE_OBJ_HANDLE_INVALID is returned.

Description

This function returns the device object handle for this Audio v1.0 Device. This returned device object handle can be used by the application to perform device-level operations such as getting the string descriptors.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
audioDeviceObj	Audio V1.0 device object handle returned in the USB_HOST_AUDIO_V1_0_ATTACH_EVENT_HANDLER function.

Function

```
USB_HOST_DEVICE_OBJ_HANDLE USB_HOST_AUDIO_V1_0_DeviceObjHandleGet
(
    USB_HOST_AUDIO_V1_0_OBJ audioDeviceObj
);
```

USB_HOST_AUDIO_V1_0_DIRECTION_IN Macro

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_DIRECTION_IN USB_HOST_AUDIO_V1_DIRECTION_IN
```

Description

This is macro USB_HOST_AUDIO_V1_0_DIRECTION_IN.

USB_HOST_AUDIO_V1_0_DIRECTION_OUT Macro

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_DIRECTION_OUT USB_HOST_AUDIO_V1_DIRECTION_OUT
```

Description

This is macro USB_HOST_AUDIO_V1_0_DIRECTION_OUT.

USB_HOST_AUDIO_V1_0_EVENT_ATTACH Macro

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_EVENT_ATTACH USB_HOST_AUDIO_V1_EVENT_ATTACH
```

Description

This is macro USB_HOST_AUDIO_V1_0_EVENT_ATTACH.

USB_HOST_AUDIO_V1_0_EVENT_DETACH Macro

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_EVENT_DETACH USB_HOST_AUDIO_V1_EVENT_DETACH
```

Description

This is macro USB_HOST_AUDIO_V1_0_EVENT_DETACH.

USB_HOST_AUDIO_V1_0_STREAM_EVENT_RESPONSE_NONE Macro

Returns the type of the USB Host Audio v1.0 stream event handler.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_STREAM_EVENT_RESPONSE_NONE USB_HOST_AUDIO_V1_STREAM_EVENT_RESPONSE_NONE
```

Description

USB Host Audio v1.0 Stream Event Handler Return Type

This enumeration lists the possible return values of the USB Host Audio v1.0 stream event handler.

Remarks

None.

USB_HOST_AUDIO_V1_0_StreamClose Macro

Closes the audio stream.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_StreamClose USB_HOST_AUDIO_V1_StreamClose
```

Returns

None.

Description

This function will close the open audio stream. This closes the association between the application entity that opened the audio stream and the audio stream. The audio stream handle becomes invalid.

Remarks

The device handle becomes invalid after calling this function.

Preconditions

None.

Parameters

Parameters	Description
audioSteamHandle	handle to the audio stream obtained from the USB_HOST_AUDIO_V1_0_StreamOpen function.

Function

void USB_HOST_AUDIO_V1_0_StreamClose

(

USB_HOST_AUDIO_V1_0_STREAM_HANDLE audioSteamHandle

);

USB_HOST_AUDIO_V1_0_StreamOpen Macro

Opens the specified audio stream.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_0_StreamOpen USB_HOST_AUDIO_V1_StreamOpen
```

Returns

This function will return a valid handle if the audio stream could be opened successfully; otherwise, it will return USB_HOST_AUDIO_V1_0_STREAM_RESULT_HANDLE_INVALID. The function will return a valid handle if the stream is ready to be opened.

Description

This function will open the specified audio stream. Once opened, the audio stream can be accessed via the handle which this function returns. The audioStreamObj parameter is the value returned in the USB_HOST_AUDIO_V1_0_StreamGetFirst or USB_HOST_AUDIO_V1_0_StreamGetNext functions.

Remarks

None.

Preconditions

The audio stream object should be valid.

Parameters

Parameters	Description
audioStreamObj	Audio stream object

Section

Audio Stream Access Functions

    USB_HOST_AUDIO_V1_0_STREAM_OBJ audioStreamObj
);
```

USB_HOST_AUDIO_V1_SAMPLING_FREQUENCIES_NUMBER Macro

This structure defines USB Host audio stream information structure.

File

usb_host_audio_v1_0.h

C

```
#define USB_HOST_AUDIO_V1_SAMPLING_FREQUENCIES_NUMBER USB_HOST_AUDIO_V1_0_SAMPLING_FREQUENCIES_NUMBER
```

Description

USB Host Audio stream Info table structure

This structure is an out parameter to the functions USB_HOST_AUDIO_V1_0_StreamGetFirst and USB_HOST_AUDIO_V1_0_StreamGetNext

functions. This structure contains information about an audio stream in the attached Audio Device. This structure contains the stream object, audio format, etc.

Remarks

None.

USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_RATE_GET_COMPLETE_DATA Structure

USB Host Audio v1.0 class stream control event data.

File

usb_host_audio_v1_0.h

C

```
typedef struct {
  USB_HOST_AUDIO_V1_REQUEST_HANDLE requestHandle;
  USB_HOST_AUDIO_V1_RESULT requestStatus;
} USB_HOST_AUDIO_V1_STREAM_EVENT_INTERFACE_SET_COMPLETE_DATA,
USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE_DATA,
USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_RATE_GET_COMPLETE_DATA;
```

Members

Members	Description
USB_HOST_AUDIO_V1_REQUEST_HANDLE requestHandle;	Transfer handle of this transfer
USB_HOST_AUDIO_V1_RESULT requestStatus;	Transfer termination status

Description

USB Host Audio v1.0 Class Stream Control Event Data.

This data type defines the data structure returned by the Audio V1.0 stream in conjunction with the following events:

- USB_HOST_AUDIO_V1_STREAM_EVENT_INTERFACE_SET_COMPLETE
- USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_FREQUENCY_SET_COMPLETE
- USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_FREQUENCY_GET_COMPLETE

Remarks

None.

USB Host Audio v1_0 Class Driver Interface Header

Enumerations

	Name	Description
	USB_HOST_AUDIO_V1_0_RESULT	USB Host Audio v1.0 Class Driver audio result enumeration.
	USB_HOST_AUDIO_V1_0_STREAM_EVENT	Identifies the possible events that the Audio v1.0 stream can generate.
	USB_HOST_AUDIO_V1_0_STREAM_RESULT	USB Host Audio v1.0 stream result enumeration.
	USB_HOST_AUDIO_V1_EVENT	Identifies the possible events that the Audio v1.0 Class Driver attach event handler can generate.
	USB_HOST_AUDIO_V1_RESULT	USB Host Audio v1.0 Class Driver result enumeration.
	USB_HOST_AUDIO_V1_STREAM_DIRECTION	USB Host Audio v1.0 Class Driver stream direction.

	USB_HOST_AUDIO_V1_STREAM_EVENT	Identifies the possible events that the Audio v1.0 Stream can generate.
	USB_HOST_AUDIO_V1_STREAM_EVENT_RESPONSE	Returns the type of the USB Host Audio v1.0 stream event handler.

Functions

	Name	Description
	USB_HOST_AUDIO_V1_0_ControlRequest	Schedules an Audio v1.0 control transfer.
	USB_HOST_AUDIO_V1_0_NumberOfStreamGroupsGet	Gets the number of stream groups present in the attached Audio v1.0 Device.
	USB_HOST_AUDIO_V1_0_StreamDisable	Schedules an audio stream disable request for the specified audio stream.
	USB_HOST_AUDIO_V1_0_StreamEnable	Schedules an audio stream enable request for the specified audio stream.
	USB_HOST_AUDIO_V1_0_StreamEventHandlerSet	Registers an event handler with the Audio v1.0 Client Driver stream.
	USB_HOST_AUDIO_V1_0_StreamGetFirst	Returns information about first audio stream in the specified audio stream group.
	USB_HOST_AUDIO_V1_0_StreamGetNext	Returns information about the next audio stream in the specified audio stream group.
	USB_HOST_AUDIO_V1_0_StreamRead	Schedules an audio stream read request for the specified audio stream.
	USB_HOST_AUDIO_V1_0_StreamSamplingRateSet	Schedules an audio stream set sampling rate request for the specified audio stream.
	USB_HOST_AUDIO_V1_0_StreamWrite	Schedules an audio stream write request for the specified audio stream.
	USB_HOST_AUDIO_V1_AttachEventHandlerSet	Sets an attach/detach event handler.
	USB_HOST_AUDIO_V1_ControlEntityGetFirst	Retrieves the handle to the first audio control entity
	USB_HOST_AUDIO_V1_ControlEntityGetNext	Retrieves the handle to the next audio control entity.
	USB_HOST_AUDIO_V1_DeviceObjHandleGet	Returns the device object handle for this Audio v1.0 Device.
	USB_HOST_AUDIO_V1_EntityObjectGet	Retrieves the entity object for the entity ID.
	USB_HOST_AUDIO_V1_EntityRequestCallbackSet	Registers an audio entity request callback function with the Audio v1.0 Client Driver.
	USB_HOST_AUDIO_V1_EntityTypeGet	Returns the entity type of the audio control entity.
	USB_HOST_AUDIO_V1_FeatureUnitChannelMuteExists	Returns "true" if mute control exists for the specified channel of the feature unit.
	USB_HOST_AUDIO_V1_FeatureUnitChannelMuteGet	Schedules a get mute control request to the specified channel.
	USB_HOST_AUDIO_V1_FeatureUnitChannelMuteSet	Schedules a set mute control request to the specified channel.
	USB_HOST_AUDIO_V1_FeatureUnitChannelNumbersGet	Returns the number of channels.
	USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeExists	Returns "true" if volume control exists for the specified channel of the feature unit.
	USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeGet	Schedules a get current volume control request to the specified channel.
	USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeRangeGet	Schedules a control request to the Audio Device feature unit to get the range supported by the volume control on the specified channel.
	USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeSet	Schedules a set current volume control request to the specified channel.
	USB_HOST_AUDIO_V1_FeatureUnitChannelVolumeSubRangeNumbersGet	Schedules a control request to an Audio Device feature unit to get the number of sub-ranges supported by the volume control on the specified channel.
	USB_HOST_AUDIO_V1_FeatureUnitIDGet	Returns ID of the Feature Unit.
	USB_HOST_AUDIO_V1_FeatureUnitSourceIDGet	Returns the ID of the unit or terminal to which this feature unit is connected.
	USB_HOST_AUDIO_V1_StreamClose	Closes the audio stream.
	USB_HOST_AUDIO_V1_StreamEventHandlerSet	Registers an event handler with the Audio v1.0 Client Driver stream.
	USB_HOST_AUDIO_V1_StreamingInterfaceBitResolutionGet	Returns the bit resolution of the specified streaming interface setting.

	USB_HOST_AUDIO_V1_StreamingInterfaceChannelNumbersGet	Returns the number of channels of the specified streaming interface setting.
	USB_HOST_AUDIO_V1_StreamingInterfaceDirectionGet	Returns the direction of the specified streaming interface setting.
	USB_HOST_AUDIO_V1_StreamingInterfaceFormatTagGet	Returns the format tag of the specified streaming interface setting.
	USB_HOST_AUDIO_V1_StreamingInterfaceGetFirst	Gets the first streaming interface object from the attached Audio Device.
	USB_HOST_AUDIO_V1_StreamingInterfaceGetNext	Gets the next streaming interface object from the attached Audio Device.
	USB_HOST_AUDIO_V1_StreamingInterfaceSamplingFrequenciesGet	Returns the sampling frequencies supported by the specified streaming interface setting.
	USB_HOST_AUDIO_V1_StreamingInterfaceSamplingFrequencyTypeGet	Returns the sampling frequency type of the specified streaming interface setting.
	USB_HOST_AUDIO_V1_StreamingInterfaceSet	Schedules a SET_INTERFACE request to the specified audio stream.
	USB_HOST_AUDIO_V1_StreamingInterfaceSettingGetFirst	Gets the first streaming interface setting object within an audio streaming interface.
	USB_HOST_AUDIO_V1_StreamingInterfaceSettingGetNext	Gets the next streaming interface setting object within an audio streaming interface.
	USB_HOST_AUDIO_V1_StreamingInterfaceSubFrameSizeGet	Returns the sub-frame size of the specified streaming interface setting.
	USB_HOST_AUDIO_V1_StreamingInterfaceTerminalLinkGet	Returns the terminal link of the specified streaming interface setting.
	USB_HOST_AUDIO_V1_StreamOpen	Opens the specified audio stream.
	USB_HOST_AUDIO_V1_StreamRead	Schedules an audio stream read request for the specified audio stream.
	USB_HOST_AUDIO_V1_StreamSamplingFrequencyGet	Schedules an audio stream get sampling rate request for the specified audio stream.
	USB_HOST_AUDIO_V1_StreamSamplingFrequencySet	Schedules an audio stream set sampling rate request for the specified audio stream.
	USB_HOST_AUDIO_V1_StreamWrite	Schedules an audio stream write request for the specified audio stream.
	USB_HOST_AUDIO_V1_TerminalAssociationGet	Returns the associated terminal ID of the audio control terminal.
	USB_HOST_AUDIO_V1_TerminalIDGet	Returns the terminal ID of the audio control entity.
	USB_HOST_AUDIO_V1_TerminalInputChannelConfigGet	Returns a structure that describes the spatial location of the logical channels of in the terminal's output audio channel cluster.
	USB_HOST_AUDIO_V1_TerminalInputChannelNumbersGet	Returns the number of logical output channels in the terminal's output audio channel cluster.
	USB_HOST_AUDIO_V1_TerminalSourceIDGet	Returns the ID of the unit or terminal to which this terminal is connected.
	USB_HOST_AUDIO_V1_TerminalTypeGet	Returns the terminal type of the audio control entity.

Macros

	Name	Description
	USB_HOST_AUDIO_V1_0_AttachEventHandlerSet	Sets an attach/detach event handler.
	USB_HOST_AUDIO_V1_0_DeviceObjHandleGet	Returns the device object handle for this Audio v1.0 Device.
	USB_HOST_AUDIO_V1_0_DIRECTION_IN	This is macro USB_HOST_AUDIO_V1_0_DIRECTION_IN.
	USB_HOST_AUDIO_V1_0_DIRECTION_OUT	This is macro USB_HOST_AUDIO_V1_0_DIRECTION_OUT.
	USB_HOST_AUDIO_V1_0_EVENT	Identifies the possible events that the Audio v1.0 Class Driver can generate.
	USB_HOST_AUDIO_V1_0_EVENT_ATTACH	This is macro USB_HOST_AUDIO_V1_0_EVENT_ATTACH.
	USB_HOST_AUDIO_V1_0_EVENT_DETACH	This is macro USB_HOST_AUDIO_V1_0_EVENT_DETACH.
	USB_HOST_AUDIO_V1_0_INTERFACE	USB HOST Audio Client Driver interface.
	USB_HOST_AUDIO_V1_0_OBJ	Defines the type of the Audio v1.0 Host client object.

	USB_HOST_AUDIO_V1_0_REQUEST_HANDLE	USB Host Audio v1.0 Client Driver request handle.
	USB_HOST_AUDIO_V1_0_REQUEST_HANDLE_INVALID	USB Host Audio v1.0 Client Driver invalid request handle.
	USB_HOST_AUDIO_V1_0_STREAM_DIRECTION	USB Host Audio v1.0 Class Driver stream direction.
	USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE_DATA	This is macro USB_HOST_AUDIO_V1_0_STREAM_EVENT_READ_COMPLETE_DATA.
	USB_HOST_AUDIO_V1_0_STREAM_EVENT_RESPONSE	Returns the type of the USB Audio v1.0 Host Client Driver event handler.
	USB_HOST_AUDIO_V1_0_STREAM_EVENT_RESPONSE_NONE	Returns the type of the USB Host Audio v1.0 stream event handler.
	USB_HOST_AUDIO_V1_0_STREAM_EVENT_WRITE_COMPLETE_DATA	USB Host Audio v1.0 class stream transfer event data.
	USB_HOST_AUDIO_V1_0_STREAM_HANDLE	Defines the type of the Audio v1.0 Host stream handle.
	USB_HOST_AUDIO_V1_0_STREAM_HANDLE_INVALID	Defines the type of the Audio v1.0 Host stream invalid handle.
	USB_HOST_AUDIO_V1_0_STREAM_TRANSFER_HANDLE	USB Host Audio v1.0 Class Driver transfer handle.
	USB_HOST_AUDIO_V1_0_STREAM_TRANSFER_HANDLE_INVALID	USB Host Audio v1.0 Class Driver invalid transfer handle definition.
	USB_HOST_AUDIO_V1_0_StreamClose	Closes the audio stream.
	USB_HOST_AUDIO_V1_0_StreamOpen	Opens the specified audio stream.
	USB_HOST_AUDIO_V1_INTERFACE	USB HOST Audio v1.0 Client Driver interface.
	USB_HOST_AUDIO_V1_REQUEST_HANDLE_INVALID	USB Host Audio v1.0 Client Driver invalid request handle.
	USB_HOST_AUDIO_V1_SAMPLING_FREQUENCIES_NUMBER	This structure defines USB Host audio stream information structure.
	USB_HOST_AUDIO_V1_STREAM_HANDLE_INVALID	Defines Audio v1.0 Host stream invalid handle.
	USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE_INVALID	USB Host Audio v1.0 Class Driver invalid stream data transfer handle.

Structures

	Name	Description
	USB_HOST_AUDIO_V1_0_STREAM_EVENT_DISABLE_COMPLETE_DATA	USB Host Audio v1.0 class stream control event data.
	USB_HOST_AUDIO_V1_0_STREAM_EVENT_ENABLE_COMPLETE_DATA	USB Host Audio v1.0 class stream control event data.
	USB_HOST_AUDIO_V1_0_STREAM_INFO	This is type USB_HOST_AUDIO_V1_0_STREAM_INFO.
	USB_HOST_AUDIO_V1_STREAM_EVENT_INTERFACE_SET_COMPLETE_DATA	USB Host Audio v1.0 class stream control event data.
	USB_HOST_AUDIO_V1_STREAM_EVENT_READ_COMPLETE_DATA	USB Host Audio v1.0 class stream data transfer event data.
	USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_RATE_GET_COMPLETE_DATA	USB Host Audio v1.0 class stream control event data.
	USB_HOST_AUDIO_V1_STREAM_EVENT_SAMPLING_RATE_SET_COMPLETE_DATA	USB Host Audio v1.0 class stream control event data.
	USB_HOST_AUDIO_V1_STREAM_EVENT_WRITE_COMPLETE_DATA	USB Host Audio v1.0 class stream data transfer event data.

Types

	Name	Description
	USB_HOST_AUDIO_V1_0_ATTACH_EVENT_HANDLER	USB Host Audio v1.0 Client Driver attach event handler function pointer type.
	USB_HOST_AUDIO_V1_0_CONTROL_CALLBACK	USB Host Audio v1.0 Class Driver control transfer complete callback function pointer type.
	USB_HOST_AUDIO_V1_0_STREAM_EVENT_HANDLER	USB Host Audio v1.0 Class Driver stream event handler function pointer type.
	USB_HOST_AUDIO_V1_0_STREAM_OBJ	Defines the type of the Audio v1.0 Host stream object.
	USB_HOST_AUDIO_V1_ATTACH_EVENT_HANDLER	USB Host Audio v1.0 Client Driver attach event handler function pointer type.

	USB_HOST_AUDIO_V1_CONTROL_ENTITY_OBJ	Defines the type of the Audio v1.0 Host control entity object.
	USB_HOST_AUDIO_V1_ENTITY_REQUEST_CALLBACK	USB Host Audio v1.0 class driver control transfer complete callback function pointer type.
	USB_HOST_AUDIO_V1_OBJ	Defines the type of the Audio v1.0 Host client object.
	USB_HOST_AUDIO_V1_REQUEST_HANDLE	USB Host Audio v1.0 Client Driver request handle.
	USB_HOST_AUDIO_V1_STREAM_EVENT_HANDLER	USB Host Audio v1.0 Class Driver stream event handler function pointer type.
	USB_HOST_AUDIO_V1_STREAM_HANDLE	Defines the type of the Audio v1.0 Host stream handle.
	USB_HOST_AUDIO_V1_STREAM_TRANSFER_HANDLE	USB Host Audio v1.0 Class Driver stream data transfer handle.
	USB_HOST_AUDIO_V1_STREAMING_INTERFACE_OBJ	Defines the type of the Audio v1.0 Host streaming interface object.
	USB_HOST_AUDIO_V1_STREAMING_INTERFACE_SETTING_OBJ	Defines the type of the Audio v1.0 Host streaming interface setting object.

Description

USB Host Audio v1.0 Class Driver Interface Definition

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the USB Host Audio v1.0 Class Driver.

File Name

usb_host_audio_v1_0.h

Company

Microchip Technology Inc.

usb_host_audio_v1_0_config_template.h

USB host Audio v1.0 Class configuration definitions template

Macros

	Name	Description
	USB_HOST_AUDIO_V1_ATTACH_LISTENERS_NUMBER	Defines the number of attach event listeners that can be registered with Audio v1.0 Host Client Driver.
	USB_HOST_AUDIO_V1_INSTANCES_NUMBER	Specifies the number of Audio v1.0 instances.
	USB_HOST_AUDIO_V1_STREAMING_INTERFACE_ALTERNATE_SETTINGS_NUMBER	Defines maximum number of alternate settings per Streaming interface provided by any Device that will be connected to this Audio Host.
	USB_HOST_AUDIO_V1_STREAMING_INTERFACES_NUMBER	Defines the maximum number of streaming interfaces could be present in an Audio v1.0 device that this Audio v1.0 Host Client Driver can support.

Description

USB Host Audio v1.0 Class Configuration Definitions

This file contains configurations macros needed to configure the Audio v1.0 host Driver. This file is a template file only. It should not be included by the application. The configuration macros defined in the file should be defined in the configuration specific system_config.h.

File Name

usb_host_cdc_config_template.h

Microchip Technology Inc.

USB CDC Host Library

This section describes the USB CDC Host Library.

Introduction

Introduces the MPLAB Harmony USB CDC Host Library.

Description

The CDC Host Client Driver in the MPLAB Harmony USB Host Stack allows USB Host applications to support and interact with Communications Device Class (CDC) USB devices. The CDC Host Client Driver has the following features:

- Supports CDC ACM devices
- Supports CDC device matching at both the device descriptor and interface descriptor level
- Supports composite CDC devices (multiple CDC interfaces or CDC with other device classes)
- Designed to support multi-client operation
- RTOS ready
- An event driver non-clocking application interaction model
- Allows the application to send CDC ACM commands to the device
- Supports queuing of read and write data transfers

Using the Library

This topic describes the basic architecture of the USB CDC Host Client Driver Library and provides information and examples on its use.

Abstraction Model

Describes the Abstraction Model of the USB CDC Host Client Driver Library.

Description

The CDC Host Client Driver interacts with the Host Layer to control the attached CDC device. The USB Host Layer attaches the CDC Host Client Driver to the CDC device when it meets the matching criteria specified in the USB Host TPL table. The CDC Host Client Driver abstracts the details of sending CDC class specific control transfer commands by providing easy to use non-blocking API to send these command. A command, when issued, is assigned a request handle. This request handle is returned in the event that is generated when the command has been processed, and can be used by the application to track the command. The class specific command functions are implemented in `usb_host_cdc_acm.c`.

While transferring data over the data interface, the CDC Host Client Driver abstracts details such as the bulk interface, endpoints and endpoint size. The CDC Host Client Driver internally (and without application intervention) validates the CDC class specific device descriptors and opens communication pipes. While transferring data, multiple read and write requests can be queued. Each such request gets assigned a transfer handle. The transfer handle for a transfer request is returned along with the completion event for that transfer request. The data transfer routines are implemented in `usb_host_cdc.c`.

Library Overview

The USB CDC Host Client Driver API is grouped functionally, as shown in the following table.

Library Interface Section	Description
Client Access Functions	These functions allow application clients to open, close the client and register event handlers. These functions are implemented in `usb_host_cdc.c`.
Data Transfer Functions	These functions allow the application client to transfer data to the attached device. These functions are implemented in `usb_host_cdc.c`.
CDC Class-specific Command Functions	These functions allow the application to send class specific control transfer requests to the application. These functions are implemented in `usb_host_cdc_acm.c`.

How the Library Works

Describes how the Library works and how it should be used.

Description

The CDC Host Client Driver provides the user application with an easy-to-use interface to the attached CDC device. The USB Host Layer initializes the CDC Host Client Driver when a device is attached. This process does not require application intervention.

The following sections describe the steps and methods required for the user application to interact with the attached devices:

- TPL Table Configuration for CDC Devices
- Detecting Device Attach
- Opening the CDC Host Client Driver
- Sending Class-specific Control Transfers
- Reading and Writing Data
- Event Handling

TPL Table Configuration for CDC Devices

Provides information on configuring the TPL table for CDC devices.

Description

The Host Layer attaches the CDC Host Client Driver to a device when the device class, subclass, protocol in the device descriptor or when the class, subclass and protocol fields in the Interface Association Descriptor (IAD) or Interface descriptor matches the entry in the TPL table. When specifying the entry for the CDC device, the entry for the CDC device, the driver interface must be set to USB_HOST_CDC_INTERFACE. This will attach the CDC Host Client Driver to the device when the USB Host matches the TPL entry to the device. The following code shows possible TPL table options for matching CDC Devices.

Example:

```
/* This code shows an example of TPL table entries for supporting CDC
 * devices. Note the driver interface is set to USB_HOST_CDC_INTERFACE. This
 * will load the CDC Host Client Driver when there is TPL match */

const USB_HOST_TPL_ENTRY USBTPList[1] =
{
    /* This entry looks for any CDC device. The CDC Host Client Driver will
     * check if this is an ACM device and will then load itself */
    TPL_INTERFACE_CLASS_SUBCLASS_PROTOCOL(USB_CDC_CLASS_CODE, USB_CDC_SUBCLASS_CODE, 0x0 , NULL,
USB_HOST_CDC_INTERFACE),

    /* This entry looks specifically for the communications class protocol.
     * This entry should be used if the host application is expected to support
     * CDC as a part of an composite device */
    TPL_INTERFACE_CLASS_SUBCLASS_PROTOCOLUSB_CDC_COMMUNICATIONS_INTERFACE_CLASS_CODE,
USB_CDC_SUBCLASS_ABSTRACT_CONTROL_MODEL, USB_CDC_PROTOCOL_AT_V250 , NULL,  USB_HOST_CDC_INTERFACE),

};
```

Detecting Device Attach

Describes how to register an Attach Event Handler.

Description

The application will need to know when a CDC Device is attached. To receive this attach event from the CDC Host Client Driver, the application must register an Attach Event Handler by calling the USB_HOST_CDC_AttachEventHandlerSet function. This function should be called before the USB_HOST_BusEnable function is called, else the application may miss CDC attach events. It can be called multiple times to register multiple event handlers, each for different application clients that need to know about CDC Device Attach events.

The total number of event handlers that can be registered is defined by USB_HOST_CDC_ATTACH_LISTENERS_NUMBER configuration option in `system_config.h`. When a device is attached, the CDC Host Client Driver will send the attach event to all the registered event handlers. In this event handler, the CDC Host Client Driver will pass a USB_HOST_CDC_OBJ that can be opened to gain access to the device. The following code shows an example of how to register attach event handlers.

Example:

```
/* This code shows an example of CDC Attach Event Handler and how this
 * attach event handler can be registered with the CDC Host Client Driver */

void APP_USBHostCDCAttachEventListener(USB_HOST_CDC_OBJ cdcObj, uintptr_t context)
{
    /* This function gets called when the CDC device is attached. In this
     * example we let the application know that a device is attached and we
     * store the CDC device object. This object will be required to open the
     * device. */

    appData.deviceIsAttached = true;
    appData.cdcObj = cdcObj;
}
```

```
void APP_Tasks(void)
{
    switch (appData.state)
    {
        case APP_STATE_BUS_ENABLE:

            /* In this state the application enables the USB Host Bus. Note
             * how the CDC Attach event handler is registered before the bus
             * is enabled. */

            USB_HOST_CDC_AttachEventHandlerSet(APP_USBHostCDCAttachEventListener, (uintptr_t) 0);
            USB_HOST_BusEnable(0);
            appData.state = APP_STATE_WAIT_FOR_BUS_ENABLE_COMPLETE;
            break;

        case APP_STATE_WAIT_FOR_BUS_ENABLE_COMPLETE:
            /* Here we wait for the bus enable operation to complete. */
            break;
    }
}
```

Opening the CDC Host Client Driver

Describes how an application can open the CDC Host Client Driver.

Description

The application must open the CDC Host Client Driver to communicate and control the attached device. The device can be opened by using the USB_HOST_CDC_Open function and specifying the USB_HOST_CDC_OBJ object that was returned in the attached event handler. If the open function fails, it returns an invalid handle (USB_HOST_CDC_HANDLE_INVALID). Once opened successfully, a valid handle tracks the relationship between the client and the CDC Host Client Driver. This handle should be used with other CDC Host Client Driver functions to specify the instance of the CDC Host Client Driver being accessed.

A CDC Host Client Driver instance can be opened multiple times by different application clients. In an ROTS based application each client could running its own thread. Multiple clients can read write data to the one CDC device. In such a case, the read and write requests are queued. The following code shows an example of how the CDC Driver is opened.

Example:

```
/* This code shows an example of the how to open the CDC Host Client
 * driver. The application state machine waits for a device attach and then
 * opens the CDC Host Client Driver. */

void APP_USBHostCDCAttachEventListener(USB_HOST_CDC_OBJ cdcObj, uintptr_t context)
{
    /* This function gets called when the CDC device is attached. Update the
     * application data structure to let the application know that this device
     * is attached */

    appData.deviceIsAttached = true;
    appData.cdcObj = cdcObj;
}

void APP_Tasks(void)
{
    switch (appData.state)
    {
        case APP_STATE_BUS_ENABLE:

            /* In this state the application enables the USB Host Bus. Note
             * how the CDC Attach event handler are registered before the bus
             * is enabled. */

            USB_HOST_EventHandlerSet(APP_USBHostEventHandler, (uintptr_t)0);
            USB_HOST_CDC_AttachEventHandlerSet(APP_USBHostCDCAttachEventListener, (uintptr_t) 0);
            USB_HOST_BusEnable(0);
            appData.state = APP_STATE_WAIT_FOR_BUS_ENABLE_COMPLETE;
            break;

        case APP_STATE_WAIT_FOR_BUS_ENABLE_COMPLETE:
```

```
            /* In this state we wait for the Bus enable to complete */
            if(USB_HOST_BusIsEnabled(0))
            {
                appData.state = APP_STATE_WAIT_FOR_DEVICE_ATTACH;
            }
            break;

        case APP_STATE_WAIT_FOR_DEVICE_ATTACH:

            /* In this state the application is waiting for the device to be
             * attached */
            if(appData.deviceIsAttached)
            {
                /* A device is attached. We can open this device */
                appData.state = APP_STATE_OPEN_DEVICE;
                appData.deviceIsAttached = false;
            }
            break;

        case APP_STATE_OPEN_DEVICE:

            /* In this state the application opens the attached device */
            appData.cdcHostHandle = USB_HOST_CDC_Open(appData.cdcObj);
            if(appData.cdcHostHandle != USB_HOST_CDC_HANDLE_INVALID)
            {
                /* The driver was opened successfully. Set the event handler
                 * and then go to the next state. */
                USB_HOST_CDC_EventHandlerSet(appData.cdcHostHandle,
                                             APP_USBHostCDCEventHandler,
                                            (uintptr_t)0);
                appData.state = APP_STATE_SET_LINE_CODING;
            }
            break;

        default:
            break;
    }
}
```

Sending Class-specific Control Transfers

Describes how the application client can send CDC Class-specific commands to the connected device.

Description

The CDC Host Client Driver allows the application client to send CDC Class specific commands to the connected device. These commands allows the application client to:

- Set the device line coding (USB_HOST_CDC_LineCodingSet)
- Retrieve the device line coding (USB_HOST_CDC_LineCodingGet)
- Set the device control line state (USB_HOST_CDC_ControlLineStateSet)
- Ask the device to send a break signal (USB_HOST_CDC_BreakSend)

These functions are non-blocking. The functions will return before the actual command execution is complete. The return value indicates if the command was scheduled successfully, or if the driver is busy and cannot accept commands, or if the command failed due to an unknown reason. If the command failed because the driver was busy, it can be retried. If scheduled successfully, the function will return a valid request handle. This request handle is unique and tracks the requested command.

When the command related control transfer has completed, the CDC Host Client Driver generates a command specific completion event. This event is accompanied by a data structure that contains information about the completion of the command. The request handler generated at the time of calling the command request function is also returned along with the event. The request handle expires after the event handler exits. The following tables show the command functions, along with the respective events and the type of the event related data.

Table 1: Set Line Coding

Function	USB_HOST_CDC_ACM_LineCodingSet
Event	USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE
Event Data Type	USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE_DATA

Table 2: Get Line Coding

Function	USB_HOST_CDC_ACM_LineCodingGet
Event	USB_HOST_CDC_EVENT_ACM_GET_LINE_CODING_COMPLETE
Event Data Type	USB_HOST_CDC_EVENT_ACM_GET_LINE_CODING_COMPLETE_DATA

Table 3: Set Control Line State

Function	USB_HOST_CDC_ACM_ControlLineStateSet
Event	USB_HOST_CDC_EVENT_ACM_CONTROL_LINE_STATE_SET_COMPLETE
Event Data Type	USB_HOST_CDC_EVENT_ACM_CONTROL_LINE_STATE_SET_COMPLETE _DATA

Table 4: Send Break

Function	USB_HOST_CDC_ACM_SendBreak
Event	USB_HOST_CDC_EVENT_ACM_SEND_BREAK_COMPLETE
Event Data Type	USB_HOST_CDC_EVENT_ACM_SEND_BREAK_COMPLETE _DATA

The following code shows an example of sending a CDC class specific commands. Refer to the Event Handling section for details on setting the event handler function.

Example:

```
/* This code shows an example of how to send CDC Class specific command
 * requests. The event handling related to each command is also shown. */

USB_HOST_CDC_EVENT_RESPONSE APP_USBHostCDCEventHandler
(
    USB_HOST_CDC_HANDLE cdcHandle,
    USB_HOST_CDC_EVENT event,
    void * eventData,
    uintptr_t context
)
{
    /* This function is called when a CDC Host event has occurred. A pointer to
     * this function is registered after opening the device. See the call to
     * USB_HOST_CDC_EventHandlerSet() function. */

    USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE_DATA * setLineCodingEventData;
    USB_HOST_CDC_EVENT_ACM_SET_CONTROL_LINE_STATE_COMPLETE_DATA * setControlLineStateEventData;
    USB_HOST_CDC_EVENT_WRITE_COMPLETE_DATA * writeCompleteEventData;
    USB_HOST_CDC_EVENT_READ_COMPLETE_DATA * readCompleteEventData;

    switch(event)
    {
        case USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE:

                    appData.state = APP_STATE_SEND_PROMPT_TO_DEVICE;
                }
            }

            break;

        default:
            break;
    }
}
```

Reading and Writing Data

Describes how to transfer data to the attached CDC device.

Description

The application can use the USB_HOST_CDC_Read and USB_HOST_CDC_Write functions to transfer data to the attached CDC device. While calling these function, the client handle specifies the target CDC device and the event handler function to which the events should be sent. It is possible for multiple client to open the same instance of the CDC Host Client Driver instance and transfer data to the attached CDC Device.

Calling the USB_HOST_CDC_Read and USB_HOST_CDC_Write functions while a read/write transfer is already in progress will cause the transfer result to be queued. If the transfer was successfully queued or scheduled, the USB_HOST_CDC_Read and USB_HOST_CDC_Write functions will return a valid transfer handle. This transfer handle identifies the transfer request. The application clients can use the transfer handles to keep track of multiple queued transfers. When a transfer completes, the CDC Host Client Driver generates an event. The following tables shows the event and the event data associated with the event.

Table 1: Read

Function	USB_HOST_CDC_Read
Event	USB_HOST_CDC_EVENT_READ_COMPLETE
Event Data Type	USB_HOST_CDC_EVENT_READ_COMPLETE_DATA

Table 2: Write

Function	USB_HOST_CDC_ACM_LineCodingGet
Event	USB_HOST_CDC_EVENT_READ_COMPLETE
Event Data Type	USB_HOST_CDC_EVENT_READ_COMPLETE_DATA

The event data contains information on the amount of data transferred, completion status and the transfer handle of the transfer. The following code shows an example of reading and writing data.

Example:

```
/* In this code example, the USB_HOST_CDC_Read and the USB_HOST_CDC_Write
 * functions are used to read and write data. The event related to the read and
 * write operations are handled in the APP_USBHostCDCEventHandler function. */

USB_HOST_CDC_EVENT_RESPONSE APP_USBHostCDCEventHandler
(
    USB_HOST_CDC_HANDLE cdcHandle,
    USB_HOST_CDC_EVENT event,
    void * eventData,
```

```
    uintptr_t context
)
{
    /* This function is called when a CDC Host event has occurred. A pointer to
     * this function is registered after opening the device. */

    USB_HOST_CDC_EVENT_WRITE_COMPLETE_DATA * writeCompleteEventData;
    USB_HOST_CDC_EVENT_READ_COMPLETE_DATA * readCompleteEventData;

    switch(event)
    {
        case USB_HOST_CDC_EVENT_WRITE_COMPLETE:

            /* This means an application requested write has completed */
            appData.writeTransferDone = true;
            writeCompleteEventData = (USB_HOST_CDC_EVENT_WRITE_COMPLETE_DATA *)(eventData);
            appData.writeTransferResult = writeCompleteEventData->result;
            break;

        case USB_HOST_CDC_EVENT_READ_COMPLETE:

            /* This means an application requested write has completed */
            appData.readTransferDone = true;
            readCompleteEventData = (USB_HOST_CDC_EVENT_READ_COMPLETE_DATA *)(eventData);
            appData.readTransferResult = readCompleteEventData->result;
            break;

        default:
            break;
    }

    return(USB_HOST_CDC_EVENT_RESPONE_NONE);
}

void APP_Tasks(void)
{
    switch(appData.state)
    {
        /* The application states that wait for device attach and open the CDC
         * Host Client Driver are not shown here for brevity */

        case APP_STATE_SEND_PROMPT_TO_DEVICE:

            /* The prompt is sent to the device here. The write transfer done
             * flag is updated in the event handler. */

            appData.writeTransferDone = false;
            result = USB_HOST_CDC_Write(appData.cdcHostHandle, NULL, prompt, 8);

                    /* Now to get data from the device */
                    appData.state = APP_STATE_GET_DATA_FROM_DEVICE;
                }
                else
                {
                    /* Try sending the prompt again. */
                    appData.state = APP_STATE_SEND_PROMPT_TO_DEVICE;
```

```
                }
            }

            break;

        case APP_STATE_GET_DATA_FROM_DEVICE:

            /* Here we request data from the device */
            appData.readTransferDone = false;
            result = USB_HOST_CDC_Read(appData.cdcHostHandle, NULL, appData.inDataArray, 1);
            if(result == USB_HOST_CDC_RESULT_SUCCESS)
            {
                appData.state = APP_STATE_WAIT_FOR_DATA_FROM_DEVICE;
            }
            break;

        case APP_STATE_WAIT_FOR_DATA_FROM_DEVICE:

            /* Wait for data from device. */
            if(appData.readTransferDone)
            {
                if(appData.readTransferResult == USB_HOST_CDC_RESULT_SUCCESS)
                {
                    /* Do something with the data here */
                }
            }

            break;

        default:
            break;
    }
}
```

Event Handling

Describes how to set event handlers.

Description

The CDC Host Client Driver presents an event driven interface to the application. The CDC Host Client Driver requires the application client to set two event handlers for meaningful operation:

- The Attach event handler is not client specific and is registered before the USB_HOST_BusEnable function is called. This event handler and the attach event is discussed in the Detecting Device Attach section.
- The client specific command, data transfer and detach events. The CDC Class specific command request events are discussed in the Sending Class Specific Control Transfers section. The data transfer related events are discussed in the Reading and Writing Data section. Some general points about these events are discussed below.

A request to send a command or transfer data typically completes after the command request or transfer function has exited. The application must then use the CDC Host Client Driver event to track the completion of this command or data transfer request. In a case where multiple data transfers are queued, the transfer handles can be used to identify the transfer requests.

The application must use the USB_HOST_CDC_EventHandlerSet function to register a client specific event handler. This event handler will be called when a command, data transfer or detach event has occurred and should be registered before the client request for command or a data transfer. The following code shows an example of registering an event handler.

Example:

```
/* This code shows an example of setting an event handler and an example
 * event handler. For the full set of events that the CDC Host Client generates,
 * refer to USB_HOST_CDC_EVENT enumeration description */

USB_HOST_CDC_EVENT_RESPONSE APP_USBHostCDCEventHandler
(
    USB_HOST_CDC_HANDLE cdcHandle,
    USB_HOST_CDC_EVENT event,
    void * eventData,
    uintptr_t context
)
{
    /* This function is called when a CDC Host event has occurred. A pointer to
     * this function is registered after opening the device. See the call to
```

```
     * USB_HOST_CDC_EventHandlerSet() function. */

    USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE_DATA * setLineCodingEventData;
    USB_HOST_CDC_EVENT_ACM_SET_CONTROL_LINE_STATE_COMPLETE_DATA * setControlLineStateEventData;
    USB_HOST_CDC_EVENT_WRITE_COMPLETE_DATA * writeCompleteEventData;
    USB_HOST_CDC_EVENT_READ_COMPLETE_DATA * readCompleteEventData;

    switch(event)
    {
        case USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE:

            /* This means the application requested Set Line Coding request is
             * complete. */
            setLineCodingEventData = (USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE_DATA *)(eventData);
            appData.controlRequestDone = true;
            appData.controlRequestResult = setLineCodingEventData->result;
            break;

        case USB_HOST_CDC_EVENT_ACM_SET_CONTROL_LINE_STATE_COMPLETE:

            /* This means the application requested Set Control Line State
             * request has completed. */
            setControlLineStateEventData = (USB_HOST_CDC_EVENT_ACM_SET_CONTROL_LINE_STATE_COMPLETE_DATA
*)(eventData);
            appData.controlRequestDone = true;
            appData.controlRequestResult = setControlLineStateEventData->result;
            break;

        case USB_HOST_CDC_EVENT_WRITE_COMPLETE:

            /* This means an application requested write has completed */
            appData.writeTransferDone = true;
            writeCompleteEventData = (USB_HOST_CDC_EVENT_WRITE_COMPLETE_DATA *)(eventData);
            appData.writeTransferResult = writeCompleteEventData->result;
            break;

        case USB_HOST_CDC_EVENT_READ_COMPLETE:

            }
            break;

        default:
            break;

    }
}
```

Configuring the Library

Describes how to configure the USB CDC Host Library.

Macros

	Name	Description
	USB_HOST_CDC_ATTACH_LISTENERS_NUMBER	Defines the number of attach event listeners that can be registered with CDC Host Client Driver.
	USB_HOST_CDC_INSTANCES_NUMBER	Specifies the number of CDC instances.

Description

The CDC Host Client Driver requires configuration constants to be specified in `system_config.h` file. These constants define the build time configuration (functionality and static resources) of the CDC Host Client Driver.

USB_HOST_CDC_ATTACH_LISTENERS_NUMBER Macro

Defines the number of attach event listeners that can be registered with CDC Host Client Driver.

File

usb_host_cdc_config_template.h

C

```
#define USB_HOST_CDC_ATTACH_LISTENERS_NUMBER
```

Description

USB Host CDC Attach Listeners Number

The USB CDC Host Client Driver provides attach notification to listeners who have registered with the client driver via the USB_HOST_CDC_AttachEventHandlerSet() function. The USB_HOST_CDC_ATTACH_LISTENERS_NUMBER configuration constant defines the maximum number of event handlers that can be set. This number should be set to equal the number of entities that interested in knowing when a CDC device is attached.

Remarks

None.

USB_HOST_CDC_INSTANCES_NUMBER Macro

Specifies the number of CDC instances.

File

usb_host_cdc_config_template.h

C

```
#define USB_HOST_CDC_INSTANCES_NUMBER
```

Description

USB Host CDC Maximum Number of Instances

This macro defines the number of instances of the CDC host Driver. For example, if the application needs to implement two instances of the CDC host Driver should be set to 2.

Remarks

None.

Building the Library

Describes the files to be included in the project while using the USB CDC Host Client Driver.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/usb`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
usb_host_cdc.h	This header file should be included in any `.c` file that accesses the CDC Host Client Driver API.
sub_host_cdc_acm.h	This header file should be included in any `.c` file that accesses the CDC Host Client Driver command request API.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/dynamic/usb_host_cdc.c	This file implements the CDC Host Client Driver interface and should be included in the project if the CDC Host Client Driver operation is desired.
/src/dynamic/usb_host_cdc_acm.c	This file implements the CDC Host Client Driver command request functions and should be included if any class specific function must be called.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The USB CDC Host Library depends on the following modules:

- USB Host Layer Library

Library Interface

a) Client Access Functions

	Name	Description
	USB_HOST_CDC_Open	This function opens the specified CDC device.
	USB_HOST_CDC_Close	This function closes the CDC device.
	USB_HOST_CDC_AttachEventHandlerSet	This function will set an attach event handler.
	USB_HOST_CDC_EventHandlerSet	Registers an event handler with the CDC Host Client Driver.
	USB_HOST_CDC_DeviceObjHandleGet	This function returns the Device Object Handle for this CDC device.

b) Data Transfer Functions

	Name	Description
	USB_HOST_CDC_Read	This function will read data from the attached device.
	USB_HOST_CDC_SerialStateNotificationGet	This function will request Serial State Notification from the attached device.
	USB_HOST_CDC_Write	This function will write data to the attached device.

c) CDC Class-specific Functions

	Name	Description
	USB_HOST_CDC_ACM_BreakSend	This function sends a request to the attached device to update its break duration.
	USB_HOST_CDC_ACM_ControlLineStateSet	This function sends a request to the attached device to set its Control Line State.
	USB_HOST_CDC_ACM_LineCodingGet	This function sends a request to the attached device to get its Line Coding.
	USB_HOST_CDC_ACM_LineCodingSet	This function sends a request to the attached device to set its Line Coding.

d) Data Types and Constants

	Name	Description
	USB_HOST_CDC_EVENT	Identifies the possible events that the CDC Class Driver can generate.
	USB_HOST_CDC_RESULT	USB Host CDC Client Driver Result enumeration.
	USB_HOST_CDC_TRANSFER_HANDLE	USB Host CDC Client Driver Transfer Handle
	USB_HOST_CDC_TRANSFER_HANDLE_INVALID	USB Host CDC Client Driver Invalid Transfer Handle Definition.
	USB_HOST_CDC_ATTACH_EVENT_HANDLER	USB Host CDC Client Driver Attach Event Handler Function Pointer Type.
	USB_HOST_CDC_EVENT_ACM_GET_LINE_CODING_COMPLETE_DATA	USB Host CDC Client Driver Command Event Data.
	USB_HOST_CDC_HANDLE	Defines the type of the CDC Host Client Driver Handle
	USB_HOST_CDC_EVENT_ACM_SEND_BREAK_COMPLETE_DATA	USB Host CDC Client Driver Command Event Data.
	USB_HOST_CDC_EVENT_ACM_SET_CONTROL_LINE_STATE_COMPLETE_DATA	USB Host CDC Client Driver Command Event Data.
	USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE_DATA	USB Host CDC Client Driver Command Event Data.
	USB_HOST_CDC_EVENT_HANDLER	USB Host CDC Client Driver Event Handler Function Pointer Type.
	USB_HOST_CDC_EVENT_READ_COMPLETE_DATA	USB Host CDC Client Driver Event Data.
	USB_HOST_CDC_EVENT_RESPONSE	Return type of the USB CDC Host Client Driver Event Handler.
	USB_HOST_CDC_EVENT_SERIAL_STATE_NOTIFICATION_RECEIVED_DATA	USB Host CDC Client Driver Event Data.
	USB_HOST_CDC_EVENT_WRITE_COMPLETE_DATA	USB Host CDC Client Driver Event Data.
	USB_HOST_CDC_OBJ	Defines the type of the CDC Host Client Object.
	USB_HOST_CDC_REQUEST_HANDLE	USB Host CDC Client Driver Request Handle
	USB_HOST_CDC_INTERFACE	USB HOST CDC Client Driver Interface
	USB_HOST_CDC_REQUEST_HANDLE_INVALID	USB Host CDC Client Driver Invalid Request Handle
	USB_HOST_CDC_HANDLE_INVALID	Defines an Invalid CDC Client Driver Handle.

Description

a) Client Access Functions

USB_HOST_CDC_Open Function

This function opens the specified CDC device.

File

usb_host_cdc.h

C

```
USB_HOST_CDC_HANDLE USB_HOST_CDC_Open(USB_HOST_CDC_OBJ cdcDeviceObj);
```

Returns

Will return a valid handle if the device could be opened successfully, else will return USB_HOST_CDC_HANDLE_INVALID. The function will return a valid handle if the device is ready to be opened.

Description

This function will open the specified CDC device. Once opened, the CDC device can be accessed via the handle which this function returns. The cdcDeviceObj parameter is the value returned in the USB_HOST_CDC_ATTACH_EVENT_HANDLER event handling function.

Remarks

None.

Preconditions

The client handle should be valid.

Example

Parameters

Parameters	Description
cdcDeviceObj	CDC device object handle returned in the USB_HOST_CDC_ATTACH_EVENT_HANDLER function.

Function

```
USB_HOST_CDC_HANDLE USB_HOST_CDC_Open
(
    USB_HOST_CDC_OBJ cdcDeviceObj
);
```

USB_HOST_CDC_Close Function

This function closes the CDC device.

File

usb_host_cdc.h

C

```
void USB_HOST_CDC_Close(USB_HOST_CDC_HANDLE cdcDeviceHandle);
```

Returns

None.

Description

This function will close the open CDC device. This closes the association between the application entity that opened the device and device. The driver handle becomes invalid.

Remarks

The device handle becomes invalid after calling this function.

Preconditions

None.

Example

Parameters

Parameters	Description
cdcDeviceHandle	handle to the CDC device obtained from the USB_HOST_CDC_Open() function.

Function

void USB_HOST_CDC_Close
(
USB_HOST_CDC_HANDLE cdcDeviceHandle
);

USB_HOST_CDC_AttachEventHandlerSet Function

This function will set an attach event handler.

File

usb_host_cdc.h

C

```
USB_HOST_CDC_RESULT USB_HOST_CDC_AttachEventHandlerSet(USB_HOST_CDC_ATTACH_EVENT_HANDLER eventHandler,
uintptr_t context);
```

Returns

USB_HOST_CDC_RESULT_SUCCESS - if the attach event handler was registered successfully.

USB_HOST_CDC_RESULT_FAILURE - if the number of registered event handlers has exceeded USB_HOST_CDC_ATTACH_LISTENERS_NUMBER.

Description

This function will set an attach event handler. The attach event handler will be called when a CDC device has been attached. The context will be returned in the event handler. This function should be called before the bus has been enabled.

Remarks

Function should be called before USB_HOST_BusEnable() function is called.

Preconditions

None.

Example

Parameters

Parameters	Description
eventHandler	pointer to the attach event handler
context	an application defined context that will be returned in the event handler.

Function

USB_HOST_CDC_RESULT USB_HOST_CDC_AttachEventHandlerSet
(
USB_HOST_CDC_ATTACH_EVENT_HANDLER eventHandler,
uintptr_t context
);

USB_HOST_CDC_EventHandlerSet Function

Registers an event handler with the CDC Host Client Driver.

File

usb_host_cdc.h

C

```
USB_HOST_CDC_RESULT USB_HOST_CDC_EventHandlerSet(USB_HOST_CDC_HANDLE handle, USB_HOST_CDC_EVENT_HANDLER
eventHandler, uintptr_t context);
```

Returns

USB_HOST_CDC_RESULT_SUCCESS - The operation was successful USB_HOST_CDC_RESULT_HANDLE_INVALID - The specified instance does not exist. USB_HOST_CDC_RESULT_FAILURE - An unknown failure occurred.

Description

This function registers a client specific CDC Host Client Driver event handler. The CDC Host Client Driver will call this function with relevant event and associated event data, in response to command requests and data transfers that have been scheduled by the client.

Remarks

None.

Preconditions

None.

Example

Parameters

Parameters	Description
handle	handle to the CDC Host Client Driver.
eventHandler	A pointer to event handler function. If NULL, then events will not be generated.
context	Application specific context that is returned in the event handler.

Function

```
USB_HOST_CDC_RESULT USB_HOST_CDC_EventHandlerSet
(
    USB_HOST_CDC_HANDLE handle,
    USB_HOST_CDC_EVENT_HANDLER eventHandler,
uintptr_t context
);
```

USB_HOST_CDC_DeviceObjHandleGet Function

This function returns the Device Object Handle for this CDC device.

File

usb_host_cdc.h

C

```
USB_HOST_DEVICE_OBJ_HANDLE USB_HOST_CDC_DeviceObjHandleGet(USB_HOST_CDC_OBJ cdcDeviceObj);
```

Returns

Will return a valid device object handle if the device is still connected to the system. Will return an USB_HOST_DEVICE_OBJ_HANDLE_INVALID otherwise.

Description

This function returns the Device Object Handle for this CDC device. This returned Device Object Handle can be used by the application to perform device level operations such as getting the string descriptors.

Remarks

None.

Preconditions

None.

Example

Parameters

Parameters	Description
cdcDeviceObj	CDC device object handle returned in the USB_HOST_CDC_ATTACH_EVENT_HANDLER function.

Function

USB_HOST_DEVICE_OBJ_HANDLE USB_HOST_CDC_DeviceObjHandleGet
(
USB_HOST_CDC_OBJ cdcDeviceObj
);

b) Data Transfer Functions

USB_HOST_CDC_Read Function

This function will read data from the attached device.

File

usb_host_cdc.h

C

```
USB_HOST_CDC_RESULT USB_HOST_CDC_Read(USB_HOST_CDC_HANDLE handle, USB_HOST_CDC_TRANSFER_HANDLE *
transferHandle, void * data, size_t size);
```

Returns

USB_HOST_CDC_RESULT_SUCCESS - The operation was successful.

USB_HOST_CDC_RESULT_DEVICE_UNKNOWN - The device that this request was targeted to does not exist in the system.

USB_HOST_CDC_RESULT_BUSY - The request could not be scheduled at this time. The client should try again.

USB_HOST_CDC_RESULT_INVALID_PARAMETER - An input parameter was NULL.

USB_HOST_CDC_RESULT_FAILURE - An unknown failure occurred.

USB_HOST_CDC_RESULT_HANDLE_INVALID - The client handle is not valid.

Description

This function will read data from the attached CDC device. The function will try to read size amount of bytes but will stop reading when the device terminates the USB transfer (sends a short packet or a ZLP). If the request was accepted, transferHandle will contain a valid transfer handle, else it will contain USB_HOST_CDC_TRANSFER_HANDLE_INVALID. The completion of the request will be indicated by the USB_HOST_CDC_EVENT_READ_COMPLETE event. The transfer handle will be returned in the event.

Remarks

None.

Preconditions

The client handle should be valid.

Example

Parameters

Parameters	Description
handle	handle to the CDC device instance to which the request should be sent.
transferHandle	Pointer to USB_HOST_CDC_TRANSFER_HANDLE type of a variable. This will contain a valid transfer handle if the request was successful.
data	pointer to the buffer where the received data will be stored. The contents of the buffer will be valid only when the USB_HOST_CDC_EVENT_READ_COMPLETE event has occurred.
size	size of the data buffer. Only these many bytes or less will be read.

Function

USB_HOST_CDC_RESULT USB_HOST_CDC_Read
(
USB_HOST_CDC_HANDLE handle,
USB_HOST_CDC_TRANSFER_HANDLE * transferHandle,
void * data,
size_t size

);

USB_HOST_CDC_SerialStateNotificationGet Function

This function will request Serial State Notification from the attached device.

File

usb_host_cdc.h

C

```
USB_HOST_CDC_RESULT USB_HOST_CDC_SerialStateNotificationGet(USB_HOST_CDC_HANDLE handle,
USB_HOST_CDC_TRANSFER_HANDLE * transferHandle, USB_CDC_SERIAL_STATE * serialState);
```

Returns

USB_HOST_CDC_RESULT_SUCCESS - The operation was successful.

USB_HOST_CDC_RESULT_DEVICE_UNKNOWN - The device that this request was targeted to does not exist in the system.

USB_HOST_CDC_RESULT_BUSY - The request could not be scheduled at this time. The client should try again.

USB_HOST_CDC_RESULT_INVALID_PARAMETER - An input parameter was NULL.

USB_HOST_CDC_RESULT_FAILURE - An unknown failure occurred.

USB_HOST_CDC_RESULT_HANDLE_INVALID - The client handle is not valid.

Description

This function will request Serial State Notification from the attached device. If the request was accepted, transferHandle will contain a valid transfer handle, else it will contain USB_HOST_CDC_TRANSFER_HANDLE_INVALID. The completion of the request will be indicated by the USB_HOST_CDC_EVENT_SERIAL_STATE_NOTIFICATION_RECEIVED event. The transfer handle will be returned in the event.

Remarks

None.

Preconditions

The client handle should be valid.

Example

Parameters

Parameters	Description
handle	handle to the CDC device instance to which the request should be sent.
transferHandle	Pointer to USB_HOST_CDC_TRANSFER_HANDLE type of a variable. This will contain a valid transfer handle if the request was successful.
serialState	Pointer to the serial state data structure where the received serial state will be stored.

Function

USB_HOST_CDC_RESULT USB_HOST_CDC_SerialStateNotificationGet

(

USB_HOST_CDC_HANDLE handle,

USB_HOST_CDC_TRANSFER_HANDLE * transferHandle,

USB_CDC_SERIAL_STATE * serialState

);

USB_HOST_CDC_Write Function

This function will write data to the attached device.

File

usb_host_cdc.h

C

```
USB_HOST_CDC_RESULT USB_HOST_CDC_Write(USB_HOST_CDC_HANDLE handle, USB_HOST_CDC_TRANSFER_HANDLE *
transferHandle, void * data, size_t size);
```

Returns

USB_HOST_CDC_RESULT_SUCCESS - The operation was successful.

USB_HOST_CDC_RESULT_DEVICE_UNKNOWN - The device that this request was targeted to does not exist in the system.

USB_HOST_CDC_RESULT_BUSY - The request could not be scheduled at this time. The client should try again.

USB_HOST_CDC_RESULT_INVALID_PARAMETER - An input parameter was NULL.

USB_HOST_CDC_RESULT_FAILURE - An unknown failure occurred.

USB_HOST_CDC_RESULT_HANDLE_INVALID - The client handle is not valid.

Description

This function will write data to the attached CDC device. The function will write size amount of bytes. If the request was accepted, transferHandle will contain a valid transfer handle, else it will contain USB_HOST_CDC_TRANSFER_HANDLE_INVALID. The completion of the request will be indicated by the USB_HOST_CDC_EVENT_WRITE_COMPLETE event. The transfer handle will be returned in the event.

Remarks

None.

Preconditions

The client handle should be valid.

Example

Parameters

Parameters	Description
handle	handle to the CDC device instance to which the request should be sent.
transferHandle	Pointer to USB_HOST_CDC_TRANSFER_HANDLE type of a variable. This will contain a valid transfer handle if the request was successful.
data	pointer to the buffer containing the data to be written. The contents of the buffer should not be changed till the USB_HOST_CDC_EVENT_WRITE_COMPLETE event has occurred.
size	Number of bytes to write.

Function

```
USB_HOST_CDC_RESULT USB_HOST_CDC_Write
(
    USB_HOST_CDC_HANDLE handle,
    USB_HOST_CDC_TRANSFER_HANDLE * transferHandle,
void * data,
size_t size
);
```

c) CDC Class-specific Functions

USB_HOST_CDC_ACM_BreakSend Function

This function sends a request to the attached device to update its break duration.

File

usb_host_cdc_acm.h

C

```
USB_HOST_CDC_RESULT USB_HOST_CDC_ACM_BreakSend(USB_HOST_CDC_HANDLE handle, USB_HOST_CDC_REQUEST_HANDLE *
requestHandle, uint16_t breakDuration);
```

Returns

USB_HOST_CDC_RESULT_SUCCESS - The operation was successful.

USB_HOST_CDC_RESULT_DEVICE_UNKNOWN - The device that this request was targeted to does not exist in the system.

USB_HOST_CDC_RESULT_BUSY - The request could not be scheduled at this time. The client should try again.

USB_HOST_CDC_RESULT_INVALID_PARAMETER - An input parameter was NULL.

USB_HOST_CDC_RESULT_FAILURE - An unknown failure occurred.

USB_HOST_CDC_RESULT_HANDLE_INVALID - The client handle is not valid.

Description

This function sends a request to the attached to update its break duration. The function schedules a SEND BREAK control transfer. If successful, the transferHandle parameter will contain a valid request handle, else it will contain USB_HOST_CDC_REQUEST_HANDLE_INVALID. When completed, the CDC client driver will generate a USB_HOST_CDC_EVENT_ACM_SEND_BREAK_COMPLETE event.

Remarks

None.

Preconditions

The client handle should be valid.

Example

Parameters

Parameters	Description
handle	handle to the CDC device instance to which the request should be sent.
requestHandle	Pointer to USB_HOST_CDC_REQUEST_HANDLE type of a variable. This will contain a valid transfer handle if the request was successful.
breakDuration	Break duration.

Function

```
USB_HOST_CDC_RESULT USB_HOST_CDC_ACM_BreakSend
(
    USB_HOST_CDC_HANDLE handle,
    USB_HOST_CDC_REQUEST_HANDLE * requestHandle,
uint16_t breakDuration
);
```

USB_HOST_CDC_ACM_ControlLineStateSet Function

This function sends a request to the attached device to set its Control Line State.

File

usb_host_cdc_acm.h

C

```
USB_HOST_CDC_RESULT USB_HOST_CDC_ACM_ControlLineStateSet(USB_HOST_CDC_HANDLE handle,
USB_HOST_CDC_REQUEST_HANDLE * requestHandle, USB_CDC_CONTROL_LINE_STATE * controlLineState);
```

Returns

USB_HOST_CDC_RESULT_SUCCESS - The operation was successful.

USB_HOST_CDC_RESULT_DEVICE_UNKNOWN - The device that this request was targeted to does not exist in the system.

USB_HOST_CDC_RESULT_BUSY - The request could not be scheduled at this time. The client should try again.

USB_HOST_CDC_RESULT_INVALID_PARAMETER - An input parameter was NULL.

USB_HOST_CDC_RESULT_FAILURE - An unknown failure occurred.

USB_HOST_CDC_RESULT_HANDLE_INVALID - The client handle is not valid.

Description

This function sends a request to the attached to set its Control Line State. The function schedules a SET CONTROL LINE STATE control transfer. If successful, the requestHandle parameter will contain a valid request handle, else it will contain USB_HOST_CDC_REQUEST_HANDLE_INVALID. When completed, the CDC client driver will generate a USB_HOST_CDC_EVENT_ACM_SET_CONTROL_LINE_STATE_COMPLETE event.

Remarks

None.

Preconditions

The client handle should be valid.

Example

Parameters

Parameters	Description
handle	handle to the CDC device instance to which the request should be sent.
requestHandle	Pointer to USB_HOST_CDC_REQUEST_HANDLE type of a variable. This will contain a valid transfer handle if the request was successful.
controlLineState	Pointer to the control line state data structure.

Function

```
  USB_HOST_CDC_RESULT USB_HOST_CDC_ACM_ControlLineStateSet
(
    USB_HOST_CDC_HANDLE handle,
    USB_HOST_CDC_REQUEST_HANDLE * requestHandle,
USB_CDC_HOST_CONTROL_LINE_STATE * controlLineState
);
```

USB_HOST_CDC_ACM_LineCodingGet Function

This function sends a request to the attached device to get its Line Coding.

File

usb_host_cdc_acm.h

C

```
USB_HOST_CDC_RESULT USB_HOST_CDC_ACM_LineCodingGet(USB_HOST_CDC_HANDLE handle, USB_HOST_CDC_REQUEST_HANDLE
* requestHandle, USB_CDC_LINE_CODING * lineCoding);
```

Returns

USB_HOST_CDC_RESULT_SUCCESS - The operation was successful.

USB_HOST_CDC_RESULT_DEVICE_UNKNOWN - The device that this request was targeted to does not exist in the system.

USB_HOST_CDC_RESULT_BUSY - The request could not be scheduled at this time. The client should try again.

USB_HOST_CDC_RESULT_INVALID_PARAMETER - An input parameter was NULL.

USB_HOST_CDC_RESULT_FAILURE - An unknown failure occurred.

USB_HOST_CDC_RESULT_HANDLE_INVALID - The client handle is not valid.

Description

This function sends a request to the attached device to get its line coding. The function schedules a GET LINE CODING control transfer. If successful, the requestHandle parameter will contain a valid request handle, else it will contain USB_HOST_CDC_REQUEST_HANDLE_INVALID. When completed, the CDC client driver will generate a USB_HOST_CDC_EVENT_ACM_GET_LINE_CODING_COMPLETE event.

Remarks

None.

Preconditions

The client handle should be valid.

Example

Parameters

Parameters	Description
handle	handle to the CDC device instance to which the request should be sent.
requestHandle	Pointer to USB_HOST_CDC_REQUEST_HANDLE type of a variable. This will contain a valid transfer handle if the request was successful.

lineCoding	Pointer to the line coding data structure where the obtained line coding will be stored. The contents of this data structure will be valid only when the USB_HOST_CDC_EVENT_ACM_GET_LINE_CODING_COMPLETE event has been generated.

Function

```
USB_HOST_CDC_RESULT USB_HOST_CDC_ACM_LineCodingGet
(
    USB_HOST_CDC_HANDLE handle,
    USB_HOST_CDC_REQUEST_HANDLE * requestHandle,
USB_CDC_LINE_CODING * lineCoding
);
```

USB_HOST_CDC_ACM_LineCodingSet Function

This function sends a request to the attached device to set its Line Coding.

File

usb_host_cdc_acm.h

C

```
USB_HOST_CDC_RESULT USB_HOST_CDC_ACM_LineCodingSet(USB_HOST_CDC_HANDLE handle, USB_HOST_CDC_REQUEST_HANDLE
* requestHandle, USB_CDC_LINE_CODING * lineCoding);
```

Returns

USB_HOST_CDC_RESULT_SUCCESS - The operation was successful.

USB_HOST_CDC_RESULT_DEVICE_UNKNOWN - The device that this request was targeted to does not exist in the system.

USB_HOST_CDC_RESULT_BUSY - The request could not be scheduled at this time. The client should try again.

USB_HOST_CDC_RESULT_INVALID_PARAMETER - An input parameter was NULL.

USB_HOST_CDC_RESULT_FAILURE - An unknown failure occurred.

USB_HOST_CDC_RESULT_HANDLE_INVALID - The client handle is not valid.

Description

This function sends a request to the attached device to set its line coding. The function schedules a SET LINE CODING control transfer. If successful, the requestHandle parameter will contain a valid request handle, else it will contain USB_HOST_CDC_REQUEST_HANDLE_INVALID. When completed, the CDC client driver will generate a USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE event.

Remarks

None.

Preconditions

The client handle should be valid.

Example

Parameters

Parameters	Description
handle	handle to the CDC device instance to which the request should be sent.
requestHandle	Pointer to USB_HOST_CDC_REQUEST_HANDLE type of a variable. This will contain a valid transfer handle if the request was successful.
lineCoding	Pointer to the line coding data structure containing the line coding to be set. The contents of this data structure should not be changed until the USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE event has been generated.

Function

```
USB_HOST_CDC_RESULT USB_HOST_CDC_ACM_LineCodingSet
(
    USB_HOST_CDC_HANDLE handle,
```

```
    USB_HOST_CDC_REQUEST_HANDLE * requestHandle,
USB_CDC_LINE_CODING * lineCoding
);
```

d) Data Types and Constants

USB_HOST_CDC_EVENT Enumeration

Identifies the possible events that the CDC Class Driver can generate.

File

usb_host_cdc.h

C

```
typedef enum {
  USB_HOST_CDC_EVENT_READ_COMPLETE,
  USB_HOST_CDC_EVENT_WRITE_COMPLETE,
  USB_HOST_CDC_EVENT_ACM_SEND_BREAK_COMPLETE,
  USB_HOST_CDC_EVENT_ACM_SET_CONTROL_LINE_STATE_COMPLETE,
  USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE,
  USB_HOST_CDC_EVENT_ACM_GET_LINE_CODING_COMPLETE,
  USB_HOST_CDC_EVENT_SERIAL_STATE_NOTIFICATION_RECEIVED,
  USB_HOST_CDC_EVENT_DEVICE_DETACHED
} USB_HOST_CDC_EVENT;
```

Members

Members	Description
USB_HOST_CDC_EVENT_READ_COMPLETE	This event occurs when a CDC Client Driver Read operation has completed i.e when the data has been received from the connected CDC device. This event is generated after the application calls the USB_HOST_CDC_Read function. The eventData parameter in the event call back function will be of a pointer to a USB_HOST_CDC_EVENT_READ_COMPLETE_DATA structure. This contains details about the transfer handle associated with this read request, the amount of data read and the termination status of the read request.
USB_HOST_CDC_EVENT_WRITE_COMPLETE	This event occurs when a CDC Client Driver Write operation has completed i.e when the data has been written to the connected CDC device. This event is generated after the application calls the USB_HOST_CDC_Write function. The eventData parameter in the event call back function will be a pointer to a USB_HOST_CDC_EVENT_WRITE_COMPLETE_DATA structure. This contains details about the transfer handle associated with this write request, the amount of data written and the termination status of the write request.
USB_HOST_CDC_EVENT_ACM_SEND_BREAK_COMPLETE	This event occurs when a CDC Client Driver Send Break request has completed. This event is generated after the application calls the USB_HOST_CDC_ACM_BreakSend function and the device has either acknowledged or stalled the request. The eventData parameter in the event call back function will be of a pointer to a USB_HOST_CDC_EVENT_ACM_SET_CONTROL_LINE_STATE_COMPLETE_DATA structure. This contains details about the transfer handle associated with this request, the amount of data sent and the termination status of the set request.

USB_HOST_CDC_EVENT_ACM_SET_CONTROL_LINE_STATE_COMPLETE	This event occurs when a CDC Client Driver Set Control Line State request has completed. This event is generated after the application calls the USB_HOST_CDC_ACM_ControlLineStateSet function and the device has either acknowledged or stalled the request. The eventData parameter in the event call back function will be of a pointer to a USB_HOST_CDC_EVENT_ACM_SET_CONTROL_LINE_STATE_COMPLETE_DATA structure. This contains details about the transfer handle associated with this request, the amount of data sent and the termination status of the set request.
USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE	This event occurs when a CDC Client Driver Set Line Coding request has completed. This event is generated after the application calls the USB_HOST_CDC_ACM_LineCodingSet function and the device either acknowledged or stalled the request. The eventData parameter in the event call back function will be of a pointer to a USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE_DATA structure. This contains details about the transfer handle associated with this request, the amount of data sent and the termination status of the set request.
USB_HOST_CDC_EVENT_ACM_GET_LINE_CODING_COMPLETE	This event occurs when a CDC Client Driver Get Line Coding request has completed. This event is generated after the application calls the USB_HOST_CDC_ACM_LineCodingGet function and the device sends the line coding to the host. The eventData parameter in the event call back function will be of a pointer to a USB_HOST_CDC_EVENT_ACM_GET_LINE_CODING_COMPLETE_DATA structure. This contains details about the transfer handle associated with this request, the amount of data received and the termination status of the get request.
USB_HOST_CDC_EVENT_SERIAL_STATE_NOTIFICATION_RECEIVED	This event occurs when a CDC Client Driver Serial State Notification Get operation has completed. This event is generated after the application calls the USB_HOST_CDC_SerialStateNotificationGet and the device sends a serial state notification to the host. The eventData parameter in the event call back function will be of a pointer to a USB_HOST_CDC_EVENT_SERIAL_STATE_NOTIFICATION_RECEIVED_DATA structure. This contains details about the transfer handle associated with this request, the amount of data received and the termination status of the get request.
USB_HOST_CDC_EVENT_DEVICE_DETACHED	This event occurs when the device that this client was connected to has • been detached. The client should close the CDC instance. There is no • event data associated with this event

Description

CDC Class Driver Events

This enumeration identifies the possible events that the CDC Class Driver can generate. The application should register an event handler using the USB_HOST_CDC_EventHandlerSet function to receive CDC Class Driver events.

An event may have data associated with it. Events that are generated due to a transfer of data between the host and device are accompanied by data structures that provide the status of the transfer termination. For example, the USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE event is accompanied by a pointer to a USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE_DATA data structure. The transferStatus member of this data structure indicates the success or failure of the transfer. A transfer may fail due to device not responding on the bus, if the device stalls any stages of the transfer or due to NAK timeouts. The event description provides details on the nature of the event and the data that is associated with the event.

Remarks

None.

USB_HOST_CDC_RESULT Enumeration

USB Host CDC Client Driver Result enumeration.

File

usb_host_cdc.h

C

```
typedef enum {
  USB_HOST_CDC_RESULT_FAILURE,
  USB_HOST_CDC_RESULT_BUSY,
  USB_HOST_CDC_RESULT_REQUEST_STALLED,
  USB_HOST_CDC_RESULT_INVALID_PARAMETER,
  USB_HOST_CDC_RESULT_DEVICE_UNKNOWN,
  USB_HOST_CDC_RESULT_ABORTED,
  USB_HOST_CDC_RESULT_HANDLE_INVALID,
  USB_HOST_CDC_RESULT_SUCCESS
} USB_HOST_CDC_RESULT;
```

Members

Members	Description
USB_HOST_CDC_RESULT_FAILURE	An unknown failure has occurred
USB_HOST_CDC_RESULT_BUSY	The transfer or request could not be scheduled because internal • queues are full. The request or transfer should be retried
USB_HOST_CDC_RESULT_REQUEST_STALLED	The request was stalled
USB_HOST_CDC_RESULT_INVALID_PARAMETER	A required parameter was invalid
USB_HOST_CDC_RESULT_DEVICE_UNKNOWN	The associated device does not exist in the system.
USB_HOST_CDC_RESULT_ABORTED	The transfer or requested was aborted
USB_HOST_CDC_RESULT_HANDLE_INVALID	The specified handle is not valid
USB_HOST_CDC_RESULT_SUCCESS	The operation was successful

Description

USB Host CDC Client Driver Result.

This enumeration lists the possible results the CDC client driver uses. Only some results are applicable to some functions and events. Refer to the event and function documentation for more details.

Remarks

None.

USB_HOST_CDC_TRANSFER_HANDLE Type

USB Host CDC Client Driver Transfer Handle

File

usb_host_cdc.h

C

```
typedef uintptr_t USB_HOST_CDC_TRANSFER_HANDLE;
```

Description

USB Host CDC Client Driver Transfer Handle

This is returned by the CDC Client driver data transfer routines and should be used by the application to track the transfer especially in cases where transfers are queued.

Remarks

None.

USB_HOST_CDC_TRANSFER_HANDLE_INVALID Macro

USB Host CDC Client Driver Invalid Transfer Handle Definition.

File

usb_host_cdc.h

C

```
#define USB_HOST_CDC_TRANSFER_HANDLE_INVALID ((USB_HOST_CDC_TRANSFER_HANDLE)(-1))
```

Description

USB Host CDC Client Driver Invalid Transfer Handle Definition

This definition defines a USB Host CDC Client Driver Invalid Transfer Handle. A Invalid Transfer Handle is returned by the CDC Client Driver data transfer routines when the request was not successful.

Remarks

None.

USB_HOST_CDC_ATTACH_EVENT_HANDLER Type

USB Host CDC Client Driver Attach Event Handler Function Pointer Type.

File

usb_host_cdc.h

C

```
typedef void (* USB_HOST_CDC_ATTACH_EVENT_HANDLER)(USB_HOST_CDC_OBJ cdcObjHandle, uintptr_t context);
```

Description

USB Host CDC Client Driver Attach Event Handler Function Pointer Type.

This data type defines the required function signature of the USB Host CDC Client Driver attach event handling callback function. The application must register a pointer to a CDC Client Driver attach events handling function whose function signature (parameter and return value types) match the types specified by this function pointer in order to receive attach event call backs from the CDC Client Driver. The client driver will invoke this function with event relevant parameters. The description of the event handler function parameters is given here.

cdcObjHandle - Handle of the client to which this event is directed.

context - Value identifying the context of the application that was registered along with the event handling function.

Remarks

None.

USB_HOST_CDC_EVENT_ACM_GET_LINE_CODING_COMPLETE_DATA Structure

USB Host CDC Client Driver Command Event Data.

File

usb_host_cdc.h

C

```
typedef struct {
  USB_HOST_CDC_REQUEST_HANDLE requestHandle;
  USB_HOST_CDC_RESULT result;
  size_t length;
} USB_HOST_CDC_EVENT_ACM_GET_LINE_CODING_COMPLETE_DATA,
USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE_DATA,
USB_HOST_CDC_EVENT_ACM_SET_CONTROL_LINE_STATE_COMPLETE_DATA,
USB_HOST_CDC_EVENT_ACM_SEND_BREAK_COMPLETE_DATA;
```

Members

Members	Description
USB_HOST_CDC_REQUEST_HANDLE requestHandle;	Request handle of this request
USB_HOST_CDC_RESULT result;	Termination status
size_t length;	Size of the data transferred in the request

Description

USB Host CDC Client Driver Command Event Data.

This data type defines the data structure returned by the driver along with the following events:
USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE_DATA,
USB_HOST_CDC_EVENT_ACM_SEND_BREAK_COMPLETE_DATA,

USB_HOST_CDC_EVENT_ACM_GET_LINE_CODING_COMPLETE_DATA,
USB_HOST_CDC_EVENT_ACM_SET_CONTROL_LINE_STATE_COMPLETE_DATA,

Remarks

None.

USB_HOST_CDC_HANDLE Type

Defines the type of the CDC Host Client Driver Handle

File

usb_host_cdc.h

C

```
typedef uintptr_t USB_HOST_CDC_HANDLE;
```

Description

USB Host CDC Client Driver Handle

This type defines the type of the handle returned by USB_HOST_CDC_Open() function. This application uses this handle to specify the instance of the CDC client driver being accessed while calling a CDC Client driver function.

Remarks

None.

USB_HOST_CDC_EVENT_ACM_SEND_BREAK_COMPLETE_DATA Structure

USB Host CDC Client Driver Command Event Data.

File

usb_host_cdc.h

C

```
typedef struct {
  USB_HOST_CDC_REQUEST_HANDLE requestHandle;
  USB_HOST_CDC_RESULT result;
  size_t length;

Description

USB Host CDC Client Driver Command Event Data.

This data type defines the data structure returned by the driver along with the following events:
USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE_DATA,
USB_HOST_CDC_EVENT_ACM_SEND_BREAK_COMPLETE_DATA,
USB_HOST_CDC_EVENT_ACM_GET_LINE_CODING_COMPLETE_DATA,
USB_HOST_CDC_EVENT_ACM_SET_CONTROL_LINE_STATE_COMPLETE_DATA,

Remarks

None.

USB_HOST_CDC_EVENT_HANDLER Type

USB Host CDC Client Driver Event Handler Function Pointer Type.

File

usb_host_cdc.h

C

```
typedef USB_HOST_CDC_EVENT_RESPONSE (* USB_HOST_CDC_EVENT_HANDLER)(USB_HOST_CDC_HANDLE cdcHandle,
USB_HOST_CDC_EVENT event, void * eventData, uintptr_t context);
```

Description

USB Host CDC Client Driver Event Handler Function Pointer Type.

This data type defines the required function signature of the USB Host CDC Client Driver event handling callback function. The application must register a pointer to a CDC Client Driver events handling function whose function signature (parameter and return value types) match the types specified by this function pointer in order to receive event call backs from the CDC Client Driver. The class driver will invoke this function with event relevant parameters. The description of the event handler function parameters is given here.

handle - Handle of the client to which this event is directed.

event - Type of event generated.

eventData - This parameter should be type casted to a event specific pointer type based on the event that has occurred. Refer to the USB_HOST_CDC_EVENT enumeration description for more details.

context - Value identifying the context of the application that was registered along with the event handling function.

Remarks

None.

USB_HOST_CDC_EVENT_READ_COMPLETE_DATA Structure

USB Host CDC Client Driver Event Data.

File

usb_host_cdc.h

C

```
typedef struct {
  USB_HOST_CDC_TRANSFER_HANDLE transferHandle;
  USB_HOST_CDC_RESULT result;
  size_t length;
} USB_HOST_CDC_EVENT_SERIAL_STATE_NOTIFICATION_RECEIVED_DATA, USB_HOST_CDC_EVENT_READ_COMPLETE_DATA,
USB_HOST_CDC_EVENT_WRITE_COMPLETE_DATA;
```

Members

Members	Description
USB_HOST_CDC_TRANSFER_HANDLE transferHandle;	Transfer handle of this transfer
USB_HOST_CDC_RESULT result;	Termination transfer status
size_t length;	Size of the data transferred in the request

Description

USB Host CDC Client Driver Event Data.

This data type defines the data structure returned by the driver along with the following events: USB_HOST_CDC_EVENT_READ_COMPLETE_DATA, USB_HOST_CDC_EVENT_WRITE_COMPLETE_DATA,

Remarks

None.

USB_HOST_CDC_EVENT_RESPONSE Enumeration

Return type of the USB CDC Host Client Driver Event Handler.

File

usb_host_cdc.h

C

```
typedef enum {
  USB_HOST_CDC_EVENT_RESPONE_NONE
} USB_HOST_CDC_EVENT_RESPONSE;
```

Members

Members	Description
USB_HOST_CDC_EVENT_RESPONE_NONE	This means no response is required

Description

USB Host CDC Event Handler Return Type

This enumeration list the possible return values of the USB CDC Host Client Driver Event Handler.

Remarks

None.

USB_HOST_CDC_EVENT_SERIAL_STATE_NOTIFICATION_RECEIVED_DATA Structure

USB Host CDC Client Driver Event Data.

File

usb_host_cdc.h

C

```
typedef struct {
  USB_HOST_CDC_TRANSFER_HANDLE transferHandle;
  USB_HOST_CDC_RESULT result;
  size_t length;
} USB_HOST_CDC_EVENT_SERIAL_STATE_NOTIFICATION_RECEIVED_DATA, USB_HOST_CDC_EVENT_READ_COMPLETE_DATA,
USB_HOST_CDC_EVENT_WRITE_COMPLETE_DATA;
```

Members

Members	Description
USB_HOST_CDC_TRANSFER_HANDLE transferHandle;	Transfer handle of this transfer
USB_HOST_CDC_RESULT result;	Termination transfer status
size_t length;	Size of the data transferred in the request

Description

USB Host CDC Client Driver Event Data.

This data type defines the data structure returned by the driver along with the following events:
USB_HOST_CDC_EVENT_READ_COMPLETE_DATA, USB_HOST_CDC_EVENT_WRITE_COMPLETE_DATA,

Remarks

None.

USB_HOST_CDC_EVENT_WRITE_COMPLETE_DATA Structure

USB Host CDC Client Driver Event Data.

File

usb_host_cdc.h

C

```
typedef struct {
  USB_HOST_CDC_TRANSFER_HANDLE transferHandle;
  USB_HOST_CDC_RESULT result;
  size_t length;
} USB_HOST_CDC_EVENT_SERIAL_STATE_NOTIFICATION_RECEIVED_DATA, USB_HOST_CDC_EVENT_READ_COMPLETE_DATA,
USB_HOST_CDC_EVENT_WRITE_COMPLETE_DATA;
```

Members

Members	Description
USB_HOST_CDC_TRANSFER_HANDLE transferHandle;	Transfer handle of this transfer
USB_HOST_CDC_RESULT result;	Termination transfer status
size_t length;	Size of the data transferred in the request

Description

USB Host CDC Client Driver Event Data.

This data type defines the data structure returned by the driver along with the following events: USB_HOST_CDC_EVENT_READ_COMPLETE_DATA, USB_HOST_CDC_EVENT_WRITE_COMPLETE_DATA,

Remarks

None.

USB_HOST_CDC_OBJ Type

Defines the type of the CDC Host Client Object.

File

usb_host_cdc.h

C

```
typedef uintptr_t USB_HOST_CDC_OBJ;
```

Description

USB Host CDC Object

This type defines the type of the CDC Host Client Object. This type is returned by the Attach Event Handler and is used by the application to open the attached CDC Device.

Remarks

None.

USB_HOST_CDC_REQUEST_HANDLE Type

USB Host CDC Client Driver Request Handle

File

usb_host_cdc.h

C

```
typedef uintptr_t USB_HOST_CDC_REQUEST_HANDLE;
```

Description

USB Host CDC Client Driver Request Handle

This is returned by the CDC Client driver command routines and should be used by the application to track the command especially in cases where transfers are queued.

Remarks

None.

USB_HOST_CDC_INTERFACE Macro

USB HOST CDC Client Driver Interface

File

usb_host_cdc.h

C

```
#define USB_HOST_CDC_INTERFACE
```

Description

USB HOST CDC Client Driver Interface

This macro should be used by the application in TPL table while adding support for the USB CDC Host Client Driver.

Remarks

None.

USB_HOST_CDC_REQUEST_HANDLE_INVALID Macro

USB Host CDC Client Driver Invalid Request Handle

File

usb_host_cdc.h

C

```
#define USB_HOST_CDC_REQUEST_HANDLE_INVALID ((USB_HOST_CDC_REQUEST_HANDLE)(-1))
```

Description

USB Host CDC Client Driver Invalid Request Handle

This is returned by the CDC Client driver command routines when the request could not be scheduled.

Remarks

None.

USB_HOST_CDC_HANDLE_INVALID Macro

Defines an Invalid CDC Client Driver Handle.

File

usb_host_cdc.h

C

```
#define USB_HOST_CDC_HANDLE_INVALID ((USB_HOST_CDC_HANDLE)(-1))
```

Description

USB Host CDC Client Driver Invalid Handle

This type defines an Invalid CDC Client Driver Handle. The USB_HOST_CDC_Open() function returns an invalid handle when it fails to open the specified CDC device instance.

Remarks

None.

Enumerations

	Name	Description
	USB_HOST_CDC_EVENT	Identifies the possible events that the CDC Class Driver can generate.
	USB_HOST_CDC_EVENT_RESPONSE	Return type of the USB CDC Host Client Driver Event Handler.
	USB_HOST_CDC_RESULT	USB Host CDC Client Driver Result enumeration.

Functions

	Name	Description
	USB_HOST_CDC_AttachEventHandlerSet	This function will set an attach event handler.
	USB_HOST_CDC_Close	This function closes the CDC device.
	USB_HOST_CDC_DeviceObjHandleGet	This function returns the Device Object Handle for this CDC device.
	USB_HOST_CDC_EventHandlerSet	Registers an event handler with the CDC Host Client Driver.
	USB_HOST_CDC_Open	This function opens the specified CDC device.
	USB_HOST_CDC_Read	This function will read data from the attached device.
	USB_HOST_CDC_SerialStateNotificationGet	This function will request Serial State Notification from the attached device.
	USB_HOST_CDC_Write	This function will write data to the attached device.

Macros

	Name	Description
	USB_HOST_CDC_HANDLE_INVALID	Defines an Invalid CDC Client Driver Handle.
	USB_HOST_CDC_INTERFACE	USB HOST CDC Client Driver Interface
	USB_HOST_CDC_REQUEST_HANDLE_INVALID	USB Host CDC Client Driver Invalid Request Handle
	USB_HOST_CDC_TRANSFER_HANDLE_INVALID	USB Host CDC Client Driver Invalid Transfer Handle Definition.

Structures

	Name	Description
	USB_HOST_CDC_EVENT_ACM_GET_LINE_CODING_COMPLETE_DATA	USB Host CDC Client Driver Command Event Data.
	USB_HOST_CDC_EVENT_ACM_SEND_BREAK_COMPLETE_DATA	USB Host CDC Client Driver Command Event Data.
	USB_HOST_CDC_EVENT_ACM_SET_CONTROL_LINE_STATE_COMPLETE_DATA	USB Host CDC Client Driver Command Event Data.
	USB_HOST_CDC_EVENT_ACM_SET_LINE_CODING_COMPLETE_DATA	USB Host CDC Client Driver Command Event Data.
	USB_HOST_CDC_EVENT_READ_COMPLETE_DATA	USB Host CDC Client Driver Event Data.
	USB_HOST_CDC_EVENT_SERIAL_STATE_NOTIFICATION_RECEIVED_DATA	USB Host CDC Client Driver Event Data.
	USB_HOST_CDC_EVENT_WRITE_COMPLETE_DATA	USB Host CDC Client Driver Event Data.

Types

	Name	Description
	USB_HOST_CDC_ATTACH_EVENT_HANDLER	USB Host CDC Client Driver Attach Event Handler Function Pointer Type.
	USB_HOST_CDC_EVENT_HANDLER	USB Host CDC Client Driver Event Handler Function Pointer Type.
	USB_HOST_CDC_HANDLE	Defines the type of the CDC Host Client Driver Handle
	USB_HOST_CDC_OBJ	Defines the type of the CDC Host Client Object.
	USB_HOST_CDC_REQUEST_HANDLE	USB Host CDC Client Driver Request Handle
	USB_HOST_CDC_TRANSFER_HANDLE	USB Host CDC Client Driver Transfer Handle

Description

USB Host CDC Client Driver Interface Definition

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the USB Host CDC

Client Driver.

USB HID Host Mouse Driver Library

This section describes the USB HID Host Mouse Driver Library.

Introduction

Introduces the MPLAB Harmony USB HID Host Mouse Driver Library.

Description

The HID Host Mouse Driver in the MPLAB Harmony USB Host Stack allows USB Host Applications to support and interact with USB Mouse devices. The USB HID Host Mouse Driver has the following features:

- Supports USB HID Mouse devices
- Supports HID device matching at both device descriptor and interface descriptor level
- Supports both Boot and Non Boot interface USB Mouse devices
- Performs parsing of Mouse Report descriptor by using USB HID Host client driver APIs
- Supports detection of Mouse X, Y, and Z movements, as well as button click events

Using the Library

This topic describes the basic architecture of the USB HID Host Mouse Driver Library and provides information and examples on its use.

Library Overview

The USB HID Host Mouse Driver can be grouped functionally as shown in the following table.

Library Interface Section	Description
Mouse Access Functions	These functions allow application to register event handlers with the mouse driver. These functions are implemented in `usb_host_hid_mouse.c`.

Abstraction Model

Describes the Abstraction Model of the USB HID Host Mouse Driver Library.

Description

The USB HID Host Mouse Driver interacts with the USB Host HID Client Driver to control the attached HID device. The USB Host Layer attaches the USB HID Host Client Driver to the HID device when it meets the matching criteria specified in the USB Host TPL table.

The USB HID Host Client driver notifies the mouse driver of device attach and detach information and with report receive events with relevant event data. On a report receive event, the USB Host HID Mouse Driver obtains all of the field information present in the Report Descriptor of the mouse device and uses that field information and the INTERRUPT IN data received to understand mouse parameter values.

How the Library Works

Describes how the library works and how it should be used.

Description

The USB HID Host Mouse Driver provides the user application with an easy to use interface to the attached HID device. The USB Host Layer initializes the USB HID Host Client Driver when a device is attached. This process does not require application intervention. The following sections describe the steps and methods required for the user application to interact with the attached mouse devices through the USB Host HID Mouse Driver.

HID Device TPL Table Configuration

Provides information on configuring the TPL table for HID devices.

Description

The Host Layer attaches the USB HID Host Client Driver to a device when the device class, subclass, protocol in the device descriptor or when the class, subclass and protocol fields in the Interface descriptor matches the entry in the TPL table. When specifying the entry for the HID device along with the Usage driver, the driver interface must be set to USB_HOST_HID_INTERFACE and the usage driver interface must be set to usageDriverInterface. usageDriverInterface must be properly initialized to capture the Mouse driver APIs. This will attach the USB HID Host Mouse Driver to the device when the USB Host HID Client Driver is attached. The following code shows possible TPL table options for matching HID Devices.

Example:

```
/* This code shows an example of TPL table entries for supporting HID mouse devices.
 * Note that the driver interface is set to USB_HOST_HID_INTERFACE. This
 * will load the HID Host Client Driver when there is TPL match. Usage driver
 * interface is initialized with appropriate function pointer for Mouse driver.
 * This facilitates subsequent loading of Mouse driver post HID client driver.
 */
```

```
 USB_HOST_HID_USAGE_DRIVER_INTERFACE usageDriverInterface =
{
  .initialize = NULL,
  .deinitialize = NULL,
  .usageDriverEventHandler = _USB_HOST_HID_MOUSE_EventHandler,
  .usageDriverTask = _USB_HOST_HID_MOUSE_Task
};

USB_HOST_HID_USAGE_DRIVER_TABLE_ENTRY usageDriverTableEntry[1] =
{
    {
        .usage = USB_HID_USAGE_MOUSE,
        .initializeData = NULL,
        .interface = &usageDriverInterface
    }
};
const USB_HOST_TPL_ENTRY USBTPList[1] =
{
    /* This entry looks for any HID Mouse device */
    TPL_INTERFACE_CLASS_SUBCLASS_PROTOCOL(0x03, 0x01, 0x02, usageDriverTableEntry,
                                          USB_HOST_HID_INTERFACE) ,
};
```

Detecting Device Attach

Describe how to detect when a HID mouse device is attached.

Description

The application will need to know when a HID mouse device is attached. To receive this attach event from the USB HID Host Mouse Driver, the application must register an Attach Event Handler by calling the USB_HOST_HID_MOUSE_EventHandlerSet function. This function should be called before calling the USB_HOST_BusEnable function; otherwise, the application may miss HID attach events.

Mouse Data Event Handling

Describes mouse data event handling, which includes a code example.

Description

No extra event handler is required to be registered to receive mouse data. A call to function USB_HOST_HID_MOUSE_EventHandlerSet once is adequate to receive mouse data as well.

The mouse button state along with the X, Y, and Z relative coordinate positions are provided by the USB Host HID Mouse Driver. The data type is USB_HOST_HID_MOUSE_DATA and is defined in `usb_host_hid_mouse.h`. The following code shows an event handler example.

Example:

```
/* This code shows an example of HID Mouse Event Handler */

void APP_USBHostHIDMouseEventHandler
(
    USB_HOST_HID_MOUSE_HANDLE handle,
    USB_HOST_HID_MOUSE_EVENT event,
    void * pData
)
{
    /* This function gets called in the following scenarios:
    1. USB Mouse is Attached
    2. USB Mouse is detached
    3. USB Mouse data has been obtained.
    */

    switch ( event)
    {
        case USB_HOST_HID_MOUSE_EVENT_ATTACH:
            /* Mouse Attached */
            appData.state =  APP_STATE_DEVICE_ATTACHED;
            break;

        case USB_HOST_HID_MOUSE_EVENT_DETACH:
            /* Mouse Detached */
```

```
                appData.state = APP_STATE_DEVICE_DETACHED;
                break;

            case USB_HOST_HID_MOUSE_EVENT_REPORT_RECEIVED:

                appData.state = APP_STATE_READ_HID;
                /* Mouse Data from device */
                memcpy(&appData.data, pData, sizeof(appData.data));

                /* Now the Mouse data has been obtained. This is a parsed data
                in a simple format defined by USB_HOST_HID_MOUSE_DATA type.
                */
                break;
        }

    }

    void APP_Tasks(void)
    {
        switch (appData.state)
        {
            case APP_STATE_BUS_ENABLE:

                /* In this state the application enables the USB Host Bus. Note
                 * how the USB Mouse event handler is registered before the bus
                 * is enabled. */

                USB_HOST_HID_MOUSE_EventHandlerSet(APP_USBHostHIDMouseEventHandler);
                USB_HOST_BusEnable(0);
                appData.state = APP_STATE_WAIT_FOR_BUS_ENABLE_COMPLETE;
                break;

            case APP_STATE_WAIT_FOR_BUS_ENABLE_COMPLETE:
                /* Here we wait for the bus enable operation to complete. */
                break;
        }
    }
```

Configuring the Library

Describes how to configure the USB HID Host Mouse Driver.

Macros

	Name	Description
	USB_HID_GLOBAL_PUSH_POP_STACK_SIZE	Specifies the Global PUSH POP stack size supported.
	USB_HOST_HID_INSTANCES_NUMBER	Specifies the number of HID instances.
	USB_HOST_HID_INTERRUPT_IN_ENDPOINTS_NUMBER	Specifies the maximum number of INTERRUPT IN endpoints supported.
	USB_HOST_HID_MOUSE_BUTTONS_NUMBER	Specifies the number of Mouse buttons supported.
	USB_HOST_HID_USAGE_DRIVER_SUPPORT_NUMBER	Specifies the number of Usage driver registered

Description

The USB HID Host Mouse Driver requires configuration constants to be specified in the `system_config.h` file. These constants define the build time configuration (functionality and static resources) of the USB HID Host Mouse Driver.

USB_HID_GLOBAL_PUSH_POP_STACK_SIZE Macro

Specifies the Global PUSH POP stack size supported.

File

usb_host_hid_config_template.h

C

```
#define USB_HID_GLOBAL_PUSH_POP_STACK_SIZE
```

Description

USB Host HID Global PUSH POP stack size supported

This macro defines the size of the Global PUSH POP stack per HID driver instance. If the application wants to support HID device having 2 continuous PUSH item or 2 continuous POP item in the Report Descriptor, then the value should be set to 2.

Remarks

None.

USB_HOST_HID_INSTANCES_NUMBER Macro

Specifies the number of HID instances.

File

usb_host_hid_config_template.h

C

```
#define USB_HOST_HID_INSTANCES_NUMBER
```

Description

USB host HID Maximum Number of instances

This macro defines the number of instances of the HID host Driver. For example, if the application needs to implement two instances of the HID host Driver, value should be set to 2.

Remarks

None.

USB_HOST_HID_INTERRUPT_IN_ENDPOINTS_NUMBER Macro

Specifies the maximum number of INTERRUPT IN endpoints supported.

File

usb_host_hid_config_template.h

C

```
#define USB_HOST_HID_INTERRUPT_IN_ENDPOINTS_NUMBER
```

Description

USB Host HID Maximum Number of INTERRUPT IN endpoints supported

This macro defines the number of INTERRUPT IN endpoints supported by USB Host HID driver. If the application needs to work with HID device which has 2 INTERRUPT IN endpoints, the value should be set to 2.

Remarks

None.

USB_HOST_HID_MOUSE_BUTTONS_NUMBER Macro

Specifies the number of Mouse buttons supported.

File

usb_host_hid_config_template.h

C

```
#define USB_HOST_HID_MOUSE_BUTTONS_NUMBER
```

Description

USB Host HID number of Mouse buttons supported

This macro defines the number of Mouse buttons supported. If the application wants to support HID Mouse device having 5 buttons, then the value should be set to 5.

Remarks

None.

USB_HOST_HID_USAGE_DRIVER_SUPPORT_NUMBER Macro

Specifies the number of Usage driver registered

File

usb_host_hid_config_template.h

C

```
#define USB_HOST_HID_USAGE_DRIVER_SUPPORT_NUMBER
```

Description

USB Host HID number of Usage driver registered

This macro defines the number of Usage driver registered with USB Host Hid driver. If the application wants HID driver to support 2 HID device having different usage, then the value should be set to 2.

Remarks

None.

Building the Library

Describes the files to be included in the project while using the USB HID Host Mouse Driver.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/usb`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
usb_host_hid_mouse.h	This header file should be included in any `.c` file that accesses the YSB HID Host Mouse Driver API.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/dynamic/usb_host_hid.c`	This file implements the USB HID Host Client Driver interface and should be included in the project if any usage driver operation is desired.
`/src/dynamic/usb_host_hid_mouse.c`	This file implements the USB HID Host Mouse Driver interface and should be included in the project if any usage driver operation is desired.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The USB HID Host Mouse Driver Library depends on the following modules:

- USB Host Layer Library
- USB Host HID Client Driver Library

Library Interface

a) Mouse Access Functions

	Name	Description
	USB_HOST_HID_MOUSE_EventHandlerSet	This function registers application callback function with the mouse driver.
	_USB_HOST_HID_MOUSE_EventHandler	This is function _USB_HOST_HID_MOUSE_EventHandler.
	_USB_HOST_HID_MOUSE_Task	This is function _USB_HOST_HID_MOUSE_Task.

b) Data Types and Constants

	Name	Description
	USB_HOST_HID_MOUSE_DATA	Defines the USB Host HID mouse data object.
	USB_HOST_HID_MOUSE_EVENT	Defines the possible USB HOST HID mouse driver events.
	USB_HOST_HID_MOUSE_EVENT_HANDLER	USB HOST mouse driver event handler function pointer type.
	USB_HOST_HID_MOUSE_HANDLE	USB HOST HID mouse driver instance handle.
	USB_HOST_HID_MOUSE_RESULT	USB Host HID mouse driver results.
	USB_HOST_HID_MOUSE_RESULT_MIN	USB Host HID mouse driver result minimum constant.
	USB_HOST_HID_MOUSE_HANDLE_INVALID	This is macro USB_HOST_HID_MOUSE_HANDLE_INVALID.

Description

This section describes the Application Programming Interface (API) functions of the USB HID Host Mouse Driver Library.

The USB Mouse driver does not require explicit API call by the application to obtain Mouse data. The data in the appropriate format is sent to the application during an application event handler function call.

a) Mouse Access Functions

USB_HOST_HID_MOUSE_EventHandlerSet Function

This function registers application callback function with the mouse driver.

File

usb_host_hid_mouse.h

C

```
USB_HOST_HID_MOUSE_RESULT USB_HOST_HID_MOUSE_EventHandlerSet(USB_HOST_HID_MOUSE_EVENT_HANDLER
appMouseEventHandler);
```

Returns

Returns data structure of USB_HOST_HID_MOUSE_RESULT type. USB_HOST_HID_MOUSE_RESULT_INVALID_PARAMETER: Invalid Parameter USB_HOST_HID_MOUSE_RESULT_FAILURE: On failure USB_HOST_HID_MOUSE_RESULT_SUCCESS: On success

Description

This function registers application callback function with the mouse driver. Any subsequent mouse events is passed to the application by calling the registered application function. The function prototype should be of the USB_HOST_HID_MOUSE_EVENT_HANDLER type.

Remarks

This function should be called before the USB bus is enabled.

Preconditions

This function should be called before the USB bus is enabled.

Parameters

Parameters	Description
appMouseEventHandler	Function pointer to the application function.

Function

USB_HOST_HID_MOUSE_RESULT USB_HOST_HID_MOUSE_EventHandlerSet

(

```
    USB_HOST_HID_MOUSE_EVENT_HANDLER appMouseEventHandler
);
```

_USB_HOST_HID_MOUSE_EventHandler Function

File

usb_host_hid_mouse.h

C

```
void _USB_HOST_HID_MOUSE_EventHandler(USB_HOST_HID_OBJ_HANDLE handle, USB_HOST_HID_EVENT event, void *
eventData);
```

Description

This is function _USB_HOST_HID_MOUSE_EventHandler.

_USB_HOST_HID_MOUSE_Task Function

File

usb_host_hid_mouse.h

C

```
void _USB_HOST_HID_MOUSE_Task(USB_HOST_HID_OBJ_HANDLE handle);
```

Description

This is function _USB_HOST_HID_MOUSE_Task.

b) Data Types and Constants

USB_HOST_HID_MOUSE_DATA Structure

Defines the USB Host HID mouse data object.

File

usb_host_hid_mouse.h

C

```
typedef struct {
  USB_HID_BUTTON_STATE buttonState[USB_HOST_HID_MOUSE_BUTTONS_NUMBER];
  USB_HID_BUTTON_ID buttonID[USB_HOST_HID_MOUSE_BUTTONS_NUMBER];
  int16_t xMovement;
  int16_t yMovement;
  int16_t zMovement;
} USB_HOST_HID_MOUSE_DATA;
```

Members

Members	Description
USB_HID_BUTTON_STATE buttonState[USB_HOST_HID_MOUSE_BUTTONS_NUMBER];	Button state for the buttons. USB_HOST_HID_MOUSE_BUTTONS_NUMBER is system configurable option. The actual number of buttons in the mouse needs to be <= USB_HOST_HID_MOUSE_BUTTONS_NUMBER
int16_t xMovement;	Applicable for 2D Mouse Y - Coordinate displacement
int16_t yMovement;	Applicable for 2D Mouse Z - Coordinate displacement
int16_t zMovement;	Applicable only for 3D Mouse

Description

USB Host HID Mouse Data Object

This structure defines the USB Host HID mouse data object.

Remarks

None.

USB_HOST_HID_MOUSE_EVENT Enumeration

Defines the possible USB HOST HID mouse driver events.

File

usb_host_hid_mouse.h

C

```
typedef enum {
  USB_HOST_HID_MOUSE_EVENT_ATTACH = 0,
  USB_HOST_HID_MOUSE_EVENT_DETACH,
  USB_HOST_HID_MOUSE_EVENT_REPORT_RECEIVED
} USB_HOST_HID_MOUSE_EVENT;
```

Members

Members	Description
USB_HOST_HID_MOUSE_EVENT_ATTACH = 0	Mouse has been attached
USB_HOST_HID_MOUSE_EVENT_DETACH	Mouse has been detached
USB_HOST_HID_MOUSE_EVENT_REPORT_RECEIVED	Mouse IN Report data available

Description

USB HOST HID Mouse Driver Events

This enumeration lists the possible mouse events that the mouse driver can provide to the application. Some of these events have event data associated with them.

USB_HOST_HID_MOUSE_EVENT_HANDLER Type

USB HOST mouse driver event handler function pointer type.

File

usb_host_hid_mouse.h

C

```
typedef void (* USB_HOST_HID_MOUSE_EVENT_HANDLER)(USB_HOST_HID_MOUSE_HANDLE handle,
USB_HOST_HID_MOUSE_EVENT event, void *pData);
```

Description

USB HOST Mouse Driver Event Handler Function Pointer Type.

This defines the USB HOST HID mouse driver event handler function pointer type. Application must register a function of this type to receive HID mouse events. Registration should happen before USB BUS is enabled by the application.

USB_HOST_HID_MOUSE_HANDLE Type

USB HOST HID mouse driver instance handle.

File

usb_host_hid_mouse.h

C

```
typedef uintptr_t USB_HOST_HID_MOUSE_HANDLE;
```

Description

USB HOST HID Mouse Driver Instance Handle

This defines a USB Host HID mouse driver handle.

Remarks

None.

USB_HOST_HID_MOUSE_RESULT Enumeration

USB Host HID mouse driver results.

File

usb_host_hid_mouse.h

C

```
typedef enum {
  USB_HOST_HID_MOUSE_RESULT_FAILURE = USB_HOST_HID_MOUSE_RESULT_MIN,
  USB_HOST_HID_MOUSE_RESULT_INVALID_PARAMETER,
  USB_HOST_HID_MOUSE_RESULT_SUCCESS = 0
} USB_HOST_HID_MOUSE_RESULT;
```

Members

Members	Description
USB_HOST_HID_MOUSE_RESULT_FAILURE = USB_HOST_HID_MOUSE_RESULT_MIN	An unknown failure occurred
USB_HOST_HID_MOUSE_RESULT_INVALID_PARAMETER	Invalid or NULL parameter passed
USB_HOST_HID_MOUSE_RESULT_SUCCESS = 0	Indicates that the operation succeeded or the request was accepted and will be processed.

Description

USB Host HID MOUSE Result

This enumeration defines the possible returns values of USB Host HID mouse driver API. A function may only return some of the values in this enumeration. Refer to function description for details on which values will be returned.

Remarks

None.

USB_HOST_HID_MOUSE_RESULT_MIN Macro

USB Host HID mouse driver result minimum constant.

File

usb_host_hid_mouse.h

C

```
#define USB_HOST_HID_MOUSE_RESULT_MIN -50
```

Description

USB Host HID Mouse Driver Result Minimum Constant

This constant identifies the minimum value of the USB Host HID mouse driver and is used in the USB_HOST_HID_MOUSE_RESULT enumeration.

Remarks

None.

USB_HOST_HID_MOUSE_HANDLE_INVALID Macro

File

usb_host_hid_mouse.h

C

```
#define USB_HOST_HID_MOUSE_HANDLE_INVALID ((USB_HOST_HID_MOUSE_HANDLE)(-1))
```

Description

This is macro USB_HOST_HID_MOUSE_HANDLE_INVALID.

Files

Microchip Technology Inc.

USB Hub Host Client Driver Library

This section describes the USB Hub Host Client Driver Library.

Introduction

Introduces the MPLAB Harmony USB Hub Host Client Driver Library.

Description

The USB Hub Host Client Driver in the MPLAB Harmony USB Host Stack allows USB Host Applications to interact with a USB Hub and thus manage multiple USB devices simultaneously in one application. The key features of the Hub Host Client Driver include:

- Allows multiple USB devices to be connected to the host and hence allow the USB Host application to interact simultaneously with multiple USB devices.
- Implemented as per Chapter 11 of the USB 2.0 specification.
- Support multiple Hub tiers. A Hub can be connected to another Hub.
- Does not require application intervention for its operation. The application does not have to call an Hub Driver API.

Abstraction Model

Describes the Abstraction Model of the USB Hub Host Client Driver Library.

Description

The USB Hub Host Client Driver abstracts the complexities of Hub operation and presents a simple interface to the Host Layer. The interface allows the Host Layer to perform port operations such as port reset, port suspend and port resume. The port interface offered by the Hub Host Client Driver is the same as that offered by the root hub driver. In that, the Host Layer does not differentiate between an external hub and the root hub.

The USB Hub Host Client Driver does not have any application callable API. It only interacts with the Host Layer. The USB Hub Host Client Driver performs the task of powering up the ports, detecting device attach and detach and notifying the same to the Host Layer and detecting over current conditions. The USB Hub Host Client Driver performs the control transfers required for these tasks.

Library Overview

The USB Hub Host Client Driver does not contain any application callable functions.

Using the Library

This topic describes the basic architecture of the USB Hub Host Client Driver Library and provides information and examples on its use.

How the Library Works

Describes how the Library works and how it should be used.

Description

The USB Hub Host Client Driver does not contain any application callable functions. The only step that the application code must implement is to enable USB Host Layer Hub support and to provision the USB Hub Host Client Driver in the TPL table.

The USB Host Layer enables Hub Support when the USB_HOST_HUB_SUPPORT_ENABLE configuration macro is defined in `system_config.h`. Refer to the Configuring the Library section of the USB Host Layer Library Help Topic for more information.

Hub TPL Table Configuration

Provides information on configuring the TPL table for adding Hub support.

Description

The Host Layer attaches the USB Hub Host Client Driver to a Hub device only if the TPL table contains an entry to enable this feature. The driver interface for such a TPL entry should point to USB_HOST_HUB_INTERFACE. The following code shows an example of the TPL entry for the adding Hub support to the application.

Example:

```
/* This code shows an example of how to initialize the TPL table to
 * support a USB Hub Host Client Driver */

#include "usb/usb_host_hub.h"
#include "usb/usb_hub.h"

const USB_HOST_TPL_ENTRY USBTPList[ 2 ] =
{
    TPL_INTERFACE_CLASS_SUBCLASS_PROTOCOL(USB_HUB_CLASS_CODE, 0x00, 0x00, NULL,  USB_HOST_HUB_INTERFACE),

    /* A high-speed hub will report the number of transaction translators in the
     * protocol field. We can ignore this and let the host layer load the hub
     * driver for a high-speed hub */

    TPL_INTERFACE_CLASS (USB_HUB_CLASS_CODE, NULL, USB_HOST_HUB_INTERFACE)
};
```

USB Hub Host Client Driver Test Results

Provides test results for the USB Hub Host Client Driver.

Description

The following table lists the commercially available USB hubs, which have been tested to successfully enumerate and operate with the USB Hub Host Client Driver in the MPLAB Harmony USB Host Stack. Note that if the Hub you are using is not included in the table, this indicates that this Hub has not been tested with the USB Hub Host Client Driver. However, the Hub could still potentially work with the USB Hub Host Client Driver.

The hubs were tested with the hub_msd USB Host demonstration in the latest version of the MPLAB Harmony USB Host Stack.

Hub Model	Number of Ports	VID	PID
Belkin USB 2.0	4	0x050D	0x0233
QHMPL	4	0x1A40	0x0101
Portronics	3	0x1A40	0x0101
Sanda	4	0x05E3	0x0606
iBall	4	0x1A40	0x0101

Configuring the Library

Describes how to configure the USB Hub Host Client Driver.

Macros

	Name	Description
	USB_HOST_HUB_INSTANCES_NUMBER	Specifies the number of Hub to be supported in the system.
	USB_HOST_HUB_PORTS_NUMBER	Specifies the number of ports per Hub.

Description

The USB Hub Host Client Driver requires configuration constants to be specified in `system_config.h` file. These constants define the build time configuration (functionality and static resources) of the Hub Host Client Driver.

USB_HOST_HUB_INSTANCES_NUMBER Macro

Specifies the number of Hub to be supported in the system.

File

usb_host_hub_config_template.h

C

```
#define USB_HOST_HUB_INSTANCES_NUMBER
```

Description

USB Host Hub Instances Number

This configuration constant defines the total number of hubs to be supported in the application. This includes hubs connected across multiple USBs. If the hub connected to the host exceed this number, then the additional hubs will not be enumerated.

Remarks

Increasing number of Hubs to be supported will also increase memory consumption.

USB_HOST_HUB_PORTS_NUMBER Macro

Specifies the number of ports per Hub.

File

usb_host_hub_config_template.h

C

```
#define USB_HOST_HUB_PORTS_NUMBER
```

Description

USB Host Hub Number of Ports per Hub

This configuration macros specifies the number of Ports per Hub. If any Hub connected to host will a have a maximum of 4 ports, then this number should be set to 4. A hub with more ports than the value defined by this constant will not be supported.

Remarks

Supporting a hub with more ports increases the memory requirement.

Building the Library

Describes the files to be included in the project while using the USB Hub Host Client Driver.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/usb`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
usb_host_hub.h	This header file should be included in any `.c` file that accesses the USB Hub Host Client Driver API.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/dynamic/usb_host_hub.c	This file implements the USB Hub Host Client Driver interface and should be included in the project if the USB Hub Host Client Driver operation is desired.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The USB Hub Host Client Driver Library depends on the following modules:

- USB Host Layer Library

Library Interface

Data Types and Constants

	Name	Description
	USB_HOST_HUB_INTERFACE	USB Hub Host Client Driver Interface Pointer.

Description

This section describes the Application Programming Interface (API) functions of the USB Hub Host Client Driver Library.

Refer to each section for a detailed description.

Data Types and Constants

USB_HOST_HUB_INTERFACE Macro

USB Hub Host Client Driver Interface Pointer.

File

usb_host_hub.h

C

```
#define USB_HOST_HUB_INTERFACE
```

Description

USB Hub Host Client Driver Interface Pointer

This constant is a pointer to a table of function pointers that define the interface between the Hub Host Client Driver and the USB Host Layer. This constant should be used while adding support for the Hub Driver in TPL table.

Remarks

None.

USB MSD Host Client Driver Library

This section describes the USB MSD Host Client Driver Library.

Introduction

Introduces the MPLAB Harmony USB Mass Storage Device (MSD) Host Client Driver Library.

Description

The USB MSD Host Client Driver in the MPLAB Harmony USB Host Stack allows USB Host Applications to support and interact with Mass Storage Class (MSC) USB devices. Examples of such devices are USB Pen Drives and USB Card readers. The USB MSD Host Client Driver along with the SCSI Block Storage Driver Library implement a multi-layer solution to reading and writing to mass storage USB device that implement the SCSI command protocol. The USB MSD Host Client Driver has the following features:

- Implements the Bulk Only Transport (BOT) protocol in the USB MSD specification
- Supports multiple instances, which allows the application to interact with multiple storage devices
- Supports multi-LUN devices such as USB Card Reader
- Automatically (without application intervention) attaches the SCSI Block Driver to an identified device
- Implements automatic clearing of endpoint stall conditions
- Implements all three stages of a BOT transfer and provide a simple event driver transfer interface to the top-level application (which is typically a block storage driver library such as the SCSI Block Storage Driver Library)
- Typically operates without application intervention. The BOT transfers are typically invoked by the SCSI Block Storage Driver Library.

Using the Library

This topic describes the basic architecture of the USB MSD Host Client Drier Library and provides information and examples on its use.

Library Overview

Provides an overview of the USB Host MSD Library.

Description

The USB MSD Host Client Driver can be grouped functionally as shown in the following table.

Library Interface Section	Descriptions
Data Transfer Functions	These functions allow the application client to transfer data to the attached device.

Abstraction Model

Describes the Abstraction Model of the USB MSD Host Client Driver Library.

Description

The USB MSD Host Client Driver provides the transport for SCSI commands that implements that media read, write and control operations. If abstracts the details of initiating and completing a BOT transfer and performing error handling and presents a simple event driven interface to the top-level block storage command driver library.

The USB MSD Host Client Driver uses the USB Host data transfer and pipe management routines to implement the three stages of a BOT transfer. The library accepts a SCSI command from the SCSI Block Storage driver and transports this command in the command block of the Command Block Wrapper in the CBW stage of the BOT transfer. If the command requires a data stage, the USB MSD Host Client Driver library will transfer data between the USB Host and the device. The USB MSD Host Client Driver will then terminate the BOT transfer by requesting for the Command Status Wrapper (CSW) from the device.

If the device stalls any stage of the transfer, the USB MSD Host Client Driver will clear the stall and will automatically initiate the CSW stage to complete the transfer. The transfer result is communicated to the top level block storage driver library through a callback mechanism.

The USB Host layer will attach the USB MSD Host Client Driver to a mass storage device based on a TPL entry match. The USB MSD Host Client Driver will then open data and communication control pipes to the device. It will first get the number of logical units (LUN) that the device contains. It will then initialize the SCSI block storage driver for each reported LUN and mark the device state as being ready for data transfers.

How the Library Works

Describes how the library works and how it should be used.

Description

The USB MSD Host Client Driver provides the top level block storage driver with an easy to use, event driven, interface to transport the block storage command and data between the block storage command driver library and a compliant mass storage device. The USB MSD Host Client Driver in the MPLAB Harmony USB Host stack immediately supports mass storage devices that advertise support of the SCSI command set. Indeed, most of the commercially available USB storage devices such as USB pen driver and USB card readers respond to SCSI command requests.

The process of initializing the SCSI block storage driver library when a device is attached is performed automatically, by the USB MSD Host Client Driver. This does not require user application intervention. The following sections describe the TPL table design (application responsibility) and USB MSD Host Client Driver data transfer function (typically called by the SCSI block storage driver library).

MSD TPL Table Configuration

Describes TPL table design for matching MSD devices.

Description

The Host Layer attaches the MSD Host Client Driver to a device when the class, subclass and protocol fields in the Interface Association Descriptor (IAD) or Interface descriptor match the entry in the TPL table. When specifying the entry for the MSD device, the driver interface must be set to USB_HOST_MSD_INTERFACE. This will attach the USB MSD Host Client Driver to the device when the USB Host matches the TPL entry to the device. The following code shows a TPL table design for matching MSD Devices.

Example:

```
/* This code shows an example TPL table entry for supporting a Mass
 * Storage Device */

const USB_HOST_TPL_ENTRY USBTPList[ 1 ] =
{
    TPL_INTERFACE_CLASS_SUBCLASS_PROTOCOL(USB_MSD_CLASS_CODE,
            USB_MSD_SUBCLASS_CODE_SCSI_TRANSPARENT_COMMAND_SET, USB_MSD_PROTOCOL, NULL,
USB_HOST_MSD_INTERFACE)
```

```
};
```

Data Transfer

Describes how to transfer data, which includes a code example.

Description

The USB MSD Host Client Driver data transfer function is typically called by the SCSI Block Storage Driver Library. The USB_HOST_MSD_Transfer function allows the SCSI Block Storage Driver to transport SCSI commands to the mass storage device. The cdb parameter and the cdbLength parameter of the function specify the command and its size respectively. If the command requires the transport of data, then data must contain the pointer to the buffer and size specifies the amount of data expected to be transported. When the BOT transfer complete, the USB MSD Host Client Diver will call the callback function. The following code snippet shows an example of using the USB_HOST_MSD_Transfer function.

Example:

```
/* This code shows usage of the USB_HOST_MSD_Transfer function. The SCSI Block
 * Driver Library uses this function to send a SCSI Inquiry Command to the
 * device. Note how the commandCompleted flag in the SCSI instance object
 * tracks the completion of the transfer. This flag is updated in the transfer
 * callback. */

void _USB_HOST_SCSI_TransferCallback
(
    USB_HOST_MSD_LUN_HANDLE lunHandle,
    USB_HOST_MSD_TRANSFER_HANDLE transferHandle,
    USB_HOST_MSD_RESULT result,
    size_t size,
    uintptr_t context
)
{
    int scsiObjIndex;
    USB_HOST_SCSI_OBJ * scsiObj;
    USB_HOST_SCSI_COMMAND_OBJ * commandObj;
    USB_HOST_SCSI_EVENT event;

    /* Get the SCSI object index from the lunHandle */
    scsiObjIndex = _USB_HOST_SCSI_LUNHandleToSCSIInstance(lunHandle);

    /* Get the pointer to the SCSI object */
    scsiObj = &gUSBHostSCSIObj[scsiObjIndex];

    /* Pointer to the command object */
    commandObj = &scsiObj->commandObj;

    /* The processed size */
    commandObj->size = size;

    /* The result of the command */
    commandObj->result = result;

    /* Let the main state machine know that the command is completed */
    commandObj->commandCompleted = true;

    /* The rest of code is not shown here for the sake of brevity */
}

void USB_HOST_SCSI_Tasks(USB_HOST_MSD_LUN_HANDLE lunHandle)
{
    switch(scsiObj->state)
    {
        /* For the sake of brevity, only one SCSI command is show here */
        case USB_HOST_SCSI_STATE_INQUIRY_RESPONSE:

            /* We get the SCSI Enquiry response. Although there isn't much
             * that we can do with this data */
            _USB_HOST_SCSI_InquiryResponseCommand(scsiObj->commandObj.cdb);

            /* The commandCompleted flag will be updated in the callback.
             * Update the state and send the command.   */
```

```
            scsiObj->commandObj.inUse = true;
            scsiObj->commandObj.commandCompleted = false;
            scsiObj->commandObj.generateEvent = false;

            result = USB_HOST_MSD_Transfer(scsiObj->lunHandle,
                    scsiObj->commandObj.cdb, 6, scsiObj->buffer, 36,
                    USB_HOST_MSD_TRANSFER_DIRECTION_DEVICE_TO_HOST,
                    _USB_HOST_SCSI_TransferCallback, (uintptr_t)(scsiObj));

            if(result == USB_HOST_MSD_RESULT_SUCCESS)
            {
                scsiObj->state = USB_HOST_SCSI_STATE_WAIT_INQUIRY_RESPONSE;
            }

            break;

        default:
            break;

    }
}
```

Configuring the Library

Describes how to configure the USB Host Layer.

Macros

	Name	Description
	USB_HOST_MSD_INSTANCES_NUMBER	Defines the maximum number of MSD devices to be supported by this host application.
	USB_HOST_MSD_LUNS_NUMBER	Defines the maximum number of MSD Device LUNs to be supported in the application.

Description

The USB MSD Host Client Driver requires configuration constants to be specified in `system_config.h` file. These constants define the build time configuration (functionality and static resources) of the USB MSD Host Client Driver.

USB_HOST_MSD_INSTANCES_NUMBER Macro

Defines the maximum number of MSD devices to be supported by this host application.

File

usb_host_msd_config_template.h

C

```
#define USB_HOST_MSD_INSTANCES_NUMBER
```

Description

USB Host MSD Client Driver Instances Number.

This constant defines the maximum number of MSD devices to be supported by this host application. For example, if 3 USB Pen Drives need to be supported, then this value should be 3. This value cannot be greater than USB_HOST_DEVICES_NUMBER, which defines the maximum number of devices to be supported in the application. If this constant is less than USB_HOST_DEVICES_NUMBER, then only USB_HOST_MSD_INSTANCES_NUMBER of MSD devices will be enumerated.

Remarks

None

USB_HOST_MSD_LUNS_NUMBER Macro

Defines the maximum number of MSD Device LUNs to be supported in the application.

File

usb_host_msd_config_template.h

C

```
#define USB_HOST_MSD_LUNS_NUMBER
```

Description

USB Host MSD Client Driver LUNs Number.

An MSD device may have mutliple storage units, each addressable through a LUN number. An example is a USB Card reader with multiple card slots. Each card slot has a LUN number. The USB_HOST_MSD_LUNS_NUMBER constant defines the maximum number of such logical units that can be managed by the USB Host application. This number should atleast be equal to USB_HOST_MSD_INSTANCES_NUMBER. To configure this value, consider an example of an application that will support a maximum of 2 USB Storage device. These 2 storage devices are expected to have at the most 3 LUNs each. Then the the USB_HOST_MSD_LUNS_NUMBER constant should be set to 6 (2 devices and 3 LUNs per device)/

Remarks

None

Building the Library

Describes the files to be included in the project while using the MSD Host Function Driver.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/usb`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`usb_host_msd.h`	This header file should be included in any `.c` file that accesses the USB Host MSD Client Driver API.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/dynamic/usb_host_msd.c`	This file implements the USB Host MSD Client Driver interface and should be included in the project if USB Host MSD Client Driver operation is desired.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The USB MSD Host Library depends on the following modules:

- USB Host Layer Library

Library Interface

a) Data Transfer Functions

	Name	Description
	USB_HOST_MSD_Transfer	This function schedules a MSD BOT transfer.
	USB_HOST_MSD_TransferErrorTasks	This function maintains the MSD transfer error handling state machine.

b) Data Types and Constants

	Name	Description
	USB_HOST_MSD_RESULT	USB HOST MSD Result
	USB_HOST_MSD_TRANSFER_CALLBACK	USB HOST MSD Transfer Complete Callback
	USB_HOST_MSD_TRANSFER_DIRECTION	USB HOST MSD Transfer Direction.
	USB_HOST_MSD_TRANSFER_HANDLE	USB HOST MSD Transfer Handle
	USB_HOST_MSD_INTERFACE	USB HOST MSD Client Driver Interface
	USB_HOST_MSD_TRANSFER_HANDLE_INVALID	USB HOST MSD Transfer Handle Invalid
	USB_HOST_MSD_LUN_HANDLE	USB HOST MSD LUN Handle
	USB_HOST_MSD_LUN_HANDLE_INVALID	USB HOST MSD LUN Handle Invalid
	USB_HOST_MSD_ERROR_CODE	USB Host MSD Error Codes.

Description

a) Data Transfer Functions

USB_HOST_MSD_Transfer Function

This function schedules a MSD BOT transfer.

File

usb_host_msd.h

C

```
USB_HOST_MSD_RESULT USB_HOST_MSD_Transfer(USB_HOST_MSD_LUN_HANDLE lunHandle, uint8_t * cdb, uint8_t
cdbLength, void * data, size_t size, USB_HOST_MSD_TRANSFER_DIRECTION transferDirection,
USB_HOST_MSD_TRANSFER_CALLBACK callback, uintptr_t context);
```

Returns

USB_HOST_MSD_RESULT_FAILURE - An unknown failure occurred. USB_HOST_MSD_RESULT_BUSY - The transfer cannot be scheduled right now. The caller should retry. USB_HOST_MSD_RESULT_LUN_HANDLE_INVALID - This LUN does not exist in the system. USB_HOST_MSD_RESULT_SUCCESS - The transfer request was scheduled.

Description

This function schedules a MSD BOT transfer. The command to be executed is specified in the cdb. This should be pointer to a 16 byte command descriptor block. The actual length of the command is specified by cdbLength. If there is data to be transferred, the pointer to the buffer is specified by data. The size of the buffer is specified in size. When the transfer completes, the callback function will be called. The context will be returned in the callback function.

Remarks

This is a local function and should not be called directly by the application.

Preconditions

None.

Parameters

Parameters	Description
cdb	pointer to the command to be executted. Should be a pointer to a 16 byte array. Unused bytes should be zero-padded.
cdbLength	Actual size of the command.
data	pointer to the data buffer if a data stage is involved.
size	size of the data buffer.
callback	callback function to called when the transfer has completed.
transferDirection	specifies the direction of the MSD transfer.
context	caller defined context that is returned in the callback function.

Function

USB_HOST_MSD_RESULT USB_HOST_MSD_Transfer
(
uint8_t * cdb,
uint8_t cdbLength,
void * data,
size_t size,
USB_HOST_MSD_TRANSFER_CALLBACK callback,
uintptr_t context
)

USB_HOST_MSD_TransferErrorTasks Function

This function maintains the MSD transfer error handling state machine.

File

usb_host_msd.h

C

```
void USB_HOST_MSD_TransferErrorTasks(USB_HOST_MSD_LUN_HANDLE lunHandle);
```

Returns

None.

Description

This function maintains the MSD transfer error handling state machine. This function should be called periodically after the USB_HOST_MSD_Transfer function has been called to schedule a transfer. The function should be called periodically atleast till the transfer completion event has been received. Calling this function while a BOT transfer is in progress allows the MSD Host Client driver to perform BOT error handling in a non-blocking manner.

Calling this function when there is no BOT transfer in progress will not have any effect. In case of BOT error handling, calling this function will eventually result in a BOT transfer event. It is not necessary to call this function after this event has occurred (till the next BOT transfer has been scheduled).

Remarks

While running in an RTOS application, this function should be called in the same thread that requested the BOT Transfer and operating the logical unit.

Preconditions

The lunHandle should be valid.

Parameters

Parameters	Description
lunHandle	handle to valid LUN.

Function

void USB_HOST_MSD_TransferErrorTasks
(
USB_HOST_MSD_LUN_HANDLE lunHandle,
);

b) Data Types and Constants

USB_HOST_MSD_RESULT Enumeration

USB HOST MSD Result

File

usb_host_msd.h

C

```
typedef enum {
  USB_HOST_MSD_RESULT_COMMAND_PASSED = 0,
  USB_HOST_MSD_RESULT_COMMAND_FAILED = 1,
  USB_HOST_MSD_RESULT_COMMAND_PHASE_ERROR = 2,
  USB_HOST_MSD_RESULT_SUCCESS,
  USB_HOST_MSD_RESULT_FAILURE,
  USB_HOST_MSD_RESULT_BUSY,
  USB_HOST_MSD_RESULT_LUN_HANDLE_INVALID,
  USB_HOST_MSD_RESULT_COMMAND_STALLED
} USB_HOST_MSD_RESULT;
```

Members

Members	Description
USB_HOST_MSD_RESULT_COMMAND_PASSED = 0	MSD Command result was success. The command issued to the MSD device • passed.
USB_HOST_MSD_RESULT_COMMAND_FAILED = 1	MSD Command failed. The command issued to the MSD device failed. The • device BOT state machine is in sync with the host. The data residue • length is valid.
USB_HOST_MSD_RESULT_COMMAND_PHASE_ERROR = 2	MSD Command failed with phase error. The command issued to the MSD device • has failed. The failure reason is unknown. The MSD Host Client driver has • reset the device BOT state machine.
USB_HOST_MSD_RESULT_SUCCESS	The operation was successful
USB_HOST_MSD_RESULT_FAILURE	An unknown failure has occurred.
USB_HOST_MSD_RESULT_BUSY	The request cannot be accepted at this time
USB_HOST_MSD_RESULT_LUN_HANDLE_INVALID	The specified LUN is not valid
USB_HOST_MSD_RESULT_COMMAND_STALLED	The MSD request was stalled

Description

USB HOST MSD Result

This enumeration defines the possible return values of different USB HOST MSD Client driver function call. Refer to the specific function documentation for details on the return values.

Remarks

None.

USB_HOST_MSD_TRANSFER_CALLBACK Type

USB HOST MSD Transfer Complete Callback

File

usb_host_msd.h

C

```
typedef void (* USB_HOST_MSD_TRANSFER_CALLBACK)(USB_HOST_MSD_LUN_HANDLE lunHandle,
USB_HOST_MSD_TRANSFER_HANDLE transferHandle, USB_HOST_MSD_RESULT result, size_t size, uintptr_t context);
```

Description

USB HOST MSD Transfer Complete Callback

This type defines the type of the callback function that the application must register in the USB_HOST_MSD_Transfer function to receive notification when a transfer has completed. The callback function will be called with the following parameters.

lunHandle - The handle to the LUN from where this notification originated.

transferHandle - the handle to the MSD transfer.

result - result of the transfer.

size - of the transfer.

context - context that specified when this transfer was scheduled.

Remarks

None.

USB_HOST_MSD_TRANSFER_DIRECTION Enumeration

USB HOST MSD Transfer Direction.

File

usb_host_msd.h

C

```
typedef enum {
  USB_HOST_MSD_TRANSFER_DIRECTION_HOST_TO_DEVICE = 0x00,
  USB_HOST_MSD_TRANSFER_DIRECTION_DEVICE_TO_HOST = 0x80
} USB_HOST_MSD_TRANSFER_DIRECTION;
```

Members

Members	Description
USB_HOST_MSD_TRANSFER_DIRECTION_HOST_TO_DEVICE = 0x00	Data moves from host to device
USB_HOST_MSD_TRANSFER_DIRECTION_DEVICE_TO_HOST = 0x80	Data moves from device to host

Description

USB HOST Transfer Direction

This enumeration specifies the direction of the data stage.

Remarks

None.

USB_HOST_MSD_TRANSFER_HANDLE Type

USB HOST MSD Transfer Handle

File

usb_host_msd.h

C

```
typedef uintptr_t USB_HOST_MSD_TRANSFER_HANDLE;
```

Description

USB HOST MSD Transfer Handle

This type defines a USB Host MSD Transfer Handle.

Remarks

None.

USB_HOST_MSD_INTERFACE Macro

USB HOST MSD Client Driver Interface

File

usb_host_msd.h

C

```
#define USB_HOST_MSD_INTERFACE
```

Description

USB HOST MSD Client Driver Interface

This macro should be used by the application in TPL table while adding support for the USB MSD Host Client Driver.

Remarks

None.

USB_HOST_MSD_TRANSFER_HANDLE_INVALID Macro

USB HOST MSD Transfer Handle Invalid

File

usb_host_msd.h

C

```
#define USB_HOST_MSD_TRANSFER_HANDLE_INVALID
```

Description

USB HOST MSD Transfer Handle Invalid

This value defines an invalid Transfer Handle.

Remarks

None.

USB_HOST_MSD_LUN_HANDLE Type

USB HOST MSD LUN Handle

File

usb_host_msd.h

C

```
typedef uintptr_t USB_HOST_MSD_LUN_HANDLE;
```

Description

USB HOST MSD LUN Handle

This type defines a MSD LUN Handle. This handle is used by SCSI driver to identify the LUN.

Remarks

None.

USB_HOST_MSD_LUN_HANDLE_INVALID Macro

USB HOST MSD LUN Handle Invalid

File

usb_host_msd.h

C

```
#define USB_HOST_MSD_LUN_HANDLE_INVALID
```

Description

USB HOST MSD LUN Handle Invalid

This value defines an invalid LUN Handle.

Remarks

None.

USB_HOST_MSD_ERROR_CODE Enumeration

USB Host MSD Error Codes.

File

usb_host_msd.h

C

```
typedef enum {
  USB_HOST_MSD_ERROR_CODE_INSUFFICIENT_INSTANCES = 1,
```

```
    USB_HOST_MSD_ERROR_CODE_NOT_FOUND_BULK_IN_ENDPOINT,
    USB_HOST_MSD_ERROR_CODE_NOT_FOUND_BULK_OUT_ENDPOINT,
    USB_HOST_MSD_ERROR_CODE_FAILED_PIPE_OPEN,
    USB_HOST_MSD_ERROR_CODE_FAILED_GET_MAX_LUN,
    USB_HOST_MSD_ERROR_CODE_FAILED_BOT_TRANSFER,
    USB_HOST_MSD_ERROR_CODE_FAILED_RESET_RECOVERY,
    USB_HOST_MSD_ERROR_CODE_CBW_STALL_RESET_RECOVERY,
    USB_HOST_MSD_ERROR_CODE_TRANSFER_BUSY,
    USB_HOST_MSD_ERROR_CODE_CSW_PHASE_ERROR,
    USB_HOST_MSD_ERROR_CODE_CSW_UNKNOWN_ERROR
} USB_HOST_MSD_ERROR_CODE;
```

Members

Members	Description
USB_HOST_MSD_ERROR_CODE_INSUFFICIENT_INSTANCES = 1	This error occurs when the number of MSD instances defined via • USB_HOST_MSD_INSTANCES_NUMBER (in system_config.h) is insufficient. For • example, this error would occur if the value of • USB_HOST_MSD_INSTANCES_NUMBER is 2, two MSC devices are already connected • and third MSC device is connected to the host. The object identifier in • this case will be the USB_HOST_DEVICE_OBJ_HANDLE value.
USB_HOST_MSD_ERROR_CODE_NOT_FOUND_BULK_IN_ENDPOINT	This error occurs when the driver descriptor parser could not find a Bulk • IN endpoint in the interface descriptor. The object identifier in this • case will be the USB_HOST_DEVICE_OBJ_HANDLE value.
USB_HOST_MSD_ERROR_CODE_NOT_FOUND_BULK_OUT_ENDPOINT	This error occurs when the driver descriptor parser could not find a Bulk • OUT endpoint in the interface descriptor. The object identifier in this • case will be USB_HOST_DEVICE_OBJ_HANDLE value.
USB_HOST_MSD_ERROR_CODE_FAILED_PIPE_OPEN	This error occurs when the driver could not open a Bulk pipe. This • typically happens either due to a host layer error or due to insufficient • number of pipes (which is configured via USB_HOST_PIPES_NUMBER). The • object idenfier in this case will be USB_HOST_DEVICE_OBJ_HANDLE value.
USB_HOST_MSD_ERROR_CODE_FAILED_GET_MAX_LUN	This error occurs when the Get Max LUN request issued by the driver fails • for any reason. The object identifier in this case will be the MSC device • instance index.
USB_HOST_MSD_ERROR_CODE_FAILED_BOT_TRANSFER	This error occurs when any stage of the BOT has failed due to bus error • or an unknown failure. The object identifier in this case will be the MSC • device instance index.
USB_HOST_MSD_ERROR_CODE_FAILED_RESET_RECOVERY	This error occurs when the MSD Reset Recovery procedure has failed. A MSC • device should not fail a MSD Reset Recovery procedure. The object • identifier in this case will be the device instance index.

USB_HOST_MSD_ERROR_CODE_CBW_STALL_RESET_RECOVERY	This error code indicates a condtion where the CBW stage of the BOT was • stalled and the driver is about to launch MSD reset recovery. The • identifier in this case if the MSC Device instance index. This code is • generated from an interrupt context. The driver may continue to function • normally post this condition.
USB_HOST_MSD_ERROR_CODE_TRANSFER_BUSY	This error code indicates a condition where the BOT transfer could not be • initiated because a transfer is already in progress. The identifier in • this case is the MSC Device Instance Index. The driver may continue to • function normall post this condition. This condition may occur several • times.
USB_HOST_MSD_ERROR_CODE_CSW_PHASE_ERROR	This error code indicates a condition where the BOT transfer failed due a • phase error in the CSW stage of the BOT. The identifier in this case if • the MSC Device instance index. This code is generated from an interrupt • context. The driver may continue to function normally post this • condition.
USB_HOST_MSD_ERROR_CODE_CSW_UNKNOWN_ERROR	This error code indicates that a condition where an unknown error has • occured during the CSW stage of the BOT. The identifier in this case if • the MSC Device instance index. This code is generated from an interrupt • context. The driver may continue to function normally post this • condition.

Description

USB Host MSD Error Codes.

This enumeration defines the codes that the MSD Client Driver returns for possible errors that lead to the device being placed in an error state. The MSD client driver will not operate on a device which is in an error state. The error are returned in the USB_HOST_MSD_ErrorCallback function.

Remarks

None.
