1. Either wait for an interrupt, which will be generated when the reception is completed, or poll using PLIB_USART_ReceiverDataIsAvailable.
2. Read the status of the device using PLIB_USART_ReceiverOverrunHasOccurred, PLIB_USART_ReceiverParityErrorHasOccurred, and PLIB_USART_ReceiverFramingErrorHasOccurred.
3. Read the data using PLIB_USART_ReceiverByteReceive.
4. If an overrun error occurred, clear the error using PLIB_USART_ReceiverOverrunErrorClear.

Example: Asynchronous Reception

```
// TODO - Either wait for Receive buffer to have data or wait for
// a receive interrupt.
// read the data
my_byte = PLIB_USART_ReceiverByteReceive(MY_USART_INSTANCE);
// where, my_byte is the 8 bit data received

// If overrun error clear the error.
if(PLIB_USART_ReceiverOverrunHasOccurred(MY_USART_INSTANCE))
{
    PLIB_USART_ReceiverOverrunErrorClear(MY_USART_INSTANCE);
}
```

Asynchronous Reception with Address Detection Mode

A typical multi-processor communication protocol will differentiate between data bytes and address/control bytes. A common method is to use a 9th data bit to identify whether a data byte is address or data information. If the 9th bit is set, the data is processed as address or control information. If the 9th bit is cleared, the received data word is processed as data associated with the previous address/control byte.

The protocol operates as follows:

- The master device transmits a data word with 9th bit set. The data word contains the address of a slave device.
- All slave devices in the communication chain receive the address word and check the slave address.
- The slave device that was addressed will receive and process subsequent data bytes sent by the master device. All other slave devices will discard subsequent data bytes until a new address word(9th bit set) is received.

This mode will typically be used in RS-485 systems.

Setup

1. Set the desired baud rate using PLIB_USART_BaudRateHighSet or PLIB_USART_BaudRateSet.
2. Set the appropriate I/O direction and corresponding RX and TX I/O pins.
3. *If available on the device*, enable the asynchronous serial port using PLIB_USART_SyncModeSelect.
4. Set the number of data bits (8 or 9) and other line control modes using PLIB_USART_LineControlModeSelect.
5. *Optional (if available on the device):* If desired, enable the receive interrupt.

- Ensure that the interrupts are enabled for the system and the peripherals. Also select the interrupt priority.
- Set up the receive FIFO interrupt mode by using the function PLIB_USART_ReceiverInterruptModeSelect. Refer to USART_RECEIVE_INTR_MODE for a list of possible values.
- For Address Detect mode, configure PLIB_USART_ReceiverInterruptModeSelect with the receive FIFO interrupt mode as USART_RECEIVE_FIFO_ONE_CHAR.

6. *Optional:* If inverted receive polarity is desired, use PLIB_USART_ReceiverIdleStateLowEnable.
7. *If available on the device*, enable the reception using PLIB_USART_ReceiverEnable.
8. Enable address detection using PLIB_USART_ReceiverAddressDetectEnable.
9. Enable the USART module using PLIB_USART_Enable.

Note: This feature is not available on all devices. On devices where automatic address detection is available, configure automatic address detection using PLIB_USART_ReceiverAddressAutoDetectEnable. Skip steps 2-6 in the following Reception section during the reception phase.

Example: Asynchronous Reception Setup (with address detect enable)

```
// Set the desired baud rate
uint32_t baudRate = 9600;

// where, MY_USART_INSTANCE - is a specific instance of the hardware peripheral.
// where, MY_CLOCK_FREQUENCY - is hardware clock frequency which is currently
// being used by the system.
PLIB_USART_BaudRateHighSet(MY_USART_INSTANCE, baudRate, MY_CLOCK_FREQUENCY);

// Enable the synchronous slave serial port.
// enable sync mode
PLIB_USART_SyncModeSelect(MY_USART_INSTANCE, USART_ASYNC_MODE);
// enable USART
PLIB_USART_Enable(MY_USART_INSTANCE);

// Set the appropriate IO direction for USART pins
// TODO - Call the appropriate function.

// Set the reception to 9 bits to enable address byte.
PLIB_USART_LineControlModeSelect(MY_USART_INSTANCE, USART_9N1);

// Enable address detection.
PLIB_USART_ReceiverAddressDetectEnable(MY_USART_INSTANCE);

// Start the reception
// Enable the continuous reception
PLIB_USART_ReceiverEnable(MY_USART_INSTANCE);
```

Reception

1. Either wait for an interrupt, which will be generated when the reception is completed or poll using PLIB_USART_ReceiverDataIsAvailable.
2. Read the address using PLIB_USART_ReceiverByteReceive.
3. The application determines if this is the device address. If the device is addressed, disable address detect using PLIB_USART_ReceiverAddressDetectDisable to allow subsequent data bytes to be received; otherwise, discard the received word.
4. Read the status of the device using PLIB_USART_ReceiverOverrunHasOccurred, PLIB_USART_ReceiverParityErrorHasOccurred, and PLIB_USART_ReceiverFramingErrorHasOccurred.
5. If an overrun error occurred, clear the error using PLIB_USART_ReceiverOverrunErrorClear.
6. If the device has been addressed, disable the address detection using PLIB_USART_ReceiverAddressDetectDisable, which will allow all received data into the receive buffer and generate interrupts if desired.
7. *Optional (if available on the device):* If a long packet is expected, the receive interrupt mode could be changed to buffer more than one data word between interrupts. Use PLIB_USART_ReceiverInterruptModeSelect with USART_RECEIVE_FIFO_HALF_FULL or USART_RECEIVE_FIFO_3B4FULL.
8. When the last data byte has been received, enable the address detect using PLIB_USART_ReceiverAddressDetectEnable, so that only address bytes will be received.
9. *Optional (if available on the device):* Ensure that the receive interrupt is configured to be triggered after each received word using PLIB_USART_ReceiverInterruptModeSelect with USART_RECEIVE_FIFO_ONE_CHAR.

Example: Asynchronous Reception (with Address Detect)

```
// Either wait for Receive buffer to have data or wait for a receive interrupt.
int8_t my_address;

// Receive the address
if(PLIB_USART_ReceiverDataIsAvailable(MY_USART_INSTANCE))
{
    my_address = PLIB_USART_ReceiverByteReceive(MY_USART_INSTANCE);
    // where, my_address is the address received
}

// If overrun error clear the error.
if(PLIB_USART_ReceiverOverrunHasOccurred(MY_USART_INSTANCE))
{
    PLIB_USART_ReceiverOverrunErrorClear(MY_USART_INSTANCE);
}

if(my_address == MY_DEVICE_ADDRESS)
{
    // The device has been addressed.
    PLIB_USART_ReceiverAddressDetectDisable(MY_USART_INSTANCE);
}
```

```
// TODO - Receive the data bytes for the packet. Either wait for RX buffer
//to have data or wait for a receive interrupt.

// When all the bytes for the packet are received.

// Enable address detection mode
PLIB_USART_ReceiverAddressDetectEnable(MY_USART_INSTANCE);
```

Synchronous Master Mode

This section provides processes for setting up synchronous master transmission and reception.

Note: The features described in this section are not available on all devices. Please refer to the **"USART"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details.

Description

Synchronous Master Transmission

Setup

1. Set the desired baud rate using PLIB_USART_BaudRateSet or PLIB_USART_BaudRateHighSet.
2. Enable the synchronous master serial port using PLIB_USART_SyncModeSelect, PLIB_USART_SyncClockSourceSelect, and PLIB_USART_Enable.
3. Set the appropriate I/O direction and corresponding RX and TX I/O pins.
4. Disable receive using PLIB_USART_ReceiverDisable.
5. *Optional:* If desired set the number of data bits to 9 (to send address byte or to enable parity check) using PLIB_USART_LineControlModeSelect.
6. *Optional:* If desired, enable the transmit interrupt, ensuring that the interrupts are enabled for the system and the peripherals.

Example: Synchronous Master Transmission Setup

```
// Set the desired baud rate
uint32_t baudRate = 9600;

// where, MY_USART_INSTANCE - is a specific instance of the hardware peripheral.
// where, MY_CLOCK_FREQUENCY - is hardware clock frequency which is currently being used by the system.
PLIB_USART_BaudRateHighSet(MY_USART_INSTANCE, baudRate, MY_CLOCK_FREQUENCY);

// Enable the synchronous master serial port.
// enable sync mode
PLIB_USART_SyncModeSelect(MY_USART_INSTANCE, USART_ASYNC_MODE);
// enable master clock
PLIB_USART_SyncClockSourceSelect(MY_USART_INSTANCE, USART_SYNC_CLOCK_SOURCE_MASTER);
// enable USART
PLIB_USART_Enable(MY_USART_INSTANCE);

// Set the appropriate IO direction for USART pins
// TODO Call the appropriate function.
```

Transmission

1. Enable transmission using PLIB_USART_TransmitterEnable.
2. Ensure that the transmit buffer is not full before attempting to write onto the transmit buffer. Either poll using PLIB_USART_TransmitterBufferIsFull or wait for the transmit interrupt.

Note: If using interrupts, make sure that interrupts are also enabled for the system and the peripherals.

3. Start the transmission using PLIB_USART_TransmitterByteSend (if transmitting 8 - bit data) or PLIB_USART_Transmitter9BitsSend (if transmitting address or if transmitting a byte with parity).
4. After the transmission is complete, disable the transmitter.

Example: Synchronous Master Transmission

```
// Enable the transmission
PLIB_USART_TransmitterEnable(MY_USART_INSTANCE);

// TODO Either wait for Transmit buffer to be not full or wait for an transmit interrupt.

// Transmit the byte when Transmit buffer is empty.
// where, my_byte is the 8 bit data to be transmitted
PLIB_USART_TransmitterByteSend(MY_USART_INSTANCE, my_byte);
```

Synchronous Master Reception

Setup

1. Set the desired baud rate using PLIB_USART_BaudRateSet or PLIB_USART_BaudRateHighSet.
2. Enable the synchronous master serial port using PLIB_USART_SyncModeSelect, PLIB_USART_SyncClockSourceSelect, and PLIB_USART_Enable.
3. Set the appropriate IO direction and corresponding to RX and TX I/O pins.
4. *Optional:* If desired, enable the receive interrupt, ensuring that the interrupts are enabled for the system and the peripherals.
5. Start the reception using PLIB_USART_ReceiverDisable.

Example: Synchronous Master Reception Setup

```
uint32_t baudRate = 9600;
// where, MY_USART_INSTANCE - is a specific instance of the hardware peripheral.
// where, MY_CLOCK_FREQUENCY - is hardware clock frequency which is currently being used by the system.
PLIB_USART_BaudRateHighSet(MY_USART_INSTANCE, baudRate, MY_CLOCK_FREQUENCY);

PLIB_USART_HandshakeModeSelect(MY_USART_INSTANCE,
                                    USART_HANDSHAKE_MODE_SIMPLEX);
// Enable the synchronous master serial port.
// enable sync mode
PLIB_USART_SyncModeSelect(MY_USART_INSTANCE, USART_SYNC_MODE);
// enable master clock
PLIB_USART_SyncClockSourceSelect(MY_USART_INSTANCE, USART_SYNC_CLOCK_SOURCE_MASTER);
// enable USART
PLIB_USART_Enable(MY_USART_INSTANCE);

// Set the appropriate IO direction for USART pins
// TODO - Call the appropriate function.

// Enable receive mode
PLIB_USART_ReceiverEnable(MY_USART_INSTANCE);
```

Reception

1. Either wait for an interrupt, which will be generated when the reception is completed, or poll using PLIB_USART_ReceiverDataIsAvailable.

Note: If using interrupts, make sure that interrupts are also enabled for the system and the peripherals.

2. Read the status of the device using PLIB_USART_ReceiverOverrunHasOccurred, PLIB_USART_ReceiverParityErrorHasOccurred and PLIB_USART_ReceiverFramingErrorHasOccurred.
3. Read the data using PLIB_USART_ReceiverByteReceive.
4. If an overrun error occurred, clear the error using the function PLIB_USART_ReceiverOverrunErrorClear.

Example: Synchronous Master Reception

```
// Read the byte
// where, my_byte is the 8 bit data to be transmitted
my_byte = PLIB_USART_ReceiverByteReceive(MY_USART_INSTANCE);

if(PLIB_USART_ReceiverOverrunHasOccurred(MY_USART_INSTANCE))
{
    PLIB_USART_ReceiverOverrunErrorClear(MY_USART_INSTANCE);
}
```

Synchronous Slave Mode

This section provides processes for setting up synchronous slave transmission and reception.

Note: This feature is not available on all devices. Please refer to the **"USART"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details.

Description

Synchronous Slave Transmission

Setup

1. Set the desired baud rate using either PLIB_USART_BaudRateHighSet or PLIB_USART_BaudRateSet.
2. Enable the synchronous slave serial port using PLIB_USART_SyncModeSelect, PLIB_USART_SyncClockSourceSelect, and PLIB_USART_Enable.

3. Set the appropriate I/O direction and corresponding RX and TX I/O pins.
4. Disable receive mode using PLIB_USART_ReceiverDisable.
5. *Optional:* If desired, enable the transmit interrupt,ensuring that the interrupts are enabled for the system and the peripherals.

Example: Synchronous Slave Transmission Setup

```
// Set the desired baud rate
uint32_t baudRate = 9600;

// where, MY_USART_INSTANCE - is a specific instance of the hardware
//peripheral MY_CLOCK_FREQUENCY - is hardware clock frequency which is
//currently being used by the system.
PLIB_USART_BaudRateHighSet(MY_USART_INSTANCE, baudRate, MY_CLOCK_FREQUENCY);

// Enable the synchronous slave serial port.
// enable sync mode
PLIB_USART_SyncModeSelect(MY_USART_INSTANCE, USART_SYNC_MODE);
// enable slave clock
PLIB_USART_SyncClockSourceSelect(MY_USART_INSTANCE, USART_SYNC_CLOCK_SOURCE_SLAVE);
// enable USART
PLIB_USART_Enable(MY_USART_INSTANCE);

// Set the appropriate IO direction for USART pins
// TODO - Call the appropriate function.

// Disable receive mode
PLIB_USART_ReceiverDisable(MY_USART_INSTANCE);

// TODO - If using interrupts Enable the transmit interrupt
// TODO - Call the appropriate function for the transmit enable interrupt,
// TODO - Also, make sure that the interrupts are enabled for system and the peripherals.
```

Transmission

1. Enable transmission using PLIB_USART_TransmitterEnable.
2. Ensure that the transmit buffer is not full before attempting to write into the transmit buffer. Either poll using PLIB_USART_TransmitterBufferIsFull or wait for the transmit interrupt.

Note: If using interrupts, ensure that interrupts are also enabled for the system and the peripherals.

3. Start the transmission using PLIB_USART_TransmitterByteSend (if transmitting 8-bit data) or PLIB_USART_Transmitter9BitsSend (if transmitting address if transmitting a byte with parity)
4. After the transmission is complete, disable the transmitter.

Example: Synchronous Slave Transmission

```
// Enable the transmission
PLIB_USART_TransmitterEnable(MY_USART_INSTANCE);

// TODO - Either wait for Transmit buffer to be not full or wait
//for an transmit interrupt.

// Transmit the byte when Transmit buffer is empty.
PLIB_USART_TransmitterByteSend(MY_USART_INSTANCE, my_word);
// where, my_word is the 9 bit data to be transmitted
```

Synchronous Slave Reception

Setup

1. Set the desired baud rate using PLIB_USART_BaudRateHighSet or PLIB_USART_BaudRateSet.
2. Enable the synchronous master serial port using PLIB_USART_SyncModeSelect, PLIB_USART_SyncClockSourceSelect, and PLIB_USART_Enable.
3. Set the appropriate I/O direction and corresponding RX and TX I/O pins.
4. *Optional:* If desired, enable the receive interrupt, ensuring that the interrupts are enabled for the system and the peripherals.
5. Start the reception using PLIB_USART_ReceiverEnable.

Example: Synchronous Slave Reception Setup

```
// Set the desired baud rate
uint32_t baudRate = 9600;

// where, MY_USART_INSTANCE - is a specific instance of the hardware peripheral.
// where, MY_CLOCK_FREQUENCY - is hardware clock frequency which is currently
```

```
//being used by the system.
PLIB_USART_BaudRateHighSet(MY_USART_INSTANCE, baudRate, MY_CLOCK_FREQUENCY);

// Enable the synchronous slave serial port.
// enable sync mode
PLIB_USART_SyncModeSelect(MY_USART_INSTANCE, USART_SYNC_MODE);
// enable master clock
PLIB_USART_SyncClockSourceSelect(MY_USART_INSTANCE, USART_SYNC_CLOCK_SOURCE_SLAVE);
// enable USART
PLIB_USART_Enable(MY_USART_INSTANCE);

// Set the appropriate IO direction for USART pins
// TODO - Call the appropriate function.

// Start the reception
// Enable the continuous reception
PLIB_USART_ReceiverDisable(MY_USART_INSTANCE);
```

Reception

1. Either wait for an interrupt, which will be generated when the reception is completed, or poll using PLIB_USART_ReceiverDataIsAvailable.

Note: If using interrupts, ensure that interrupts are also enabled for the system and the peripherals.

2. Read the status of the device using PLIB_USART_ReceiverOverrunHasOccurred, PLIB_USART_ReceiverParityErrorHasOccurred, and PLIB_USART_ReceiverFramingErrorHasOccurred.
3. Read the data using PLIB_USART_ReceiverByteReceive.
4. If an overrun error occurred, clear the error using PLIB_USART_ReceiverOverrunErrorClear.

Example: Synchronous Slave Reception

```
// Transmit the data
my_byte = PLIB_USART_ReceiverByteReceive(MY_USART_INSTANCE);
// where, my_byte is the 8 bit data received

// If overrun error clear the error.
if(PLIB_USART_ReceiverOverrunHasOccurred(MY_USART_INSTANCE))
{
 PLIB_USART_ReceiverOverrunErrorClear(MY_USART_INSTANCE);
}
```

Other Features

This section describes additional features of the USART Peripheral Library.

Note: The features described in this section are not available on all devices. Please refer to the **"USART"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details.

Description

IrDA Support

Support for IrDA is available in some microcontrollers.

1. Enable IrDA support using PLIB_USART_IrDAEnable. IrDA support can be disabled using PLIB_USART_IrDADisable.
2. *Optional:* If using the external IrDA encoder and decoder, use the function PLIB_USART_OperationModeSelect with USART_ENABLE_TX_RX_BCLK_USED to output the 16x baud clock.
3. *Optional:* IrDA Transmit Polarity can be inverted using PLIB_USART_TransmitterIdleIsLowEnable.
4. *Optional:* IrDA Receive Polarity can be inverted using PLIB_USART_ReceiverIdleStateLowEnable.
5. Enable the USART using PLIB_USART_Enable.

Loopback Support

This is the mode in which the transmission is internally connected to reception.

1. Set the desired baud rate using PLIB_USART_BaudRateSet or PLIB_USART_BaudRateHighSet.
2. Set up the line control parameters (data bits, stop bits, parity, flow control) using PLIB_USART_LineControlModeSelect. Refer to USART_LINECONTROL_MODE for a list of possible values.
3. Set the appropriate I/O direction and corresponding RX and TX I/O pins.
4. *Optional:* If desired, enable the transmit interrupt, also make sure that the interrupts are enabled for the system and the peripherals.
5. *Optional:* Also select the interrupt priority.

6. *Optional:* Also, set up the transmit FIFO interrupt mode using PLIB_USART_TransmitterInterruptModeSelect. Refer to USART_TRANSMIT_INTR_MODE for a list of possible values.
7. Enable the USART module using PLIB_USART_Enable and enable the transmission using PLIB_USART_TransmitterEnable.
8. Enable loopback using PLIB_USART_LoopbackEnable. Loopback can be disabled at any time using PLIB_USART_LoopbackDisable
9. Continue with transmission and/or reception using the same steps as for asynchronous transmission/reception.

Auto Baud Support

1. Enable the auto baud detection using the function PLIB_USART_BaudRateAutoDetectEnable, which requires a reception of the Sync character (0x55).
2. *Optional:* Poll PLIB_USART_BaudRateAutoDetectIsComplete to check if the baud rate is detected.
3. *Optional:* Call PLIB_USART_BaudRateGet to get the baud rate that was detected.
4. Clear the receive interrupt.
5. On some microcontrollers, reading the data using PLIB_USART_ReceiverByteReceive may be required.

Flow Control Support

The USART can use Simplex or Flow Control modes:

- Use PLIB_USART_HandshakeModeSelect to enable flow control (USART_HANDSHAKE_MODE_FLOW_CONTROL) or use simplex mode (USART_HANDSHAKE_MODE_SIMPLEX) selected from USART_HANDSHAKE_MODE.
- To configure the USART line control features, use PLIB_USART_LineControlModeSelect selected from USART_LINECONTROL_MODE.
- Additionally, the USART pins may need to be configured using PLIB_USART_OperationModeSelect and the appropriate values from USART_OPERATION_MODE.

Operation During Sleep Mode

When the device enters Sleep mode, all clock sources supplied to the USART modules are shut down. If the device enters Sleep mode in the middle of a USART transmission or reception operation, the operation is aborted and the USART pins are driven to default state.

A Start bit, when detected, can wake up the device.

- The application needs to enable the wake-up on start bit using PLIB_USART_WakeOnStartEnable just before entering Sleep mode, to wake-up the device
- For the device to wake-up from sleep, reception of the Sync character or Wake-up Signal character is required
- *Optional:* If using interrupts, a receive interrupt is generated

Operation During Idle Mode

When the device enters Idle mode, the system clock sources remain functional and the CPU stops code execution.

- USART operation during Idle mode can be stopped using PLIB_USART_StopInIdleEnable. When the device enters Idle mode, the USART module operation is similar to that as in Sleep mode(Refer to Operation in Sleep Mode).
- By default, the USART module continues to operate in Idle mode and provide full functionality

USART Operation With DMA

The DMA module can be used to transfer data between the USART and the CPU, without CPU assistance.

1. Set the desired baud rate using the function PLIB_USART_BaudRateSet or PLIB_USART_BaudRateHighSet.
2. Set up the line control parameters (data bits, stop bits, parity, flow control) using the function PLIB_USART_LineControlModeSelect. Refer to USART_LINECONTROL_MODE for a list of possible values.
3. Set the appropriate I/O direction and corresponding RX and TX I/O pins.
4. Enable the USART module using PLIB_USART_Enable and enable the transmission using PLIB_USART_TransmitterEnable.
5. Enable the Transmit, Receive, and Error interrupts, ensuring that the interrupts are enabled for the system and the peripherals.
6. Select the interrupt priority.
7. Set up the Transmit FIFO Interrupt mode and Receive FIFO Interrupt mode using the PLIB_USART_TransmitterInterruptModeSelect and PLIB_USART_ReceiverInterruptModeSelect functions. To generate interrupts for every character received, use USART_RECEIVE_FIFO_ONE_CHAR from USART_RECEIVE_INTR_MODE.
8. Configure the DMA to be used with the USART receiver and transmitter.

Configuring the Library

The library is configured for the supported USART modules when the processor is chosen in the MPLAB X IDE.

Library Interface

a) General Functions

	Name	Description
	PLIB_USART_Disable	Disables the specific USART module
	PLIB_USART_Enable	Enables the specific USART module.
	PLIB_USART_HandshakeModeSelect	Sets the data flow configuration.
	PLIB_USART_IrDADisable	Disables the IrDA encoder and decoder.
	PLIB_USART_IrDAEnable	Enables the IrDA encoder and decoder.
	PLIB_USART_LineControlModeSelect	Sets the data flow configuration.
	PLIB_USART_LoopbackDisable	Disables Loopback mode.
	PLIB_USART_LoopbackEnable	Enables Loopback mode.
	PLIB_USART_OperationModeSelect	Configures the operation mode of the USART module.
	PLIB_USART_StopInIdleDisable	Disables the Stop in Idle mode (the USART module continues operation when the device is in Idle mode).
	PLIB_USART_StopInIdleEnable	Discontinues operation when the device enters Idle mode.
	PLIB_USART_WakeOnStartDisable	Disables the wake-up on start bit detection feature during Sleep mode.
	PLIB_USART_WakeOnStartEnable	Enables the wake-up on start bit detection feature during Sleep mode.
	PLIB_USART_WakeOnStartIsEnabled	Gets the state of the sync break event completion.
	PLIB_USART_ErrorsGet	Return the status of all errors in the specified USART module.
	PLIB_USART_InitializeModeGeneral	Enables or disables general features of the USART module.
	PLIB_USART_InitializeOperation	Configures the Receive and Transmit FIFO interrupt levels and the hardware lines to be used by the module.
	PLIB_USART_AddressGet	Gets the address for the Address Detect mode.
	PLIB_USART_AddressMaskGet	Gets the address mask for the Address Detect mode.
	PLIB_USART_AddressMaskSet	Sets the address mask for the Address Detect mode.
	PLIB_USART_AddressSet	Sets the address for the Address Detect mode.
	PLIB_USART_ModuleIsBusy	Returns the USART module's running status.
	PLIB_USART_RunInOverflowDisable	Disables the Run in overflow condition mode.
	PLIB_USART_RunInOverflowEnable	Enables the USART module to continue to operate when an overflow error condition has occurred.
	PLIB_USART_RunInOverflowIsEnabled	Gets the status of the Run in Overflow condition.
	PLIB_USART_RunInSleepModeDisable	Turns off the USART module's BRG clock during Sleep mode.
	PLIB_USART_RunInSleepModeEnable	Allows the USART module's BRG clock to run when the device enters Sleep mode.
	PLIB_USART_RunInSleepModeIsEnabled	Gets the status of Run in Sleep mode.

b) Baud Rate Generator Functions

	Name	Description
	PLIB_USART_BaudRateAutoDetectEnable	Enables baud rate measurement on the next character, which requires reception of the Sync character.
	PLIB_USART_BaudRateAutoDetectIsComplete	Gets the state of the automatic baud detection.
	PLIB_USART_BaudRateGet	Gets the baud rate current in use.
	PLIB_USART_BaudRateHighDisable	Disables the high baud rate selection.
	PLIB_USART_BaudRateHighEnable	Enables high baud rate selection.
	PLIB_USART_BaudRateHighSet	Sets the baud rate to the desired value.
	PLIB_USART_BaudRateSet	Sets the baud rate to the desired value.
	PLIB_USART_BaudSetAndEnable	Sets the baud rate to the desired value and enables the USART receiver, transmitter and the USART module.
	PLIB_USART_BRGClockSourceGet	Gets the BRG clock source of the USART module.
	PLIB_USART_BRGClockSourceSelect	Configures the BRG clock source of the USART module.

c) Transmitter Functions

	Name	Description
	PLIB_USART_Transmitter9BitsSend	Data to be transmitted in the byte mode with the 9th bit.
	PLIB_USART_TransmitterBreakSend	Transmits the break character.

	PLIB_USART_TransmitterBreakSendIsComplete	Returns the status of the break transmission
	PLIB_USART_TransmitterBufferIsFull	Gets the transmit buffer full status.
	PLIB_USART_TransmitterByteSend	Data to be transmitted in the Byte mode.
	PLIB_USART_TransmitterDisable	Disables the specific USART module transmitter.
	PLIB_USART_TransmitterEnable	Enables the specific USART module transmitter.
	PLIB_USART_TransmitterIdleIsLowDisable	Disables the Transmit Idle Low state.
	PLIB_USART_TransmitterIdleIsLowEnable	Enables the Transmit Idle Low state.
	PLIB_USART_TransmitterInterruptModeSelect	Sets the USART transmitter interrupt mode.
	PLIB_USART_TransmitterIsEmpty	Gets the transmit shift register empty status.
	PLIB_USART_TransmitterAddressGet	Returns the address of the USART TX register

d) Receiver Functions

	Name	Description
	PLIB_USART_ReceiverAddressAutoDetectDisable	Disables the automatic Address Detect mode.
	PLIB_USART_ReceiverAddressAutoDetectEnable	Setup the automatic Address Detect mode.
	PLIB_USART_ReceiverAddressDetectDisable	Enables the Address Detect mode.
	PLIB_USART_ReceiverAddressDetectEnable	Enables the Address Detect mode.
	PLIB_USART_ReceiverAddressIsReceived	Checks and return if the data received is an address.
	PLIB_USART_ReceiverByteReceive	Data to be received in the Byte mode.
	PLIB_USART_ReceiverDataIsAvailable	Identifies if the receive data is available for the specified USART module.
	PLIB_USART_ReceiverDisable	Disables the USART receiver.
	PLIB_USART_ReceiverEnable	Enables the USART receiver.
	PLIB_USART_ReceiverFramingErrorHasOccurred	Gets the framing error status.
	PLIB_USART_ReceiverIdleStateLowDisable	Disables receive polarity inversion.
	PLIB_USART_ReceiverIdleStateLowEnable	Enables receive polarity inversion.
	PLIB_USART_ReceiverInterruptModeSelect	Sets the USART receiver FIFO level.
	PLIB_USART_ReceiverIsIdle	Identifies if the receiver is idle.
	PLIB_USART_ReceiverOverrunErrorClear	Clears a USART vverrun error.
	PLIB_USART_ReceiverOverrunHasOccurred	Identifies if there was a receiver overrun error.
	PLIB_USART_ReceiverParityErrorHasOccurred	Gets the parity error status.
	PLIB_USART_ReceiverAddressGet	Returns the address of the USART RX register
	PLIB_USART_Receiver9BitsReceive	Data to be received in the byte mode with the 9th bit.

e) Feature Existence Functions

	Name	Description
	PLIB_USART_ExistsBaudRate	Identifies whether the BaudRate feature exists on the USART module.
	PLIB_USART_ExistsBaudRateAutoDetect	Identifies whether the BaudRateAutoDetect feature exists on the USART module.
	PLIB_USART_ExistsBaudRateHigh	Identifies whether the BaudRateHigh feature exists on the USART module.
	PLIB_USART_ExistsEnable	Identifies whether the EnableControl feature exists on the USART module.
	PLIB_USART_ExistsHandshakeMode	Identifies whether the HandShakeMode feature exists on the USART module.
	PLIB_USART_ExistsIrDA	Identifies whether the IrDAControl feature exists on the USART module.
	PLIB_USART_ExistsLineControlMode	Identifies whether the LineControlMode feature exists on the USART module.
	PLIB_USART_ExistsLoopback	Identifies whether the Loopback feature exists on the USART module.
	PLIB_USART_ExistsOperationMode	Identifies whether the OperationMode feature exists on the USART module.
	PLIB_USART_ExistsReceiver	Identifies whether the Receiver feature exists on the USART module.
	PLIB_USART_ExistsReceiverAddressAutoDetect	Identifies whether the ReceiverAddressAutoDetect feature exists on the USART module.
	PLIB_USART_ExistsReceiverAddressDetect	Identifies whether the ReceiverAddressDetect feature exists on the USART module.
	PLIB_USART_ExistsReceiverDataAvailableStatus	Identifies whether the ReceiverDataAvailable feature exists on the USART module
	PLIB_USART_ExistsReceiverEnable	Identifies whether the ReceiverEnableControl feature exists on the USART module.
	PLIB_USART_ExistsReceiverFramingErrorStatus	Identifies whether the ReceiverFramingError feature exists on the USART module.

	PLIB_USART_ExistsReceiverIdleStateLowEnable	Identifies whether the ReceiverPolarityInvert feature exists on the USART module.
	PLIB_USART_ExistsReceiverIdleStatus	Identifies whether the ReceiverIdle feature exists on the USART module.
	PLIB_USART_ExistsReceiverInterruptMode	Identifies whether the ReceiverInterruptMode feature exists on the USART module.
	PLIB_USART_ExistsReceiverOverrunStatus	Identifies whether the ReceiverOverrunError feature exists on the USART module.
	PLIB_USART_ExistsReceiverParityErrorStatus	Identifies whether the ReceiverParityError feature exists on the USART module.
	PLIB_USART_ExistsStopInIdle	Identifies whether the StopInIdle feature exists on the USART module.
	PLIB_USART_ExistsTransmitter	Identifies whether the Transmitter feature exists on the USART module.
	PLIB_USART_ExistsTransmitter9BitsSend	Identifies whether the Transmitter9Bits feature exists on the USART module.
	PLIB_USART_ExistsTransmitterBreak	Identifies whether the TransmitterBreak feature exists on the USART module.
	PLIB_USART_ExistsTransmitterBufferFullStatus	Identifies whether the TransmitterBufferFull feature exists on the USART module.
	PLIB_USART_ExistsTransmitterEmptyStatus	Identifies whether the TransmitterEmpty feature exists on the USART module.
	PLIB_USART_ExistsTransmitterEnable	Identifies whether the TransmitterEnableControl feature exists on the USART module
	PLIB_USART_ExistsTransmitterIdleIsLow	Identifies whether the TransmitterIdleIsLow feature exists on the USART module.
	PLIB_USART_ExistsTransmitterInterruptMode	Identifies whether the TransmitterInterruptMode feature exists on the USART module.
	PLIB_USART_ExistsWakeOnStart	Identifies whether the WakeOnStart feature exists on the USART module.
	PLIB_USART_ExistsReceiver9Bits	Identifies whether the 9 Bits Receiver feature exists on the USART module.
	PLIB_USART_ExistsBRGClockSourceSelect	Identifies whether the BRG Clock source select feature exists on the USART module.
	PLIB_USART_ExistsModuleBusyStatus	Identifies whether the module running status feature exists on the USART module.
	PLIB_USART_ExistsReceiverAddress	Identifies whether the Receiver Address feature exists on the USART module.
	PLIB_USART_ExistsReceiverAddressMask	Identifies whether the Receiver Address Mask feature exists on the USART module.
	PLIB_USART_ExistsRunInOverflow	Identifies whether the Run in overflow condition feature exists on the USART module.
	PLIB_USART_ExistsRunInSleepMode	Identifies whether the Run in Sleep mode feature exists on the USART module.

f) Data Types and Constants

	Name	Description
	USART_HANDSHAKE_MODE	Lists the USART handshake modes.
	USART_LINECONTROL_MODE	Data type defining the different configurations by which the USART data flow can be configured.
	USART_MODULE_ID	Enumeration: USART_MODULE_ID This enumeration defines the number of modules that are available on the microcontroller. This is the superset of all of the possible instances that might be available on Microchip microcontrollers. Refer to the data sheet to get the correct number of modules defined for desired microcontroller.
	_USART_MODULE_ID	
	USART_OPERATION_MODE	Data type defining the different configurations by which the USART can be enabled.
	USART_RECEIVE_INTR_MODE	Data type defining the different Receive FIFO levels by which the USART receive interrupt modes can be configured.
	USART_TRANSMIT_INTR_MODE	Data type defining the different transmit FIFO levels by which the USART transmit interrupt modes can be configured.

Description

This section describes the Application Programming Interface (API) functions of the USART Peripheral Library.

Refer to each section for a detailed description.

a) General Functions

PLIB_USART_Disable Function

Disables the specific USART module

File

plib_usart.h

C

```
void PLIB_USART_Disable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the specific USART module.

Remarks

The default state after any reset for a USART module is the disable state. If the USART is disabled, all of the related pins are in control of the general purpose I/O logic.

Disabling the USART module resets the buffers to empty states. Any data characters in the buffers are lost and the baud rate is reset. All error and status bits are also reset.

Disabling the USART while the USART is active, will abort all pending transmissions and receptions. Re-enabling the USART will restart the module in the same configuration.

When disabled, the USART power consumption is minimal. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_Disable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_Disable (USART_MODULE_ID index)

PLIB_USART_Enable Function

Enables the specific USART module.

File

plib_usart.h

C

```
void PLIB_USART_Enable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the specific USART module.

Remarks

By calling this function, the USART pins are controlled by the USART module. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_Enable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_Enable (USART_MODULE_ID index)

PLIB_USART_HandshakeModeSelect Function

Sets the data flow configuration.

File

plib_usart.h

C

```
void PLIB_USART_HandshakeModeSelect(USART_MODULE_ID index, USART_HANDSHAKE_MODE handshakeConfig);
```

Returns

None.

Description

This function sets the USART data flow configuration based on the mask provided and the specified baud rate.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsHandshakeMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_HandshakeModeSelect(MY_USART_INSTANCE,
                                    USART_HANDSHAKE_MODE_SIMPLEX);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
mode	For possible data flow configurations, refer to USART_HANDSHAKE_MODE

Function

void PLIB_USART_HandshakeModeSelect(USART_MODULE_ID index,
USART_HANDSHAKE_MODE handshakeConfig)

PLIB_USART_IrDADisable Function

Disables the IrDA encoder and decoder.

File

plib_usart.h

C

```
void PLIB_USART_IrDADisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the IrDA encoder and decoder.

Remarks

By default, the IrDA Encoder and Decoder are disabled.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsIrDA in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_IrDADisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_IrDADisable (USART_MODULE_ID index)

PLIB_USART_IrDAEnable Function

Enables the IrDA encoder and decoder.

File

plib_usart.h

C

```
void PLIB_USART_IrDAEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the IrDA encoder and decoder.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsIrDA in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_IrDAEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_IrDAEnable (USART_MODULE_ID index)

PLIB_USART_LineControlModeSelect Function

Sets the data flow configuration.

File

plib_usart.h

C

```
void PLIB_USART_LineControlModeSelect(USART_MODULE_ID index, USART_LINECONTROL_MODE dataFlowConfig);
```

Returns

None.

Description

This function sets the USART data flow configuration based on the mask provided and the specified baud rate.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsLineControlMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_LineControlModeSelect(MY_USART_INSTANCE,
                                 USART_8N1);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
mode	For possible data flow configurations, refer to USART_LINECONTROL_MODE

Function

void PLIB_USART_LineControlModeSelect(USART_MODULE_ID index,
USART_LINECONTROL_MODE dataFlowConfig)

PLIB_USART_LoopbackDisable Function

Disables Loopback mode.

File

plib_usart.h

C

```
void PLIB_USART_LoopbackDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables Loopback mode.

Remarks

By default, Loopback mode is disabled. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsLoopback in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_LoopbackDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_LoopbackDisable (USART_MODULE_ID index)

PLIB_USART_LoopbackEnable Function

Enables Loopback mode.

File

plib_usart.h

C

```
void PLIB_USART_LoopbackEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables Loopback mode.

Remarks

By default, Loopback mode is disabled.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsLoopback in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_LoopbackEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_LoopbackEnable (USART_MODULE_ID index)

PLIB_USART_OperationModeSelect Function

Configures the operation mode of the USART module.

File

plib_usart.h

C

```
void PLIB_USART_OperationModeSelect(USART_MODULE_ID index, USART_OPERATION_MODE operationmode);
```

Returns

None.

Description

This function configures the operation mode of the USART (i.e., controls the pins used by the USART module). Refer to USART_OPERATION_MODE for the possible settings.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsOperationMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_OperationModeSelect(MY_USART_INSTANCE, USART_ENABLE_TX_RX_BCLK_USED);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
operationmode	One of the possible values from USART_OPERATION_MODE

Function

void PLIB_USART_OperationModeSelect(USART_MODULE_ID index,
USART_OPERATION_MODE operationmode)

PLIB_USART_StopInIdleDisable Function

Disables the Stop in Idle mode (the USART module continues operation when the device is in Idle mode).

File

plib_usart.h

C

```
void PLIB_USART_StopInIdleDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the Stop in Idle mode. The USART module continues operation when the device is in Idle mode.

Remarks

By default, the USART module will continue operation in Idle mode.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsStopInIdle in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_StopInIdleDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_StopInIdleDisable (USART_MODULE_ID index)

PLIB_USART_StopInIdleEnable Function

Discontinues operation when the device enters Idle mode.

File

plib_usart.h

C

```
void PLIB_USART_StopInIdleEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the USART module to discontinue operation when the device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsStopInIdle in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_StopInIdleEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_StopInIdleEnable (USART_MODULE_ID index)

PLIB_USART_WakeOnStartDisable Function

Disables the wake-up on start bit detection feature during Sleep mode.

File

plib_usart.h

C

```
void PLIB_USART_WakeOnStartDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the wake-up on start bit detection feature during Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsWakeOnStart in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_WakeOnStartDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_WakeOnStartDisable (USART_MODULE_ID index)

PLIB_USART_WakeOnStartEnable Function

Enables the wake-up on start bit detection feature during Sleep mode.

File

plib_usart.h

C

```
void PLIB_USART_WakeOnStartEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the wake-up on start feature during Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsWakeOnStart in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_WakeOnStartEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_WakeOnStartEnable (USART_MODULE_ID index)

PLIB_USART_WakeOnStartIsEnabled Function

Gets the state of the sync break event completion.

File

plib_usart.h

C

```
bool PLIB_USART_WakeOnStartIsEnabled(USART_MODULE_ID index);
```

Returns

None.

Description

This function returns the status of the sync break event, when called after enabling using PLIB_USART_WakeOnStartEnable.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsWakeOnStart in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

//Call the interface just prior to entering the sleep mode.
PLIB_USART_WakeOnStartEnable(MY_USART_INSTANCE);

// Check the status if the Sync break event is over.
if(PLIB_USART_WakeOnStartIsEnabled(MY_USART_INSTANCE))
{
   // Do Something
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_WakeOnStartIsEnabled (USART_MODULE_ID index)

PLIB_USART_ErrorsGet Function

Return the status of all errors in the specified USART module.

File

plib_usart.h

C

```
USART_ERROR PLIB_USART_ErrorsGet(USART_MODULE_ID index);
```

Returns

Returns a bitmap of USART error status.

Description

This function returns status of all errors in the specified USART module. The return value can be bitwise AND'ed with a USART_ERROR type to know the status of a specific error.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability. Availability of this function can also be determined if all of the followings functions return true:

- PLIB_USART_ExistsReceiverFramingErrorStatus
- PLIB_USART_ExistsReceiverParityErrorStatus
- PLIB_USART_ExistsReceiverOverrunStatus

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

USART_ERROR error;

// Get the status of all errors.
```

```
error = PLIB_USART_ErrorsGet(MY_USART_INSTANCE);

// Check if parity error is active
if(error & USART_ERROR_PARITY)
{
    // Parity error is active.
}
else if(error & USART_ERROR_FRAMING)
{
    // Framing error is active.
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

USART_ERROR PLIB_USART_ErrorsGet (USART_MODULE_ID index)

PLIB_USART_InitializeModeGeneral Function

Enables or disables general features of the USART module.

File

plib_usart.h

C

```
void PLIB_USART_InitializeModeGeneral(USART_MODULE_ID index, bool autobaud, bool loopBackMode, bool
wakeFromSleep, bool irdaMode, bool stopInIdle);
```

Returns

None.

Description

This function enables or disables general features of the USART module.

Remarks

Enabling the wake from sleep feature will cause the first character that is received by the USART module to be discarded. This feature should only be enabled if the CPU is to placed in power saving mode.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability. Availability of this function can also be determined if all of the following functions return true:

- PLIB_USART_ExistsLoopback
- PLIB_USART_ExistsBaudRateAutoDetect
- PLIB_USART_ExistsWakeOnStart
- PLIB_USART_ExistsIrDA
- PLIB_USART_ExistsStopInIdle

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

// Enable loopback, disable IrDA, disable auto baud detection and disable
// wake from sleep. Enable stop in idle
PLIB_USART_InitializeModeGeneral(MY_USART_INSTANCE, false, true,
                                                    false, false, true);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
autobaud	If true, auto baud rate detection is enabled. If false the feature is disabled.
loopBackMode	If true, loop back is enabled. If false the feature is disabled.

wakeFromSleep	If true, the USART module will wake up the CPU from sleep mode on USART activity. If false the feature is disabled.
irdaMode	If true, the IrDA mode is enabled. If false the feature is disabled.
stopInIdle	If true, module will stop functioning when CPU enters Idle mode. If false, the feature is disabled.

Function

void PLIB_USART_InitializeModeGeneral(USART_MODULE_ID index, bool autobaud,
bool loopBackMode, bool wakeFromSleep, bool irdaMode, bool stopInIdle);

PLIB_USART_InitializeOperation Function

Configures the Receive and Transmit FIFO interrupt levels and the hardware lines to be used by the module.

File

plib_usart.h

C

```
void PLIB_USART_InitializeOperation(USART_MODULE_ID index, USART_RECEIVE_INTR_MODE receiveInterruptMode,
USART_TRANSMIT_INTR_MODE transmitInterruptMode, USART_OPERATION_MODE operationMode);
```

Returns

None.

Description

This function configures the Receive and Transmit FIFO interrupt levels and the hardware lines to be used by the module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability. Availability of this function can also be determined if all of the following functions return true:

- PLIB_USART_ExistsReceiverInterruptMode
- PLIB_USART_ExistsTransmitterInterruptMode
- PLIB_USART_ExistsOperationMode

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

// Set receive FIFO to interrupt when FIFO is 3/4 level full
// Set Transmit FIFO to interrupt when FIFO is empty
// USART module will only use RX and TX hardware lines

PLIB_USART_InitializeOperation(MY_USART_INSTANCE, USART_RECEIVE_FIFO_3B4FULL,
    USART_TRANSMIT_FIFO_EMPTY  , USART_ENABLE_TX_RX_USED);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
receiveInterruptMode	Receiver FIFO interrupt level
transmitInterruptMode	Transmit FIFO interrupt level
operationMode	Hardware lines to be used by the USART.

Function

void PLIB_USART_InitializeOperation(USART_MODULE_ID index ,
USART_RECEIVE_INTR_MODE receiveInterruptMode,
USART_TRANSMIT_INTR_MODE transmitInterruptMode,
USART_OPERATION_MODE operationMode);

PLIB_USART_AddressGet Function

Gets the address for the Address Detect mode.

File

plib_usart.h

C

```
uint8_t PLIB_USART_AddressGet(USART_MODULE_ID index);
```

Returns

- address - The address being used

Description

This function returns the address value being used for the Address Detect mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddress in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1
uint8_t address = 0;
address = PLIB_USART_AddressGet (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance

Function

uint8_t PLIB_USART_AddressGet

(

USART_MODULE_ID index

)

PLIB_USART_AddressMaskGet Function

Gets the address mask for the Address Detect mode.

File

plib_usart.h

C

```
uint8_t PLIB_USART_AddressMaskGet(USART_MODULE_ID index);
```

Returns

- mask - Address mask being used

Description

This function returns the address mask value being used for the Address Detect mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddressMask in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1
uint8_t mask = 0;
mask = PLIB_USART_AddressMaskGet (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_USART_AddressMaskGet

(

USART_MODULE_ID index

)

PLIB_USART_AddressMaskSet Function

Sets the address mask for the Address Detect mode.

File

plib_usart.h

C

```
void PLIB_USART_AddressMaskSet(USART_MODULE_ID index, uint8_t mask);
```

Returns

None.

Description

This function sets the address mask for the Address Detect mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddressMask in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1
uint8_t mask = 0x0F;
PLIB_USART_AddressMaskSet (MY_USART_INSTANCE, mask);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
mask	Address match mask bits

Function

void PLIB_USART_AddressMaskSet

(

USART_MODULE_ID index,

uint8_t mask

)

PLIB_USART_AddressSet Function

Sets the address for the Address Detect mode.

File

plib_usart.h

C

```
void PLIB_USART_AddressSet(USART_MODULE_ID index, uint8_t address);
```

Returns

None.

Description

This function sets the address for the Address Detect mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddress in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1
uint8_t address = 0x02;
PLIB_USART_AddressSet (MY_USART_INSTANCE, address);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
address	Address

Function

void PLIB_USART_AddressSet
(
    USART_MODULE_ID index,
uint8_t address
)

PLIB_USART_ModuleIsBusy Function

Returns the USART module's running status.

File

plib_usart.h

C

```
bool PLIB_USART_ModuleIsBusy(USART_MODULE_ID index);
```

Returns

- true - USART module is busy
- false - USART module is idle

Description

This function checks if the USART module status is busy. The following functions should not be used when the module status is busy:

- PLIB_USART_LineControlModeSelect
- PLIB_USART_BaudRateHighSet
- PLIB_USART_BaudRateHighEnable
- PLIB_USART_BaudRateHighDisable
- PLIB_USART_ReceiverIdleStateLowEnable
- PLIB_USART_ReceiverIdleStateLowDisable
- PLIB_USART_BaudRateAutoDetectEnable
- PLIB_USART_LoopbackEnable

- PLIB_USART_LoopbackDisable
- PLIB_USART_WakeOnStartEnable
- PLIB_USART_WakeOnStartDisable
- PLIB_USART_OperationModeSelect
- PLIB_USART_HandshakeModeSelect
- PLIB_USART_IrDAEnable
- PLIB_USART_IrDADisable
- PLIB_USART_StopInIdleEnable
- PLIB_USART_StopInIdleDisable
- PLIB_USART_RunInOverflowEnable
- PLIB_USART_RunInOverflowDisable
- PLIB_USART_BRGClockSourceSelect
- PLIB_USART_RunInSleepModeEnable
- PLIB_USART_RunInSleepModeDisable

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsModuleBusyStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1
bool moduleStatus;

moduleStatus = PLIB_USART_ModuleIsBusy (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_USART_ModuleIsBusy (USART_MODULE_ID index)

PLIB_USART_RunInOverflowDisable Function

Disables the Run in overflow condition mode.

File

plib_usart.h

C

```
void PLIB_USART_RunInOverflowDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the USART module from accepting new data when an overflow error condition is detected.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsRunInOverflow in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_RunInOverflowDisable (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_RunInOverflowDisable (USART_MODULE_ID index)

PLIB_USART_RunInOverflowEnable Function

Enables the USART module to continue to operate when an overflow error condition has occurred.

File

plib_usart.h

C

```
void PLIB_USART_RunInOverflowEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the USART module to continue to operate when an overflow error condition has occurred.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsRunInOverflow in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_RunInOverflowEnable (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_RunInOverflowEnable (USART_MODULE_ID index)

PLIB_USART_RunInOverflowIsEnabled Function

Gets the status of the Run in Overflow condition.

File

plib_usart.h

C

```
bool PLIB_USART_RunInOverflowIsEnabled(USART_MODULE_ID index);
```

Returns

- true - Run in overflow condition is enabled
- false - Run in overflow condition is disabled

Description

This function indicates if the USART module has been enabled to run in an overflow condition.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use

PLIB_USART_ExistsRunInOverflow in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

bool status;
status = PLIB_USART_RunInOverflowIsEnabled (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_USART_RunInOverflowIsEnabled (USART_MODULE_ID index)

PLIB_USART_RunInSleepModeDisable Function

Turns off the USART module's BRG clock during Sleep mode.

File

plib_usart.h

C

```
void PLIB_USART_RunInSleepModeDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function turns off the USART module's BRG clock during Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsRunInSleepMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_RunInSleepModeDisable (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_RunInSleepModeDisable (USART_MODULE_ID index)

PLIB_USART_RunInSleepModeEnable Function

Allows the USART module's BRG clock to run when the device enters Sleep mode.

File

plib_usart.h

C

```
void PLIB_USART_RunInSleepModeEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the USART module's BRG clock to continue operation when the device enters the Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsRunInSleepMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_RunInSleepModeEnable (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_RunInSleepModeEnable (USART_MODULE_ID index)

PLIB_USART_RunInSleepModeIsEnabled Function

Gets the status of Run in Sleep mode.

File

plib_usart.h

C

```
bool PLIB_USART_RunInSleepModeIsEnabled(USART_MODULE_ID index);
```

Returns

- true - Run in Sleep mode is enabled
- false - Run in Sleep mode is disabled

Description

This function indicates if the USART module has been enabled to run in Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsRunInSleepMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

bool status;
status = PLIB_USART_RunInSleepModeIsEnabled (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_USART_RunInSleepModeIsEnabled (USART_MODULE_ID index)

b) Baud Rate Generator Functions

PLIB_USART_BaudRateAutoDetectEnable Function

Enables baud rate measurement on the next character, which requires reception of the Sync character.

File

plib_usart.h

C

```
void PLIB_USART_BaudRateAutoDetectEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the baud rate measurement on the next character, which requires reception of the Sync character.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBaudRateAutoDetect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_BaudRateAutoDetectEnable(MY_USART_INSTANCE);

// Wait until the baud rate is detected.
while(!PLIB_USART_BaudRateAutoDetectIsComplete(MY_USART_INSTANCE));
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_BaudRateAutoDetectEnable (USART_MODULE_ID index)

PLIB_USART_BaudRateAutoDetectIsComplete Function

Gets the state of the automatic baud detection.

File

plib_usart.h

C

```
bool PLIB_USART_BaudRateAutoDetectIsComplete(USART_MODULE_ID index);
```

Returns

- true - Baud rate detection is not complete
- false - Baud rate detection is complete

Description

This function gets the state of the automatic baud detection and returns a '0' if the baud rate auto detection is complete.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBaudRateAutoDetect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_BaudRateAutoDetectEnable(MY_USART_INSTANCE);

// Wait until the baud rate is detected.
while(!PLIB_USART_BaudRateAutoDetectIsComplete(MY_USART_INSTANCE));
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_BaudRateAutoDetectIsComplete (USART_MODULE_ID index)

PLIB_USART_BaudRateGet Function

Gets the baud rate current in use.

File

plib_usart.h

C

```
uint32_t PLIB_USART_BaudRateGet(USART_MODULE_ID index, int32_t clockFrequency);
```

Returns

- BaudRate - Baud rate value

Description

This function gets the baud rate that is currently in use. The clock frequency needs to be passed to the function.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBaudRate in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

uint32_t baudRate ;
PLIB_USART_BaudRateSet(MY_USART_INSTANCE, MY_CLOCK_FREQUENCY, 9600);
baudRate = PLIB_USART_BaudRateGet(MY_USART_INSTANCE, MY_CLOCK_FREQUENCY);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
clockFrequency	Clock Frequency

Function

uint32_t PLIB_USART_BaudRateGet (USART_MODULE_ID index,
int32_t clockFrequency);

PLIB_USART_BaudRateHighDisable Function

Disables the high baud rate selection.

File

plib_usart.h

C

```
void PLIB_USART_BaudRateHighDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the high baud rate selection.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBaudRateHigh in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_BaudRateHighDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_BaudRateHighDisable (USART_MODULE_ID index)

PLIB_USART_BaudRateHighEnable Function

Enables high baud rate selection.

File

plib_usart.h

C

```
void PLIB_USART_BaudRateHighEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables high baud rate selection.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBaudRateHigh in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_BaudRateHighEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_BaudRateHighEnable (USART_MODULE_ID index)

PLIB_USART_BaudRateHighSet Function

Sets the baud rate to the desired value.

File

plib_usart.h

C

```
void PLIB_USART_BaudRateHighSet(USART_MODULE_ID index, uint32_t clockFrequency, uint32_t baudRate);
```

Returns

None.

Description

This function sets the baud rate to the desired value.

Remarks

Setting a new baud rate value causes the baud rate timer to reset. This ensures that the baud rate timer does not have to overflow before outputting the new baud rate.

If the system clock is changed during an active receive operation, a receiver error or data loss may result. To avoid this issue verify that no receptions are in progress before changing the system clock.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBaudRateHigh in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

uint32_t baudRateValue ;
PLIB_USART_BaudRateHighSet(MY_USART_INSTANCE, MY_CLOCK_FREQUENCY, 9600);
baudRateValue = PLIB_USART_BaudRateGet(MY_USART_INSTANCE, MY_CLOCK_FREQUENCY);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
baudRate	Baud Rate Value, it is the baud rate value
clockFrequency	Clock Frequency

Function

void PLIB_USART_BaudRateHighSet (USART_MODULE_ID index,

uint32_t clockFrequency, uint32_t baudRate);

PLIB_USART_BaudRateSet Function

Sets the baud rate to the desired value.

File

plib_usart.h

C

```
void PLIB_USART_BaudRateSet(USART_MODULE_ID index, uint32_t clockFrequency, uint32_t baudRate);
```

Returns

None.

Description

This function sets the baud rate to the desired value.

Remarks

Setting a new baud rate value causes the baud rate timer to reset. This ensures that the baud rate timer does not have to overflow before outputting the new baud rate.

If the system clock is changed during an active receive operation, a receiver error or data loss may result. To avoid this issue verify that no receptions are in progress before changing the system clock.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBaudRate in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

uint32_t baudRateValue ;
PLIB_USART_BaudRateSet(MY_USART_INSTANCE, MY_CLOCK_FREQUENCY, 9600);
baudRateValue = PLIB_USART_BaudRateGet(MY_USART_INSTANCE, MY_CLOCK_FREQUENCY);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
baudRate	Baud Rate Value
clockFrequency	Clock Frequency

Function

void PLIB_USART_BaudRateSet (USART_MODULE_ID index, uint32_t clockFrequency,

uint32_t baudRate);

PLIB_USART_BaudSetAndEnable Function

Sets the baud rate to the desired value and enables the USART receiver, transmitter and the USART module.

File

plib_usart.h

C

```
void PLIB_USART_BaudSetAndEnable(USART_MODULE_ID index, uint32_t systemClock, uint32_t baud);
```

Returns

None.

Description

This function sets the baud rate to the desired value and enables the USART receiver, USART transmitter and USART module.

Remarks

Setting a new baud rate value causes the baud rate timer to reset. This ensures that the baud rate timer does not have to overflow before outputting the new baud rate.

If the system clock is changed during an active receive operation, a receiver error or data loss may result. To avoid this issue verify that no receptions are in progress before changing the system clock.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability. Availability of this function can also be determined if all of the following functions return true:

- PLIB_USART_ExistsBaudRate
- PLIB_USART_ExistsTransmitterEnable
- PLIB_USART_ExistsReceiverEnable

- PLIB_USART_ExistsEnable

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

uint32_t baudRateValue ;
PLIB_USART_BaudSetAndEnable(MY_USART_INSTANCE, MY_CLOCK_FREQUENCY, 9600);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
baudRate	Baud Rate Value
clockFrequency	Clock Frequency

Function

void PLIB_USART_BaudSetAndEnable (USART_MODULE_ID index, uint32_t clockFrequency, uint32_t baudRate);

PLIB_USART_BRGClockSourceGet Function

Gets the BRG clock source of the USART module.

File

plib_usart.h

C

```
USART_BRG_CLOCK_SOURCE PLIB_USART_BRGClockSourceGet(USART_MODULE_ID index);
```

Returns

One of the possible values of USART_BRG_CLOCK_SOURCE

Description

This function returns the BRG Clock source of the USART. Refer to USART_BRG_CLOCK_SOURCE for the possible clock sources.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBRGClockSourceSelect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

USART_BRG_CLOCK_SOURCE brgClockSource;
brgClockSource = PLIB_USART_BRGClockSourceGet (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance

Function

USART_BRG_CLOCK_SOURCE PLIB_USART_BRGClockSourceGet (USART_MODULE_ID index)

PLIB_USART_BRGClockSourceSelect Function

Configures the BRG clock source of the USART module.

File

plib_usart.h

C

```
void PLIB_USART_BRGClockSourceSelect(USART_MODULE_ID index, USART_BRG_CLOCK_SOURCE brgClockSource);
```

Returns

None.

Description

This function configures the BRG Clock source of the USART. Refer to USART_BRG_CLOCK_SOURCE for the possible clock sources.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBRGClockSourceSelect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_BRGClockSourceSelect (MY_USART_INSTANCE, USART_BRG_CLOCK_SOURCE_FRC_IN_SLEEP);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
brgClockSource	One of the possible values from USART_BRG_CLOCK_SOURCE

Function

void PLIB_USART_BRGClockSourceSelect
(
USART_MODULE_ID index,
USART_BRG_CLOCK_SOURCE brgClockSource
)

c) Transmitter Functions

PLIB_USART_Transmitter9BitsSend Function

Data to be transmitted in the byte mode with the 9th bit.

File

plib_usart.h

C

```
void PLIB_USART_Transmitter9BitsSend(USART_MODULE_ID index, int8_t data, bool Bit9th);
```

Returns

None.

Description

The data is transmitted in the byte mode for the specified USART module, with 9th bit.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitter9BitsSend in your application to determine whether this feature is available.

Preconditions

The USART module should be configured to use the 9 data bits.

Example

```
#define MY_USART_INSTANCE USART_ID_1

uint8_t data = 'a';

if(!PLIB_USART_TransmitterBufferIsFull(MY_USART_INSTANCE))
{
    PLIB_USART_Transmitter9BitsSend(MY_USART_INSTANCE, data, false);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
data	Data to be transmitted.
9thBit	9th bit of the data to be transmitted.

Function

void PLIB_USART_Transmitter9BitsSend (USART_MODULE_ID index,

int8_t data, bool 9thBit)

PLIB_USART_TransmitterBreakSend Function

Transmits the break character.

File

plib_usart.h

C

```
void PLIB_USART_TransmitterBreakSend(USART_MODULE_ID index);
```

Returns

None.

Description

This function transmits the break character.

Remarks

After the break has been transmitted, the application can start transmitting next bytes.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterBreak in your application to determine whether this feature is available.

Preconditions

The application should wait for the transmitter to be idle, before calling this function.

Example

```
#define MY_USART_INSTANCE USART_ID_1

// Wait for the Transmit buffer to be empty.
while(PLIB_USART_TransmitterBufferIsFull(MY_USART_INSTANCE));

// Transmit the break character.
PLIB_USART_TransmitterBreakSend(MY_USART_INSTANCE);

// wait for the break transmission to complete
while(!PLIB_USART_TransmitterBreakSendIsComplete(MY_USART_INSTANCE));
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_TransmitterBreakSend (USART_MODULE_ID index)

PLIB_USART_TransmitterBreakSendIsComplete Function

Returns the status of the break transmission

File

plib_usart.h

C

```
bool PLIB_USART_TransmitterBreakSendIsComplete(USART_MODULE_ID index);
```

Returns

- true - Transmit break on the next transmission
- false - Break transmission completed or not started

Description

The function returns the status of the break transmission.

Remarks

After the break has been transmitted, the application can start transmitting next bytes.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterBreak in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

// Wait for the Transmit buffer to be empty.
while(PLIB_USART_TransmitterBufferIsFull(MY_USART_INSTANCE));

// Transmit the break character.
PLIB_USART_TransmitterBreakSend(MY_USART_INSTANCE);

// wait for the break transmission to complete
while(!PLIB_USART_TransmitterBreakSendIsComplete(MY_USART_INSTANCE));
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_TransmitterBreakSendIsComplete (USART_MODULE_ID index)

PLIB_USART_TransmitterBufferIsFull Function

Gets the transmit buffer full status.

File

plib_usart.h

C

```
bool PLIB_USART_TransmitterBufferIsFull(USART_MODULE_ID index);
```

Returns

- true - The transmit buffer is full
- false - The transmit buffer is not full, at least one more character can be written

Description

This function gets the transmit status of the specified USART module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterBufferFullStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

// Wait for the Transmit buffer to be empty.
while(PLIB_USART_TransmitterBufferIsFull(MY_USART_INSTANCE));

// Transmit the break character.
PLIB_USART_TransmitterBreakSend(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_TransmitterBufferIsFull (USART_MODULE_ID index)

PLIB_USART_TransmitterByteSend Function

Data to be transmitted in the Byte mode.

File

plib_usart.h

C

```
void PLIB_USART_TransmitterByteSend(USART_MODULE_ID index, int8_t data);
```

Returns

None.

Description

The data is transmitted in the Byte mode for the specified USART module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitter in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

uint8_t data = 'a';
if(!PLIB_USART_TransmitterBufferIsFull(MY_USART_INSTANCE))
{
    PLIB_USART_TransmitterByteSend(MY_USART_INSTANCE, data);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
data	Data to be transmitted.

Function

void PLIB_USART_TransmitterByteSend (USART_MODULE_ID index, int8_t data)

PLIB_USART_TransmitterDisable Function

Disables the specific USART module transmitter.

File

plib_usart.h

C

```
void PLIB_USART_TransmitterDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the specific USART module transmitter.

Remarks

Disabling the transmitter during a transmission will cause the transmission to be aborted.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_TransmitterDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_TransmitterDisable (USART_MODULE_ID index)

PLIB_USART_TransmitterEnable Function

Enables the specific USART module transmitter.

File

plib_usart.h

C

```
void PLIB_USART_TransmitterEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the specific USART module transmitter.

Remarks

The transmitter should not be enabled until the USART is enabled. The transmissions will not be enabled otherwise.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterEnable in your application to determine whether this feature is available.

Preconditions

The USART module should be enabled using the function PLIB_USART_Enable before this function is called.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_TransmitterEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_TransmitterEnable (USART_MODULE_ID index)

PLIB_USART_TransmitterIdleIsLowDisable Function

Disables the Transmit Idle Low state.

File

plib_usart.h

C

```
void PLIB_USART_TransmitterIdleIsLowDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the Transmit Idle Low state. In USART Synchronous mode, this function configures that the TX polarity the idle state is high.

When IrDA is enabled, this function sets the IrDA encoded Transmit Idle state to a '0'.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterIdleIsLow in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_TransmitterIdleIsLowDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_TransmitterIdleIsLowDisable (USART_MODULE_ID index)

PLIB_USART_TransmitterIdleIsLowEnable Function

Enables the Transmit Idle Low state.

File

plib_usart.h

C

```
void PLIB_USART_TransmitterIdleIsLowEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the Transmit Idle Low state. In the USART Synchronous mode, this function configures that the TX polarity, the idle state is low.

When IrDA is enabled, this function sets that IrDA encoded Transmit Idle state to a '1'.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterIdleIsLow in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_TransmitterIdleIsLowEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_TransmitterIdleIsLowEnable (USART_MODULE_ID index)

PLIB_USART_TransmitterInterruptModeSelect Function

Sets the USART transmitter interrupt mode.

File

plib_usart.h

C

```
void PLIB_USART_TransmitterInterruptModeSelect(USART_MODULE_ID index, USART_TRANSMIT_INTR_MODE fifolevel);
```

Returns

None.

Description

This function sets the condition in which the USART module should generate an interrupt.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterInterruptMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_TransmitterInterruptModeSelect(MY_USART_INSTANCE,
    USART_TRANSMIT_FIFO_EMPTY );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
interruptMode	Interrupt mode; for possible configurations, refer to USART_TRANSMIT_INTR_MODE

Function

void PLIB_USART_TransmitterInterruptModeSelect(USART_MODULE_ID index,
USART_TRANSMIT_INTR_MODE interruptMode)

PLIB_USART_TransmitterIsEmpty Function

Gets the transmit shift register empty status.

File

plib_usart.h

C

```
bool PLIB_USART_TransmitterIsEmpty(USART_MODULE_ID index);
```

Returns

- true - The transmit shift register is empty
- false - The transmit shift register is not empty

Description

This function gets the transmit shift register empty status.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterEmptyStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

// Wait for the Transmit buffer to be empty.
while(!PLIB_USART_TransmitterIsEmpty(MY_USART_INSTANCE));

// Transmit the break character.
PLIB_USART_TransmitterBreakSend(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_TransmitterIsEmpty (USART_MODULE_ID index)

PLIB_USART_TransmitterAddressGet Function

Returns the address of the USART TX register

File

plib_usart.h

C

```
void* PLIB_USART_TransmitterAddressGet(USART_MODULE_ID index);
```

Returns

Address of the USART TX register

Description

This function returns the address of the USART TX register.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_TransmitterAddressGet(USART_MODULE_ID index)

d) Receiver Functions

PLIB_USART_ReceiverAddressAutoDetectDisable Function

Disables the automatic Address Detect mode.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverAddressAutoDetectDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the automatic Address Detect mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddressAutoDetect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverAddressAutoDetectDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_ReceiverAddressAutoDetectDisable (
USART_MODULE_ID index)

PLIB_USART_ReceiverAddressAutoDetectEnable Function

Setup the automatic Address Detect mode.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverAddressAutoDetectEnable(USART_MODULE_ID index, int8_t Mask);
```

Returns

None.

Description

This function configures the automatic Address Detect mode. Uses the mask as the address character for automatic address detection.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddressAutoDetect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverAddressAutoDetectEnable(MY_USART_INSTANCE,
                                           MY_DEVICE_ADDRESS);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
Mask	Address character to be used, when enabled

Function

void PLIB_USART_ReceiverAddressAutoDetectEnable(USART_MODULE_ID index,
int8_t Mask)

PLIB_USART_ReceiverAddressDetectDisable Function

Enables the Address Detect mode.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverAddressDetectDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the Address Detect mode. If it is enabled, and the device is addressed, disable the Address Detect mode to continue receiving bytes.

Remarks

All bytes are received, and the 9th bit can be used as the parity bit. By default, the address detect is disabled.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddressDetect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverAddressDetectDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_ReceiverAddressDetectDisable (USART_MODULE_ID index)

PLIB_USART_ReceiverAddressDetectEnable Function

Enables the Address Detect mode.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverAddressDetectEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the Address Detect mode. If it is enabled, and the device is addressed, disable the Address Detect mode to continue receiving bytes.

Remarks

If 9 data bits are not selected, this bit has no effect.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddressDetect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverAddressDetectEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_ReceiverAddressDetectEnable (USART_MODULE_ID index)

PLIB_USART_ReceiverAddressIsReceived Function

Checks and return if the data received is an address.

File

plib_usart.h

C

```
bool PLIB_USART_ReceiverAddressIsReceived(USART_MODULE_ID index);
```

Returns

- true - if the data received has the 9th bit set
- false - if the address received has the 9th bit cleared

Description

Checks and return if the data received is an address. The address has the 9th bit set. If data received has the 9th bit set, the function returns true; otherwise, the function returns false.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddressDetect in your application to determine whether this feature is available.

Preconditions

The USART module should be configured to use the 9 data bits.

Example

```
#define MY_USART_INSTANCE USART_ID_1

int8_t address;

if(PLIB_USART_ReceiverAddressIsReceived(MY_USART_INSTANCE))
{
    address = PLIB_USART_ReceiverByteReceive(MY_USART_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_ReceiverAddressIsReceived (USART_MODULE_ID index)

PLIB_USART_ReceiverByteReceive Function

Data to be received in the Byte mode.

File

plib_usart.h

C

```
int8_t PLIB_USART_ReceiverByteReceive(USART_MODULE_ID index);
```

Returns

- data - Data to be received

Description

The data to be received in Byte mode from the specified USART module. Call the functions PLIB_USART_ReceiverFramingErrorHasOccurred, PLIB_USART_ReceiverParityErrorHasOccurred and PLIB_USART_ReceiverOverrunHasOccurred to get any error that occurred.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiver in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

bool isError;
uint8_t mydata;

if(PLIB_USART_ReceiverDataIsAvailable(MY_USART_INSTANCE))
{
    mydata = PLIB_USART_ReceiverByteReceive(MY_USART_INSTANCE);
}

isError = PLIB_USART_ReceiverFramingErrorHasOccurred(MY_USART_INSTANCE)     |
              PLIB_USART_ReceiverParityErrorHasOccurred(MY_USART_INSTANCE) |
              PLIB_USART_ReceiverOverrunHasOccurred(MY_USART_INSTANCE);
```

```
if(PLIB_USART_ReceiverOverrunHasOccurred(MY_USART_INSTANCE))
{
    PLIB_USART_ReceiverOverrunErrorClear(MY_USART_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

int8_t PLIB_USART_ReceiverByteReceive (USART_MODULE_ID index)

PLIB_USART_ReceiverDataIsAvailable Function

Identifies if the receive data is available for the specified USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ReceiverDataIsAvailable(USART_MODULE_ID index);
```

Returns

- true - The data is available
- false - The data is not available

Description

This function identifies if the receive data is available for the specified USART module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverDataAvailableStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

int8_t mydata;

if(PLIB_USART_ReceiverDataIsAvailable(MY_USART_INSTANCE))
{
    mydata = PLIB_USART_ReceiverByteReceive(MY_USART_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_ReceiverDataIsAvailable (USART_MODULE_ID index)

PLIB_USART_ReceiverDisable Function

Disables the USART receiver.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the USART receiver.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_ReceiverDisable (USART_MODULE_ID index)

PLIB_USART_ReceiverEnable Function

Enables the USART receiver.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the USART receiver.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_ReceiverEnable (USART_MODULE_ID index)

PLIB_USART_ReceiverFramingErrorHasOccurred Function

Gets the framing error status.

File

plib_usart.h

C

```
bool PLIB_USART_ReceiverFramingErrorHasOccurred(USART_MODULE_ID index);
```

Returns

- true - The framing error was detected on the current character
- false - The framing error was not detected on the current character

Description

This function gets the framing error status.

Remarks

Reading the error clears the error.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverFramingErrorStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

status = PLIB_USART_ReceiverFramingErrorHasOccurred(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_ReceiverFramingErrorHasOccurred (USART_MODULE_ID index)

PLIB_USART_ReceiverIdleStateLowDisable Function

Disables receive polarity inversion.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverIdleStateLowDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables receive polarity inversion. In the USART Synchronous mode, this function configures that the data is not inverted.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverIdleStateLowEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverIdleStateLowDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_ReceiverIdleStateLowDisable (USART_MODULE_ID index);

PLIB_USART_ReceiverIdleStateLowEnable Function

Enables receive polarity inversion.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverIdleStateLowEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables receive polarity inversion. In the USART Synchronous mode, this function configures that the data is inverted.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverIdleStateLowEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverIdleStateLowEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_ReceiverIdleStateLowEnable (USART_MODULE_ID index)

PLIB_USART_ReceiverInterruptModeSelect Function

Sets the USART receiver FIFO level.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverInterruptModeSelect(USART_MODULE_ID index, USART_RECEIVE_INTR_MODE interruptMode);
```

Returns

None.

Description

This function sets the USART receiver FIFO level.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverInterruptMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverInterruptModeSelect(MY_USART_INSTANCE,
    USART_RECEIVE_FIFO_ONE_CHAR );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
fifolevel	For possible configurations, refer to USART_RECEIVE_INTR_MODE

Function

void PLIB_USART_ReceiverInterruptModeSelect(USART_MODULE_ID index,
USART_RECEIVE_INTR_MODE interruptMode)

PLIB_USART_ReceiverIsIdle Function

Identifies if the receiver is idle.

File

plib_usart.h

C

```
bool PLIB_USART_ReceiverIsIdle(USART_MODULE_ID index);
```

Returns

- true - The receive buffer is idle
- false - The receive buffer is not idle

Description

This function identifies if the receiver is idle.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverIdleStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

int8_t mydata;

if(PLIB_USART_ReceiverIsIdle(MY_USART_INSTANCE))
{
    mydata = PLIB_USART_ReceiverByteReceive(MY_USART_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_ReceiverIsIdle (USART_MODULE_ID index)

PLIB_USART_ReceiverOverrunErrorClear Function

Clears a USART vverrun error.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverOverrunErrorClear(USART_MODULE_ID index);
```

Returns

None.

Description

This function clears an overrun error. Clearing the error, resets the receive buffer.

Remarks

WARNING: Calling this API will clear all of the previously received data.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverOverrunStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

if(PLIB_USART_ReceiverOverrunHasOccurred(MY_USART_INSTANCE))
{
    PLIB_USART_ReceiverOverrunErrorClear(MY_USART_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_ReceiverOverrunErrorClear (USART_MODULE_ID index)

PLIB_USART_ReceiverOverrunHasOccurred Function

Identifies if there was a receiver overrun error.

File

plib_usart.h

C

```
bool PLIB_USART_ReceiverOverrunHasOccurred(USART_MODULE_ID index);
```

Returns

- true - The receive buffer has overflowed
- false - The receive buffer has not overflowed

Description

This function identifies if there was a receiver overrun error.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverOverrunStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

if(PLIB_USART_ReceiverOverrunHasOccurred(MY_USART_INSTANCE))
{
    PLIB_USART_ReceiverOverrunErrorClear(MY_USART_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_ReceiverOverrunHasOccurred (USART_MODULE_ID index)

PLIB_USART_ReceiverParityErrorHasOccurred Function

Gets the parity error status.

File

plib_usart.h

C

```
bool PLIB_USART_ReceiverParityErrorHasOccurred(USART_MODULE_ID index);
```

Returns

- true - The parity error was detected on the current character
- false - The parity error was not detected on the current character

Description

This function gets the parity error status.

Remarks

Reading the error clears the error. A Parity error is irrelevant in case of 9-bit mode. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverParityErrorStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

status = PLIB_USART_ReceiverParityErrorHasOccurred(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_ReceiverParityErrorHasOccurred (USART_MODULE_ID index)

PLIB_USART_ReceiverAddressGet Function

Returns the address of the USART RX register

File

plib_usart.h

C

```
void* PLIB_USART_ReceiverAddressGet(USART_MODULE_ID index);
```

Returns

Address of the USART RX register

Description

This function returns the address of the USART RX register.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ReceiverAddressGet(USART_MODULE_ID index)

PLIB_USART_Receiver9BitsReceive Function

Data to be received in the byte mode with the 9th bit.

File

plib_usart.h

C

```
int16_t PLIB_USART_Receiver9BitsReceive(USART_MODULE_ID index);
```

Returns

- data - Data to be received

Description

The data to be received in Byte mode from the specified USART module. with the 9th bit.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiver9Bits in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

uint16_t mydata;

if(PLIB_USART_ReceiverDataIsAvailable(MY_USART_INSTANCE))
{
    mydata = PLIB_USART_Receiver9BitsReceive (MY_USART_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

int16_t PLIB_USART_Receiver9BitsReceive (USART_MODULE_ID index)

e) Feature Existence Functions

PLIB_USART_ExistsBaudRate Function

Identifies whether the BaudRate feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsBaudRate(USART_MODULE_ID index);
```

Returns

- true - The BaudRate feature is supported on the device
- false - The BaudRate feature is not supported on the device

Description

This function identifies whether the BaudRate feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_BaudRateSet
- PLIB_USART_BaudRateGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsBaudRate(USART_MODULE_ID index)

PLIB_USART_ExistsBaudRateAutoDetect Function

Identifies whether the BaudRateAutoDetect feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsBaudRateAutoDetect(USART_MODULE_ID index);
```

Returns

- true - The BaudRateAutoDetect feature is supported on the device
- false - The BaudRateAutoDetect feature is not supported on the device

Description

This function identifies whether the BaudRateAutoDetect feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_BaudRateAutoDetectEnable
- PLIB_USART_BaudRateAutoDetectIsComplete

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsBaudRateAutoDetect(USART_MODULE_ID index)

PLIB_USART_ExistsBaudRateHigh Function

Identifies whether the BaudRateHigh feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsBaudRateHigh(USART_MODULE_ID index);
```

Returns

- true - The BaudRateHigh feature is supported on the device
- false - The BaudRateHigh feature is not supported on the device

Description

This function identifies whether the BaudRateHigh feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_BaudRateHighSet
- PLIB_USART_BaudRateHighDisable
- PLIB_USART_BaudRateHighEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsBaudRateHigh(USART_MODULE_ID index)

PLIB_USART_ExistsEnable Function

Identifies whether the EnableControl feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsEnable(USART_MODULE_ID index);
```

Returns

- true - The EnableControl feature is supported on the device
- false - The EnableControl feature is not supported on the device

Description

This function identifies whether the EnableControl feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_Disable
- PLIB_USART_Enable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsEnable(USART_MODULE_ID index)

PLIB_USART_ExistsHandshakeMode Function

Identifies whether the HandShakeMode feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsHandshakeMode(USART_MODULE_ID index);
```

Returns

- true - The HandShakeMode feature is supported on the device
- false - The HandShakeMode feature is not supported on the device

Description

This function identifies whether the HandShakeMode feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_HandshakeModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsHandshakeMode(USART_MODULE_ID index)

PLIB_USART_ExistsIrDA Function

Identifies whether the IrDAControl feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsIrDA(USART_MODULE_ID index);
```

Returns

- true - The IrDAControl feature is supported on the device
- false - The IrDAControl feature is not supported on the device

Description

This function identifies whether the IrDAControl feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_IrDADisable
- PLIB_USART_IrDAEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsIrDA(USART_MODULE_ID index)

PLIB_USART_ExistsLineControlMode Function

Identifies whether the LineControlMode feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsLineControlMode(USART_MODULE_ID index);
```

Returns

- true - The LineControlMode feature is supported on the device
- false - The LineControlMode feature is not supported on the device

Description

This function identifies whether the LineControlMode feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_LineControlModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsLineControlMode(USART_MODULE_ID index)

PLIB_USART_ExistsLoopback Function

Identifies whether the Loopback feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsLoopback(USART_MODULE_ID index);
```

Returns

- true - The Loopback feature is supported on the device
- false - The Loopback feature is not supported on the device

Description

This function identifies whether the Loopback feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_LoopbackEnable
- PLIB_USART_LoopbackDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsLoopback(USART_MODULE_ID index)

PLIB_USART_ExistsOperationMode Function

Identifies whether the OperationMode feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsOperationMode(USART_MODULE_ID index);
```

Returns

- true - The OperationMode feature is supported on the device
- false - The OperationMode feature is not supported on the device

Description

This function identifies whether the OperationMode feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_OperationModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsOperationMode(USART_MODULE_ID index)

PLIB_USART_ExistsReceiver Function

Identifies whether the Receiver feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiver(USART_MODULE_ID index);
```

Returns

- true - The Receiver feature is supported on the device
- false - The Receiver feature is not supported on the device

Description

This function identifies whether the Receiver feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_ReceiverByteReceive
- PLIB_USART_ReceiverAddressGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiver(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverAddressAutoDetect Function

Identifies whether the ReceiverAddressAutoDetect feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverAddressAutoDetect(USART_MODULE_ID index);
```

Returns

- true - The ReceiverAddressAutoDetect feature is supported on the device
- false - The ReceiverAddressAutoDetect feature is not supported on the device

Description

This function identifies whether the ReceiverAddressAutoDetect feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_ReceiverAddressAutoDetectEnable
- PLIB_USART_ReceiverAddressAutoDetectDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverAddressAutoDetect(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverAddressDetect Function

Identifies whether the ReceiverAddressDetect feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverAddressDetect(USART_MODULE_ID index);
```

Returns

- true - The ReceiverAddressDetect feature is supported on the device
- false - The ReceiverAddressDetect feature is not supported on the device

Description

This function identifies whether the ReceiverAddressDetect feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_ReceiverAddressDetectEnable
- PLIB_USART_ReceiverAddressDetectDisable
- PLIB_USART_ReceiverAddressIsReceived

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverAddressDetect(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverDataAvailableStatus Function

Identifies whether the ReceiverDataAvailable feature exists on the USART module

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverDataAvailableStatus(USART_MODULE_ID index);
```

Returns

- true - The ReceiverDataAvailable feature is supported on the device
- false - The ReceiverDataAvailable feature is not supported on the device

Description

This function identifies whether the ReceiverDataAvailable feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_ReceiverDataIsAvailable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverDataAvailableStatus(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverEnable Function

Identifies whether the ReceiverEnableControl feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverEnable(USART_MODULE_ID index);
```

Returns

- true - The ReceiverEnableControl feature is supported on the device
- false - The ReceiverEnableControl feature is not supported on the device

Description

This function identifies whether the ReceiverEnableControl feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_ReceiverEnable
- PLIB_USART_ReceiverDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverEnable(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverFramingErrorStatus Function

Identifies whether the ReceiverFramingError feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverFramingErrorStatus(USART_MODULE_ID index);
```

Returns

- true - The ReceiverFramingError feature is supported on the device
- false - The ReceiverFramingError feature is not supported on the device

Description

This function identifies whether the ReceiverFramingError feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_ReceiverFramingErrorHasOccurred

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverFramingErrorStatus(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverIdleStateLowEnable Function

Identifies whether the ReceiverPolarityInvert feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverIdleStateLowEnable(USART_MODULE_ID index);
```

Returns

- true - The ReceiverPolarityInvert feature is supported on the device
- false - The ReceiverPolarityInvert feature is not supported on the device

Description

This function identifies whether the ReceiverPolarityInvert feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_ReceiverIdleStateLowEnable
- PLIB_USART_ReceiverIdleStateLowDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverIdleStateLowEnable(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverIdleStatus Function

Identifies whether the ReceiverIdle feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverIdleStatus(USART_MODULE_ID index);
```

Returns

- true - The ReceiverIdle feature is supported on the device
- false - The ReceiverIdle feature is not supported on the device

Description

This function identifies whether the ReceiverIdle feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_ReceiverIsIdle

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverIdleStatus(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverInterruptMode Function

Identifies whether the ReceiverInterruptMode feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverInterruptMode(USART_MODULE_ID index);
```

Returns

- true - The ReceiverInterruptMode feature is supported on the device
- false - The ReceiverInterruptMode feature is not supported on the device

Description

This function identifies whether the ReceiverInterruptMode feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_ReceiverInterruptModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverInterruptMode(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverOverrunStatus Function

Identifies whether the ReceiverOverrunError feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverOverrunStatus(USART_MODULE_ID index);
```

Returns

- true - The ReceiverOverrunError feature is supported on the device
- false - The ReceiverOverrunError feature is not supported on the device

Description

This function identifies whether the ReceiverOverrunError feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_ReceiverOverrunErrorClear
- PLIB_USART_ReceiverOverrunHasOccurred

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverOverrunStatus(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverParityErrorStatus Function

Identifies whether the ReceiverParityError feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverParityErrorStatus(USART_MODULE_ID index);
```

Returns

- true - The ReceiverParityError feature is supported on the device
- false - The ReceiverParityError feature is not supported on the device

Description

This function identifies whether the ReceiverParityError feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_ReceiverParityErrorHasOccurred

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverParityErrorStatus(USART_MODULE_ID index)

PLIB_USART_ExistsStopInIdle Function

Identifies whether the StopInIdle feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsStopInIdle(USART_MODULE_ID index);
```

Returns

- true - The StopInIdle feature is supported on the device
- false - The StopInIdle feature is not supported on the device

Description

This function identifies whether the StopInIdle feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_StopInIdleEnable
- PLIB_USART_StopInIdleDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsStopInIdle(USART_MODULE_ID index)

PLIB_USART_ExistsTransmitter Function

Identifies whether the Transmitter feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsTransmitter(USART_MODULE_ID index);
```

Returns

- true - The Transmitter feature is supported on the device
- false - The Transmitter feature is not supported on the device

Description

This function identifies whether the Transmitter feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_TransmitterByteSend
- PLIB_USART_TransmitterAddressGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsTransmitter(USART_MODULE_ID index)

PLIB_USART_ExistsTransmitter9BitsSend Function

Identifies whether the Transmitter9Bits feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsTransmitter9BitsSend(USART_MODULE_ID index);
```

Returns

- true - The Transmitter9Bits feature is supported on the device
- false - The Transmitter9Bits feature is not supported on the device

Description

This function identifies whether the Transmitter9Bits feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_Transmitter9BitsSend

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsTransmitter9BitsSend(USART_MODULE_ID index)

PLIB_USART_ExistsTransmitterBreak Function

Identifies whether the TransmitterBreak feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsTransmitterBreak(USART_MODULE_ID index);
```

Returns

- true - The TransmitterBreak feature is supported on the device
- false - The TransmitterBreak feature is not supported on the device

Description

This function identifies whether the TransmitterBreak feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_TransmitterBreakSend
- PLIB_USART_TransmitterBreakSendIsComplete

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsTransmitterBreak(USART_MODULE_ID index)

PLIB_USART_ExistsTransmitterBufferFullStatus Function

Identifies whether the TransmitterBufferFull feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsTransmitterBufferFullStatus(USART_MODULE_ID index);
```

Returns

- true - The TransmitterBufferFull feature is supported on the device
- false - The TransmitterBufferFull feature is not supported on the device

Description

This function identifies whether the TransmitterBufferFull feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_TransmitterBufferIsFull

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsTransmitterBufferFullStatus(USART_MODULE_ID index)

PLIB_USART_ExistsTransmitterEmptyStatus Function

Identifies whether the TransmitterEmpty feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsTransmitterEmptyStatus(USART_MODULE_ID index);
```

Returns

- true - The TransmitterEmpty feature is supported on the device
- false - The TransmitterEmpty feature is not supported on the device

Description

This function identifies whether the TransmitterEmpty feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_TransmitterIsEmpty

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsTransmitterEmptyStatus(USART_MODULE_ID index)

PLIB_USART_ExistsTransmitterEnable Function

Identifies whether the TransmitterEnableControl feature exists on the USART module

File

plib_usart.h

C

```
bool PLIB_USART_ExistsTransmitterEnable(USART_MODULE_ID index);
```

Returns

- true - The TransmitterEnableControl feature is supported on the device
- false - The TransmitterEnableControl feature is not supported on the device

Description

This function identifies whether the TransmitterEnableControl feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_TransmitterEnable
- PLIB_USART_TransmitterDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsTransmitterEnable(USART_MODULE_ID index)

PLIB_USART_ExistsTransmitterIdleIsLow Function

Identifies whether the TransmitterIdleIsLow feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsTransmitterIdleIsLow(USART_MODULE_ID index);
```

Returns

- true - The TransmitterIdleIsLow feature is supported on the device
- false - The TransmitterIdleIsLow feature is not supported on the device

Description

This function identifies whether the TransmitterIdleIsLow feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_TransmitterIdleIsLowDisable
- PLIB_USART_TransmitterIdleIsLowEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsTransmitterIdleIsLow(USART_MODULE_ID index)

PLIB_USART_ExistsTransmitterInterruptMode Function

Identifies whether the TransmitterInterruptMode feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsTransmitterInterruptMode(USART_MODULE_ID index);
```

Returns

- true - The TransmitterInterruptMode feature is supported on the device
- false - The TransmitterInterruptMode feature is not supported on the device

Description

This function identifies whether the TransmitterInterruptMode feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_TransmitterInterruptModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsTransmitterInterruptMode(USART_MODULE_ID index)

PLIB_USART_ExistsWakeOnStart Function

Identifies whether the WakeOnStart feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsWakeOnStart(USART_MODULE_ID index);
```

Returns

- true - The WakeOnStart feature is supported on the device
- false - The WakeOnStart feature is not supported on the device

Description

This function identifies whether the WakeOnStart feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_WakeOnStartEnable
- PLIB_USART_WakeOnStartDisable
- PLIB_USART_WakeOnStartIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsWakeOnStart(USART_MODULE_ID index)

PLIB_USART_ExistsReceiver9Bits Function

Identifies whether the 9 Bits Receiver feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiver9Bits(USART_MODULE_ID index);
```

Returns

- true - The feature is supported on the device
- false - The feature is not supported on the device

Description

This function identifies whether the 9 Bits Receiver feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_Receiver9BitsReceive

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiver9Bits (USART_MODULE_ID index)

PLIB_USART_ExistsBRGClockSourceSelect Function

Identifies whether the BRG Clock source select feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsBRGClockSourceSelect(USART_MODULE_ID index);
```

Returns

- true - The BRG clock source select feature is supported on the device
- false - The BRG clock source select feature is not supported on the device

Description

This function identifies whether the BRG Clock source select feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_BRGClockSourceSelect
- PLIB_USART_BRGClockSourceGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsBRGClockSourceSelect (USART_MODULE_ID index)

PLIB_USART_ExistsModuleBusyStatus Function

Identifies whether the module running status feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsModuleBusyStatus(USART_MODULE_ID index);
```

Returns

- true - The Module running status feature is supported on the device
- false - The Module running status feature is not supported on the device

Description

This function identifies whether the module running status feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_ModuleIsBusy

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsModuleBusyStatus (USART_MODULE_ID index)

PLIB_USART_ExistsReceiverAddress Function

Identifies whether the Receiver Address feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverAddress(USART_MODULE_ID index);
```

Returns

- true - The Receiver address feature is supported on the device
- false - The Receiver address feature is not supported on the device

Description

This function identifies whether the Receiver Address feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_AddressSet
- PLIB_USART_AddressGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverAddress (USART_MODULE_ID index)

PLIB_USART_ExistsReceiverAddressMask Function

Identifies whether the Receiver Address Mask feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverAddressMask(USART_MODULE_ID index);
```

Returns

- true - The Receiver address mask feature is supported on the device
- false - The Receiver address mask feature is not supported on the device

Description

This function identifies whether the Receiver Address Mask feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_AddressMaskSet
- PLIB_USART_AddressMaskGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverAddressMask (USART_MODULE_ID index)

PLIB_USART_ExistsRunInOverflow Function

Identifies whether the Run in overflow condition feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsRunInOverflow(USART_MODULE_ID index);
```

Returns

- true - The Run in Overflow condition feature is supported on the device
- false - The Run in Overflow condition feature is not supported on the device

Description

This function identifies whether the Run in Overflow condition feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_RunInOverflowEnable
- PLIB_USART_RunInOverflowDisable
- PLIB_USART_RunInOverflowIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsRunInOverflow (USART_MODULE_ID index)

PLIB_USART_ExistsRunInSleepMode Function

Identifies whether the Run in Sleep mode feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsRunInSleepMode(USART_MODULE_ID index);
```

Returns

- true - The Run in Sleep mode feature is supported on the device
- false - The Run in Sleep mode feature is not supported on the device

Description

This function identifies whether the Run in Sleep mode feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_RunInSleepModeEnable
- PLIB_USART_RunInSleepModeDisable
- PLIB_USART_RunInSleepModeIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsRunInSleepMode (USART_MODULE_ID index)

f) Data Types and Constants

USART_HANDSHAKE_MODE Enumeration

Lists the USART handshake modes.

File

plib_usart_help.h

C

```
typedef enum {
  USART_HANDSHAKE_MODE_FLOW_CONTROL,
  USART_HANDSHAKE_MODE_SIMPLEX
} USART_HANDSHAKE_MODE;
```

Members

Members	Description
USART_HANDSHAKE_MODE_FLOW_CONTROL	Enables flow control
USART_HANDSHAKE_MODE_SIMPLEX	Enables simplex mode communication, no flow control

Description

USART Handshake modes

This enumeration lists the USART handshake modes.

Remarks

None.

USART_LINECONTROL_MODE Enumeration

Data type defining the different configurations by which the USART data flow can be configured.

File

plib_usart_help.h

C

```
typedef enum {
  USART_8N1,
  USART_8E1,
  USART_8O1,
  USART_8N2,
  USART_8E2,
  USART_8O2,
  USART_9N1,
  USART_9N2
} USART_LINECONTROL_MODE;
```

Members

Members	Description
USART_8N1	8 Data Bits, No Parity,one Stop Bit
USART_8E1	8 Data Bits, Even Parity, 1 stop bit
USART_8O1	8 Data Bits, odd Parity, 1 stop bit
USART_8N2	8 Data Bits, No Parity,two Stop Bits
USART_8E2	8 Data Bits, Even Parity, 2 stop bits
USART_8O2	8 Data Bits, odd Parity, 2 stop bits
USART_9N1	9 Data Bits, No Parity, 1 stop bit
USART_9N2	9 Data Bits, No Parity, 2 stop bits

Description

Data Flow configuration

This data type defines the different configurations by which the USART can be configured for the data flow.

Remarks

None.

USART_MODULE_ID Enumeration

File

plib_usart_help.h

C

```
typedef enum {
  USART_ID_1,
  USART_ID_2,
  USART_ID_3,
  USART_ID_4,
  USART_ID_5,
  USART_ID_6,
  USART_NUMBER_OF_MODULES
} USART_MODULE_ID;
```

Members

Members	Description
USART_ID_1	USART 1
USART_ID_2	USART 2
USART_ID_3	USART 3
USART_ID_4	USART 4
USART_ID_5	USART 5
USART_ID_6	USART 6
USART_NUMBER_OF_MODULES	Total number of USART modules available

Description

Enumeration: USART_MODULE_ID

This enumeration defines the number of modules that are available on the microcontroller. This is the superset of all of the possible instances that might be available on Microchip microcontrollers.

Refer to the data sheet to get the correct number of modules defined for desired microcontroller.

_USART_MODULE_ID Macro

File

plib_usart_help.h

C

```
#define _USART_MODULE_ID
```

USART_OPERATION_MODE Enumeration

Data type defining the different configurations by which the USART can be enabled.

File

plib_usart_help.h

C

```
typedef enum {
  USART_ENABLE_TX_RX_BCLK_USED,
  USART_ENABLE_TX_RX_CTS_RTS_USED,
  USART_ENABLE_TX_RX_RTS_USED,
  USART_ENABLE_TX_RX_USED
} USART_OPERATION_MODE;
```

Members

Members	Description
USART_ENABLE_TX_RX_BCLK_USED	TX, RX and BCLK pins are used by USART module
USART_ENABLE_TX_RX_CTS_RTS_USED	TX, RX, CTS and RTS pins are used by USART module
USART_ENABLE_TX_RX_RTS_USED	TX, RX and RTS pins are used by USART module
USART_ENABLE_TX_RX_USED	TX and RX pins are used by USART module

Description

Enable configuration

This data type defines the different configurations by which the USART can be enabled.

Remarks

The actual definition of this enumeration is device-specific.

USART_RECEIVE_INTR_MODE Enumeration

Data type defining the different Receive FIFO levels by which the USART receive interrupt modes can be configured.

File

plib_usart_help.h

C

```
typedef enum {
  USART_RECEIVE_FIFO_HALF_FULL,
  USART_RECEIVE_FIFO_3B4FULL,
  USART_RECEIVE_FIFO_ONE_CHAR
} USART_RECEIVE_INTR_MODE;
```

Members

Members	Description
USART_RECEIVE_FIFO_HALF_FULL	Interrupt when receive buffer is half full
USART_RECEIVE_FIFO_3B4FULL	Interrupt when receive buffer is 3/4 full
USART_RECEIVE_FIFO_ONE_CHAR	Interrupt when a character is received

Description

Receive Interrupt mode configuration

This data type defining the different Receive FIFO levels by which the USART receive interrupt modes can be configured.

Remarks

None.

USART_TRANSMIT_INTR_MODE Enumeration

Data type defining the different transmit FIFO levels by which the USART transmit interrupt modes can be configured.

File

plib_usart_help.h

C

```
typedef enum {
  USART_TRANSMIT_FIFO_EMPTY,
  USART_TRANSMIT_FIFO_IDLE,
  USART_TRANSMIT_FIFO_NOT_FULL
} USART_TRANSMIT_INTR_MODE;
```

Members

Members	Description
USART_TRANSMIT_FIFO_EMPTY	Interrupt when the transmit buffer becomes empty
USART_TRANSMIT_FIFO_IDLE	Interrupt when all characters are transmitted
USART_TRANSMIT_FIFO_NOT_FULL	Interrupt when at least one location is empty in the transmit buffer

Description

Transmit Interrupt mode configuration

This data type defining the different transmit FIFO levels by which the USART transmit interrupt modes can be configured.

Remarks

None.

Files

Files

Name	Description
plib_usart.h	USART Peripheral Library interface header.
plib_usart_help.h	

Description

This section lists the source and header files used by the library.

plib_usart.h

USART Peripheral Library interface header.

Functions

	Name	Description
	PLIB_USART_AddressGet	Gets the address for the Address Detect mode.
	PLIB_USART_AddressMaskGet	Gets the address mask for the Address Detect mode.
	PLIB_USART_AddressMaskSet	Sets the address mask for the Address Detect mode.
	PLIB_USART_AddressSet	Sets the address for the Address Detect mode.
	PLIB_USART_BaudRateAutoDetectEnable	Enables baud rate measurement on the next character, which requires reception of the Sync character.
	PLIB_USART_BaudRateAutoDetectIsComplete	Gets the state of the automatic baud detection.
	PLIB_USART_BaudRateGet	Gets the baud rate current in use.

	PLIB_USART_BaudRateHighDisable	Disables the high baud rate selection.
	PLIB_USART_BaudRateHighEnable	Enables high baud rate selection.
	PLIB_USART_BaudRateHighSet	Sets the baud rate to the desired value.
	PLIB_USART_BaudRateSet	Sets the baud rate to the desired value.
	PLIB_USART_BaudSetAndEnable	Sets the baud rate to the desired value and enables the USART receiver, transmitter and the USART module.
	PLIB_USART_BRGClockSourceGet	Gets the BRG clock source of the USART module.
	PLIB_USART_BRGClockSourceSelect	Configures the BRG clock source of the USART module.
	PLIB_USART_Disable	Disables the specific USART module
	PLIB_USART_Enable	Enables the specific USART module.
	PLIB_USART_ErrorsGet	Return the status of all errors in the specified USART module.
	PLIB_USART_ExistsBaudRate	Identifies whether the BaudRate feature exists on the USART module.
	PLIB_USART_ExistsBaudRateAutoDetect	Identifies whether the BaudRateAutoDetect feature exists on the USART module.
	PLIB_USART_ExistsBaudRateHigh	Identifies whether the BaudRateHigh feature exists on the USART module.
	PLIB_USART_ExistsBRGClockSourceSelect	Identifies whether the BRG Clock source select feature exists on the USART module.
	PLIB_USART_ExistsEnable	Identifies whether the EnableControl feature exists on the USART module.
	PLIB_USART_ExistsHandshakeMode	Identifies whether the HandShakeMode feature exists on the USART module.
	PLIB_USART_ExistsIrDA	Identifies whether the IrDAControl feature exists on the USART module.
	PLIB_USART_ExistsLineControlMode	Identifies whether the LineControlMode feature exists on the USART module.
	PLIB_USART_ExistsLoopback	Identifies whether the Loopback feature exists on the USART module.
	PLIB_USART_ExistsModuleBusyStatus	Identifies whether the module running status feature exists on the USART module.
	PLIB_USART_ExistsOperationMode	Identifies whether the OperationMode feature exists on the USART module.
	PLIB_USART_ExistsReceiver	Identifies whether the Receiver feature exists on the USART module.
	PLIB_USART_ExistsReceiver9Bits	Identifies whether the 9 Bits Receiver feature exists on the USART module.
	PLIB_USART_ExistsReceiverAddress	Identifies whether the Receiver Address feature exists on the USART module.
	PLIB_USART_ExistsReceiverAddressAutoDetect	Identifies whether the ReceiverAddressAutoDetect feature exists on the USART module.
	PLIB_USART_ExistsReceiverAddressDetect	Identifies whether the ReceiverAddressDetect feature exists on the USART module.
	PLIB_USART_ExistsReceiverAddressMask	Identifies whether the Receiver Address Mask feature exists on the USART module.
	PLIB_USART_ExistsReceiverDataAvailableStatus	Identifies whether the ReceiverDataAvailable feature exists on the USART module
	PLIB_USART_ExistsReceiverEnable	Identifies whether the ReceiverEnableControl feature exists on the USART module.
	PLIB_USART_ExistsReceiverFramingErrorStatus	Identifies whether the ReceiverFramingError feature exists on the USART module.
	PLIB_USART_ExistsReceiverIdleStateLowEnable	Identifies whether the ReceiverPolarityInvert feature exists on the USART module.
	PLIB_USART_ExistsReceiverIdleStatus	Identifies whether the ReceiverIdle feature exists on the USART module.
	PLIB_USART_ExistsReceiverInterruptMode	Identifies whether the ReceiverInterruptMode feature exists on the USART module.
	PLIB_USART_ExistsReceiverOverrunStatus	Identifies whether the ReceiverOverrunError feature exists on the USART module.
	PLIB_USART_ExistsReceiverParityErrorStatus	Identifies whether the ReceiverParityError feature exists on the USART module.
	PLIB_USART_ExistsRunInOverflow	Identifies whether the Run in overflow condition feature exists on the USART module.
	PLIB_USART_ExistsRunInSleepMode	Identifies whether the Run in Sleep mode feature exists on the USART module.
	PLIB_USART_ExistsStopInIdle	Identifies whether the StopInIdle feature exists on the USART module.
	PLIB_USART_ExistsTransmitter	Identifies whether the Transmitter feature exists on the USART module.
	PLIB_USART_ExistsTransmitter9BitsSend	Identifies whether the Transmitter9Bits feature exists on the USART module.
	PLIB_USART_ExistsTransmitterBreak	Identifies whether the TransmitterBreak feature exists on the USART module.
	PLIB_USART_ExistsTransmitterBufferFullStatus	Identifies whether the TransmitterBufferFull feature exists on the USART module.
	PLIB_USART_ExistsTransmitterEmptyStatus	Identifies whether the TransmitterEmpty feature exists on the USART module.

	PLIB_USART_ExistsTransmitterEnable	Identifies whether the TransmitterEnableControl feature exists on the USART module
	PLIB_USART_ExistsTransmitterIdleIsLow	Identifies whether the TransmitterIdleIsLow feature exists on the USART module.
	PLIB_USART_ExistsTransmitterInterruptMode	Identifies whether the TransmitterInterruptMode feature exists on the USART module.
	PLIB_USART_ExistsWakeOnStart	Identifies whether the WakeOnStart feature exists on the USART module.
	PLIB_USART_HandshakeModeSelect	Sets the data flow configuration.
	PLIB_USART_InitializeModeGeneral	Enables or disables general features of the USART module.
	PLIB_USART_InitializeOperation	Configures the Receive and Transmit FIFO interrupt levels and the hardware lines to be used by the module.
	PLIB_USART_IrDADisable	Disables the IrDA encoder and decoder.
	PLIB_USART_IrDAEnable	Enables the IrDA encoder and decoder.
	PLIB_USART_LineControlModeSelect	Sets the data flow configuration.
	PLIB_USART_LoopbackDisable	Disables Loopback mode.
	PLIB_USART_LoopbackEnable	Enables Loopback mode.
	PLIB_USART_ModuleIsBusy	Returns the USART module's running status.
	PLIB_USART_OperationModeSelect	Configures the operation mode of the USART module.
	PLIB_USART_Receiver9BitsReceive	Data to be received in the byte mode with the 9th bit.
	PLIB_USART_ReceiverAddressAutoDetectDisable	Disables the automatic Address Detect mode.
	PLIB_USART_ReceiverAddressAutoDetectEnable	Setup the automatic Address Detect mode.
	PLIB_USART_ReceiverAddressDetectDisable	Enables the Address Detect mode.
	PLIB_USART_ReceiverAddressDetectEnable	Enables the Address Detect mode.
	PLIB_USART_ReceiverAddressGet	Returns the address of the USART RX register
	PLIB_USART_ReceiverAddressIsReceived	Checks and return if the data received is an address.
	PLIB_USART_ReceiverByteReceive	Data to be received in the Byte mode.
	PLIB_USART_ReceiverDataIsAvailable	Identifies if the receive data is available for the specified USART module.
	PLIB_USART_ReceiverDisable	Disables the USART receiver.
	PLIB_USART_ReceiverEnable	Enables the USART receiver.
	PLIB_USART_ReceiverFramingErrorHasOccurred	Gets the framing error status.
	PLIB_USART_ReceiverIdleStateLowDisable	Disables receive polarity inversion.
	PLIB_USART_ReceiverIdleStateLowEnable	Enables receive polarity inversion.
	PLIB_USART_ReceiverInterruptModeSelect	Sets the USART receiver FIFO level.
	PLIB_USART_ReceiverIsIdle	Identifies if the receiver is idle.
	PLIB_USART_ReceiverOverrunErrorClear	Clears a USART vverrun error.
	PLIB_USART_ReceiverOverrunHasOccurred	Identifies if there was a receiver overrun error.
	PLIB_USART_ReceiverParityErrorHasOccurred	Gets the parity error status.
	PLIB_USART_RunInOverflowDisable	Disables the Run in overflow condition mode.
	PLIB_USART_RunInOverflowEnable	Enables the USART module to continue to operate when an overflow error condition has occurred.
	PLIB_USART_RunInOverflowIsEnabled	Gets the status of the Run in Overflow condition.
	PLIB_USART_RunInSleepModeDisable	Turns off the USART module's BRG clock during Sleep mode.
	PLIB_USART_RunInSleepModeEnable	Allows the USART module's BRG clock to run when the device enters Sleep mode.
	PLIB_USART_RunInSleepModeIsEnabled	Gets the status of Run in Sleep mode.
	PLIB_USART_StopInIdleDisable	Disables the Stop in Idle mode (the USART module continues operation when the device is in Idle mode).
	PLIB_USART_StopInIdleEnable	Discontinues operation when the device enters Idle mode.
	PLIB_USART_Transmitter9BitsSend	Data to be transmitted in the byte mode with the 9th bit.
	PLIB_USART_TransmitterAddressGet	Returns the address of the USART TX register
	PLIB_USART_TransmitterBreakSend	Transmits the break character.
	PLIB_USART_TransmitterBreakSendIsComplete	Returns the status of the break transmission
	PLIB_USART_TransmitterBufferIsFull	Gets the transmit buffer full status.
	PLIB_USART_TransmitterByteSend	Data to be transmitted in the Byte mode.
	PLIB_USART_TransmitterDisable	Disables the specific USART module transmitter.
	PLIB_USART_TransmitterEnable	Enables the specific USART module transmitter.
	PLIB_USART_TransmitterIdleIsLowDisable	Disables the Transmit Idle Low state.

	PLIB_USART_TransmitterIdleIsLowEnable	Enables the Transmit Idle Low state.
	PLIB_USART_TransmitterInterruptModeSelect	Sets the USART transmitter interrupt mode.
	PLIB_USART_TransmitterIsEmpty	Gets the transmit shift register empty status.
	PLIB_USART_WakeOnStartDisable	Disables the wake-up on start bit detection feature during Sleep mode.
	PLIB_USART_WakeOnStartEnable	Enables the wake-up on start bit detection feature during Sleep mode.
	PLIB_USART_WakeOnStartIsEnabled	Gets the state of the sync break event completion.

Description

USART Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the USART Peripheral Library for all families of Microchip microcontrollers. The functions in this file are common to the USART module.

File Name

plib_usart.h

Company

Microchip Technology Inc.

plib_usart_help.h

Enumerations

	Name	Description
	USART_HANDSHAKE_MODE	Lists the USART handshake modes.
	USART_LINECONTROL_MODE	Data type defining the different configurations by which the USART data flow can be configured.
	USART_MODULE_ID	Enumeration: USART_MODULE_ID This enumeration defines the number of modules that are available on the microcontroller. This is the superset of all of the possible instances that might be available on Microchip microcontrollers. Refer to the data sheet to get the correct number of modules defined for desired microcontroller.
	USART_OPERATION_MODE	Data type defining the different configurations by which the USART can be enabled.
	USART_RECEIVE_INTR_MODE	Data type defining the different Receive FIFO levels by which the USART receive interrupt modes can be configured.
	USART_TRANSMIT_INTR_MODE	Data type defining the different transmit FIFO levels by which the USART transmit interrupt modes can be configured.

Macros

	Name	Description
	_USART_MODULE_ID	

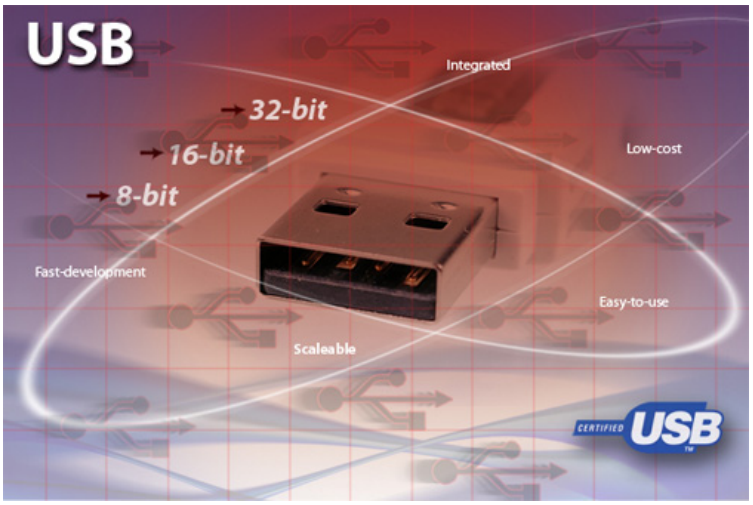
USB Peripheral Library

This section describes the USB Peripheral Library.

Introduction

This library provides a low-level abstraction of the USB module on Microchip family of microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thus hiding differences from one microcontroller variant to another.

Description



USB Overview

USB is an asynchronous serial interface with a tiered star configuration. USB is implemented as a master/slave configuration. On a given bus, there can be multiple (up to 127) slaves (devices), but there is only one master (host). There are three possible module implementations: host, device and OTG dual role. The user should have an understanding of the USB documents available on the USB implementers web site (www.usb.org).

Device

The USB device accepts data from the host and responds to requests for data. It performs some peripheral functions, such as a mouse or data storage device.

- Functionality may be class or vendor-specific
- Draws 100 mA or less before configuration
- Can draw up to 500 mA after successful negotiation with the host
- Can support low-speed, full-speed or high-speed protocol. Hi-speed support requires implementation of full-speed. (*Low, Full, and Hi-Speed supported by this module.*)
- Supports control transfers. Supports data transfers required for implementation
- Optionally supports Session Request Protocol (SRP)
- Can be bus-powered or self-powered

Host

The host is the master in a USB system and is responsible for identifying all devices connected to it (enumeration), initiating all transfers, allocating bus bandwidth and supplying power to any bus-powered USB devices connected directly to it. There are two types of hosts.

USB Standard Host:

- A large variety of devices are supported
- This host supports all USB transfer types
- USB hubs are supported to allow connection of multiple devices simultaneously
- Device drivers can be updated to support new devices
- A type ‘A’ receptacle is used for each port
- Each port must be able to deliver a minimum of 100 mA for a configured or unconfigured
- device, and optionally, up to 500 mA for a configured device
- Full-Speed and Low-Speed must be supported. Hi-Speed can be supported.
- This is a typical personal computer implementation

Embedded Host

- Only supports a specific list of devices, referred to as a Targeted Peripheral List (TPL)
- This type of host is only required to support transfer types required by devices in the TPL
- USB hub support is optional (*Provided in this module*)
- Device drivers are not required to be pocketable
- A type ‘A’ receptacle is used for each port
- Only speeds required by devices in the TLP must be supported. (*Low, Full, and Hi-Speed supported by this module.*)
- Each port must be able to deliver a minimum of 100 mA for a configured or unconfigured device, and optionally, up to 500 mA for a configured device

- This is a typical implementation for a microcontroller

USB On-the-Go (OTG)

The OTG dual role device supports both USB host and device functionality. OTG dual role devices use a micro-AB receptacle. This allows a micro-A or a micro-B plug to be attached. Both the micro-A and micro-B plugs have an additional pin, the ID pin, to signify the connection type. The plug type, micro-A or micro-B, determines the default role of the OTG device, host or USB device. An OTG device will perform the role of a host when a micro-A plug is detected. When a micro-B plug is detected, the role of a USB device is performed.

When an OTG device is directly connected to another OTG device using an OTG cable, micro-A to micro-B, Host Negotiation Protocol (HNP) can be used to swap the roles of the host and USB device between the two without disconnecting and reconnecting cabling. To differentiate between the two OTG devices, the term, "A-device", is used to refer to the device connected to the micro-A plug and "B-device" is used to refer to the OTG device connected to the micro-B plug.

OTG dual role operating as a host (A-device):

- Only supports a specific list of devices, referred to as a Targeted Peripheral List (TPL). Generic class support is not allowed.
- Only required to support transaction types required by devices in the TPL
- USB hub support is optional. (*Multi-point support provided by this module.*)
- Device drivers are not required to be pocketable
- Only a single micro-AB receptacle is used
- Only Full-Speed must be supported. Hi-Speed and/or Low-Speed can be supported. (*Low, Full, and Hi-Speed supported by this module.*)
- The USB port must be able to deliver a minimum of 8 mA for a configured or unconfigured device, and optionally, up to 500 mA for a configured device
- Supports Host Negotiation Protocol (HNP) and Session Request Protocol (SRP). The host can switch roles to become a device. The initial role as a host or device is determined by the plug type, micro-A or micro-B, inserted into the micro-AB receptacle
- The A-device supplies VBUS power, when the bus is powered, even if the roles are swapped using HNP

OTG dual role operating as a USB device (B-device):

- Class or vendor-specific functionality
- Draws 8 mA or less before configuration
- Is typically self-powered due to low-current requirements, but can draw up to 500 mA after successful negotiation with the host
- Only a single micro-AB receptacle is used
- Must support Full-Speed. Support of Low-Speed and/or Hi-Speed is optional
- Supports control transactions. Supports data transactions required for implementation.
- Supports Session Request Protocol (SRP) and/or Host Negotiation Protocol (HNP). (*This module supports both SRP and HNP.*)
- The A-device supplies VBUS power, when the bus is powered, even if the roles are swapped using HNP

Additional Features of the Hi-Speed USB Module

- Operates either as a function controller of a Hi-Speed/Full-Speed USB device or as the host/device in a point-to-point or multi-point communications with other USB function
- Supports OTG communications with on or more Hi-Speed, Full-Speed, or Low-Speed devices
- Provides soft connect/disconnect.
- In addition to Endpoint Zero, supports seven transmit and seven receive endpoints
- Dynamic FIFO sizing for Endpoints 1-7. (Endpoint Zero FIFO fixed at 64 bytes.) FIFOs use module-internal SRAM.
- Module-internal eight channel DMA with access to all FIFOs
- All host transaction scheduling supported in hardware
- Supports Link Power Management

Using the Library

This topic describes the basic architecture of the USB Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_usb.h`

The interface to the USB Peripheral Library is defined in the `plib_usb.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the USB Peripheral Library must include `peripheral.h`.

Library File:

The USB Peripheral Library is part of the processor-specific peripheral library archive (`.a`) file installed with the compiler. Libraries in this archive are automatically available to the linker (in the default search path) for any project built using the Microchip compiler.

Please refer to the What is MPLAB Harmony? section for how the library interacts with the framework.

Hardware Abstraction Models

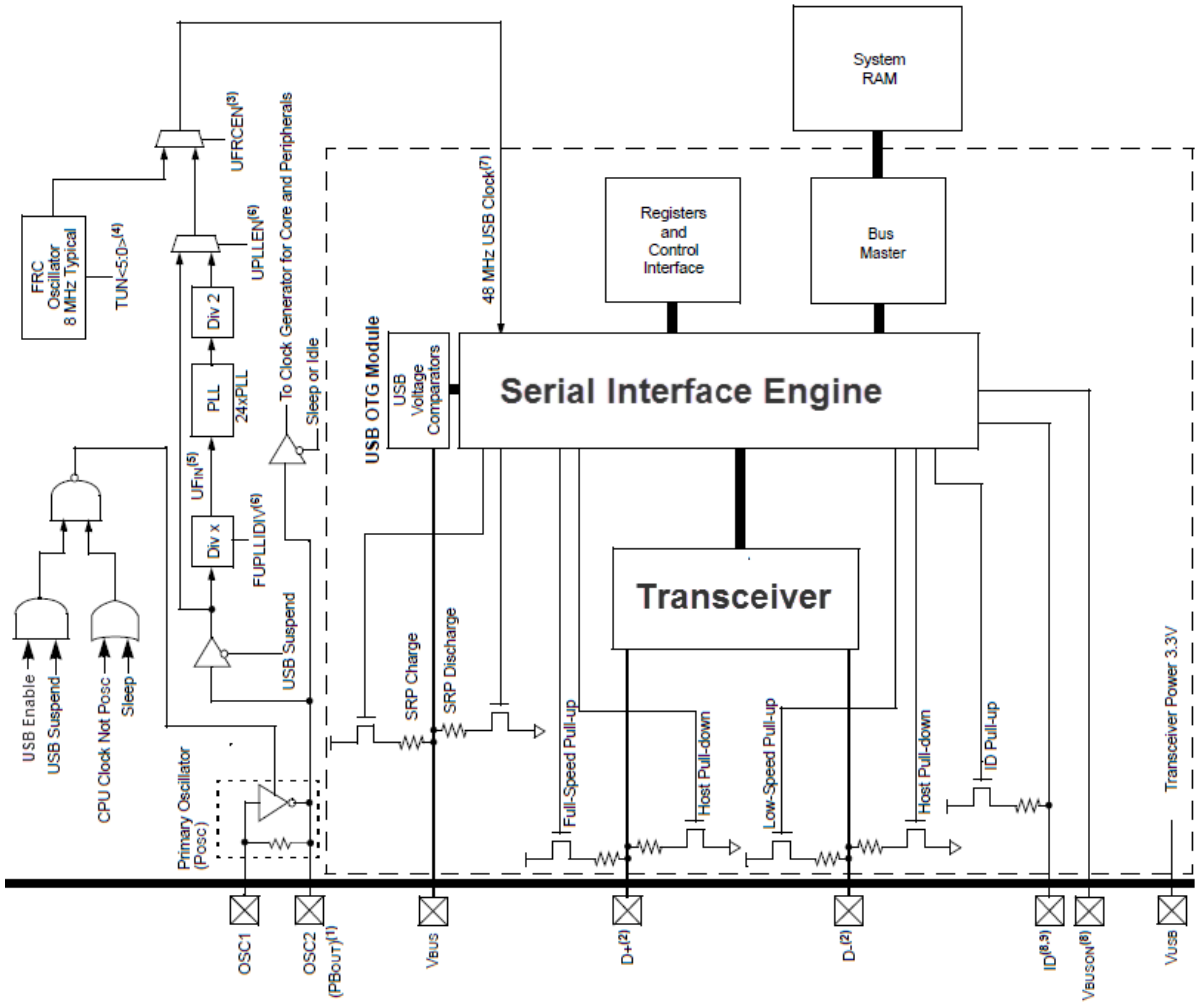
This section describes the hardware abstraction model for the USB Peripheral Library.

Description

Hardware Abstraction Model

The following figure shows the USB Module for the PIC32 family of devices.

PIC32 USB Module



Note 1: PB clock is only available on this pin for select EC modes.
2: Pins can be used as digital inputs when USB is not enabled.
3: This bit field is contained in the OSCCON register.
4: This bit field is contained in the OSCTRM register.
5: USB PLL UF_{IN} requirements: 4 MHz $\leq UF_{IN} \leq$ 5 MHz.
6: This bit field is contained in the DEVCFG2 register.
7: A 48 MHz clock is required for proper USB operation.
8: Pins can be used as GPIO when the USB OTG module is disabled.
9: Pin is pulled high internally when USB OTG module is enabled.

The USB OTG module contains analog and digital components to provide a USB 2.0 full-speed and low-speed embedded host, full-speed device, or On-The-Go (OTG) implementation with a minimum of external components. This module in Host mode is intended for use as an embedded host and therefore does not implement a Universal Host Controller Interface (UHCI) or a Open Host Controller Interface (OHCI).

The USB OTG module consists of the clock generator, the USB voltage comparators, the transceiver, the Serial Interface Engine (SIE), a dedicated USB Bus Master, pull-up and pull-down resistors and the register interface.

The clock generator provides the 48 MHz clock, which is required for USB full-speed and low-speed communication. The voltage comparators monitor the voltage on the VBUS pin to determine the state of the bus. The transceiver provides the analog translation between the USB bus and the digital logic. The SIE is a state machine that transfers data to and from the endpoint buffers, and generates the hardware protocol for data transfers. The USB Bus Master transfers data between the data buffers in RAM and the SIE. The integrated pull-up and pull-down resistors eliminate the need for external signaling components. The register interface allows the CPU to configure and communicate with the module.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the USB module.

Library Interface Section	Description
USB Setup Functions	This section provides functions to perform general USB peripheral setup such as functions to set USB Speed, control on-chip pull ups, etc.
Buffer Descriptor Table Functions	This section provides functions that allow the application to setup, configure and access/modify the Buffer Descriptors in the Buffer Descriptor Table.
USB Activity Functions	This section provides function that allow the application to monitor bus conditions on the USB.
USB Bus Signaling Functions	This section provides functions that allow the application to generate Reset and Resume Signaling.
Last Transaction Status Functions	This section provides functions that allow the application to query conditions of the USB peripheral.
Endpoints Functions	This section provides functions that allow the application to manage endpoints.
Interrupts Functions	This section provides functions that allow the application to enable, disable and query the status interrupts in the USB peripheral.
Host Functions	This section provides functions that are required to operate the USB module while in Host mode.
On-The-Go (OTG) Functions	This section provides functions that are required to operate the USB module while in OTG mode.
External Transceiver Support Functions	This section provides function that are required to operate to enable/disable the external transceiver interface.

VBUS Support Functions	This section provides functions that allow VBUS level monitoring and VBUS boost PWM module control.
Test Support Functions	This section provides functions that enable/disable test signals needed for eye pattern measurement.

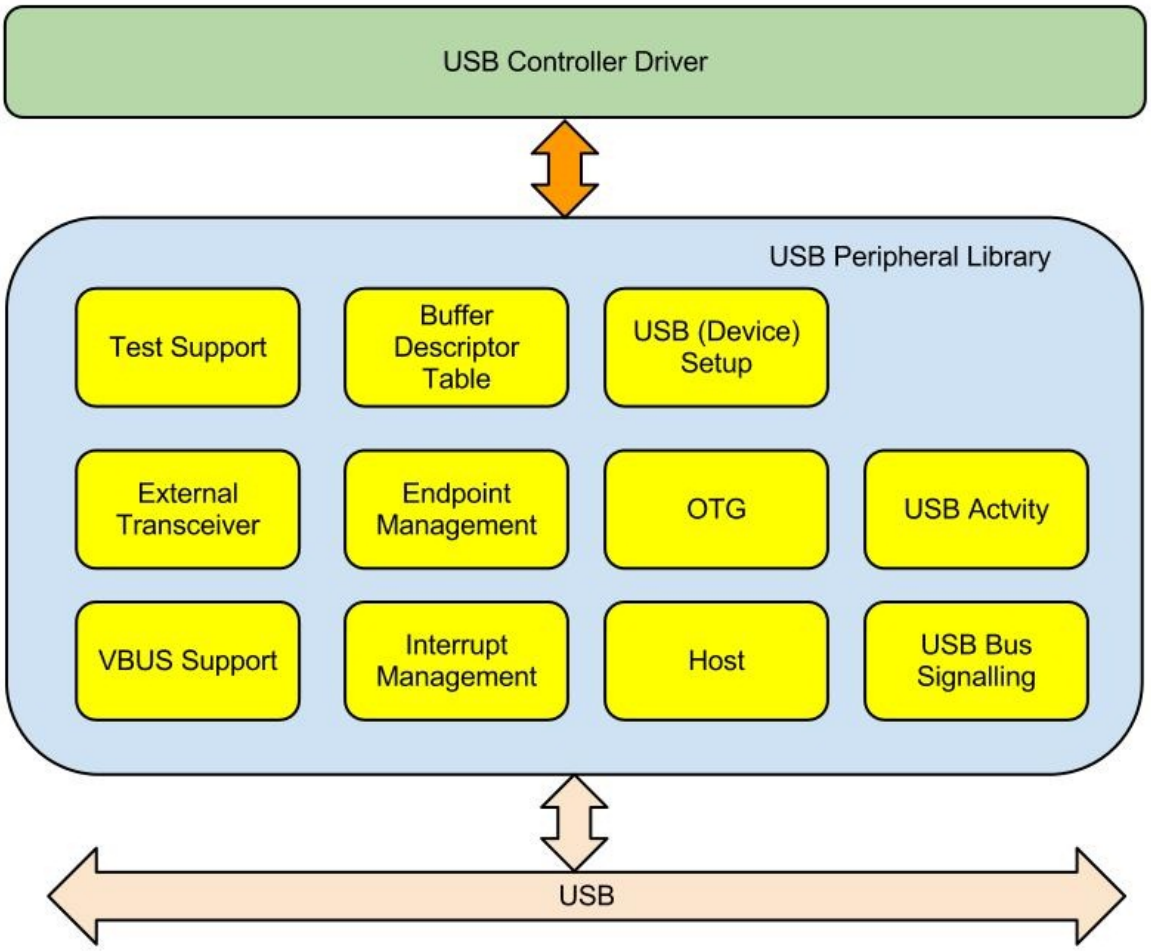
How the Library Works

Provides information on how the library works.

Description

The following figure describes the abstraction model employed by the USB Peripheral Library.

USB Peripheral Library Abstraction Model



USB Buffers and the Buffer Descriptor Table (BDT)

This section describes USB buffers and the Buffer Descriptor Table.

Description

All USB endpoints are implemented using buffers and control bits in RAM. Both software and the USB module have access to these buffers and control bits. To arbitrate this access a semaphore flag system is used.

Each endpoint can be configured for transmit only, receive only or transmit *and* receive. Transmit and receive functions have separate buffers. For each buffer there is a Buffer Descriptor (BD) in the Buffer Descriptor Table (BDT). On most devices the BDT has room for two transmit and two receive buffers for each endpoint, supporting ping-pong buffering. Buffer descriptors must be aligned on 512 byte boundaries to enable the USB module to correctly read each entry.

The starting address of the Buffer Descriptor Table is set by the PLIB_USB_BDTBaseAddressSet.

```
#define USB_MAX_EP_NUMBER 15
```

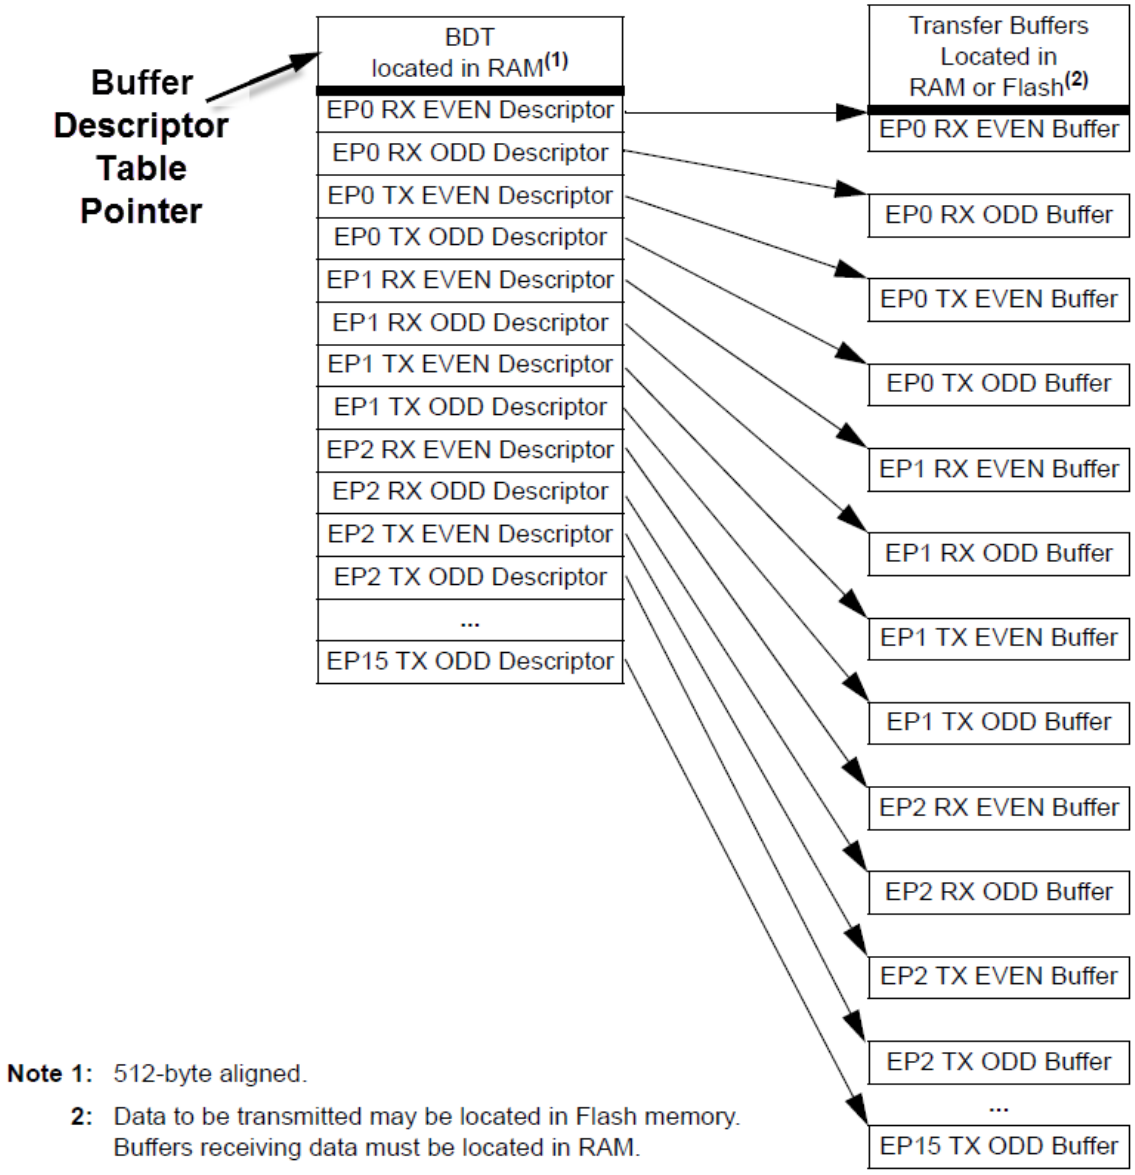
```
#define BDT_NUM_ENTRIES      (((USB_MAX_EP_NUMBER + 1) * 4)-2)

volatile union USB_BDT_ENTRY_TAG gBDT[BDT_NUM_ENTRIES] __attribute__ (( aligned (512) ));
```

Each Buffer Descriptor entry in the BDT has a **bufferAddress** pointer to the Buffer Descriptor's buffer in memory (RAM or FLASH).

The following figure shows the structure for PIC32 devices. These devices support ping-pong buffering for all endpoints.

Buffer Descriptor Table and Endpoint Buffers



Note 1: 512-byte aligned.

2: Data to be transmitted may be located in Flash memory. Buffers receiving data must be located in RAM.

With 16 endpoints (Endpoints 0 - 15) there are 64 possible entries in the Buffer Descriptor Table:

```
//                                          (Even,Odd) or (Ping,Pong)
//                                             (RX,TX) |
//                           (EP0      to       EPn)  |  |
volatile USB_BDT_ENTRY myBDT[(USB_MAX_EP_NUMBER + 1)][2][2] __attribute__ (( aligned (512) ));
```

Peripheral library functions are provided to support reading each BD while hiding the details of BDT addressing that can change when ping-pong buffering is disabled for one or more endpoints. The format of Buffer Descriptors vary from family to family and it is not important to know the differences, since peripheral library functions hide these details. To understand the information stored in each Buffer Descriptor Table entry it is informative to look at the C language description for one family of devices. (All device families support the same information but with different ways of packing the data into memory.)

For PIC32 devices each BD is 8 bytes long and is described by this C code:

```
typedef union _USB_BDT_ENTRY __attribute__ ((packed))
{
    uint64_t          dlValue;        //Double Long Integer Value
    uint32_t           lValue[2];     //Long  Integer Values
    uint16_t           sValue[4];     //Short Integer Values
```

```
        struct __attribute__ ((packed))
        {
            USB_BD_STATUS  bufferStatus;  //(RW) Buffer Status
            uint16_t       byteCount:10;  //(RW) Byte Count
            uint8_t                : 6;  //(  ) Reserved
            uint32_t       bufferAddress; //(RW) Buffer Address in Data Ram or Flash
        };
    } USB_BDT_ENTRY;
```

For transmit buffers, byteCount, is set to the length of the buffer using PLIB_USB_BufferByteCountSet. For receive buffers PLIB_USB_BufferByteCountSet is used to set the maximum allowable receive data length. PLIB_USB_BufferByteCountGet is used to determine how many bytes were actually transmitted or received. The memory address of each buffer is found in bufferAddress. The functions PLIB_USB_BufferAddressSet and PLIB_USB_BufferAddressGet support this field in the Buffer Descriptor.

Buffer status is stored in the 16 least significant bits of each BDT entry:

```
    typedef union _USB_BD_STATUS __attribute__ ((packed))
    {
        uint16_t       sValue;                  //Short Integer Value
        struct __attribute__ ((packed))
        {
            uint8_t                          :2; //(  )Reserved
            uint8_t    stallEnable           :1; //( W) Buffer Stall Enable
            uint8_t    dataToggleSyncEnable :1; //( W) Data Toggle Synch Enable
            uint8_t                          :1; //(  ) Reserved
            uint8_t                          :1; //(  ) Reserved
            uint8_t    dataToggle            :1; //(RW) Data Toggle Synch Value
            uint8_t    uSBOwnsBuffer         :1; //(RW) USB Ownership of buffer and BDT entry
        };
        struct __attribute__ ((packed))
        {
            uint8_t                          :2; //(  ) Reserved
            uint8_t    packetID              :4; //(R ) Packet Identifier (PID)
        };
    } USB_BD_STATUS;
```

The fields stallEnable and dataToggleSyncEnable in the Buffer Descriptor status structure are writeable but not readable. The function PLIB_USB_BufferStallEnable sets the stallEnable bit. (Hardware will clear the bit after receiving a SETUP token from the host.) The functions PLIB_USB_BufferDataToggleSyncEnable and PLIB_USB_BufferDataToggleSyncDisable manipulate dataToggleSyncEnable .

On a read from the status structure stallEnable and dataToggleSyncEnable and the next two (reserved) bits are replaced by the Packet Identifier (PID), called packetID in the structure. The function PLIB_USB_BufferPIDGet reads packetID.

The rest of the status structure is writeable and readable: dataToggle and uSBOwnsBuffer.

The dataToggle (DATA0 or DATA1) of a receive buffer is determined by using PLIB_USB_BufferDataToggleGet. For transmit buffers the dataToggle value is set using PLIB_USB_BufferDataToggleSelect .

The field uSBOwnsBuffer is used by both software and the USB module as a semaphore. The function PLIB_USB_BufferReleaseToUSB releases the buffer to the USB module and the function PLIB_USB_BufferReleasedToSW returns a Boolean true when the buffer is released back to software by the USB module. As long as PLIB_USB_BufferReleasedToSW returns false, software should not change the Buffer Descriptor Table entry or its associated buffer.

USB Setup Example

This section provides example code for setting up the USB module.

Description

Following is an example of how to set up the USB module:

```
#define USB_MAX_EP_NUMBER 15

#define BDT_NUM_ENTRIES      (((USB_MAX_EP_NUMBER + 1) * 4)-2)

volatile union USB_BDT_ENTRY_TAG gBDT[BDT_NUM_ENTRIES] __attribute__ (( aligned (512) ));

unsigned int bufferTransactionCount[BDT_NUM_ENTRIES];

    // Turn off USB module
    PLIB_USB_Disable( usbID );

    // Set up the Hardware
    if ( usbModuleSetup.StopInIdle )
    {
        PLIB_USB_StopInIdleEnable( usbID );
```

```
    }
    else
    {
        PLIB_USB_StopInIdleDisable( usbID );
    }

    if ( usbModuleSetup.SuspendInSleep )
    {
        PLIB_USB_AutoSuspendEnable( usbID );
    }
    else
    {
        PLIB_USB_AutoSuspendDisable( usbID );
    }

    PLIB_USB_OperatingModeSelect( usbID, usbModuleSetup.OpMode );

    PLIB_USB_PingPongModeSelect( usbID, usbModuleSetup.ppMode );

    // Reset all ping pong buffers to "Even"
    PLIB_USB_PingPongFreeze( usbID );
    PLIB_USB_PingPongUnfreeze( usbID );

    // Interrupt flag cleared on the safer side
    IFS1bits.USBIF = 0;

    // Enable USB module interrupts
    PLIB_USB_InterruptEnable( usbID, DRV_USB_GEN_INT_ENABLES );

    // Disable all OTG interrupts
    PLIB_USB_OTG_InterruptDisable( usbID, DRV_USB_OTB_INT_ENABLES );

    // Enable all Error interrupts
    PLIB_USB_ErrorInterruptEnable( usbID, DRV_USB_ERR_INT_ENABLES );

    // Enable the interrupt source in case of interrupt mode
    IEC1bits.USBIE = 1;

    // Setting the Interrupt Priority in case of interrupt mode.
    IPC11bits.USBIP = 4;

    // Initialize BDT
    for ( iEntry = 0; iEntry < BDT_NUM_ENTRIES; iEntry++ )
    {
        gBDT[iEntry].lValue[0] = 0ul;
        gBDT[iEntry].lValue[1] = 0ul;

        bufferTransactionCount[iEntry] = 0;
    }//end for ( iEntry = 0; iEntry < BDT_NUM_ENTRIES; iEntry++ )

    // Inform USB module of BDT's address in memory
    PLIB_USB_BDTBaseAddressSet( usbID , (void *)((uint32_t)KVA_TO_PA(gBDT)) );

    /***********************/
    /* SET UP ENDPOINT ZERO */
    /***********************/
    PLIB_USB_BufferAddressSet( usbID, (void*)gBDT, PLIB_USB_PingPongModeGet( usbID ),
                               0, USB_BUFFER_RX, USB_BUFFER_EVEN, pSetupRcvBuffer );

    // Configure Endpoint Zero control register
    PLIB_USB_EP0LSDirectConnectDisable( usbID );   // For Hosts, included for completeness
    PLIB_USB_EP0NakRetryEnable( usbID );           // For Hosts, included for completeness
    PLIB_USB_EPnControlTransferEnable( usbID, 0 ); // Enable control transfers
    PLIB_USB_EPnRxSelect( usbID, 0, USB_EP_RX );   // Enable receive
    PLIB_USB_EPnHandshakeEnable( usbID, 0 );       // Enable handshaking

    // Set up Endpoint Zero's receive buffer BDT entries
    ppMode = PLIB_USB_PingPongModeGet( usbID ); // Ping Pong Mode needed for BDT entry indexing
```

```
    // Clear PID bits
    PLIB_USB_BufferPIDBitsClear(usbID,(void*)gBDT,ppMode,0,USB_BUFFER_RX,USB_BUFFER_EVEN); //Rx0

    // Disable buffer stall
    PLIB_USB_BufferStallDisable(usbID,(void*)gBDT,ppMode,0,USB_BUFFER_RX,USB_BUFFER_EVEN); //Rx0

    // Enable Data Toggle Synchronization
    PLIB_USB_BufferDataToggleSyncEnable(usbID,(void*)gBDT,ppMode,0,USB_BUFFER_RX,USB_BUFFER_EVEN); //Rx0

    // Set Data0/1 to Data0
    PLIB_USB_BufferDataToggleSelect(usbID,(void*)gBDT,ppMode,0,USB_BUFFER_RX,USB_BUFFER_EVEN,USB_BUFFER_DATA
0);
//Rx0

    // Setup packets have 8 bytes of data payload
    PLIB_USB_BufferByteCountSet(usbID,(void*)gBDT,ppMode,0,USB_BUFFER_RX,USB_BUFFER_EVEN,8);

    // Release buffers to USB module
    PLIB_USB_BufferReleaseToUSB(usbID,(void*)gBDT,ppMode,0,USB_BUFFER_RX,USB_BUFFER_EVEN);

    PLIB_USB_Enable( gDrvUSBObj[hDriver].usbID ); // Turn on USB module
```

Configuring the Library

The library is configured for the supported USB module when the processor is chosen in the MPLAB X IDE.

Library Interface

a) USB Setup Functions

	Name	Description
	PLIB_USB_AllInterruptEnable	Configures the USB peripheral general interrupts, error interrupts and OTG interrupts.
	PLIB_USB_AutoSuspendDisable	Disables USB OTG Auto-suspend mode.
	PLIB_USB_AutoSuspendEnable	Enables USB Auto-suspend mode.
	PLIB_USB_DeviceAddressGet	Returns the address of the USB module in Device mode.
	PLIB_USB_DeviceAddressSet	Sets the USB Device's address.
	PLIB_USB_Disable	Disables (powers down) the USB module.
	PLIB_USB_Enable	Enables (powers up) the USB module.
	PLIB_USB_FullSpeedDisable	Forces the USB module to operate at low speed.
	PLIB_USB_FullSpeedEnable	Enables the USB to operate at full speed.
	PLIB_USB_OnChipPullUpDisable	Disables on-chip pull-ups.
	PLIB_USB_OnChipPullUpEnable	Enables on-chip pull-ups.
	PLIB_USB_OperatingModeSelect	Selects the operating mode of the USB module.
	PLIB_USB_PingPongModeGet	Returns the Ping-Pong Configuration setting.
	PLIB_USB_PingPongModeSelect	Selects the Ping-Pong Configuration setting.
	PLIB_USB_SleepGuardDisable	This function disables Sleep Guard. Entry into Sleep mode is immediate.
	PLIB_USB_SleepGuardEnable	Entry into Sleep mode is blocked if bus activity is detected or if an interrupt is pending.
	PLIB_USB_StopInIdleDisable	Allows the USB module to continue operation when the device enters Idle mode.
	PLIB_USB_StopInIdleEnable	Enables USB module operation to stop when the device enters Idle mode.
	PLIB_USB_SuspendDisable	Disables USB OTG Suspend mode.
	PLIB_USB_SuspendEnable	Enables USB Suspend mode.
	PLIB_USB_UOEMonitorDisable	Disables the OE signal output.
	PLIB_USB_UOEMonitorEnable	Enables the OE signal output.

b) Buffer Descriptor Table Functions

	Name	Description
	PLIB_USB_BDTBaseAddressGet	Returns the base address of the Buffer Descriptor Table.
	PLIB_USB_BDTBaseAddressSet	Sets the base address for the Buffer Descriptor Table for PIC32 devices.
	PLIB_USB_BufferAddressGet	Gets the memory address of an endpoint buffer.
	PLIB_USB_BufferAddressSet	Sets the endpoint buffer address.

	PLIB_USB_BufferAllCancelReleaseToUSB	Cancels all endpoint buffer releases to the USB module and hands over the buffer to the CPU.
	PLIB_USB_BufferByteCountGet	Returns the endpoint buffer byte count.
	PLIB_USB_BufferByteCountSet	Sets the buffer byte count.
	PLIB_USB_BufferCancelReleaseToUSB	Cancels release of the endpoint buffer by software, allowing software to again access the buffer.
	PLIB_USB_BufferClearAll	Clears (zeros out) entries in the Buffer Descriptor Table.
	PLIB_USB_BufferClearAllDTSEnable	Clears the endpoint descriptor entry and enables data toggle synchronization.
	PLIB_USB_BufferDataToggleGet	Returns data synchronization (DATA0 or DATA1) for the endpoint buffer.
	PLIB_USB_BufferDataToggleSelect	Sets the endpoint buffer to DATA0 or DATA1.
	PLIB_USB_BufferDataToggleSyncDisable	Disables DATA0/DATA1 synchronization between the device and host.
	PLIB_USB_BufferDataToggleSyncEnable	Enables DATA0/DATA1 synchronization between the device and host.
	PLIB_USB_BufferEP0RxStatusInitialize	Initializes the Endpoint 0 RX endpoint buffer descriptors.
	PLIB_USB_BufferIndexGet	Gets the Buffer Descriptor Table index for a buffer.
	PLIB_USB_BufferPIDBitsClear	Clears the Buffer Status bits in the Buffer Descriptor Table.
	PLIB_USB_BufferPIDGet	Returns the token packet ID (PID) from the endpoint buffer status.
	PLIB_USB_BufferReleasedToSW	Returns the boolean flag value of 'true' when the buffer has been released by the USB module.
	PLIB_USB_BufferReleaseToUSB	Releases the endpoint buffer by software, allowing the USB module access to the buffer.
	PLIB_USB_BufferSchedule	Hands over a buffer to the USB module along with the buffer address and byte count.
	PLIB_USB_BufferStallDisable	Disables STALL handshaking for the associated endpoint buffer.
	PLIB_USB_BufferStallEnable	Enables STALL handshaking for the associated endpoint buffer.
	PLIB_USB_BufferStallGet	Returns the buffer stall status for an endpoint/direction/ping-pong.

c) Endpoints Functions

	Name	Description
	PLIB_USB_EP0HostSetup	Sends token to the specified address.
	PLIB_USB_EP0LSDirectConnectDisable	Disables direct connection to a low-speed device for Endpoint 0.
	PLIB_USB_EP0LSDirectConnectEnable	Enables direct connection to a low-speed device for Endpoint 0.
	PLIB_USB_EP0NakRetryDisable	Disables retrying of NAKed transactions.
	PLIB_USB_EP0NakRetryEnable	Enables retrying NAK'd transactions for Endpoint 0.
	PLIB_USB_EPnAttributesClear	Clears the set attributes of the specified endpoint.
	PLIB_USB_EPnAttributesSet	Configures attributes of the endpoint such as direction, handshake capability and direction.
	PLIB_USB_EPnControlTransferDisable	Disables endpoint control transfers.
	PLIB_USB_EPnControlTransferEnable	Enables endpoint control transfers.
	PLIB_USB_EPnDirectionDisable	Disables the specified endpoint direction.
	PLIB_USB_EPnHandshakeDisable	Disables endpoint handshaking.
	PLIB_USB_EPnHandshakeEnable	Enables endpoint handshaking.
	PLIB_USB_EPnIsStalled	Tests whether the endpoint epValue is stalled.
	PLIB_USB_EPnRxDisable	Disables an endpoint's ability to process IN tokens.
	PLIB_USB_EPnRxEnable	Enables an endpoint to process IN tokens.
	PLIB_USB_EPnRxSelect	Selects receive capabilities of an endpoint.
	PLIB_USB_EPnStallClear	Clears an endpoint's stalled flag.
	PLIB_USB_EPnTxDisable	Disables an endpoint's ability to process OUT tokens.
	PLIB_USB_EPnTxEnable	Enables an endpoint to process OUT tokens.
	PLIB_USB_EPnTxRxSelect	Selects transmit and/or receive capabilities of an endpoint.
	PLIB_USB_EPnTxSelect	Selects transmit capabilities of an endpoint.

d) Interrupts Functions

	Name	Description
	PLIB_USB_InterruptDisable	Disables a general interrupt for the USB module.
	PLIB_USB_InterruptEnable	Enables a general interrupt for the USB module.
	PLIB_USB_InterruptEnableGet	Returns the enable/disable status of general USB module interrupts
	PLIB_USB_InterruptFlagAllGet	Returns a logically ORed bit map of active general USB interrupt flags.

	PLIB_USB_InterruptFlagClear	Clears a general interrupt flag for the USB module.
	PLIB_USB_InterruptFlagGet	Tests a general interrupt flag for the USB module.
	PLIB_USB_InterruptFlagSet	Sets a general interrupt flag for the USB module.
	PLIB_USB_InterruptIsEnabled	Returns true if interrupts are enabled.

e) Error Interrupts Functions

	Name	Description
	PLIB_USB_ErrorInterruptDisable	Disables an error interrupt for the USB module.
	PLIB_USB_ErrorInterruptEnable	Enables an error interrupt for the USB module.
	PLIB_USB_ErrorInterruptFlagAllGet	Returns a logically ORed bit map of active error interrupt flags.
	PLIB_USB_ErrorInterruptFlagClear	Clears an error interrupt flag for the USB module.
	PLIB_USB_ErrorInterruptFlagGet	Tests an error interrupt flag for the USB module.
	PLIB_USB_ErrorInterruptFlagSet	Sets an error interrupt flag for the USB module.
	PLIB_USB_ErrorInterruptIsEnabled	Returns true if interrupts are enabled.

f) Last Transaction Status Functions

	Name	Description
	PLIB_USB_LastTransactionDetailsGet	Returns the details of the last completed transaction.
	PLIB_USB_LastTransactionDirectionGet	Indicates the direction of the last transaction.
	PLIB_USB_LastTransactionEndPtGet	Returns the endpoint number of the last USB transfer.
	PLIB_USB_LastTransactionPingPongStateGet	Indicates whether the last transaction was to an EVEN buffer or an ODD buffer.

g) Host Functions

	Name	Description
	PLIB_USB_IsBusyWithToken	Indicates whether there is a token being executed by the USB module as Host.
	PLIB_USB_SOFDisable	Disables the automatic generation of the SOF token.
	PLIB_USB_SOFEnable	Enables the automatic generation of the SOF token every 1 ms.
	PLIB_USB_SOFThresholdGet	Returns the Start-of-Frame (SOF) Count bits.
	PLIB_USB_SOFThresholdSet	Sets the Start-of-Frame (SOF) threshold value.
	PLIB_USB_TokenEPGet	Returns the specified Endpoint address.
	PLIB_USB_TokenEPSet	Sets the Endpoint address for a host transaction.
	PLIB_USB_TokenPIDGet	Returns the token transaction type.
	PLIB_USB_TokenPIDSet	Sets the token transaction type to pidValue.
	PLIB_USB_TokenSpeedSelect	Selects low speed or full speed for subsequent token executions.

h) USB Bus Signaling Functions

	Name	Description
	PLIB_USB_ResetSignalDisable	Disables reset signaling on the USB bus.
	PLIB_USB_ResetSignalEnable	Enables reset signaling on the USB bus.
	PLIB_USB_ResumeSignalingDisable	Disables resume signaling.
	PLIB_USB_ResumeSignalingEnable	Enables resume signaling.

i) On-The-Go (OTG) Functions

	Name	Description
	PLIB_USB_OTG_BSessionHasEnded	Returns the status of the B-Session End Indicator bit.
	PLIB_USB_OTG_IDPinStateIsTypeA	Returns the ID Pin state.
	PLIB_USB_OTG_LineStateIsStable	Returns the status of the Line Stable Indicator bit.
	PLIB_USB_OTG_PullUpPullDownSetup	Enables or disables pull-up and pull-down resistors.
	PLIB_USB_OTG_SessionValid	Returns the status of the Session Valid Indicator bit.
	PLIB_USB_OTG_VBusChargeDisable	Disables VBUS line charge.
	PLIB_USB_OTG_VBusChargeEnable	Enables the VBUS line to be charged through a pull-up resistor.
	PLIB_USB_OTG_VBusChargeTo3V	Sets the VBUS line to charge to 3.3V.
	PLIB_USB_OTG_VBusChargeTo5V	Sets the VBUS line to charge to 5V.
	PLIB_USB_OTG_VBusDischargeDisable	Disables VBUS line discharge.
	PLIB_USB_OTG_VBusDischargeEnable	Enables VBUS line to be discharged through a resistor.

	PLIB_USB_OTG_VBusPowerOff	Turns off power on the VBUS Line.
	PLIB_USB_OTG_VBusPowerOn	Turns on power for the VBUS line.
	PLIB_USB_OTG_VBusValid	Returns the status of the A-VBUS valid indicator.

j) OTG Interrupts Functions

	Name	Description
	PLIB_USB_OTG_InterruptDisable	Disables a USB On-The-Go (OTG) Interrupt for the USB module.
	PLIB_USB_OTG_InterruptEnable	Enables a USB On-The-Go (OTG) Interrupt for the USB module.
	PLIB_USB_OTG_InterruptFlagClear	Clears a USB On-The-Go (OTG) Interrupt flag for the USB module.
	PLIB_USB_OTG_InterruptFlagGet	Tests a USB On-The-Go (OTG) Interrupt flag for the USB module.
	PLIB_USB_OTG_InterruptFlagSet	Sets a USB On-The-Go (OTG) Interrupt flag for the USB module.
	PLIB_USB_OTG_InterruptIsEnabled	Returns whether or not interrupts are enabled.

k) USB Activity Functions

	Name	Description
	PLIB_USB_ActivityPending	Returns whether or not USB activity is pending.
	PLIB_USB_FrameNumberGet	Returns the USB frame number.
	PLIB_USB_JStateIsActive	Live differential receiver J State flag.
	PLIB_USB_PacketTransferDisable	Disables the Serial Interface Engine (SIE).
	PLIB_USB_PacketTransferEnable	Re-enables the Serial Interface Engine (SIE), allowing token and packet processing.
	PLIB_USB_PacketTransferIsDisabled	Indicates that a setup token has been received from the Host and that token/packet processing is disabled.
	PLIB_USB_SE0InProgress	Returns whether a single-ended zero event is in progress.

l) External Transceiver Support Functions

	Name	Description
	PLIB_USB_I2CInterfaceForExtModuleDisable	Specifies external module(s) are controlled via dedicated pins.
	PLIB_USB_I2CInterfaceForExtModuleEnable	Specifies external module(s) are controlled via the I2C interface.
	PLIB_USB_TransceiverDisable	Disables the on-chip transceiver
	PLIB_USB_TransceiverEnable	Enables the on-chip transceiver.

m) VBUS Support Functions

	Name	Description
	PLIB_USB_ExternalComparatorMode2Pin	Sets the 2-pin input configuration for VBUS comparators.
	PLIB_USB_ExternalComparatorMode3Pin	Sets the 3-pin input configuration for VBUS Comparators.
	PLIB_USB_PWMCounterDisable	Disables the PWM counter used to generate the VBUS for the USB module.
	PLIB_USB_PWMCounterEnable	Enables the PWM counter used to generate the VBUS for the USB module.
	PLIB_USB_PWMDisable	Disables the PWM Generator.
	PLIB_USB_PWMEnable	Enables the PWM Generator.
	PLIB_USB_PWMPolaritiyActiveLow	Sets the PWM output to active-high and resets low.
	PLIB_USB_PWMPolarityActiveHigh	Sets the PWM output to active-low and resets high.
	PLIB_USB_VBoostDisable	Disables the On-Chip 5V Boost Regulator Circuit Disabled bit.
	PLIB_USB_VBoostEnable	Enables the On-Chip 5V Boost Regulator Circuit Enabled bit.
	PLIB_USB_VBUSComparatorDisable	Disables the on-chip VBUS Comparator.
	PLIB_USB_VBUSComparatorEnable	Enables the on-chip VBUS Comparator.
	PLIB_USB_VBUSPullUpDisable	Disables the pull-up on the VBUS pin.
	PLIB_USB_VBUSPullUpEnable	Enables the pull-up on the VBUS pin.

n) Test Support Functions

	Name	Description
	PLIB_USB_EyePatternDisable	Disables the USB eye pattern test.
	PLIB_USB_EyePatternEnable	Enables USB eye pattern test.

o) Other Functions

	Name	Description
	PLIB_USB_ModuleIsBusy	Indicates if the USB module is not ready to be enabled.

	PLIB_USB_PingPongFreeze	Resets all Ping-Pong buffer pointers to even buffers.
	PLIB_USB_PingPongReset	Resets the USB peripheral internal Ping-Pong indicator to point to even buffers.
	PLIB_USB_PingPongUnfreeze	Enables Ping-Pong buffering.
	PLIB_USB_TokenSend	Sends token to the specified address.

p) Feature Existence Functions

	Name	Description
	PLIB_USB_ExistsActivityPending	Identifies whether the ActivityPending feature exists on the USB module.
	PLIB_USB_ExistsALL_Interrupt	Identifies whether the ALL_Interrupt feature exists on the USB module.
	PLIB_USB_ExistsAutomaticSuspend	Identifies whether the AutomaticSuspend feature exists on the USB module.
	PLIB_USB_ExistsBDTBaseAddress	Identifies whether the BDTBaseAddress feature exists on the USB module.
	PLIB_USB_ExistsBDTFunctions	Identifies whether the BDTFunctions feature exists on the USB module.
	PLIB_USB_ExistsBufferFreeze	Identifies whether the BufferFreeze feature exists on the USB module.
	PLIB_USB_ExistsDeviceAddress	Identifies whether the DeviceAddress feature exists on the USB module.
	PLIB_USB_ExistsEP0LowSpeedConnect	Identifies whether the EP0LowSpeedConnect feature exists on the USB module.
	PLIB_USB_ExistsEP0NAKRetry	Identifies whether the EP0NAKRetry feature exists on the USB module.
	PLIB_USB_ExistsEPnRxEnable	Identifies whether the EPnRxEnableEnhanced feature exists on the USB module.
	PLIB_USB_ExistsEPnTxRx	Identifies whether the EPnTxRx feature exists on the USB module.
	PLIB_USB_ExistsERR_Interrupt	Identifies whether the ERR_Interrupt feature exists on the USB module.
	PLIB_USB_ExistsERR_InterruptStatus	Identifies whether the ERR_InterruptStatus feature exists on the USB module.
	PLIB_USB_ExistsEyePattern	Identifies whether the EyePattern feature exists on the USB module.
	PLIB_USB_ExistsFrameNumber	Identifies whether the FrameNumber feature exists on the USB module.
	PLIB_USB_ExistsGEN_Interrupt	Identifies whether the GEN_Interrupt feature exists on the USB module.
	PLIB_USB_ExistsGEN_InterruptStatus	Identifies whether the GEN_InterruptStatus feature exists on the USB module.
	PLIB_USB_ExistsHostBusyWithToken	Identifies whether the HostBusyWithToken feature exists on the USB module.
	PLIB_USB_ExistsHostGeneratesReset	Identifies whether the HostGeneratesReset feature exists on the USB module.
	PLIB_USB_ExistsLastDirection	Identifies whether the LastDirection feature exists on the USB module.
	PLIB_USB_ExistsLastEndpoint	Identifies whether the LastEndpoint feature exists on the USB module.
	PLIB_USB_ExistsLastPingPong	Identifies whether the LastPingPong feature exists on the USB module.
	PLIB_USB_ExistsLastTransactionDetails	Identifies whether the LastTransactionDetails feature exists on the USB module.
	PLIB_USB_ExistsLiveJState	Identifies whether the LiveJState feature exists on the USB module.
	PLIB_USB_ExistsLiveSingleEndedZero	Identifies whether the LiveSingleEndedZero feature exists on the USB module.
	PLIB_USB_ExistsModuleBusy	Identifies whether the ModuleBusy feature exists on the USB module.
	PLIB_USB_ExistsModulePower	Identifies whether the ModulePower feature exists on the USB module.
	PLIB_USB_ExistsNextTokenSpeed	Identifies whether the NextTokenSpeed feature exists on the USB module.
	PLIB_USB_ExistsOnChipPullup	Identifies whether the OnChipPullup feature exists on the USB module.
	PLIB_USB_ExistsOnChipTransceiver	Identifies whether the OnChipTransceiver feature exists on the USB module.
	PLIB_USB_ExistsOpModeSelect	Identifies whether the OpModeSelect feature exists on the USB module.
	PLIB_USB_ExistsOTG_ASessionValid	Identifies whether the OTG_ASessionValid feature exists on the USB module.
	PLIB_USB_ExistsOTG_BSessionEnd	Identifies whether the OTG_BSessionEnd feature exists on the USB module.
	PLIB_USB_ExistsOTG_IDPinState	Identifies whether the OTG_IDPinState feature exists on the USB module.
	PLIB_USB_ExistsOTG_Interrupt	Identifies whether the OTG_Interrupt feature exists on the USB module.
	PLIB_USB_ExistsOTG_InterruptStatus	Identifies whether the OTG_InterruptStatus feature exists on the USB module.
	PLIB_USB_ExistsOTG_LineState	Identifies whether the OTG_LineState feature exists on the USB module.
	PLIB_USB_ExistsOTG_PullUpPullDown	Identifies whether the OTG_PullUpPullDown feature exists on the USB module.
	PLIB_USB_ExistsOTG_SessionValid	Identifies whether the OTG_SessionValid feature exists on the USB module.
	PLIB_USB_ExistsOTG_VbusCharge	Identifies whether the OTG_VbusCharge feature exists on the USB module.
	PLIB_USB_ExistsOTG_VbusDischarge	Identifies whether the OTG_VbusDischarge feature exists on the USB module.
	PLIB_USB_ExistsOTG_VbusPowerOnOff	Identifies whether the OTG_VbusPowerOnOff feature exists on the USB module.
	PLIB_USB_ExistsPacketTransfer	Identifies whether the PacketTransfer feature exists on the USB module.
	PLIB_USB_ExistsPingPongMode	Identifies whether the PingPongMode feature exists on the USB module.
	PLIB_USB_ExistsResumeSignaling	Identifies whether the ResumeSignaling feature exists on the USB module.
	PLIB_USB_ExistsSleepEntryGuard	Identifies whether the SleepEntryGuard feature exists on the USB module.
	PLIB_USB_ExistsSOFThreshold	Identifies whether the SOFThreshold feature exists on the USB module.
	PLIB_USB_ExistsSpeedControl	Identifies whether the SpeedControl feature exists on the USB module.

	PLIB_USB_ExistsStartOfFrames	Identifies whether the StartOfFrames feature exists on the USB module.
	PLIB_USB_ExistsStopInIdle	Identifies whether the StopInIdle feature exists on the USB module.
	PLIB_USB_ExistsSuspend	Identifies whether the Suspend feature exists on the USB module.
	PLIB_USB_ExistsTokenEP	Identifies whether the TokenEP feature exists on the USB module.
	PLIB_USB_ExistsTokenPID	Identifies whether the TokenPID feature exists on the USB module.
	PLIB_USB_ExistsUOEMonitor	Identifies whether the UOEMonitor feature exists on the USB module.

q) Data Types and Constants

	Name	Description
	USB_BUFFER_DATA01	Provides enumeration data toggle for a buffer.
	USB_BUFFER_DIRECTION	Provides enumeration transmit/receive direction for a buffer.
	USB_BUFFER_PING_PONG	Enumerates the ping-pong buffer (Even vs. Odd).
	USB_BUFFER_SCHEDULE_DATA01	Provides enumeration data toggle for a buffer.
	USB_EP_TXRX	Provides enumeration transmit/receive setup for an endpoint.
	USB_OPMODES	Provides enumeration of operating modes supported by USB.
	USB_OTG_INTERRUPTS	Provides enumeration of interrupts related to the USB On-The-Go (OTG) module.
	USB_OTG_PULL_UP_PULL_DOWN	USB OTG pull-Up and pull-Down resistors for D+ and D- .
	USB_PID	Legal PID values.
	USB_PING_PONG_MODE	Supports the four modes of ping-pong buffering.
	USB_PING_PONG_STATE	Decodes which buffer (Even vs. Odd) was used for the last transaction.
	USB_TOKEN_SPEED	Provides enumeration of available token speeds.
	USB_MAX_EP_NUMBER	Maximum number of endpoints supported (not including EP0).

Description

This section describes the Application Programming Interface (API) functions of the USB Peripheral Library.

Refer to each section for a detailed description.

a) USB Setup Functions

PLIB_USB_AllInterruptEnable Function

Configures the USB peripheral general interrupts, error interrupts and OTG interrupts.

File

plib_usb.h

C

```
void PLIB_USB_AllInterruptEnable(USB_MODULE_ID index, USB_INTERRUPTS usbInterruptsFlag,
USB_ERROR_INTERRUPTS usbErrorInterruptsFlag, USB_OTG_INTERRUPTS otgInterruptFlag);
```

Returns

None.

Description

This function configures the USB peripheral general interrupts, error interrupts and OTG interrupts.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsALL_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// This code snippet disables all OTG interrupts, disables
// the SOF interrupt and enables all error interrupts.
USB_OTG_INTERRUPTS otgInterruptEnables = ~USB_OTG_INT_ALL ;
USB_INTERRUPTS generalInterruptEnables = USB_INT_ALL & ~USB_INT_SOF ;
```

```
USB_ERROR_INTERRUPTS errorInterruptEnables = USB_ERR_INT_ALL ;

PLIB_USB_AllInterruptEnable(USB_MODULE_ID index, USB_INTERRUPTS usbInterruptsFlag,
    USB_ERROR_INTERRUPTS usbErrorInterruptsFlag,
    USB_OTG_INTERRUPTS otgInterruptFlag);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
usbInterruptsFlag	General interrupts to be configured
usbErrorInterruptsFlag	USB Error interrupts to be configured
otgInterruptFlag	OTG interrupts to be configured

Function

void PLIB_USB_AllInterruptEnable(USB_MODULE_ID index, USB_INTERRUPTS usbInterruptsFlag,
USB_ERROR_INTERRUPTS usbErrorInterruptsFlag, USB_OTG_INTERRUPTS otgInterruptFlag);

PLIB_USB_AutoSuspendDisable Function

Disables USB OTG Auto-suspend mode.

File

plib_usb.h

C

```
void PLIB_USB_AutoSuspendDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables USB OTG Auto-suspend mode. The USB OTG module will operate normally and does not automatically suspend upon entry to Sleep mode. Software must use PLIB_USB_SuspendEnable to suspend the module, including the USB 48 MHz clock

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsAutomaticSuspend in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_AutoSuspendDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_AutoSuspendDisable (USB_MODULE_ID index)

PLIB_USB_AutoSuspendEnable Function

Enables USB Auto-suspend mode.

File

plib_usb.h

C

```
void PLIB_USB_AutoSuspendEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables USB Auto-suspend mode. The USB module automatically suspends upon entry to Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsAutomaticSuspend in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_AutoSuspendEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_AutoSuspendEnable (USB_MODULE_ID index)

PLIB_USB_DeviceAddressGet Function

Returns the address of the USB module in Device mode.

File

plib_usb.h

C

```
uint8_t PLIB_USB_DeviceAddressGet(USB_MODULE_ID index);
```

Returns

Device Address

Description

This function returns the address of the USB module in Device mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsDeviceAddressin your application to determine whether this feature is available.

Preconditions

None.

Example

```
myUSBAddress = PLIB_USB_DeviceAddressGet(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

uint8_t PLIB_USB_DeviceAddressGet (USB_MODULE_ID index)

PLIB_USB_DeviceAddressSet Function

Sets the USB Device's address.

File

plib_usb.h

C

```
void PLIB_USB_DeviceAddressSet(USB_MODULE_ID index, uint8_t address);
```

Returns

None.

Description

This function sets the USB Device's address as part of enumeration.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsDeviceAddressin your application to determine whether this feature is available.

Preconditions

USB module must be in Host mode.

Example

```
uint8_t myUSBAddress = ....;
PLIB_USB_DeviceAddressSet(MY_USB_INSTANCE, myUSBAddress);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
address	USB address

Function

void PLIB_USB_DeviceAddressSet (USB_MODULE_ID index, uint8_t address)

PLIB_USB_Disable Function

Disables (powers down) the USB module.

File

plib_usb.h

C

```
void PLIB_USB_Disable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables (powers down) the USB module.

Remarks

For PIC32 devices, the USB module must be in Device mode before the USB module is powered down.

For PIC32 devices, all reads or writes to module registers after powering down the module will be invalid until PLIB_USB_ModuleIsBusy (MY_USB_INSTANCE) == false.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsModulePower in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#if defined(__PIC32MX__)
  // Disable Host, Device, or OTG before powering down
  PLIB_USB_OperatingModeSelect( MY_USB_INSTANCE, USB_OPMODE_NONE );
```

```
    // Turn off USB
    PLIB_USB_Disable(MY_USB_INSTANCE);
    // For PIC32, wait until module is no longer busy before trying to
    // access any USB module registers.
    while ( PLIB_USB_ModuleIsBusy (MY_USB_INSTANCE) )
    {
        //wait
    }
#endif
    // Can now read or modify USB module status
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_Disable (USB_MODULE_ID index)

PLIB_USB_Enable Function

Enables (powers up) the USB module.

File

plib_usb.h

C

```
void PLIB_USB_Enable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables (powers up) the USB module.

Remarks

See also PLIB_USB_ModuleIsBusy.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsModulePoweryour application to determine whether this feature is available.

Preconditions

None.

Example

```
    // Complete Needed setup for the module
    PLIB_USB_Enable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_Enable (USB_MODULE_ID index)

PLIB_USB_FullSpeedDisable Function

Forces the USB module to operate at low speed.

File

plib_usb.h

C

```
void PLIB_USB_FullSpeedDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function forces the USB module to operate at low speed.

Remarks

For PIC32 devices: Host mode only.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsSpeedControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_FullSpeedDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_FullSpeedDisable (USB_MODULE_ID index)

PLIB_USB_FullSpeedEnable Function

Enables the USB to operate at full speed.

File

plib_usb.h

C

```
void PLIB_USB_FullSpeedEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the USB to operate at full speed.

Remarks

For PIC32 devices: Host mode only.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsSpeedControl in your application to determine whether this feature is available.

Preconditions

Use only before the USB module is enabled by calling PLIB_USB_Enable.

Example

```
PLIB_USB_FullSpeedEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_FullSpeedEnable (USB_MODULE_ID index)

PLIB_USB_OnChipPullUpDisable Function

Disables on-chip pull-ups.

File

plib_usb.h

C

```
void PLIB_USB_OnChipPullUpDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables on-chip pull-ups.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOnChipPullup in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OnChipPullUpDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OnChipPullUpDisable (USB_MODULE_ID index)

PLIB_USB_OnChipPullUpEnable Function

Enables on-chip pull-ups.

File

plib_usb.h

C

```
void PLIB_USB_OnChipPullUpEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables on-chip pull-ups. Pull-up on D+ in Full-Speed mode. Pull-up on D- in Low-Speed mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOnChipPullup in your application to determine whether this feature is available.

Preconditions

Use only before the USB module is enabled by calling PLIB_USB_Enable.

Example

```
PLIB_USB_OnChipPullUpEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OnChipPullUpEnable (USB_MODULE_ID index)

PLIB_USB_OperatingModeSelect Function

Selects the operating mode of the USB module.

File

plib_usb.h

C

```
void PLIB_USB_OperatingModeSelect(USB_MODULE_ID index, USB_OPMODES opMode);
```

Returns

None.

Description

This function selects the operating mode of the USB module, either Host, Device, or OTG.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOpModeSelect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OperatingModeSelect( MY_USB_INSTANCE, USB_OPMODE_DEVICE );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
opMode	Selected operating mode: USB_OPMODE_DEVICE, USB_OPMODE_HOST, or USB_OPMODE_OTG

Function

void PLIB_USB_OperatingModeSelect(USB_MODULE_ID index, USB_OPMODES opMode)

PLIB_USB_PingPongModeGet Function

Returns the Ping-Pong Configuration setting.

File

plib_usb.h

C

```
USB_PING_PONG_MODE PLIB_USB_PingPongModeGet(USB_MODULE_ID index);
```

Returns

Ping-Pong Mode - One of USB_PING_PONG__ALL_BUT_EP0, USB_PING_PONG__FULL_PING_PONG, USB_PING_PONG__EP0_OUT_ONLY, USB_PING_PONG__NO_PING_PONG

Description

This function returns the Ping-Pong Configuration setting.

Remarks

None.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsPingPongMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
ppConfig = PLIB_USB_PingPongModeGet(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USB_PING_PONG_MODE PLIB_USB_PingPongModeGet (USB_MODULE_ID index)

PLIB_USB_PingPongModeSelect Function

Selects the Ping-Pong Configuration setting.

File

plib_usb.h

C

```
void PLIB_USB_PingPongModeSelect(USB_MODULE_ID index, USB_PING_PONG_MODE ppConfig);
```

Returns

None.

Description

This function selects the Ping-Pong Configuration setting.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsPingPongMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_PingPongModeSelect(MY_USB_INSTANCE,USB_PING_PONG__ALL_BUT_EP0);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
ppConfig	Ping-Pong configuration selection. One of USB_PING_PONG__ALL_BUT_EP0, USB_PING_PONG__FULL_PING_PONG, USB_PING_PONG__EP0_OUT_ONLY, USB_PING_PONG__NO_PING_PONG

Function

void PLIB_USB_PingPongModeSelect (USB_MODULE_ID index, USB_PING_PONG_MODE ppConfig)

PLIB_USB_SleepGuardDisable Function

File

plib_usb.h

C

```
void PLIB_USB_SleepGuardDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables Sleep Guard. Entry into Sleep mode is immediate.

Remarks

Not available on all PIC32 devices. Refer to the specific device data sheet for details.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsSleepEntryGuard in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_SleepGuardDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_SleepGuardDisable (USB_MODULE_ID index)

Summary.

Disables Sleep Guard. Entry into Sleep mode is immediate.

PLIB_USB_SleepGuardEnable Function

Entry into Sleep mode is blocked if bus activity is detected or if an interrupt is pending.

File

plib_usb.h

C

```
void PLIB_USB_SleepGuardEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function block entry into Sleep mode if bus activity is detected or if an interrupt is pending.

Remarks

Not available on all PIC32 devices. Refer to the specific device data sheet for details. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsSleepEntryGuard in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_SleepGuardEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_SleepGuardEnable (USB_MODULE_ID index)

PLIB_USB_StopInIdleDisable Function

Allows the USB module to continue operation when the device enters Idle mode.

File

plib_usb.h

C

```
void PLIB_USB_StopInIdleDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function allows the USB module to continue operation when the device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsStopInIdle in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_StopInIdleDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_StopInIdleDisable (USB_MODULE_ID index)

PLIB_USB_StopInIdleEnable Function

Enables USB module operation to stop when the device enters Idle mode.

File

plib_usb.h

C

```
void PLIB_USB_StopInIdleEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables USB module operation to stop when the device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsStopInIdle in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_StopInIdleEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_StopInIdleEnable (USB_MODULE_ID index)

PLIB_USB_SuspendDisable Function

Disables USB OTG Suspend mode.

File

plib_usb.h

C

```
void PLIB_USB_SuspendDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables USB OTG Suspend mode. The USB OTG module will operate normally.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsSuspend in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_SuspendDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_SuspendDisable (USB_MODULE_ID index)

PLIB_USB_SuspendEnable Function

Enables USB Suspend mode.

File

plib_usb.h

C

```
void PLIB_USB_SuspendEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables USB Suspend mode. The 48 MHz USB clock will be gated off. The transceiver is placed in a low-power state.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsSuspend in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_SuspendEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_SuspendEnable (USB_MODULE_ID index)

PLIB_USB_UOEMonitorDisable Function

Disables the OE signal output.

File

plib_usb.h

C

```
void PLIB_USB_UOEMonitorDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the OE signal output.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsUOEMonitor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
//Disable the OE output.
PLIB_USB_UOEMonitorDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_UOEMonitorDisable(USB_MODULE_ID index);

PLIB_USB_UOEMonitorEnable Function

Enables the OE signal output.

File

plib_usb.h

C

```
void PLIB_USB_UOEMonitorEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the OE signal output.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsUOEMonitor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
//Enable the OE output.
PLIB_USB_UOEMonitorEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_UOEMonitorEnable(USB_MODULE_ID index);

b) Buffer Descriptor Table Functions

PLIB_USB_BDTBaseAddressGet Function

Returns the base address of the Buffer Descriptor Table.

File

plib_usb.h

C

```
void* PLIB_USB_BDTBaseAddressGet(USB_MODULE_ID index);
```

Returns

None.

Description

This function returns the base address of the Buffer Descriptor Table.

Remarks

Must be set for PIC32 devices using PLIB_USB_BDTBaseAddressSet.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTBaseAddress in your application to determine whether this feature is available.

Preconditions

None.

Example

```
void * pMyBDT;
pMyBDT = PLIB_USB_BDTBaseAddressGet(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void * PLIB_USB_BDTBaseAddressGet (USB_MODULE_ID index)

PLIB_USB_BDTBaseAddressSet Function

Sets the base address for the Buffer Descriptor Table for PIC32 devices.

File

plib_usb.h

C

```
void PLIB_USB_BDTBaseAddressSet(USB_MODULE_ID index, void* address);
```

Returns

None.

Description

This function sets the base address for the Buffer Descriptor Table. This function is only available on PIC32 devices.

Remarks

The address of the Buffer Descriptor Table must be 512 byte-aligned. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTBaseAddress in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#if defined(__PIC32MX__)
  // For PIC32
  PLIB_USB_BDTBaseAddressSet(MY_USB_INSTANCE, (void *)((uint32_t)KVA_TO_PA(&myBDT)) );
#else
  // Everybody else
  PLIB_USB_BDTBaseAddressSet(MY_USB_INSTANCE, (void *)(&myBDT) );
#endif
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
address	Physical memory address in RAM of Buffer Descriptor Table

Function

void PLIB_USB_BDTBaseAddressSet (USB_MODULE_ID index, void * address)

PLIB_USB_BufferAddressGet Function

Gets the memory address of an endpoint buffer.

File

plib_usb.h

C

```
void* PLIB_USB_BufferAddressGet(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

Buffer address in memory.

Description

This function gets the memory address of an endpoint buffer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint Value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void * PLIB_USB_BufferAddressGet (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferAddressSet Function

Sets the endpoint buffer address.

File

plib_usb.h

C

```
void PLIB_USB_BufferAddressSet(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong, void* bufferAddress);
```

Returns

None.

Description

This function sets the endpoint buffer address.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD
bufferAddress	address in memory of endpoint transmit or receive buffer

Function

void PLIB_USB_BufferAddressSet (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong,
void * bufferAddress)

PLIB_USB_BufferAllCancelReleaseToUSB Function

Cancels all endpoint buffer releases to the USB module and hands over the buffer to the CPU.

File

plib_usb.h

C

```
void PLIB_USB_BufferAllCancelReleaseToUSB(USB_MODULE_ID index, void * pBDT, USB_PING_PONG_MODE ppMode, int nEndpoints);
```

Returns

None.

Description

This function cancels all endpoint buffer releases to the USB module and hands over the buffer to the CPU.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

```
//Cancel all buffer releases to USB.
//BDT has 3 Endpoints.

PLIB_USB_BufferAllCancelReleaseToUSB(MY_USB_INSTANCE, pBDT,
                                USB_PING_PONG_NO_PING_PONG, 3);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
pBDT	Pointer to the Buffer Descriptor Table
ppMode	Buffer Descriptor Table Ping-Pong mode
nEndpoints	Number of endpoints in the Buffer-Descriptor table

Function

void PLIB_USB_BufferAllCancelReleaseToUSB(USB_MODULE_ID index,
void * pBDT, USB_PING_PONG_MODE ppMode, int nEndpoints);

PLIB_USB_BufferByteCountGet Function

Returns the endpoint buffer byte count.

File

plib_usb.h

C

```
uint16_t PLIB_USB_BufferByteCountGet(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

Endpoint buffer byte count.

Description

This function returns the endpoint buffer byte count, the actual number of bytes transmitted or received.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

uint16_t PLIB_USB_BufferByteCountGet (USB_MODULE_ID index,

void * pBDT,

USB_PING_PONG_MODE ppMode,

uint8_t epValue,

USB_BUFFER_DIRECTION bufferDirection,

USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferByteCountSet Function

Sets the buffer byte count.

File

plib_usb.h

C

```
void PLIB_USB_BufferByteCountSet(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong, uint16_t
bufferByteCount);
```

Returns

None.

Description

This function sets the number of bytes to be transmitted or the maximum number of bytes to be received.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD
bufferByteCount	number of bytes to be transmitted or the maximum number of bytes to be received

Function

PLIB_USB_BufferByteCountSet (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong,
uint16_t bufferByteCount)

PLIB_USB_BufferCancelReleaseToUSB Function

Cancels release of the endpoint buffer by software, allowing software to again access the buffer.

File

plib_usb.h

C

```
void PLIB_USB_BufferCancelReleaseToUSB(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

None.

Description

This function cancels the release of the endpoint buffer by software, allowing software to again access the buffer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void PLIB_USB_BufferCancelReleaseToUSB (USB_MODULE_ID index,
void * pBDT,

USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferClearAll Function

Clears (zeros out) entries in the Buffer Descriptor Table.

File

plib_usb.h

C

```
void PLIB_USB_BufferClearAll(USB_MODULE_ID index, void * pBDT, USB_PING_PONG_MODE ppMode, uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

None.

Description

This function clears (zeros out) the entries in the Buffer Descriptor Table.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void PLIB_USB_BufferClearAll(USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferClearAllDTSEnable Function

Clears the endpoint descriptor entry and enables data toggle synchronization.

File

plib_usb.h

C

```
void PLIB_USB_BufferClearAllDTSEnable(USB_MODULE_ID index, void * pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection);
```

Returns

None.

Description

This function clears the endpoint descriptor entry and enables data toggle synchronization.

Remarks

None.

Preconditions

None.

Example

```
//Clear endpoint 6 buffer descriptor transmit entry and
//enable data toggle synchronization.

PLIB_USB_BufferClearAllDTSEnable ( MY_USB_INSTANCE, pBDT,
    USB_PING_PONG_NO_PING_PONG, 6, USB_BUFFER_TX);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
pBDT	pointer to Buffer Descriptor Table
pingpong	Ping-Pong mode.
epvalue	Endpoint to be be affected
bufferDirection	Endpoint direction

Function

void PLIB_USB_BufferClearAllDTSEnable(USB_MODULE_ID index,

void * pBDT,

USB_PING_PONG_MODE ppMode,

uint8_t epValue,

USB_BUFFER_DIRECTION bufferDirection);

PLIB_USB_BufferDataToggleGet Function

Returns data synchronization (DATA0 or DATA1) for the endpoint buffer.

File

plib_usb.h

C

```
USB_BUFFER_DATA01 PLIB_USB_BufferDataToggleGet(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode,
uint8_t epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

Data Toggle value, USB_BUFFER_DATA0 or USB_BUFFER_DATA1, for the buffer

Description

This function returns data synchronization (DATA0 or DATA1) for the endpoint buffer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

USB_BUFFER_DATA01

PLIB_USB_BufferDataToggleGet (USB_MODULE_ID index,

void * pBDT,

USB_PING_PONG_MODE ppMode,

uint8_t epValue,

USB_BUFFER_DIRECTION bufferDirection,

USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferDataToggleSelect Function

Sets the endpoint buffer to DATA0 or DATA1.

File

plib_usb.h

C

```
void PLIB_USB_BufferDataToggleSelect(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong, USB_BUFFER_DATA01
bufferData01);
```

Returns

None.

Description

This function sets the endpoint buffer to DATA0 or DATA1.

Remarks

See PLIB_USB_BufferDataToggleGet to determine the received data toggle setting. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD
bufferData01	USB_BUFFER_DATA0 or USB_BUFFER_DATA1

Function

void PLIB_USB_BufferDataToggleSelect (USB_MODULE_ID index,

void * pBDT,

USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong,
USB_BUFFER_DATA01 bufferData01)

PLIB_USB_BufferDataToggleSyncDisable Function

Disables DATA0/DATA1 synchronization between the device and host.

File

plib_usb.h

C

```
void PLIB_USB_BufferDataToggleSyncDisable(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode,
uint8_t epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

None.

Description

This function disables DATA0/DATA1 synchronization between the device and host.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void PLIB_USB_BufferDataToggleSyncDisable (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferDataToggleSyncEnable Function

Enables DATA0/DATA1 synchronization between the device and host.

File

plib_usb.h

C

```
void PLIB_USB_BufferDataToggleSyncEnable(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode,
uint8_t epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

None.

Description

This function enables DATA0/DATA1 synchronization between the device and host.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void PLIB_USB_BufferDataToggleSyncEnable (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferEP0RxStatusInitialize Function

Initializes the Endpoint 0 RX endpoint buffer descriptors.

File

plib_usb.h

C

```
void PLIB_USB_BufferEP0RxStatusInitialize(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode,
USB_BUFFER_PING_PONG pingpong, uint16_t bufferByteCount);
```

Returns

None.

Description

This function initializes the Endpoint 0 RX endpoint buffer descriptors. This function will clear the Endpoint 0 RX Buffer Descriptor status field, load the endpoint size and release the buffer to the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

```
//Initialize EP0 RX even buffer descriptor and release back to
//USB. Buffer size is 64
```

```
PLIB_USB_BufferEP0RxStatusInitialize ( MY_USB_INSTANCE, pBDT,
    USB_PING_PONG_NO_PING_PONG, USB_BUFFER_EVEN, 64);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
pBDT	Pointer to Buffer Descriptor Table
pingpong	Ping-Pong mode
bufferByteCount	size of the EP0 RX buffer in bytes

Function

void PLIB_USB_BufferEP0RxStatusInitialize (USB_MODULE_ID index,
void* pBDT,
USB_PING_PONG_MODE ppMode,
USB_BUFFER_PING_PONG pingpong,
uint16_t bufferByteCount);

PLIB_USB_BufferIndexGet Function

Gets the Buffer Descriptor Table index for a buffer.

File

plib_usb.h

C

```
uint8_t PLIB_USB_BufferIndexGet(USB_MODULE_ID index, USB_PING_PONG_MODE ppMode, uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

Buffer index into the Buffer Descriptor Table.

Description

This function gets the Buffer Descriptor Table index for a buffer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

uint8_t PLIB_USB_BufferIndexGet (USB_MODULE_ID index,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferPIDBitsClear Function

Clears the Buffer Status bits in the Buffer Descriptor Table.

File

plib_usb.h

C

```
void PLIB_USB_BufferPIDBitsClear(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

None.

Description

This function clears the Buffer Status bits in the Buffer Descriptor Table.

Remarks

Call PLIB_USB_BufferPIDBitsClear before setting buffer control bits. This is equivalent to: PLIB_USB_BufferCancelReleaseToUSB(...) PLIB_USB_BufferDataToggleSelect(...,USB_BUFFER_DATA0) PLIB_USB_BufferDataToggleSyncDisable(...) PLIB_USB_BufferStallDisable(...) This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

The associated buffer must have been released by the USB module (i.e., PLIB_USB_BufferReleasedToSW returns 'true'.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void PLIB_USB_BufferPIDBitsClear (USB_MODULE_ID index,

void * pBDT,

USB_PING_PONG_MODE ppMode,

uint8_t epValue,

USB_BUFFER_DIRECTION bufferDirection,

USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferPIDGet Function

Returns the token packet ID (PID) from the endpoint buffer status.

File

plib_usb.h

C

```
uint8_t PLIB_USB_BufferPIDGet(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

Endpoint buffer packet ID (PID).

Description

This function returns the token packet ID (PID) from the endpoint buffer status.

Remarks

There is no equivalent "Set" routine, since this field is read-only in the buffer status register within the Buffer Descriptor Table. It is set when the buffer has been transmitted or received by the USB module and the usbOwnsBuffer field has been cleared by the USB module, releasing the buffer for software access. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

uint8_t PLIB_USB_BufferPIDGet (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferReleasedToSW Function

Returns the boolean flag value of 'true' when the buffer has been released by the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_BufferReleasedToSW(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

- true - The buffer has been released by hardware
- false - The buffer is still controlled by hardware

Description

This function returns the boolean flag value of 'true' when the buffer has been released by the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

bool PLIB_USB_BufferReleasedToSW (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferReleaseToUSB Function

Releases the endpoint buffer by software, allowing the USB module access to the buffer.

File

plib_usb.h

C

```
void PLIB_USB_BufferReleaseToUSB(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

None.

Description

This function releases the endpoint buffer by software, allowing the USB module access to buffer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void PLIB_USB_BufferReleaseToUSB (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,

USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferSchedule Function

Hands over a buffer to the USB module along with the buffer address and byte count.

File

plib_usb.h

C

```
void PLIB_USB_BufferSchedule(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong, void * bufferAddress, int16_t
bufferByteCount, USB_BUFFER_SCHEDULE_DATA01 bufferData01);
```

Returns

None.

Description

This function sets the endpoint descriptor buffer address, sets the send/receive byte count, and then hands over the buffer to the USB module.

Remarks

This function does the work of three other functions: PLIB_USB_BufferAddressSet, PLIB_USB_BufferByteCountSet, PLIB_USB_BufferReleaseToUSB

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD
bufferAddress	Address of the application buffer
bufferByteCount	Send or expected receive byte count
bufferData01	USB_BUFFER_SET_DATA0, USB_BUFFER_SET_DATA1, or USB_BUFFER_DONTCHANGE (The last choice leaves the existing DATA0/1 value of the buffer alone.)

Function

void PLIB_USB_BufferSchedule(USB_MODULE_ID index ,
void* pBDT ,
USB_PING_PONG_MODE ppMode ,
uint8_t epValue ,
USB_BUFFER_DIRECTION bufferDirection ,
USB_BUFFER_PING_PONG bufferPingPong ,
void * bufferAddress ,
int16_t bufferByteCount ,
USB_BUFFER_SCHEDULE_DATA01 bufferData01)

PLIB_USB_BufferStallDisable Function

Disables STALL handshaking for the associated endpoint buffer.

File

plib_usb.h

C

```
void PLIB_USB_BufferStallDisable(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

None.

Description

This function disables STALL handshaking for the associated endpoint buffer.

Remarks

Release of a STALL handshake for the buffer is done by hardware when the host sends a SETUP token to the associated endpoint or resets the USB module This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available. .

Preconditions

The associated buffer must have been released by the USB module (i.e., PLIB_USB_BufferReleasedToSW returns 'true').

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void PLIB_USB_BufferStallDisable (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferStallEnable Function

Enables STALL handshaking for the associated endpoint buffer.

File

plib_usb.h

C

```
void PLIB_USB_BufferStallEnable(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

None.

Description

This function enables STALL handshaking for the associated endpoint buffer.

Remarks

Release of a STALL handshake for the buffer is done by hardware when the host sends a SETUP token to the associated endpoint or resets the USB module. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

The associated buffer must have been released by the USB module (i.e. PLIB_USB_BufferReleasedToSW returns 'true').

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void PLIB_USB_BufferStallEnable (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferStallGet Function

Returns the buffer stall status for an endpoint/direction/ping-pong.

File

plib_usb.h

C

```
bool PLIB_USB_BufferStallGet(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

- true - Buffer stall is enabled
- false - Buffer stall is not enabled

Description

This function returns the buffer stall status for an endpoint/direction/ping-pong.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

the associated buffer must have been released by the USB module (i.e., PLIB_USB_BufferReleasedToSW returns 'true').

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

bool PLIB_USB_BufferStallGet (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,

uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

c) Endpoints Functions

PLIB_USB_EP0HostSetup Function

Sends token to the specified address.

File

plib_usb.h

C

```
void PLIB_USB_EP0HostSetup(USB_MODULE_ID index);
```

Returns

None.

Description

This function configures endpoint 0 for typical host operation. Control transfers are enable. Transmit and Receive is enabled. Handshaking is enabled. Low Speed connection is disabled. NAK retry is disabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Configure endpoint 0 for host operation

PLBIB_USB_EP0HostSetup(USB_MODULE_ID index);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_EP0HostSetup(USB_MODULE_ID index);

PLIB_USB_EP0LSDirectConnectDisable Function

Disables direct connection to a low-speed device for Endpoint 0.

File

plib_usb.h

C

```
void PLIB_USB_EP0LSDirectConnectDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables direct connection to a low-speed device for Endpoint 0.

Remarks

Host mode and U1EP0 only. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEP0LowSpeedConnect in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
PLIB_USB_EP0LSDirectConnectDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_EP0LSDirectConnectDisable (USB_MODULE_ID index)

PLIB_USB_EP0LSDirectConnectEnable Function

Enables direct connection to a low-speed device for Endpoint 0.

File

plib_usb.h

C

```
void PLIB_USB_EP0LSDirectConnectEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables direct connection to a low-speed device for Endpoint 0.

Remarks

Host Mode and U1EP0 only. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEP0LowSpeedConnect in your application to determine whether this feature is available.

Preconditions

USB module must be in Host mode.

Example

```
PLIB_USB_EP0LSDirectConnectEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_EP0LSDirectConnectEnable (USB_MODULE_ID index)

PLIB_USB_EP0NakRetryDisable Function

Disables retrying of NAKed transactions.

File

plib_usb.h

C

```
void PLIB_USB_EP0NakRetryDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables retrying of NAKed transactions.

Remarks

Host/OTG only. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEP0NAKRetry in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host or OTG modes.

Example

```
PLIB_USB_EP0NakRetryDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_EP0NakRetryDisable (USB_MODULE_ID index)

PLIB_USB_EP0NakRetryEnable Function

Enables retrying NAK'd transactions for Endpoint 0.

File

plib_usb.h

C

```
void PLIB_USB_EP0NakRetryEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables retrying NAK'd transactions for Endpoint 0.

Remarks

Host/OTG only. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEP0NAKRetry in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host or OTG modes.

Example

```
PLIB_USB_EP0NakRetryEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_EP0NakRetryEnable (USB_MODULE_ID index)

PLIB_USB_EPnAttributesClear Function

Clears the set attributes of the specified endpoint.

File

plib_usb.h

C

```
void PLIB_USB_EPnAttributesClear(USB_MODULE_ID index, uint8_t epValue);
```

Returns

None.

Description

Clears the set attributes of the specified endpoint. The endpoint transmit receive, handshake and setup packet handling capability is disabled.

Remarks

None.

Preconditions

None.

Example

```
// This clears up the endpoint 0 attributes and thus disables
// the endpoints
PLIB_USB_EPnAttributesClear(MY_USB_INSTANCE, 0);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint

Function

void PLIB_USB_EPnAttributesClear (USB_MODULE_ID index, uint8_t epValue)

PLIB_USB_EPnAttributesSet Function

Configures attributes of the endpoint such as direction, handshake capability and direction.

File

plib_usb.h

C

```
void PLIB_USB_EPnAttributesSet(USB_MODULE_ID index, uint8_t epValue, int direction, bool isControl, bool
handshake);
```

Returns

None.

Description

Configures attributes of the endpoint such as direction, handshake capability and direction. If the isControl flag is true, then the direction and handshake parameters are ignored and the endpoint is configured for control transfers.

Remarks

None.

Preconditions

None.

Example

```
// This enables endpoint 0 for control transfers.
PLIB_USB_EPnAttributesSet(MY_USB_INSTANCE, 0, 0, true, true);
// This enables endpoint 2 for non control transfer, direction
// is RX and handshake enable.
PLIB_USB_EPnAttributesSet(MY_USB_INSTANCE, 2, 1, false, true);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
direction	Endpoint direction, if 1 then RX and if 0 then TX.

isControl	If true endpoint is configured for control transfers.
handshake	If true, then handshake is enabled on the endpoint else it is disabled.

Function

void PLIB_USB_EPnAttributesSet (USB_MODULE_ID index,
uint8_t epValue, int direction, bool isControl, bool handshake)

PLIB_USB_EPnControlTransferDisable Function

Disables endpoint control transfers.

File

plib_usb.h

C

```
void PLIB_USB_EPnControlTransferDisable(USB_MODULE_ID index, uint8_t epValue);
```

Returns

None.

Description

This function disables endpoint control transfers when endpoint transmit and endpoint receive are both enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EPnControlTransferDisable(MY_USB_INSTANCE, someEP);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint

Function

void PLIB_USB_EPnControlTransferDisable (USB_MODULE_ID index, uint8_t epValue)

PLIB_USB_EPnControlTransferEnable Function

Enables endpoint control transfers.

File

plib_usb.h

C

```
void PLIB_USB_EPnControlTransferEnable(USB_MODULE_ID index, uint8_t epValue);
```

Returns

None.

Description

This function enables endpoint control transfers when endpoint transmit and endpoint receive are both enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EPnControlTransferEnable(MY_USB_INSTANCE, someEP);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint

Function

void PLIB_USB_EPnControlTransferEnable (USB_MODULE_ID index, uint8_t epValue)

PLIB_USB_EPnDirectionDisable Function

Disables the specified endpoint direction.

File

plib_usb.h

C

```
void PLIB_USB_EPnDirectionDisable(USB_MODULE_ID index, uint8_t epValue, int direction);
```

Returns

None.

Description

Disables the specified endpoint direction.

Remarks

None.

Preconditions

None.

Example

```
// This function disables the TX direction of endpoint 1
PLIB_USB_EPnDirectionDisable(MY_USB_INSTANCE, 1, 1);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
direction	If 1, then TX direction is disabled. If 0 RX direction is disabled.

Function

void PLIB_USB_EPnDirectionDisable (USB_MODULE_ID index,

uint8_t epValue, int direction)

PLIB_USB_EPnHandshakeDisable Function

Disables endpoint handshaking.

File

plib_usb.h

C

```
void PLIB_USB_EPnHandshakeDisable(USB_MODULE_ID index, uint8_t epValue);
```

Returns

None.

Description

This function disables endpoint handshaking. Typically used for Isochronous endpoints.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EPnHandshakeDisable(MY_USB_INSTANCE, someEP);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint

Function

void PLIB_USB_EPnHandshakeDisable (USB_MODULE_ID index, uint8_t epValue)

PLIB_USB_EPnHandshakeEnable Function

Enables endpoint handshaking.

File

plib_usb.h

C

```
void PLIB_USB_EPnHandshakeEnable(USB_MODULE_ID index, uint8_t epValue);
```

Returns

None.

Description

This function enables endpoint handshaking.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EPnHandshakeEnable(MY_USB_INSTANCE, someEP);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint

Function

void PLIB_USB_EPnHandshakeEnable (USB_MODULE_ID index, uint8_t epValue)

PLIB_USB_EPnIsStalled Function

Tests whether the endpoint epValue is stalled.

File

plib_usb.h

C

```
bool PLIB_USB_EPnIsStalled(USB_MODULE_ID index, uint8_t epValue);
```

Returns

- true - The endpoint is stalled
- false - The endpoint is not stalled

Description

This function tests whether the endpoint epValue is stalled.

Remarks

Not valid before an endpoint is enabled. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if( PLIB_USB_EPnIsStalled(MY_USB_INSTANCE, someEP) )
{
    // Handle the stall
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint

Function

bool PLIB_USB_EPnIsStalled (USB_MODULE_ID index, uint8_t epValue)

PLIB_USB_EPnRxDisable Function

Disables an endpoint's ability to process IN tokens.

File

plib_usb.h

C

```
void PLIB_USB_EPnRxDisable(USB_MODULE_ID index, uint8_t endpoint);
```

Returns

None.

Description

This function disables an endpoint's ability to process IN tokens.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
//De-provision endpoint 3 to process IN Token
PLIB_USB_EPnRxDisable(MY_USB_INSTANCE, 3);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
endpoint	Endpoint to be affected

Function

void PLIB_USB_EPnRxDisable(USB_MODULE_ID index, uint8_t endpoint);

PLIB_USB_EPnRxEnable Function

Enables an endpoint to process IN tokens.

File

plib_usb.h

C

```
void PLIB_USB_EPnRxEnable(USB_MODULE_ID index, uint8_t endpoint);
```

Returns

None.

Description

This function enables an endpoint to process IN tokens.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
//Provision endpoint 3 to process IN Token
PLIB_USB_EPnRxEnable(MY_USB_INSTANCE, 3);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
endpoint	Endpoint to be affected

Function

void PLIB_USB_EPnRxEnable(USB_MODULE_ID index, uint8_t endpoint);

PLIB_USB_EPnRxSelect Function

Selects receive capabilities of an endpoint.

File

plib_usb.h

C

```
void PLIB_USB_EPnRxSelect(USB_MODULE_ID index, uint8_t epValue, USB_EP_TXRX epTxRx);
```

Returns

None.

Description

This function selects receive capabilities of an endpoint.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EPnRxSelect(MY_USB_INSTANCE, someEP, USB_EP_RX);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
epTxRx	Transmit/Receive setting for endpoint: USB_EP_RX, USB_EP_NOTXRX

Function

void PLIB_USB_EPnRxSelect (USB_MODULE_ID index, uint8_t epValue, USB_EP_TXRX epTxRx)

PLIB_USB_EPnStallClear Function

Clears an endpoint's stalled flag.

File

plib_usb.h

C

```
void PLIB_USB_EPnStallClear(USB_MODULE_ID index, uint8_t epValue);
```

Returns

None.

Description

This function clears an endpoint's stalled flag.

Remarks

Not valid before an endpoint is enabled. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if( PLIB_USB_EPnIsStalled(MY_USB_INSTANCE, someEP) )
{
    // Handle the stall
    PLIB_USB_EPnStallClear(MY_USB_INSTANCE, someEP);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint

Function

void PLIB_USB_EPnStallClear (USB_MODULE_ID index, uint8_t epValue)

PLIB_USB_EPnTxDisable Function

Disables an endpoint's ability to process OUT tokens.

File

plib_usb.h

C

```
void PLIB_USB_EPnTxDisable(USB_MODULE_ID index, uint8_t endpoint);
```

Returns

None.

Description

This function disables an endpoint's ability to process OUT tokens.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
//De-provision endpoint 3 to process OUT Token
PLIB_USB_EPnTxDisable(MY_USB_INSTANCE, 3);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
endpoint	Endpoint to be affected

Function

void PLIB_USB_EPnTxDisable(USB_MODULE_ID index, uint8_t endpoint);

PLIB_USB_EPnTxEnable Function

Enables an endpoint to process OUT tokens.

File

plib_usb.h

C

```
void PLIB_USB_EPnTxEnable(USB_MODULE_ID index, uint8_t endpoint);
```

Returns

None.

Description

This function enables an endpoint to process OUT tokens.

Remarks

None.

Preconditions

None.

Example

```
//Provision endpoint 3 to process OUT Token
PLIB_USB_EPnTxEnable(MY_USB_INSTANCE, 3);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
endpoint	Endpoint to be affected

Function

void PLIB_USB_EPnTxEnable(USB_MODULE_ID index, uint8_t endpoint);

PLIB_USB_EPnTxRxSelect Function

Selects transmit and/or receive capabilities of an endpoint.

File

plib_usb.h

C

```
void PLIB_USB_EPnTxRxSelect(USB_MODULE_ID index, uint8_t epValue, USB_EP_TXRX epTxRx);
```

Returns

None.

Description

This function selects transmit and/or receive capabilities of an endpoint.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EPnTxRxSelect(MY_USB_INSTANCE, someEP, USB_EP_TXRX);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
epTxRx	Transmit/Receive setting for endpoint: USB_EP_TX, USB_EP_RX, USB_EP_TX_RX, USB_EP_NOTXRX

Function

void PLIB_USB_EPnTxRxSelect (USB_MODULE_ID index, uint8_t epValue, USB_EP_TXRX epTxRx)

PLIB_USB_EPnTxSelect Function

Selects transmit capabilities of an endpoint.

File

plib_usb.h

C

```
void PLIB_USB_EPnTxSelect(USB_MODULE_ID index, uint8_t epValue, USB_EP_TXRX epTxRx);
```

Returns

None.

Description

This function selects transmit capabilities of an endpoint.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EPnTxSelect(MY_USB_INSTANCE, someEP, USB_EP_TX);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
epTxRx	Transmit/Receive setting for endpoint: USB_EP_TX, USB_EP_NOTXRX

Function

void PLIB_USB_EPnTxSelect (USB_MODULE_ID index, uint8_t epValue, USB_EP_TXRX epTxRx)

d) Interrupts Functions

PLIB_USB_InterruptDisable Function

Disables a general interrupt for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_InterruptDisable(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function disables a general interrupt source for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_InterruptDisable( MY_USB_INSTANCE, USB_INT_ERROR );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_InterruptDisable(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag)

PLIB_USB_InterruptEnable Function

Enables a general interrupt for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_InterruptEnable(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function enables general interrupt sources of the USB module to trigger a USB interrupt.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_InterruptEnable( MY_USB_INSTANCE, USB_INT_ERROR );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_InterruptEnable(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag)

PLIB_USB_InterruptEnableGet Function

Returns the enable/disable status of general USB module interrupts

File

plib_usb.h

C

```
USB_INTERRUPTS PLIB_USB_InterruptEnableGet(USB_MODULE_ID index);
```

Returns

A bit map containing status of enabled interrupts.

Description

Returns the enable/disable status of general USB module interrupts

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
USB_INTERRUPTS enabledInterrupts;
enabledInterrupts = PLIB_USB_InterruptEnableGet( MY_USB_INSTANCE);
if(enabledInterrupts|USB_INT_ATTACH)
{
    // This means Attach interrupt is enabled.
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USB_INTERRUPTS PLIB_USB_InterruptEnableGet(USB_MODULE_ID index)

PLIB_USB_InterruptFlagAllGet Function

Returns a logically ORed bit map of active general USB interrupt flags.

File

plib_usb.h

C

```
USB_INTERRUPTS PLIB_USB_InterruptFlagAllGet(USB_MODULE_ID index);
```

Returns

Returns a logically ORed bit map of active general USB interrupt flags.

Description

This function returns a logically ORed bit map of active general USB interrupt flags.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
USB_INTERRUPTS interruptEnables;

interruptEnables = PLIB_USB_InterruptFlagAllGet(MY_USB_INSTANCE);
if(interruptEnables | USB_INT_DEVICE_RESET)
{
    // Device received reset signaling
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USB_INTERRUPTS PLIB_USB_InterruptFlagAllGet(USB_MODULE_ID index);

PLIB_USB_InterruptFlagClear Function

Clears a general interrupt flag for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_InterruptFlagClear(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function clears a general interrupt source flag for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_InterruptFlagClear( MY_USB_INSTANCE, USB_INT_ERROR );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_InterruptFlagClear(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag)

PLIB_USB_InterruptFlagGet Function

Tests a general interrupt flag for the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_InterruptFlagGet(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function tests a general interrupt source flag for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if ( PLIB_USB_InterruptFlagGet(MY_USB_INSTANCE,USB_INT_ANY) )
    if ( PLIB_USB_InterruptFlagGet(MY_USB_INSTANCE,USB_INT_ERROR) )
    {
        PLIB_USB_InterruptFlagClear(MY_USB_INSTANCE,USB_INT_ERROR);
        // Error clean up
    }
    if ( PLIB_USB_InterruptFlagGet(MY_USB_INSTANCE,USB_INT_HOST_DETACH) )
    {
        PLIB_USB_InterruptFlagClear(MY_USB_INSTANCE,USB_INT_HOST_DETACH);
        // Device detached clean up
    }
```

```
        .
        .
        .
    }
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

bool PLIB_USB_InterruptFlagGet(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag)

PLIB_USB_InterruptFlagSet Function

Sets a general interrupt flag for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_InterruptFlagSet(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function sets a general interrupt source flag for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_InterruptFlagSet( MY_USB_INSTANCE, USB_INT_ERROR );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_InterruptFlagSet(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag)

PLIB_USB_InterruptIsEnabled Function

Returns true if interrupts are enabled.

File

plib_usb.h

C

```
bool PLIB_USB_InterruptIsEnabled(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag);
```

Returns

- true - Interrupts are enabled
- false - Interrupts are not enabled

Description

This function returns true if interrupts are enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if ( PLIB_USB_InterruptIsEnabled( MY_USB_INSTANCE, USB_INT_ERROR ) )
{

}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

bool PLIB_USB_InterruptIsEnabled(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag)

e) Error Interrupts Functions

PLIB_USB_ErrorInterruptDisable Function

Disables an error interrupt for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_ErrorInterruptDisable(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function disables an error interrupt source for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsERR_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_ErrorInterruptDisable( MY_USB_INSTANCE, USB_ERR_INT_BAD_CRC16 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_ErrorInterruptDisable(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag)

PLIB_USB_ErrorInterruptEnable Function

Enables an error interrupt for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_ErrorInterruptEnable(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function enables error interrupt sources of the USB module to trigger a USB interrupt.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsERR_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_ErrorInterruptEnable( MY_USB_INSTANCE, USB_ERR_INT_BAD_CRC16 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_ErrorInterruptEnable(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag)

PLIB_USB_ErrorInterruptFlagAllGet Function

Returns a logically ORed bit map of active error interrupt flags.

File

plib_usb.h

C

```
USB_ERROR_INTERRUPTS PLIB_USB_ErrorInterruptFlagAllGet(USB_MODULE_ID index);
```

Returns

Returns a logically ORed bit map of active error interrupt flags.

Description

This function returns a logically ORed bit map of active error interrupt flags.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsERR_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
USB_ERROR_INTERRUPTS errorInterruptEnables;

errorInterruptEnables = PLIB_USB_ErrorInterruptFlagAllGet(MY_USB_INSTANCE);
```

```
if(errorInterruptEnables | USB_ERR_INT_DEVICE_EOF_ERROR)
{
    // End of frame error occurred.
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USB_ERROR_INTERRUPTS PLIB_USB_ErrorInterruptFlagAllGet(USB_MODULE_ID index);

PLIB_USB_ErrorInterruptFlagClear Function

Clears an error interrupt flag for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_ErrorInterruptFlagClear(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function clears an error interrupt source flag for the USB module.

Remarks

None.

Preconditions

None.

Example

```
PLIB_USB_ErrorInterruptFlagClear( MY_USB_INSTANCE, USB_ERR_INT_BAD_CRC16 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_ErrorInterruptFlagClear(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag)

PLIB_USB_ErrorInterruptFlagGet Function

Tests an error interrupt flag for the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ErrorInterruptFlagGet(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function tests an error interrupt source flag for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsERR_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if ( PLIB_USB_ErrorInterruptFlagGet(MY_USB_INSTANCE,USB_ERR_INT_ANY) )
    if ( PLIB_USB_ErrorInterruptFlagGet(MY_USB_INSTANCE,USB_ERR_INT_PID_CHECK_FAILURE) )
    {
        PLIB_USB_ErrorInterruptFlagClear(MY_USB_INSTANCE,USB_ERR_INT_PID_CHECK_FAILURE);
        // PID Error Check failure cleanup
    }
    if ( PLIB_USB_ErrorInterruptFlagGet(MY_USB_INSTANCE,USB_ERR_INT_DEVICE_EOF_ERROR) )
    {
        PLIB_USB_ErrorInterruptFlagClear(MY_USB_INSTANCE,USB_ERR_INT_DEVICE_EOF_ERROR);
        // EOF error cleanup
    }
    .
    .
    .
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

bool PLIB_USB_ErrorInterruptFlagGet(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag)

PLIB_USB_ErrorInterruptFlagSet Function

Sets an error interrupt flag for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_ErrorInterruptFlagSet(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function sets an error interrupt source flag for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsERR_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_ErrorInterruptFlagSet( MY_USB_INSTANCE, USB_ERR_INT_BAD_CRC16 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_ErrorInterruptFlagSet(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag)

PLIB_USB_ErrorInterruptIsEnabled Function

Returns true if interrupts are enabled.

File

plib_usb.h

C

```
bool PLIB_USB_ErrorInterruptIsEnabled(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag);
```

Returns

- true - Interrupts are enabled
- false - Interrupts are not enabled

Description

This function determines whether interrupts are enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsERR_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if ( PLIB_USB_ErrorInterruptIsEnabled( MY_USB_INSTANCE, USB_ERR_INT_BAD_CRC16 ) )
{

}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

bool PLIB_USB_ErrorInterruptIsEnabled(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag)

f) Last Transaction Status Functions

PLIB_USB_LastTransactionDetailsGet Function

Returns the details of the last completed transaction.

File

plib_usb.h

C

```
void PLIB_USB_LastTransactionDetailsGet(USB_MODULE_ID index, USB_BUFFER_DIRECTION * direction,
USB_PING_PONG_STATE * pingpong, uint8_t * endpoint);
```

Returns

None.

Description

This function returns the details of the last completed transaction.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsLastTransactionDetails in your application to determine whether this feature is available.

Preconditions

None.

Example

```
USB_BUFFER_DIRECTION direction;
USB_PING_PONG_STATE pingpong;
uint8_t endpoint;

interruptEnables = PLIB_USB_InterruptFlagAllGet(MY_USB_INSTANCE);
if(interruptEnables | USB_INT_TOKEN_DONE)
{
    // Find out details of the token
    PLIB_USB_LastTransactionDetailsGet(MY_USB_INSTANCE, &direction,
                                       &pingpong, &endpoint);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
direction	Return value contains direction of the last transfer
pingpong	Return value contains Ping-Pong indication of the the last transfer
endpoint	Return value contains the endpoint which processed the last transfer

Function

void PLIB_USB_LastTransactionDetailsGet(USB_MODULE_ID index,

USB_BUFFER_DIRECTION * direction,

USB_PING_PONG_STATE * pingpong,

uint8_t * endpoint);

PLIB_USB_LastTransactionDirectionGet Function

Indicates the direction of the last transaction.

File

plib_usb.h

C

```
USB_BUFFER_DIRECTION PLIB_USB_LastTransactionDirectionGet(USB_MODULE_ID index);
```

Returns

USB_LastDirection: USB_RECEIVE_TRANSFER or USB_TRANSMIT_TRANSFER

Description

This function indicates the direction of the last transaction, either transmit or receive.

Remarks

None.

Preconditions

None.

Example

See PLIB_USB_LastTransactionEndPtGet.

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USB_BUFFER_DIRECTION PLIB_USB_LastTransactionDirectionGet (USB_MODULE_ID index)

PLIB_USB_LastTransactionEndPtGet Function

Returns the endpoint number of the last USB transfer.

File

plib_usb.h

C

```
uint8_t PLIB_USB_LastTransactionEndPtGet(USB_MODULE_ID index);
```

Returns

endPoint - Endpoint of last completed USB transfer

Description

This function returns the endpoint number of the last USB transfer, which is actually the index into the Buffer Descriptor Table of the last USB transfer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsLastDirection in your application to determine whether this feature is available.

Preconditions

None.

Example

```
while ( !PLIB_USB_INT_FlagGet(MY_USB_INSTANCE,USB_INT_GEN,TOKEN_DONE) )
{
    // Do nothing, wait until completion of next transaction
}

// Retrieve information relating to the last completed transaction
endpoint  = PLIB_USB_LastTransactionEndPtGet(MY_USB_INSTANCE);
direction = PLIB_USB_LastTransactionDirectionGet(MY_USB_INSTANCE);
pingPongState = PLIB_USB_LastTransactionPingPongStateGet(MY_USB_INSTANCE);

// Clearing the Token Processing Done flag advances the status FIFO to
// oldest transaction in the FIFO.  Wait for completion of next transaction
// before using PLIB_USB_Last*Get functions again to read status.
PLIB_USB_INT_FlagClear(MY_USB_INSTANCE,USB_INT_GEN,TOKEN_DONE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

uint8_t PLIB_USB_LastTransactionEndPtGet (USB_MODULE_ID index)

PLIB_USB_LastTransactionPingPongStateGet Function

Indicates whether the last transaction was to an EVEN buffer or an ODD buffer.

File

plib_usb.h

C

```
USB_PING_PONG_STATE PLIB_USB_LastTransactionPingPongStateGet(USB_MODULE_ID index);
```

Returns

USB_PING_PONG_STATE.

Description

This function indicates whether the last transaction was to an Even buffer or an Odd buffer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsLastPingPong in your application to determine whether this feature is available.

Preconditions

None.

Example

See PLIB_USB_LastTransactionEndPtGet.

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USB_PING_PONG_STATE PLIB_USB_LastTransactionPingPongStateGet (USB_MODULE_ID index)

g) Host Functions

PLIB_USB_IsBusyWithToken Function

Indicates whether there is a token being executed by the USB module as Host.

File

plib_usb.h

C

```
bool PLIB_USB_IsBusyWithToken(USB_MODULE_ID index);
```

Returns

None.

Description

This function indicates whether there is a token being executed by the USB module as Host. Software should check that the previous token is finished before issuing a new token.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsHostBusyWithToken in your application to determine whether this feature is available.

Preconditions

USB module must be in Host mode.

Example

```
while( PLIB_USB_IsBusyWithToken(MY_USB_INSTANCE) )
{
    // do nothing
}
// Issue new token
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_IsBusyWithToken (USB_MODULE_ID index)

PLIB_USB_SOFDisable Function

Disables the automatic generation of the SOF token.

File

plib_usb.h

C

```
void PLIB_USB_SOFDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the automatic generation of the SOF token.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsStartOfFrames in your application to determine whether this feature is available.

Preconditions

USB module must be in Host mode.

Example

```
PLIB_USB_SOFDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_SOFDisable (USB_MODULE_ID index)

PLIB_USB_SOFEnable Function

Enables the automatic generation of the SOF token every 1 ms.

File

plib_usb.h

C

```
void PLIB_USB_SOFEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the automatic generation of the SOF token every 1 ms.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsStartOfFrames in your application to determine whether this feature is available.

Preconditions

USB module must be in Host mode.

Example

```
PLIB_USB_SOFEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_SOFEnable (USB_MODULE_ID index)

PLIB_USB_SOFThresholdGet Function

Returns the Start-of-Frame (SOF) Count bits.

File

plib_usb.h

C

```
uint8_t PLIB_USB_SOFThresholdGet(USB_MODULE_ID index);
```

Returns

SOF threshold value.

Description

This function returns the Start-of-Frame (SOF) Count bits. (Value represents 10 + (packet size of n bytes);).

Remarks

Host mode only.

```
    SOF Threshold Value = packet byte count + 10
                        = 0b0100_1010 = 0x4A = 74 for 64-byte packet
                        = 0b0010_1010 = 0x2A = 42 for 32-byte packet
                        = 0b0001_1010 = 0x1A = 26 for 16-byte packet
                        = 0x0001_0010 = 0x12 = 18 for  8-byte packet
```

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsSOFThreshold in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
  thresholdSOF = PLIB_USB_SOFThresholdGet(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

uint8_t PLIB_USB_SOFThresholdGet (USB_MODULE_ID index)

PLIB_USB_SOFThresholdSet Function

Sets the Start-of-Frame (SOF) threshold value.

File

plib_usb.h

C

```
void PLIB_USB_SOFThresholdSet(USB_MODULE_ID index, uint8_t threshold);
```

Returns

None.

Description

This function sets the Start-of-Frame (SOF) threshold value.

Remarks

Host mode only.

```
    SOF Threshold Value = packet byte count + 10
                        = 0b0100_1010 = 0x4A = 74 for 64-byte packet
                        = 0b0010_1010 = 0x2A = 42 for 32-byte packet
                        = 0b0001_1010 = 0x1A = 26 for 16-byte packet
                        = 0x0001_0010 = 0x12 = 18 for  8-byte packet
```

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsSOFThreshold in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
// Set SOF threshold for 64-byte packets
PLIB_USB_SOFThresholdSet(MY_USB_INSTANCE,64+10);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
threshold	SOF threshold

Function

void PLIB_USB_SOFThresholdSet (USB_MODULE_ID index, uint8_t threshold)

PLIB_USB_TokenEPGet Function

Returns the specified Endpoint address.

File

plib_usb.h

C

```
uint8_t PLIB_USB_TokenEPGet(USB_MODULE_ID index);
```

Returns

Endpoint value - 0 <= epValue <= Module Maximum Endpoint.

Description

This function returns the address of the specified Endpoint.

Remarks

Host mode only.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsTokenEP in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
someEP = PLIB_USB_TokenEPGet(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

uint8_t PLIB_USB_TokenEPGet (USB_MODULE_ID index)

PLIB_USB_TokenEPSet Function

Sets the Endpoint address for a host transaction.

File

plib_usb.h

C

```
void PLIB_USB_TokenEPSet(USB_MODULE_ID index, uint8_t epValue);
```

Returns

None.

Description

This function sets the Endpoint address for a host transaction.

Remarks

Host mode only. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsTokenEP in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
uint8_t someEP = 0x03;
PLIB_USB_TokenEPSet(MY_USB_INSTANCE, someEP);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint

Function

void PLIB_USB_TokenEPSet (USB_MODULE_ID index, uint8_t epValue)

PLIB_USB_TokenPIDGet Function

Returns the token transaction type.

File

plib_usb.h

C

```
USB_PID PLIB_USB_TokenPIDGet(USB_MODULE_ID index);
```

Returns

Packet ID of token, USB_PID_SETUP, USB_PID_IN, or USB_PID_OUT

Description

This function returns the token transaction type.

Remarks

Host mode only. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsTokenPID in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
somePID = PLIB_USB_TokenPIDGet(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USB_PID PLIB_USB_TokenPIDGet (USB_MODULE_ID index)

PLIB_USB_TokenPIDSet Function

Sets the token transaction type to pidValue.

File

plib_usb.h

C

```
void PLIB_USB_TokenPIDSet(USB_MODULE_ID index, USB_PID pidValue);
```

Returns

None.

Description

This function sets the token transaction type to pidValue.

Remarks

Host mode only. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsTokenPID in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
somePID = USB_PID_SETUP;
PLIB_USB_TokenPIDSet (MY_USB_INSTANCE, somePID );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
pidValue	USB_PID_SETUP, USB_PID_IN, or USB_PID_OUT

Function

void PLIB_USB_TokenPIDSet (USB_MODULE_ID index, USB_PID pidValue)

PLIB_USB_TokenSpeedSelect Function

Selects low speed or full speed for subsequent token executions.

File

plib_usb.h

C

```
void PLIB_USB_TokenSpeedSelect(USB_MODULE_ID index, USB_TOKEN_SPEED tokenSpeed);
```

Returns

None.

Description

This function selects low speed or full speed for subsequent token executions.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsNextTokenSpeed in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
PLIB_USB_TokenSpeedSet(MY_USB_INSTANCE,USB_LOWSPEED_TOKENS);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
tokenSpeed	Speed for next token execution: USB_LOWSPEED_TOKENS or USB_FULLSPEED_TOKENS

Function

void PLIB_USB_TokenSpeedSelect (USB_MODULE_ID index, USB_TOKEN_SPEED tokenSpeed)

h) USB Bus Signaling Functions

PLIB_USB_ResetSignalDisable Function

Disables reset signaling on the USB bus.

File

plib_usb.h

C

```
void PLIB_USB_ResetSignalDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables reset signaling on the USB bus.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsHostGeneratesReset in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

See PLIB_USB_ResetSignalEnable.

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_ResetSignalDisable (USB_MODULE_ID index)

PLIB_USB_ResetSignalEnable Function

Enables reset signaling on the USB bus.

File

plib_usb.h

C

```
void PLIB_USB_ResetSignalEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables reset signaling on the USB bus.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsHostGeneratesReset in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
// Snippet to perform a software reset:
PLIB_USB_ResetSignalEnable(MY_USB_INSTANCE);
// ... delay 50ms
PLIB_USB_ResetSignalDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_ResetSignalEnable (USB_MODULE_ID index)

PLIB_USB_ResumeSignalingDisable Function

Disables resume signaling.

File

plib_usb.h

C

```
void PLIB_USB_ResumeSignalingDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables resume signaling.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsResumeSignaling in your application to determine whether this feature is available.

Preconditions

None.

Example

See PLIB_USB_ResumeSignalingEnable.

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_ResumeSignalingDisable (USB_MODULE_ID index)

PLIB_USB_ResumeSignalingEnable Function

Enables resume signaling.

File

plib_usb.h

C

```
void PLIB_USB_ResumeSignalingEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables resume signaling. Resume allows the peripheral to perform a remote wake-up by executing resume signaling.

Remarks

Software must enable resume signaling for 10 ms if the device is in Device mode, or for 25 ms if the device is in Host mode, and then disable resume signaling to enable remote wake-up. In Host mode, the USB module will append a low-speed EOP to the end resume signaling when it is disabled. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsResumeSignaling in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Perform resume signaling:
PLIB_USB_ResumeSignalingEnable(MY_USB_INSTANCE);
// Delay 10ms
PLIB_USB_ResumeSignalingDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_ResumeSignalingEnable (USB_MODULE_ID index)

i) On-The-Go (OTG) Functions

PLIB_USB_OTG_BSessionHasEnded Function

Returns the status of the B-Session End Indicator bit.

File

plib_usb.h

C

```
bool PLIB_USB_OTG_BSessionHasEnded(USB_MODULE_ID index);
```

Returns

- true - The VBUS Voltage is below VB_SESS_END on the B-device
- false - The VBUS voltage is above VB_SESS_END on the B-device

Description

This function returns the status of the B-Session End Indicator bit.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_BSessionEnd in your application to determine whether this feature is available.

Preconditions

The USB module must be in OTG mode.

Example

```
if ( !PLIB_USB_OTG_BSessionHasEnded(MY_USB_INSTANCE) )
{
    // B session valid
}
else
{
    // B session not valid
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_OTG_BSessionHasEnded (USB_MODULE_ID index)

PLIB_USB_OTG_IDPinStateIsTypeA Function

Returns the ID Pin state.

File

plib_usb.h

C

```
bool PLIB_USB_OTG_IDPinStateIsTypeA(USB_MODULE_ID index);
```

Returns

- true - Type A Cable attached,
- false - No cable is attached or a Type B cable is attached

Description

This function returns ID Pin state.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_IDPinState in your application to determine whether this feature is available.

Preconditions

The USB module must be in OTG mode.

Example

```
if ( PLIB_USB_OTG_IDPinStateIsTypeA(MY_USB_INSTANCE) )
{
    // Type A cable attached
}
else
{
    // No cable or Type B cable attached
};
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_OTG_IDPinStateIsTypeA (USB_MODULE_ID index)

PLIB_USB_OTG_LineStateIsStable Function

Returns the status of the Line Stable Indicator bit.

File

plib_usb.h

C

```
bool PLIB_USB_OTG_LineStateIsStable(USB_MODULE_ID index);
```

Returns

- true - The USB line state has been stable for the previous 1 ms
- false - The USB line state has not been stable for the previous 1 ms

Description

This function returns the status of the Line Stable Indicator bit.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_LineState in your application to determine whether this feature is available.

Preconditions

The USB module must be in OTG mode.

Example

```
if( PLIB_USB_OTG_LineStateIsStable(MY_USB_INSTANCE) ) {
    // Line has been stable
    // ... rest of code ...
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_OTG_LineStateIsStable (USB_MODULE_ID index)

PLIB_USB_OTG_PullUpPullDownSetup Function

Enables or disables pull-up and pull-down resistors.

File

plib_usb.h

C

```
void PLIB_USB_OTG_PullUpPullDownSetup(USB_MODULE_ID index, USB_OTG_PULL_UP_PULL_DOWN resistor, bool
enableResistor);
```

Returns

None.

Description

This function enables or disables pull-up and pull-down resistors.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_PullUpPullDown in your application to determine whether this feature is available.

Preconditions

USB On-The-Go (OTG) must be enabled.

Example

```
// Enable pull-up resistor for D+
PLIB_USB_OTG_PullUpPullDownSetup(MY_USB_INSTANCE,USB_OTG_DPLUS_PULLUP,true);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
resistor	USB_OTG_DPLUS_PULLUP, USB_OTG_DMINUS_PULLUP, USB_OTG_DPLUS_PULLDN, or USB_OTG_DMINUS_PULLDN
enableResistor	true to enable resistor, false to disable it

Function

void PLIB_USB_OTG_PullUpPullDownSetup(USB_MODULE_ID index,
USB_OTG_PULL_UP_PULL_DOWN resistor,
bool enableResistor)

PLIB_USB_OTG_SessionValid Function

Returns the status of the Session Valid Indicator bit.

File

plib_usb.h

C

```
bool PLIB_USB_OTG_SessionValid(USB_MODULE_ID index);
```

Returns

- true - The VBUS voltage is above Session Valid on the A or B device
- false - The VBUS voltage is below Session Valid on the A or B device

Description

This function returns the status of the Session Valid Indicator bit.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_SessionValid in your application to determine whether this feature is available.

Preconditions

The USB module must be in OTG mode.

Example

```
if ( PLIB_USB_OTG_SessionValid(MY_USB_INSTANCE) )
{
    // Session valid
}
else
{
    // Session not valid
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_OTG_SessionValid (USB_MODULE_ID index)

PLIB_USB_OTG_VBusChargeDisable Function

Disables VBUS line charge.

File

plib_usb.h

C

```
void PLIB_USB_OTG_VBusChargeDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables VBUS line charge.

Remarks

Not available on PIC32 devices. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_VbusCharge in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_VBusChargeDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OTG_VBusChargeDisable (USB_MODULE_ID index)

PLIB_USB_OTG_VBusChargeEnable Function

Enables the VBUS line to be charged through a pull-up resistor.

File

plib_usb.h

C

```
void PLIB_USB_OTG_VBusChargeEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the VBUS line to be charged through a pull-up resistor.

Remarks

Not available on PIC32 devices. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_VbusDischarge in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_VBusChargeEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OTG_VBusChargeEnable (USB_MODULE_ID index)

PLIB_USB_OTG_VBusChargeTo3V Function

Sets the VBUS line to charge to 3.3V.

File

plib_usb.h

C

```
void PLIB_USB_OTG_VBusChargeTo3V(USB_MODULE_ID index);
```

Returns

None.

Description

This function sets the VBUS line to charge to 3.3V.

Remarks

Not available on PIC32 devices.

Preconditions

None.

Example

```
PLIB_USB_OTG_VBusChargeTo3V(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OTG_VBusChargeTo3V(USB_MODULE_ID index)

PLIB_USB_OTG_VBusChargeTo5V Function

Sets the VBUS line to charge to 5V.

File

plib_usb.h

C

```
void PLIB_USB_OTG_VBusChargeTo5V(USB_MODULE_ID index);
```

Returns

None.

Description

This function sets the VBUS line to charge to 5V.

Remarks

Not available on PIC32 devices.

Preconditions

None.

Example

```
PLIB_USB_OTG_VBusChargeTo5V (MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OTG_VBusChargeTo5V (USB_MODULE_ID index)

PLIB_USB_OTG_VBusDischargeDisable Function

Disables VBUS line discharge.

File

plib_usb.h

C

```
void PLIB_USB_OTG_VBusDischargeDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables VBUS line discharge.

Remarks

Not available on PIC32 devices. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_VbusDischarge in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_VBusDischargeDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OTG_VBusDischargeDisable (USB_MODULE_ID index)

PLIB_USB_OTG_VBusDischargeEnable Function

Enables VBUS line to be discharged through a resistor.

File

plib_usb.h

C

```
void PLIB_USB_OTG_VBusDischargeEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the VBUS line to be discharged through a resistor.

Remarks

Not available on PIC32 devices. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_VbusCharge in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_VBusDischargeEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OTG_VBusDischargeEnable (USB_MODULE_ID index)

PLIB_USB_OTG_VBusPowerOff Function

Turns off power on the VBUS Line.

File

plib_usb.h

C

```
void PLIB_USB_OTG_VBusPowerOff(USB_MODULE_ID index);
```

Returns

None.

Description

This function turns off power on the VBUS Line.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_VbusPowerOnOff in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_VBusPowerOff(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OTG_VBusPowerOff (USB_MODULE_ID index)

PLIB_USB_OTG_VBusPowerOn Function

Turns on power for the VBUS line.

File

plib_usb.h

C

```
void PLIB_USB_OTG_VBusPowerOn(USB_MODULE_ID index);
```

Returns

None.

Description

This function turns on power for the VBUS line.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_VbusPowerOnOff in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_VBusPowerOn(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OTG_VBusPowerOn (USB_MODULE_ID index)

PLIB_USB_OTG_VBusValid Function

Returns the status of the A-VBUS valid indicator.

File

plib_usb.h

C

```
bool PLIB_USB_OTG_VBusValid(USB_MODULE_ID index);
```

Returns

- true - The VBUS voltage is above VA_VBUS_VLD on the A-device,
- false - The VBUS voltage is below VA_VBUS_VLD on the A-device

Description

This function returns the status of the A-VBUS valid indicator.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_ASessionValid in your application to determine whether this feature is available.

Preconditions

The USB module must be in OTG mode.

Example

```
if ( PLIB_USB_OTG_VBusValid(MY_USB_INSTANCE) )
{
    // VBUS voltage above session valid for A device
}
else
{
    // VBUS voltage below session valid for A device
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_OTG_VBusValid (USB_MODULE_ID index)

j) OTG Interrupts Functions

PLIB_USB_OTG_InterruptDisable Function

Disables a USB On-The-Go (OTG) Interrupt for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_OTG_InterruptDisable(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function disables a USB On-The-Go (OTG) interrupt source for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_InterruptDisable( MY_USB_INSTANCE, USB_OTG_INT_ID_STATE_CHANGE );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_OTG_InterruptDisable(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag)

PLIB_USB_OTG_InterruptEnable Function

Enables a USB On-The-Go (OTG) Interrupt for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_OTG_InterruptEnable(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function enables USB On-The-Go (OTG) interrupt sources of the USB module to trigger a USB interrupt.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_InterruptEnable( MY_USB_INSTANCE, USB_OTG_INT_ID_STATE_CHANGE );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_OTG_InterruptEnable(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag)

PLIB_USB_OTG_InterruptFlagClear Function

Clears a USB On-The-Go (OTG) Interrupt flag for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_OTG_InterruptFlagClear(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function clears a USB On-The-Go (OTG) interrupt source flag for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_InterruptFlagClear( MY_USB_INSTANCE, USB_OTG_INT_ID_STATE_CHANGE );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_OTG_InterruptFlagClear(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag)

PLIB_USB_OTG_InterruptFlagGet Function

Tests a USB On-The-Go (OTG) Interrupt flag for the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_OTG_InterruptFlagGet(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function tests a USB On-The-Go (OTG) interrupt source flag for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if ( PLIB_USB_OTG_InterruptFlagGet(MY_USB_INSTANCE,USB_OTG_INT_ANY) )
    if ( PLIB_USB_OTG_InterruptFlagGet(MY_USB_INSTANCE,USB_OTG_INT_BDEVICE_SESSION_END) )
    {
        PLIB_USB_OTG_InterruptFlagClear(MY_USB_INSTANCE,USB_OTG_INT_ADEVICE_VBUS_VALID );
        // Device A VBUS Valid Change
    }
    if ( PLIB_USB_OTG_InterruptFlagGet(MY_USB_INSTANCE,USB_OTG_INT_BDEVICE_SESSION_END) )
    {
        PLIB_USB_OTG_InterruptFlagClear(MY_USB_INSTANCE,USB_OTG_INT_BDEVICE_SESSION_END);
        // Device B VBUS Valid Change
    }
    .
    .
    .
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

bool PLIB_USB_OTG_InterruptFlagGet(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag)

PLIB_USB_OTG_InterruptFlagSet Function

Sets a USB On-The-Go (OTG) Interrupt flag for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_OTG_InterruptFlagSet(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function sets a USB On-The-Go (OTG) interrupt source flag for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_InterruptFlagSet( MY_USB_INSTANCE, USB_OTG_INT_ID_STATE_CHANGE );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_OTG_InterruptFlagSet(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag)

PLIB_USB_OTG_InterruptIsEnabled Function

Returns whether or not interrupts are enabled.

File

plib_usb.h

C

```
bool PLIB_USB_OTG_InterruptIsEnabled(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag);
```

Returns

- true - Interrupts are enabled
- false - Interrupts are not enabled

Description

This function returns whether or not interrupts are enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if ( PLIB_USB_OTG_InterruptIsEnabled( MY_USB_INSTANCE, USB_OTG_INT_ID_STATE_CHANGE  ) )
{

}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

bool PLIB_USB_OTG_InterruptIsEnabled(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag)

k) USB Activity Functions

PLIB_USB_ActivityPending Function

Returns whether or not USB activity is pending.

File

plib_usb.h

C

```
bool PLIB_USB_ActivityPending(USB_MODULE_ID index);
```

Returns

- true - The USB module should not be suspended
- false - No interrupts are pending or module may be suspended or powered down

Description

This function returns whether or not USB bus activity has been detected, an interrupt is pending, or an interrupt is yet to be generated.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsActivityPending in your application to determine whether this feature is available.

Preconditions

None.

Example

```
while ( PLIB_USB_ActivityPending(MY_USB_INSTANCE) )
{
    // Wait
}
// Suspend USB module.
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_ActivityPending (USB_MODULE_ID index)

PLIB_USB_FrameNumberGet Function

Returns the USB frame number.

File

plib_usb.h

C

```
uint16_t PLIB_USB_FrameNumberGet(USB_MODULE_ID index);
```

Returns

Current frame number in lower 11 bits.

Description

This function returns the USB frame number in the lower 11 bits.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsFrameNumber in your application to determine whether this feature is available.

Preconditions

None.

Example

```
frameNumber = PLIB_USB_FrameNumberGet(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

uint16_t PLIB_USB_FrameNumberGet (USB_MODULE_ID index)

PLIB_USB_JStateIsActive Function

Live differential receiver J State flag.

File

plib_usb.h

C

```
bool PLIB_USB_JStateIsActive(USB_MODULE_ID index);
```

Returns

None.

Description

This function indicates the live JState (differential '0' in low speed, differential '1' in full speed) on the bus.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsLiveJState in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
// Enable Host Mode
PLIB_USB_OperatingModeSelect(MY_USB_INSTANCE,USB_OPMODE_HOST);

// Enable D+ and D- pull-down resistors
PLIB_USB_OTG_PullUpPullDownSetup(MY_USB_INSTANCE,USB_OTG_DPLUS_PULLDN, true);
PLIB_USB_OTG_PullUpPullDownSetup(MY_USB_INSTANCE,USB_OTG_DMINUS_PULLDN,true);

// Disable D+ and D- pull-up resistors
PLIB_USB_OTG_PullUpPullDownSetup(MY_USB_INSTANCE,USB_OTG_DPLUS_PULLUP, false);
PLIB_USB_OTG_PullUpPullDownSetup(MY_USB_INSTANCE,USB_OTG_DMINUS_PULLUP,false);

// Enable SOF Packet generation
PLIB_USB_SOFEnable(MY_USB_INSTANCE);

// Enable the device attach interrupt
PLIB_USB_INT_Enable(MY_USB_INSTANCE,USB_INT_OTG,ACTIVITY_DETECT);

// Wait for the Attach interrupt.
while(!PLIB_USB_INT_FlagGet(MY_USB_INSTANCE,USB_INT_OTG,ACTIVITY_DETECT) )
{
    //Do nothing
}

// Check JState
if( PLIB_USB_JStateIsActive(MY_USB_INSTANCE) )
{
    // Full Speed
    PLIB_USB_FullSpeedEnable(MY_USB_INSTANCE);
}
else
{
    // Low Speed
    PLIB_USB_FullSpeedDisable(MY_USB_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_JStateIsActive (USB_MODULE_ID index)

PLIB_USB_PacketTransferDisable Function

Disables the Serial Interface Engine (SIE).

File

plib_usb.h

C

```
void PLIB_USB_PacketTransferDisable(USB_MODULE_ID index);
```

Returns

None.

```
  if( PLIB_USB_PacketTransferIsDisabled(MY_USB_INSTANCE) )
  {
      // SETUP token received, do the needful operations
      .
      .
      .
      // SETUP handling completed, enable Setup token and packet processing:
      PLIB_USB_PacketTransferDisable(MY_USB_INSTANCE);
  }
```

Description

This function disables the Serial Interface Engine (SIE).

Remarks

Not valid when the USB module is in Host mode. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsPacketTransfer in your application to determine whether this feature is available.

Preconditions

USB module must be in device mode.

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PacketTransferDisable (USB_MODULE_ID index)

PLIB_USB_PacketTransferEnable Function

Re-enables the Serial Interface Engine (SIE), allowing token and packet processing.

File

plib_usb.h

C

```
void PLIB_USB_PacketTransferEnable(USB_MODULE_ID index);
```

Returns

None.

```
  if( PLIB_USB_PacketTransferIsDisabled(MY_USB_INSTANCE) )
  {
      // SETUP token received, do the needful operations
      .
      .
      .
      // SETUP handling completed, enable Setup token and packet processing:
      PLIB_USB_PacketTransferEnable(MY_USB_INSTANCE);
  }
```

Description

This function re-enables the Serial Interface Engine (SIE), allowing token and packet processing.

Remarks

Not valid when the USB module is in Host mode. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsPacketTransfer in your application to determine whether this feature is available.

Preconditions

USB module must be in device mode.

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PacketTransferEnable (USB_MODULE_ID index)

PLIB_USB_PacketTransferIsDisabled Function

Indicates that a setup token has been received from the Host and that token/packet processing is disabled.

File

plib_usb.h

C

```
bool PLIB_USB_PacketTransferIsDisabled(USB_MODULE_ID index);
```

Returns

None.

Description

This function indicates that a setup token has been received from the Host and that the Serial Interface Engine (SIE) has been turned off, disabling token and packet processing.

Remarks

Not valid when USB is Host. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsPacketTransfer in your application to determine whether this feature is available.

Preconditions

USB module must be in device mode.

Example

```
if( PLIB_USB_PacketTransferIsDisabled(MY_USB_INSTANCE) )
{
    // SETUP token received, do the needful operations
    .
    .
    .
    // SETUP handling completed, enable Setup token and packet processing:
    PLIB_USB_PacketTransferEnable(MY_USB_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_PacketTransferIsDisabled (USB_MODULE_ID index)

PLIB_USB_SE0InProgress Function

Returns whether a single-ended zero event is in progress.

File

plib_usb.h

C

```
bool PLIB_USB_SE0InProgress(USB_MODULE_ID index);
```

Returns

- true - A single ended zero event (SE0) is occurring

- false - A single-ended zero event (SE0) is not occurring

Description

This function returns whether a single-ended zero event is in progress.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsLiveSingleEndedZero in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if( PLIB_USB_SE0InProgress(MY_USB_INSTANCE) )
{
    // handle the SE0 event
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_SE0InProgress(USB_MODULE_ID index)

l) External Transceiver Support Functions

PLIB_USB_I2CInterfaceForExtModuleDisable Function

Specifies external module(s) are controlled via dedicated pins.

File

plib_usb.h

C

```
void PLIB_USB_I2CInterfaceForExtModuleDisable(USB_MODULE_ID index);
```

Returns

None.

Description

Specifies that external module(s) are controlled via dedicated pins.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_I2CInterfaceForExtModuleDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_I2CInterfaceForExtModuleDisable (USB_MODULE_ID index)

PLIB_USB_I2CInterfaceForExtModuleEnable Function

Specifies external module(s) are controlled via the I2C interface.

File

plib_usb.h

C

```
void PLIB_USB_I2CInterfaceForExtModuleEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function specifies that external module(s) are controlled via the I2C interface.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_I2CInterfaceForExtModuleEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_I2CInterfaceForExtModuleEnable (USB_MODULE_ID index)

PLIB_USB_TransceiverDisable Function

Disables the on-chip transceiver

File

plib_usb.h

C

```
void PLIB_USB_TransceiverDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the on-chip transceiver and enables the interface to the off-chip transceiver.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOnChipTransceiver in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_TransceiverDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_TransceiverDisable (USB_MODULE_ID index)

PLIB_USB_TransceiverEnable Function

Enables the on-chip transceiver.

File

plib_usb.h

C

```
void PLIB_USB_TransceiverEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the on-chip transceiver. The interface to the off-chip transceiver is disabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOnChipTransceiver in your application to determine whether this feature is available.

Preconditions

Use only before the USB module is enabled by calling PLIB_USB_Enable.

Example

```
PLIB_USB_TransceiverEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_TransceiverEnable (USB_MODULE_ID index)

m) VBUS Support Functions

PLIB_USB_ExternalComparatorMode2Pin Function

Sets the 2-pin input configuration for VBUS comparators.

File

plib_usb.h

C

```
void PLIB_USB_ExternalComparatorMode2Pin(USB_MODULE_ID index);
```

Returns

None.

Description

This function sets the 2-pin input configuration for VBUS Comparators.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_ExternalComparatorMode2Pin(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_ExternalComparatorMode2Pin (USB_MODULE_ID index)

PLIB_USB_ExternalComparatorMode3Pin Function

Sets the 3-pin input configuration for VBUS Comparators.

File

plib_usb.h

C

```
void PLIB_USB_ExternalComparatorMode3Pin(USB_MODULE_ID index);
```

Returns

None.

Description

This function sets the 3-pin input configuration for VBUS comparators.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_ExternalComparatorMode3Pin(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_ExternalComparatorMode3Pin (USB_MODULE_ID index)

PLIB_USB_PWMCounterDisable Function

Disables the PWM counter used to generate the VBUS for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_PWMCounterDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the PWM counter used to generate the VBUS for the USB module.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_PWMDisable(MY_USB_INSTANCE);
PLIB_USB_PWMCounterDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PWMCounterDisable(USB_MODULE_ID index);

PLIB_USB_PWMCounterEnable Function

Enables the PWM counter used to generate the VBUS for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_PWMCounterEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the PWM counter used to generate the VBUS for the USB module.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_PWMEnable(MY_USB_INSTANCE);
PLIB_USB_PWMCounterEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PWMCounterEnable(USB_MODULE_ID index)

PLIB_USB_PWMDisable Function

Disables the PWM Generator.

File

plib_usb.h

C

```
void PLIB_USB_PWMDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the PWM Generator. PWM output held in a reset state defined by PLIB_USB_PWMPolarityActiveHigh or PLIB_USB_PWMPolarityActiveLow.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_PWMDisable (MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PWMDisable (USB_MODULE_ID index)

PLIB_USB_PWMEnable Function

Enables the PWM Generator.

File

plib_usb.h

C

```
void PLIB_USB_PWMEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the PWM Generator.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_PWMEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PWMEnable (USB_MODULE_ID index)

PLIB_USB_PWMPolaritiyActiveLow Function

Sets the PWM output to active-high and resets low.

File

plib_usb.h

C

```
void PLIB_USB_PWMPolaritiyActiveLow(USB_MODULE_ID index);
```

Returns

None.

Description

This function sets the PWM output to active-high and resets low.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PWMPolaritiyActiveLow (USB_MODULE_ID index)

PLIB_USB_PWMPolarityActiveHigh Function

Sets the PWM output to active-low and resets high.

File

plib_usb.h

C

```
void PLIB_USB_PWMPolarityActiveHigh(USB_MODULE_ID index);
```

Returns

None.

Description

This function sets the PWM output to active-low and resets high.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_PWMPolaritiy (MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PWMPolarityActiveHigh (USB_MODULE_ID index)

PLIB_USB_VBoostDisable Function

Disables the On-Chip 5V Boost Regulator Circuit Disabled bit.

File

plib_usb.h

C

```
void PLIB_USB_VBoostDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the On-Chip 5V Boost Regulator Circuit Disabled bit.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_VBoostDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_VBoostDisable (USB_MODULE_ID index)

PLIB_USB_VBoostEnable Function

Enables the On-Chip 5V Boost Regulator Circuit Enabled bit.

File

plib_usb.h

C

```
void PLIB_USB_VBoostEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the On-Chip 5V Boost Regulator Circuit Enabled bit.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_VBoostEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_VBoostEnable (USB_MODULE_ID index)

PLIB_USB_VBUSComparatorDisable Function

Disables the on-chip VBUS Comparator.

File

plib_usb.h

C

```
void PLIB_USB_VBUSComparatorDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the on-chip VBUS Comparator.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_VBUSComparatorDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_VBUSComparatorDisable (USB_MODULE_ID index)

PLIB_USB_VBUSComparatorEnable Function

Enables the on-chip VBUS Comparator.

File

plib_usb.h

C

```
void PLIB_USB_VBUSComparatorEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the on-chip VBUS Comparator.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_VBUSComparatorEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_VBUSComparatorEnable (USB_MODULE_ID index)

PLIB_USB_VBUSPullUpDisable Function

Disables the pull-up on the VBUS pin.

File

plib_usb.h

C

```
void PLIB_USB_VBUSPullUpDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the pull-up on the VBUS pin.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_VBUSPullUpDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_VBUSPullUpDisable (USB_MODULE_ID index)

PLIB_USB_VBUSPullUpEnable Function

Enables the pull-up on the VBUS pin.

File

plib_usb.h

C

```
void PLIB_USB_VBUSPullUpEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the pull-up on the VBUS pin.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_VBUSPullUpEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_VBUSPullUpEnable (USB_MODULE_ID index)

n) Test Support Functions

PLIB_USB_EyePatternDisable Function

Disables the USB eye pattern test.

File

plib_usb.h

C

```
void PLIB_USB_EyePatternDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the USB eye pattern test.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEyePattern in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EyePatternDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_EyePatternDisable (USB_MODULE_ID index)

PLIB_USB_EyePatternEnable Function

Enables USB eye pattern test.

File

plib_usb.h

C

```
void PLIB_USB_EyePatternEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the USB eye pattern test.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEyePattern in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EyePatternEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_EyePatternEnable (USB_MODULE_ID index)

o) Other Functions

PLIB_USB_ModuleIsBusy Function

Indicates if the USB module is not ready to be enabled.

File

plib_usb.h

C

```
bool PLIB_USB_ModuleIsBusy(USB_MODULE_ID index);
```

Returns

- true - USB module is active or disabled, but not ready to be enabled
- false - USB module is not active and is ready to be enabled

Description

This function indicates if the USB module is not ready to be enabled.

Remarks

If PLIB_USB_ModuleIsBusy(MY_USB_INSTANCE) == true and the USB module is disabled, and all status returned for the module, all enables/disables for the module will produce undefined results.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsModuleBusyin your application to determine whether this feature is available.

Preconditions

None.

Example

```
#ifdef (__PIC32MX__)
  while ( PLIB_USB_ModuleIsBusy(MY_USB_INSTANCE) )
  {
      // wait
  }
#endif
  PLIB_USB_Disable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_ModuleIsBusy (USB_MODULE_ID index)

PLIB_USB_PingPongFreeze Function

Resets all Ping-Pong buffer pointers to even buffers.

File

plib_usb.h

C

```
void PLIB_USB_PingPongFreeze(USB_MODULE_ID index);
```

Returns

None.

Description

This function resets all Ping-Pong buffer pointers to even buffers.

Remarks

Buffers remain "frozen" at "Even" until they are unfrozen using PLIB_USB_PingPongUnfreeze.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBufferFreeze in your application to determine whether this feature is available.

Preconditions

None.

Example

```
  // Reset all ping-pong buffers to "Even"
  PLIB_USB_PingPongFreeze(MY_USB_INSTANCE);
  PLIB_USB_PingPongUnfreeze(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PingPongFreeze (USB_MODULE_ID index)

PLIB_USB_PingPongReset Function

Resets the USB peripheral internal Ping-Pong indicator to point to even buffers.

File

plib_usb.h

C

```
void PLIB_USB_PingPongReset(USB_MODULE_ID index);
```

Returns

None.

Description

This function resets the USB peripheral internal Ping-Pong indicator to point to Even buffers.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBufferFreeze in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_PingPongReset(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PingPongReset (USB_MODULE_ID index)

PLIB_USB_PingPongUnfreeze Function

Enables Ping-Pong buffering.

File

plib_usb.h

C

```
void PLIB_USB_PingPongUnfreeze(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables Ping-Pong buffering.

Remarks

See PLIB_USB_PingPongFreeze. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBufferFreeze in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Reset all Ping-Pong buffers to "Even"
PLIB_USB_PingPongFreeze(MY_USB_INSTANCE);
PLIB_USB_PingPongUnfreeze(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PingPongUnfreeze (USB_MODULE_ID index)

PLIB_USB_TokenSend Function

Sends token to the specified address.

File

plib_usb.h

C

```
void PLIB_USB_TokenSend(USB_MODULE_ID index, USB_PID pidValue, uint8_t endpoint, uint8_t deviceAddress,
bool isLowSpeed);
```

Returns

None.

Description

This function sends the specified token to the specified endpoint and address. The token is placed on the bus at the next available time. The token can be executed at low speed.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Send an OUT token to endpoint 1 device address 2 at full speed
PLIB_USB_SendToken(MY_USB_INSTANCE, USB_PID_OUT, 1, 2, false);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
pidValue	PID of the token to be placed on the bus.
endpoint	Device endpoint to which the token should be sent.
isLowSpeed	Is true if the token should be executed at low speed.

Function

void PLIB_USB_TokenSend(USB_MODULE_ID index, USB_PID pidValue,

uint8_t endpoint, uint8_t deviceAddress, bool isLowSpeed);

p) Feature Existence Functions

PLIB_USB_ExistsActivityPending Function

Identifies whether the ActivityPending feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsActivityPending(USB_MODULE_ID index);
```

Returns

- true - The ActivityPending feature is supported on the device
- false - The ActivityPending feature is not supported on the device

Description

This function identifies whether the ActivityPending feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_ActivityPending

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsActivityPending(USB_MODULE_ID index)

PLIB_USB_ExistsALL_Interrupt Function

Identifies whether the ALL_Interrupt feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsALL_Interrupt(USB_MODULE_ID index);
```

Returns

- true - The ALL_Interrupt feature is supported on the device
- false - The ALL_Interrupt feature is not supported on the device

Description

This function identifies whether the ALL_Interrupt feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_AllInterruptEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsALL_Interrupt(USB_MODULE_ID index)

PLIB_USB_ExistsAutomaticSuspend Function

Identifies whether the AutomaticSuspend feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsAutomaticSuspend(USB_MODULE_ID index);
```

Returns

- true - The AutomaticSuspend feature is supported on the device
- false - The AutomaticSuspend feature is not supported on the device

Description

This function identifies whether the AutomaticSuspend feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_AutoSuspendDisable

- PLIB_USB_AutoSuspendEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsAutomaticSuspend(USB_MODULE_ID index)

PLIB_USB_ExistsBDTBaseAddress Function

Identifies whether the BDTBaseAddress feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsBDTBaseAddress(USB_MODULE_ID index);
```

Returns

- true - The BDTBaseAddress feature is supported on the device
- false - The BDTBaseAddress feature is not supported on the device

Description

This function identifies whether the BDTBaseAddress feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_BDTBaseAddressGet
- PLIB_USB_BDTBaseAddressSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsBDTBaseAddress(USB_MODULE_ID index)

PLIB_USB_ExistsBDTFunctions Function

Identifies whether the BDTFunctions feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsBDTFunctions(USB_MODULE_ID index);
```

Returns

- true - The BDTFunctions feature is supported on the device
- false - The BDTFunctions feature is not supported on the device

Description

This function identifies whether the BDTFunctions feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_BufferAddressGet
- PLIB_USB_BufferAddressSet
- PLIB_USB_BufferByteCountGet
- PLIB_USB_BufferByteCountSet
- PLIB_USB_BufferCancelReleaseToUSB
- PLIB_USB_BufferAllCancelReleaseToUSB
- PLIB_USB_BufferClearAll
- PLIB_USB_BufferDataToggleGet
- PLIB_USB_BufferDataToggleSelect
- PLIB_USB_BufferDataToggleSyncEnable
- PLIB_USB_BufferDataToggleSyncDisable
- PLIB_USB_BufferIndexGet
- PLIB_USB_BufferPIDBitsClear
- PLIB_USB_BufferPIDGet
- PLIB_USB_BufferReleasedToSW
- PLIB_USB_BufferReleaseToUSB
- PLIB_USB_BufferSchedule
- PLIB_USB_BufferStallDisable
- PLIB_USB_BufferStallEnable
- PLIB_USB_BufferStallGet
- PLIB_USB_BufferEP0RxStatusInitialize
- PLIB_USB_BufferClearAllDTSEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsBDTFunctions(USB_MODULE_ID index)

PLIB_USB_ExistsBufferFreeze Function

Identifies whether the BufferFreeze feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsBufferFreeze(USB_MODULE_ID index);
```

Returns

- true - The BufferFreeze feature is supported on the device
- false - The BufferFreeze feature is not supported on the device

Description

This function identifies whether the BufferFreeze feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_PingPongFreeze
- PLIB_USB_PingPongUnfreeze
- PLIB_USB_PingPongReset

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsBufferFreeze(USB_MODULE_ID index)

PLIB_USB_ExistsDeviceAddress Function

Identifies whether the DeviceAddress feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsDeviceAddress(USB_MODULE_ID index);
```

Returns

- true - The DeviceAddress feature is supported on the device
- false - The DeviceAddress feature is not supported on the device

Description

This function identifies whether the DeviceAddress feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_DeviceAddressSet
- PLIB_USB_DeviceAddressGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsDeviceAddress(USB_MODULE_ID index)

PLIB_USB_ExistsEP0LowSpeedConnect Function

Identifies whether the EP0LowSpeedConnect feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsEP0LowSpeedConnect(USB_MODULE_ID index);
```

Returns

- true - The EP0LowSpeedConnect feature is supported on the device
- false - The EP0LowSpeedConnect feature is not supported on the device

Description

This function identifies whether the EP0LowSpeedConnect feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_EP0LSDirectConnectEnable
- PLIB_USB_EP0LSDirectConnectDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsEP0LowSpeedConnect(USB_MODULE_ID index)

PLIB_USB_ExistsEP0NAKRetry Function

Identifies whether the EP0NAKRetry feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsEP0NAKRetry(USB_MODULE_ID index);
```

Returns

- true - The EP0NAKRetry feature is supported on the device
- false - The EP0NAKRetry feature is not supported on the device

Description

This function identifies whether the EP0NAKRetry feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_EP0NakRetryEnable
- PLIB_USB_EP0NakRetryDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsEP0NAKRetry(USB_MODULE_ID index)

PLIB_USB_ExistsEPnRxEnable Function

Identifies whether the EPnRxEnableEnhanced feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsEPnRxEnable(USB_MODULE_ID index);
```

Returns

- true - The EPnRxEnableEnhanced feature is supported on the device
- false - The EPnRxEnableEnhanced feature is not supported on the device

Description

This function identifies whether the EPnRxEnableEnhanced feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_EPnRxEnable
- PLIB_USB_EPnRxDisable
- PLIB_USB_EPnTxEnable
- PLIB_USB_EPnTxDisable
- PLIB_USB_EPnHandshakeEnable
- PLIB_USB_EPnHandshakeDisable
- PLIB_USB_EPnControlTransferEnable
- PLIB_USB_EPnControlTransferDisable
- PLIB_USB_EPnIsStalled
- PLIB_USB_EPnStallClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsEPnRxEnable(USB_MODULE_ID index)

PLIB_USB_ExistsEPnTxRx Function

Identifies whether the EPnTxRx feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsEPnTxRx(USB_MODULE_ID index);
```

Returns

- true - The EPnTxRx feature is supported on the device
- false - The EPnTxRx feature is not supported on the device

Description

This function identifies whether the EPnTxRx feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_EPnTxSelect
- PLIB_USB_EPnRxSelect
- PLIB_USB_EPnTxRxSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsEPnTxRx(USB_MODULE_ID index)

PLIB_USB_ExistsERR_Interrupt Function

Identifies whether the ERR_Interrupt feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsERR_Interrupt(USB_MODULE_ID index);
```

Returns

- true - The ERR_Interrupt feature is supported on the device
- false - The ERR_Interrupt feature is not supported on the device

Description

This function identifies whether the ERR_Interrupt feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_ErrorInterruptEnable
- PLIB_USB_ErrorInterruptDisable
- PLIB_USB_ErrorInterruptIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsERR_Interrupt(USB_MODULE_ID index)

PLIB_USB_ExistsERR_InterruptStatus Function

Identifies whether the ERR_InterruptStatus feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsERR_InterruptStatus(USB_MODULE_ID index);
```

Returns

- true - The ERR_InterruptStatus feature is supported on the device
- false - The ERR_InterruptStatus feature is not supported on the device

Description

This function identifies whether the ERR_InterruptStatus feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_ErrorInterruptFlagSet
- PLIB_USB_ErrorInterruptFlagClear

- PLIB_USB_ErrorInterruptFlagGet
- PLIB_USB_ErrorInterruptFlagAllGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsERR_InterruptStatus(USB_MODULE_ID index)

PLIB_USB_ExistsEyePattern Function

Identifies whether the EyePattern feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsEyePattern(USB_MODULE_ID index);
```

Returns

- true - The EyePattern feature is supported on the device
- false - The EyePattern feature is not supported on the device

Description

This function identifies whether the EyePattern feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_EyePatternDisable
- PLIB_USB_EyePatternEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsEyePattern(USB_MODULE_ID index)

PLIB_USB_ExistsFrameNumber Function

Identifies whether the FrameNumber feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsFrameNumber(USB_MODULE_ID index);
```

Returns

- true - The FrameNumber feature is supported on the device

- false - The FrameNumber feature is not supported on the device

Description

This function identifies whether the FrameNumber feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_FrameNumberGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsFrameNumber(USB_MODULE_ID index)

PLIB_USB_ExistsGEN_Interrupt Function

Identifies whether the GEN_Interrupt feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsGEN_Interrupt(USB_MODULE_ID index);
```

Returns

- true - The GEN_Interrupt feature is supported on the device
- false - The GEN_Interrupt feature is not supported on the device

Description

This function identifies whether the GEN_Interrupt feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_InterruptEnable
- PLIB_USB_InterruptDisable
- PLIB_USB_InterruptIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsGEN_Interrupt(USB_MODULE_ID index)

PLIB_USB_ExistsGEN_InterruptStatus Function

Identifies whether the GEN_InterruptStatus feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsGEN_InterruptStatus(USB_MODULE_ID index);
```

Returns

- true - The GEN_InterruptStatus feature is supported on the device
- false - The GEN_InterruptStatus feature is not supported on the device

Description

This function identifies whether the GEN_InterruptStatus feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_InterruptFlagSet
- PLIB_USB_InterruptFlagClear
- PLIB_USB_InterruptFlagGet
- PLIB_USB_InterruptFlagAllGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsGEN_InterruptStatus(USB_MODULE_ID index)

PLIB_USB_ExistsHostBusyWithToken Function

Identifies whether the HostBusyWithToken feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsHostBusyWithToken(USB_MODULE_ID index);
```

Returns

- true - The HostBusyWithToken feature is supported on the device
- false - The HostBusyWithToken feature is not supported on the device

Description

This function identifies whether the HostBusyWithToken feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_IsBusyWithToken

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsHostBusyWithToken(USB_MODULE_ID index)

PLIB_USB_ExistsHostGeneratesReset Function

Identifies whether the HostGeneratesReset feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsHostGeneratesReset(USB_MODULE_ID index);
```

Returns

- true - The HostGeneratesReset feature is supported on the device
- false - The HostGeneratesReset feature is not supported on the device

Description

This function identifies whether the HostGeneratesReset feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_ResetSignalEnable
- PLIB_USB_ResetSignalDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsHostGeneratesReset(USB_MODULE_ID index)

PLIB_USB_ExistsLastDirection Function

Identifies whether the LastDirection feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsLastDirection(USB_MODULE_ID index);
```

Returns

- true - The LastDirection feature is supported on the device
- false - The LastDirection feature is not supported on the device

Description

This function identifies whether the LastDirection feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_LastTransactionDirectionGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsLastDirection(USB_MODULE_ID index)

PLIB_USB_ExistsLastEndpoint Function

Identifies whether the LastEndpoint feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsLastEndpoint(USB_MODULE_ID index);
```

Returns

- true - The LastEndpoint feature is supported on the device
- false - The LastEndpoint feature is not supported on the device

Description

This function identifies whether the LastEndpoint feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_LastTransactionEndPtGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsLastEndpoint(USB_MODULE_ID index)

PLIB_USB_ExistsLastPingPong Function

Identifies whether the LastPingPong feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsLastPingPong(USB_MODULE_ID index);
```

Returns

- true - The LastPingPong feature is supported on the device
- false - The LastPingPong feature is not supported on the device

Description

This function identifies whether the LastPingPong feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_LastTransactionPingPongStateGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsLastPingPong(USB_MODULE_ID index)

PLIB_USB_ExistsLastTransactionDetails Function

Identifies whether the LastTransactionDetails feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsLastTransactionDetails(USB_MODULE_ID index);
```

Returns

- true - The LastTransactionDetails feature is supported on the device
- false - The LastTransactionDetails feature is not supported on the device

Description

This function identifies whether the LastTransactionDetails feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_LastTransactionDetailsGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsLastTransactionDetails(USB_MODULE_ID index)

PLIB_USB_ExistsLiveJState Function

Identifies whether the LiveJState feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsLiveJState(USB_MODULE_ID index);
```

Returns

- true - The LiveJState feature is supported on the device
- false - The LiveJState feature is not supported on the device

Description

This function identifies whether the LiveJState feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_JStateIsActive

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsLiveJState(USB_MODULE_ID index)

PLIB_USB_ExistsLiveSingleEndedZero Function

Identifies whether the LiveSingleEndedZero feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsLiveSingleEndedZero(USB_MODULE_ID index);
```

Returns

- true - The LiveSingleEndedZero feature is supported on the device
- false - The LiveSingleEndedZero feature is not supported on the device

Description

This function identifies whether the LiveSingleEndedZero feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_SE0InProgress

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsLiveSingleEndedZero(USB_MODULE_ID index)

PLIB_USB_ExistsModuleBusy Function

Identifies whether the ModuleBusy feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsModuleBusy(USB_MODULE_ID index);
```

Returns

- true - The ModuleBusy feature is supported on the device
- false - The ModuleBusy feature is not supported on the device

Description

This function identifies whether the ModuleBusy feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_ModuleIsBusy

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsModuleBusy(USB_MODULE_ID index)

PLIB_USB_ExistsModulePower Function

Identifies whether the ModulePower feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsModulePower(USB_MODULE_ID index);
```

Returns

- true - The ModulePower feature is supported on the device
- false - The ModulePower feature is not supported on the device

Description

This function identifies whether the ModulePower feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_Enable
- PLIB_USB_Disable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsModulePower(USB_MODULE_ID index)

PLIB_USB_ExistsNextTokenSpeed Function

Identifies whether the NextTokenSpeed feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsNextTokenSpeed(USB_MODULE_ID index);
```

Returns

- true - The NextTokenSpeed feature is supported on the device
- false - The NextTokenSpeed feature is not supported on the device

Description

This function identifies whether the NextTokenSpeed feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_TokenSpeedSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsNextTokenSpeed(USB_MODULE_ID index)

PLIB_USB_ExistsOnChipPullup Function

Identifies whether the OnChipPullup feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOnChipPullup(USB_MODULE_ID index);
```

Returns

- true - The OnChipPullup feature is supported on the device
- false - The OnChipPullup feature is not supported on the device

Description

This function identifies whether the OnChipPullup feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_OnChipPullUpDisable
- PLIB_USB_OnChipPullUpEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOnChipPullup(USB_MODULE_ID index)

PLIB_USB_ExistsOnChipTransceiver Function

Identifies whether the OnChipTransceiver feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOnChipTransceiver(USB_MODULE_ID index);
```

Returns

- true - The OnChipTransceiver feature is supported on the device
- false - The OnChipTransceiver feature is not supported on the device

Description

This function identifies whether the OnChipTransceiver feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_TransceiverEnable
- PLIB_USB_TransceiverDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOnChipTransceiver(USB_MODULE_ID index)

PLIB_USB_ExistsOpModeSelect Function

Identifies whether the OpModeSelect feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOpModeSelect(USB_MODULE_ID index);
```

Returns

- true - The OpModeSelect feature is supported on the device
- false - The OpModeSelect feature is not supported on the device

Description

This function identifies whether the OpModeSelect feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_OperatingModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOpModeSelect(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_ASessionValid Function

Identifies whether the OTG_ASessionValid feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_ASessionValid(USB_MODULE_ID index);
```

Returns

- true - The OTG_ASessionValid feature is supported on the device
- false - The OTG_ASessionValid feature is not supported on the device

Description

This function identifies whether the OTG_ASessionValid feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_OTG_VBusValid

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_ASessionValid(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_BSessionEnd Function

Identifies whether the OTG_BSessionEnd feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_BSessionEnd(USB_MODULE_ID index);
```

Returns

- true - The OTG_BSessionEnd feature is supported on the device
- false - The OTG_BSessionEnd feature is not supported on the device

Description

This function identifies whether the OTG_BSessionEnd feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_OTG_BSessionHasEnded

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_BSessionEnd(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_IDPinState Function

Identifies whether the OTG_IDPinState feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_IDPinState(USB_MODULE_ID index);
```

Returns

- true - The OTG_IDPinState feature is supported on the device
- false - The OTG_IDPinState feature is not supported on the device

Description

This function identifies whether the OTG_IDPinState feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_OTG_IDPinStateIsTypeA

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_IDPinState(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_Interrupt Function

Identifies whether the OTG_Interrupt feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_Interrupt(USB_MODULE_ID index);
```

Returns

- true - The OTG_Interrupt feature is supported on the device
- false - The OTG_Interrupt feature is not supported on the device

Description

This function identifies whether the OTG_Interrupt feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_OTG_InterruptEnable
- PLIB_USB_OTG_InterruptDisable
- PLIB_USB_OTG_InterruptIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_Interrupt(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_InterruptStatus Function

Identifies whether the OTG_InterruptStatus feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_InterruptStatus(USB_MODULE_ID index);
```

Returns

- true - The OTG_InterruptStatus feature is supported on the device
- false - The OTG_InterruptStatus feature is not supported on the device

Description

This function identifies whether the OTG_InterruptStatus feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_OTG_InterruptFlagSet
- PLIB_USB_OTG_InterruptFlagClear
- PLIB_USB_OTG_InterruptFlagGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_InterruptStatus(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_LineState Function

Identifies whether the OTG_LineState feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_LineState(USB_MODULE_ID index);
```

Returns

- true - The OTG_LineState feature is supported on the device
- false - The OTG_LineState feature is not supported on the device

Description

This function identifies whether the OTG_LineState feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_OTG_LineStateIsStable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_LineState(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_PullUpPullDown Function

Identifies whether the OTG_PullUpPullDown feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_PullUpPullDown(USB_MODULE_ID index);
```

Returns

- true - The OTG_PullUpPullDown feature is supported on the device
- false - The OTG_PullUpPullDown feature is not supported on the device

Description

This function identifies whether the OTG_PullUpPullDown feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_OTG_PullUpPullDownSetup

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_PullUpPullDown(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_SessionValid Function

Identifies whether the OTG_SessionValid feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_SessionValid(USB_MODULE_ID index);
```

Returns

- true - The OTG_SessionValid feature is supported on the device
- false - The OTG_SessionValid feature is not supported on the device

Description

This function identifies whether the OTG_SessionValid feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_OTG_SessionValid

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_SessionValid(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_VbusCharge Function

Identifies whether the OTG_VbusCharge feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_VbusCharge(USB_MODULE_ID index);
```

Returns

- true - The OTG_VbusCharge feature is supported on the device
- false - The OTG_VbusCharge feature is not supported on the device

Description

This function identifies whether the OTG_VbusCharge feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_OTG_VBusChargeEnable
- PLIB_USB_OTG_VBusChargeDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_VbusCharge(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_VbusDischarge Function

Identifies whether the OTG_VbusDischarge feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_VbusDischarge(USB_MODULE_ID index);
```

Returns

- true - The OTG_VbusDischarge feature is supported on the device
- false - The OTG_VbusDischarge feature is not supported on the device

Description

This function identifies whether the OTG_VbusDischarge feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_OTG_VBusDischargeEnable
- PLIB_USB_OTG_VBusDischargeDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_VbusDischarge(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_VbusPowerOnOff Function

Identifies whether the OTG_VbusPowerOnOff feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_VbusPowerOnOff(USB_MODULE_ID index);
```

Returns

- true - The OTG_VbusPowerOnOff feature is supported on the device
- false - The OTG_VbusPowerOnOff feature is not supported on the device

Description

This function identifies whether the OTG_VbusPowerOnOff feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_OTG_VBusPowerOff
- PLIB_USB_OTG_VBusPowerOn

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_VbusPowerOnOff(USB_MODULE_ID index)

PLIB_USB_ExistsPacketTransfer Function

Identifies whether the PacketTransfer feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsPacketTransfer(USB_MODULE_ID index);
```

Returns

- true - The PacketTransfer feature is supported on the device
- false - The PacketTransfer feature is not supported on the device

Description

This function identifies whether the PacketTransfer feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_PacketTransferIsDisabled
- PLIB_USB_PacketTransferEnable
- PLIB_USB_PacketTransferDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsPacketTransfer(USB_MODULE_ID index)

PLIB_USB_ExistsPingPongMode Function

Identifies whether the PingPongMode feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsPingPongMode(USB_MODULE_ID index);
```

Returns

- true - The PingPongMode feature is supported on the device
- false - The PingPongMode feature is not supported on the device

Description

This function identifies whether the PingPongMode feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_PingPongModeSelect
- PLIB_USB_PingPongModeGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsPingPongMode(USB_MODULE_ID index)

PLIB_USB_ExistsResumeSignaling Function

Identifies whether the ResumeSignaling feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsResumeSignaling(USB_MODULE_ID index);
```

Returns

- true - The ResumeSignaling feature is supported on the device
- false - The ResumeSignaling feature is not supported on the device

Description

This function identifies whether the ResumeSignaling feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_ResumeSignalingEnable
- PLIB_USB_ResumeSignalingDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsResumeSignaling(USB_MODULE_ID index)

PLIB_USB_ExistsSleepEntryGuard Function

Identifies whether the SleepEntryGuard feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsSleepEntryGuard(USB_MODULE_ID index);
```

Returns

- true - The SleepEntryGuard feature is supported on the device
- false - The SleepEntryGuard feature is not supported on the device

Description

This function identifies whether the SleepEntryGuard feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_SleepGuardEnable
- PLIB_USB_SleepGuardDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsSleepEntryGuard(USB_MODULE_ID index)

PLIB_USB_ExistsSOFThreshold Function

Identifies whether the SOFThreshold feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsSOFThreshold(USB_MODULE_ID index);
```

Returns

- true - The SOFThreshold feature is supported on the device
- false - The SOFThreshold feature is not supported on the device

Description

This function identifies whether the SOFThreshold feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_SOFThresholdGet
- PLIB_USB_SOFThresholdSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsSOFThreshold(USB_MODULE_ID index)

PLIB_USB_ExistsSpeedControl Function

Identifies whether the SpeedControl feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsSpeedControl(USB_MODULE_ID index);
```

Returns

- true - The SpeedControl feature is supported on the device
- false - The SpeedControl feature is not supported on the device

Description

This function identifies whether the SpeedControl feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_FullSpeedEnable
- PLIB_USB_FullSpeedDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsSpeedControl(USB_MODULE_ID index)

PLIB_USB_ExistsStartOfFrames Function

Identifies whether the StartOfFrames feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsStartOfFrames(USB_MODULE_ID index);
```

Returns

- true - The StartOfFrames feature is supported on the device
- false - The StartOfFrames feature is not supported on the device

Description

This function identifies whether the StartOfFrames feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_SOFEnable
- PLIB_USB_SOFDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsStartOfFrames(USB_MODULE_ID index)

PLIB_USB_ExistsStopInIdle Function

Identifies whether the StopInIdle feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsStopInIdle(USB_MODULE_ID index);
```

Returns

- true - The StopInIdle feature is supported on the device
- false - The StopInIdle feature is not supported on the device

Description

This function identifies whether the StopInIdle feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_StopInIdleEnable
- PLIB_USB_StopInIdleDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsStopInIdle(USB_MODULE_ID index)

PLIB_USB_ExistsSuspend Function

Identifies whether the Suspend feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsSuspend(USB_MODULE_ID index);
```

Returns

- true - The Suspend feature is supported on the device
- false - The Suspend feature is not supported on the device

Description

This function identifies whether the Suspend feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_SuspendEnable
- PLIB_USB_SuspendDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsSuspend(USB_MODULE_ID index)

PLIB_USB_ExistsTokenEP Function

Identifies whether the TokenEP feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsTokenEP(USB_MODULE_ID index);
```

Returns

- true - The TokenEP feature is supported on the device
- false - The TokenEP feature is not supported on the device

Description

This function identifies whether the TokenEP feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_TokenEPGet
- PLIB_USB_TokenEPSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsTokenEP(USB_MODULE_ID index)

PLIB_USB_ExistsTokenPID Function

Identifies whether the TokenPID feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsTokenPID(USB_MODULE_ID index);
```

Returns

- true - The TokenPID feature is supported on the device
- false - The TokenPID feature is not supported on the device

Description

This function identifies whether the TokenPID feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_TokenPIDGet
- PLIB_USB_TokenPIDSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsTokenPID(USB_MODULE_ID index)

PLIB_USB_ExistsUOEMonitor Function

Identifies whether the UOEMonitor feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsUOEMonitor(USB_MODULE_ID index);
```

Returns

- true - The UOEMonitor feature is supported on the device
- false - The UOEMonitor feature is not supported on the device

Description

This function identifies whether the UOEMonitor feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_UOEMonitorEnable
- PLIB_USB_UOEMonitorDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsUOEMonitor(USB_MODULE_ID index)

q) Data Types and Constants

USB_BUFFER_DATA01 Enumeration

Provides enumeration data toggle for a buffer.

File

plib_usb.h

C

```
typedef enum {
  USB_BUFFER_DATA0,
  USB_BUFFER_DATA1
} USB_BUFFER_DATA01;
```

Members

Members	Description
USB_BUFFER_DATA0	DATA0/1 = 0
USB_BUFFER_DATA1	DATA0/1 = 1

Description

USB Endpoint Buffer Data Toggle Enumeration

This data type provides enumeration data toggle for a buffer.

Remarks

None.

USB_BUFFER_DIRECTION Enumeration

Provides enumeration transmit/receive direction for a buffer.

File

plib_usb.h

C

```
typedef enum {
  USB_BUFFER_RX,
  USB_BUFFER_TX
} USB_BUFFER_DIRECTION;
```

Members

Members	Description
USB_BUFFER_RX	Receive
USB_BUFFER_TX	Transmit

Description

USB Endpoint Buffer Direction Enumeration

This data type provides enumeration transmit/receive direction for a buffer.

Remarks

None.

USB_BUFFER_PING_PONG Enumeration

Enumerates the ping-pong buffer (Even vs. Odd).

File

plib_usb.h

C

```
typedef enum {
  USB_BUFFER_EVEN,
  USB_BUFFER_ODD
} USB_BUFFER_PING_PONG;
```

Members

Members	Description
USB_BUFFER_EVEN	Even Buffer
USB_BUFFER_ODD	Odd Buffer

Description

Enumeration of USB Buffer Ping-Pong

This data type enumerates the ping-pong buffer (Even vs. Odd).

Remarks

None.

USB_BUFFER_SCHEDULE_DATA01 Enumeration

Provides enumeration data toggle for a buffer.

File

plib_usb.h

C

```
typedef enum {
  USB_BUFFER_DONTCHANGE,
  USB_BUFFER_SET_DATA0,
```

```
  USB_BUFFER_SET_DATA1
} USB_BUFFER_SCHEDULE_DATA01;
```

Members

Members	Description
USB_BUFFER_DONTCHANGE	Don't Change DATA0/1
USB_BUFFER_SET_DATA0	DATA0/1 = 0
USB_BUFFER_SET_DATA1	DATA0/1 = 1

Description

USB Endpoint Buffer Data Toggle Enumeration for Buffer Schedulint

This data type provides enumeration data toggle for a buffer.

Remarks

None.

USB_EP_TXRX Enumeration

Provides enumeration transmit/receive setup for an endpoint.

File

plib_usb.h

C

```
typedef enum {
  USB_EP_NOTXRX,
  USB_EP_RX,
  USB_EP_TX,
  USB_EP_TX_RX
} USB_EP_TXRX;
```

Members

Members	Description
USB_EP_NOTXRX	Nothing enabled for endpoint
USB_EP_RX	Receive enabled for endpoint
USB_EP_TX	Transmit enabled for endpoint
USB_EP_TX_RX	Transmit and Receive enabled for endpoint

Description

Enumeration of USB Endpoint Transmit/Receive Setup

This data type provides enumeration transmit/receive setup for an endpoint.

Remarks

None.

USB_OPMODES Enumeration

Provides enumeration of operating modes supported by USB.

File

plib_usb.h

C

```
typedef enum {
  USB_OPMODE_NONE,
  USB_OPMODE_DEVICE,
  USB_OPMODE_HOST,
  USB_OPMODE_OTG
} USB_OPMODES;
```

Members

Members	Description
USB_OPMODE_NONE	None
USB_OPMODE_DEVICE	Device
USB_OPMODE_HOST	Host
USB_OPMODE_OTG	OTG

Description

USB Operating Modes Enumeration

This data type provides enumeration of the operating modes supported by the USB module.

Remarks

None.

USB_OTG_INTERRUPTS Enumeration

Provides enumeration of interrupts related to the USB On-The-Go (OTG) module.

File

plib_usb.h

C

```
typedef enum {
  USB_OTG_INT_ADEVICE_VBUS_VALID,
  USB_OTG_INT_OTG_RESERVED,
  USB_OTG_INT_BDEVICE_SESSION_END,
  USB_OTG_INT_SESSION_VALID,
  USB_OTG_INT_ACTIVITY_DETECT,
  USB_OTG_INT_STABLE_LINE_STATE,
  USB_OTG_INT_ONE_MS_TIMEOUT,
  USB_OTG_INT_ID_STATE_CHANGE,
  USB_OTG_INT_ANY,
  USB_OTG_INT_ALL
} USB_OTG_INTERRUPTS;
```

Members

Members	Description
USB_OTG_INT_ADEVICE_VBUS_VALID	State of (VBUS > Va_vbus_vld) on the A device has changed
USB_OTG_INT_OTG_RESERVED	Reserved. Don't use.
USB_OTG_INT_BDEVICE_SESSION_END	State of (VBUS < Vb_sess_end) on the B device has changed
USB_OTG_INT_SESSION_VALID	State of (VBUS > Va_sess_vld) on the A or B devices has changed
USB_OTG_INT_ACTIVITY_DETECT	Activity detected on the D+, D-, ID, or VBUS lines
USB_OTG_INT_STABLE_LINE_STATE	USB line state has been stable for 1 ms, but different from last time
USB_OTG_INT_ONE_MS_TIMEOUT	One millisecond timer has expired
USB_OTG_INT_ID_STATE_CHANGE	Change in state of ID pin detected.
USB_OTG_INT_ANY	All or Any of the above
USB_OTG_INT_ALL	All or Any of the above

Description

USB OTG Interrupts Enumeration

This data type provides enumeration of interrupts related to the USB OTG module.

Remarks

Not applicable if the USB OTG module is not enabled.

USB_OTG_PULL_UP_PULL_DOWN Enumeration

USB OTG pull-Up and pull-Down resistors for D+ and D- .

File

plib_usb.h

C

```
typedef enum {
  USB_OTG_DPLUS_PULLUP,
  USB_OTG_DMINUS_PULLUP,
  USB_OTG_DPLUS_PULLDN,
  USB_OTG_DMINUS_PULLDN
} USB_OTG_PULL_UP_PULL_DOWN;
```

Members

Members	Description
USB_OTG_DPLUS_PULLUP	D+ Pull-Up
USB_OTG_DMINUS_PULLUP	D- Pull-Up
USB_OTG_DPLUS_PULLDN	D+ Pull-Down
USB_OTG_DMINUS_PULLDN	D- Pull-Down

Description

Enumeration of Pull-Up and Pull-Down Resistors for OTG

This data type enumerates the OTG Pull-Up and Pull-Down resistors for D+ and D- .

Remarks

None.

USB_PID Enumeration

Legal PID values.

File

plib_usb.h

C

```
typedef enum {
  USB_PID_SETUP,
  USB_PID_IN,
  USB_PID_OUT
} USB_PID;
```

Members

Members	Description
USB_PID_SETUP	Setup token
USB_PID_IN	IN token
USB_PID_OUT	OUT token

Description

Enumeration of Legal Packet IDs (PIDs)

This data type enumerates the valid (i.e., legal) PID values. While the PID field is four bits long, only these values are legal and should be used. The use of any other values may cause unpredictable results.

USB_PING_PONG_MODE Enumeration

Supports the four modes of ping-pong buffering.

File

plib_usb.h

C

```
typedef enum {
  USB_PING_PONG_ALL_BUT_EP0,
  USB_PING_PONG_FULL_PING_PONG,
  USB_PING_PONG_EP0_OUT_ONLY,
```

```
  USB_PING_PONG_NO_PING_PONG
} USB_PING_PONG_MODE;
```

Members

Members	Description
USB_PING_PONG_ALL_BUT_EP0	Ping-Pong buffering on all endpoints except Endpoint Zero
USB_PING_PONG_FULL_PING_PONG	Ping-Pong buffering on all endpoints
USB_PING_PONG_EP0_OUT_ONLY	Ping-Pong buffering on just Endpoint Zero transmit
USB_PING_PONG_NO_PING_PONG	No ping-pong buffering

Description

Enumeration of USB Ping-Pong Modes

This data type supports the four modes of ping-pong buffering.

Remarks

None.

USB_PING_PONG_STATE Enumeration

Decodes which buffer (Even vs. Odd) was used for the last transaction.

File

plib_usb.h

C

```
typedef enum {
  USB_PING_PONG_EVEN,
  USB_PING_PONG_ODD
} USB_PING_PONG_STATE;
```

Members

Members	Description
USB_PING_PONG_EVEN	Last transaction on Even Buffer
USB_PING_PONG_ODD	Last transaction on Odd Buffer

Description

Enumeration of USB Ping-Pong Indicator

This data type decodes which buffer (Even vs. Odd) was used for the last transaction.

Remarks

None.

USB_TOKEN_SPEED Enumeration

Provides enumeration of available token speeds.

File

plib_usb.h

C

```
typedef enum {
  USB_LOWSPEED_TOKENS,
  USB_FULLSPEED_TOKENS
} USB_TOKEN_SPEED;
```

Members

Members	Description
USB_LOWSPEED_TOKENS	Low Speed Tokens
USB_FULLSPEED_TOKENS	Full Speed Tokens

Description

USB Token Speeds Enumeration

This data type provides enumeration of available token speeds.

Remarks

For Host mode only.

USB_MAX_EP_NUMBER Macro

Maximum number of endpoints supported (not including EP0).

File

plib_usb.h

C

```
#define USB_MAX_EP_NUMBER 15
```

Description

Maximum number of endpoints

This constant defines the maximum number of endpoints supported (not including EP0). It is used in dimensioning the Buffer Descriptor Table (BDT) array.

Files

Files

Name	Description
plib_usb.h	USB Peripheral Library Interface Header for common definitions

Description

This section lists the source and header files used by the library.

plib_usb.h

USB Peripheral Library Interface Header for common definitions

Enumerations

	Name	Description
	USB_BUFFER_DATA01	Provides enumeration data toggle for a buffer.
	USB_BUFFER_DIRECTION	Provides enumeration transmit/receive direction for a buffer.
	USB_BUFFER_PING_PONG	Enumerates the ping-pong buffer (Even vs. Odd).
	USB_BUFFER_SCHEDULE_DATA01	Provides enumeration data toggle for a buffer.
	USB_EP_TXRX	Provides enumeration transmit/receive setup for an endpoint.
	USB_OPMODES	Provides enumeration of operating modes supported by USB.
	USB_OTG_INTERRUPTS	Provides enumeration of interrupts related to the USB On-The-Go (OTG) module.
	USB_OTG_PULL_UP_PULL_DOWN	USB OTG pull-Up and pull-Down resistors for D+ and D- .
	USB_PID	Legal PID values.
	USB_PING_PONG_MODE	Supports the four modes of ping-pong buffering.
	USB_PING_PONG_STATE	Decodes which buffer (Even vs. Odd) was used for the last transaction.
	USB_TOKEN_SPEED	Provides enumeration of available token speeds.

Functions

	Name	Description
	PLIB_USB_ActivityPending	Returns whether or not USB activity is pending.
	PLIB_USB_AllInterruptEnable	Configures the USB peripheral general interrupts, error interrupts and OTG interrupts.
	PLIB_USB_AutoSuspendDisable	Disables USB OTG Auto-suspend mode.
	PLIB_USB_AutoSuspendEnable	Enables USB Auto-suspend mode.

	PLIB_USB_BDTBaseAddressGet	Returns the base address of the Buffer Descriptor Table.
	PLIB_USB_BDTBaseAddressSet	Sets the base address for the Buffer Descriptor Table for PIC32 devices.
	PLIB_USB_BufferAddressGet	Gets the memory address of an endpoint buffer.
	PLIB_USB_BufferAddressSet	Sets the endpoint buffer address.
	PLIB_USB_BufferAllCancelReleaseToUSB	Cancels all endpoint buffer releases to the USB module and hands over the buffer to the CPU.
	PLIB_USB_BufferByteCountGet	Returns the endpoint buffer byte count.
	PLIB_USB_BufferByteCountSet	Sets the buffer byte count.
	PLIB_USB_BufferCancelReleaseToUSB	Cancels release of the endpoint buffer by software, allowing software to again access the buffer.
	PLIB_USB_BufferClearAll	Clears (zeros out) entries in the Buffer Descriptor Table.
	PLIB_USB_BufferClearAllDTSEnable	Clears the endpoint descriptor entry and enables data toggle synchronization.
	PLIB_USB_BufferDataToggleGet	Returns data synchronization (DATA0 or DATA1) for the endpoint buffer.
	PLIB_USB_BufferDataToggleSelect	Sets the endpoint buffer to DATA0 or DATA1.
	PLIB_USB_BufferDataToggleSyncDisable	Disables DATA0/DATA1 synchronization between the device and host.
	PLIB_USB_BufferDataToggleSyncEnable	Enables DATA0/DATA1 synchronization between the device and host.
	PLIB_USB_BufferEP0RxStatusInitialize	Initializes the Endpoint 0 RX endpoint buffer descriptors.
	PLIB_USB_BufferIndexGet	Gets the Buffer Descriptor Table index for a buffer.
	PLIB_USB_BufferPIDBitsClear	Clears the Buffer Status bits in the Buffer Descriptor Table.
	PLIB_USB_BufferPIDGet	Returns the token packet ID (PID) from the endpoint buffer status.
	PLIB_USB_BufferReleasedToSW	Returns the boolean flag value of 'true' when the buffer has been released by the USB module.
	PLIB_USB_BufferReleaseToUSB	Releases the endpoint buffer by software, allowing the USB module access to the buffer.
	PLIB_USB_BufferSchedule	Hands over a buffer to the USB module along with the buffer address and byte count.
	PLIB_USB_BufferStallDisable	Disables STALL handshaking for the associated endpoint buffer.
	PLIB_USB_BufferStallEnable	Enables STALL handshaking for the associated endpoint buffer.
	PLIB_USB_BufferStallGet	Returns the buffer stall status for an endpoint/direction/ping-pong.
	PLIB_USB_DeviceAddressGet	Returns the address of the USB module in Device mode.
	PLIB_USB_DeviceAddressSet	Sets the USB Device's address.
	PLIB_USB_Disable	Disables (powers down) the USB module.
	PLIB_USB_Enable	Enables (powers up) the USB module.
	PLIB_USB_EP0HostSetup	Sends token to the specified address.
	PLIB_USB_EP0LSDirectConnectDisable	Disables direct connection to a low-speed device for Endpoint 0.
	PLIB_USB_EP0LSDirectConnectEnable	Enables direct connection to a low-speed device for Endpoint 0.
	PLIB_USB_EP0NakRetryDisable	Disables retrying of NAKed transactions.
	PLIB_USB_EP0NakRetryEnable	Enables retrying NAK'd transactions for Endpoint 0.
	PLIB_USB_EPnAttributesClear	Clears the set attributes of the specified endpoint.
	PLIB_USB_EPnAttributesSet	Configures attributes of the endpoint such as direction, handshake capability and direction.
	PLIB_USB_EPnControlTransferDisable	Disables endpoint control transfers.
	PLIB_USB_EPnControlTransferEnable	Enables endpoint control transfers.
	PLIB_USB_EPnDirectionDisable	Disables the specified endpoint direction.
	PLIB_USB_EPnHandshakeDisable	Disables endpoint handshaking.
	PLIB_USB_EPnHandshakeEnable	Enables endpoint handshaking.
	PLIB_USB_EPnIsStalled	Tests whether the endpoint epValue is stalled.
	PLIB_USB_EPnRxDisable	Disables an endpoint's ability to process IN tokens.
	PLIB_USB_EPnRxEnable	Enables an endpoint to process IN tokens.
	PLIB_USB_EPnRxSelect	Selects receive capabilities of an endpoint.
	PLIB_USB_EPnStallClear	Clears an endpoint's stalled flag.
	PLIB_USB_EPnTxDisable	Disables an endpoint's ability to process OUT tokens.
	PLIB_USB_EPnTxEnable	Enables an endpoint to process OUT tokens.
	PLIB_USB_EPnTxRxSelect	Selects transmit and/or receive capabilities of an endpoint.
	PLIB_USB_EPnTxSelect	Selects transmit capabilities of an endpoint.
	PLIB_USB_ErrorInterruptDisable	Disables an error interrupt for the USB module.

	PLIB_USB_ErrorInterruptEnable	Enables an error interrupt for the USB module.
	PLIB_USB_ErrorInterruptFlagAllGet	Returns a logically ORed bit map of active error interrupt flags.
	PLIB_USB_ErrorInterruptFlagClear	Clears an error interrupt flag for the USB module.
	PLIB_USB_ErrorInterruptFlagGet	Tests an error interrupt flag for the USB module.
	PLIB_USB_ErrorInterruptFlagSet	Sets an error interrupt flag for the USB module.
	PLIB_USB_ErrorInterruptIsEnabled	Returns true if interrupts are enabled.
	PLIB_USB_ExistsActivityPending	Identifies whether the ActivityPending feature exists on the USB module.
	PLIB_USB_ExistsALL_Interrupt	Identifies whether the ALL_Interrupt feature exists on the USB module.
	PLIB_USB_ExistsAutomaticSuspend	Identifies whether the AutomaticSuspend feature exists on the USB module.
	PLIB_USB_ExistsBDTBaseAddress	Identifies whether the BDTBaseAddress feature exists on the USB module.
	PLIB_USB_ExistsBDTFunctions	Identifies whether the BDTFunctions feature exists on the USB module.
	PLIB_USB_ExistsBufferFreeze	Identifies whether the BufferFreeze feature exists on the USB module.
	PLIB_USB_ExistsDeviceAddress	Identifies whether the DeviceAddress feature exists on the USB module.
	PLIB_USB_ExistsEP0LowSpeedConnect	Identifies whether the EP0LowSpeedConnect feature exists on the USB module.
	PLIB_USB_ExistsEP0NAKRetry	Identifies whether the EP0NAKRetry feature exists on the USB module.
	PLIB_USB_ExistsEPnRxEnable	Identifies whether the EPnRxEnableEnhanced feature exists on the USB module.
	PLIB_USB_ExistsEPnTxRx	Identifies whether the EPnTxRx feature exists on the USB module.
	PLIB_USB_ExistsERR_Interrupt	Identifies whether the ERR_Interrupt feature exists on the USB module.
	PLIB_USB_ExistsERR_InterruptStatus	Identifies whether the ERR_InterruptStatus feature exists on the USB module.
	PLIB_USB_ExistsEyePattern	Identifies whether the EyePattern feature exists on the USB module.
	PLIB_USB_ExistsFrameNumber	Identifies whether the FrameNumber feature exists on the USB module.
	PLIB_USB_ExistsGEN_Interrupt	Identifies whether the GEN_Interrupt feature exists on the USB module.
	PLIB_USB_ExistsGEN_InterruptStatus	Identifies whether the GEN_InterruptStatus feature exists on the USB module.
	PLIB_USB_ExistsHostBusyWithToken	Identifies whether the HostBusyWithToken feature exists on the USB module.
	PLIB_USB_ExistsHostGeneratesReset	Identifies whether the HostGeneratesReset feature exists on the USB module.
	PLIB_USB_ExistsLastDirection	Identifies whether the LastDirection feature exists on the USB module.
	PLIB_USB_ExistsLastEndpoint	Identifies whether the LastEndpoint feature exists on the USB module.
	PLIB_USB_ExistsLastPingPong	Identifies whether the LastPingPong feature exists on the USB module.
	PLIB_USB_ExistsLastTransactionDetails	Identifies whether the LastTransactionDetails feature exists on the USB module.
	PLIB_USB_ExistsLiveJState	Identifies whether the LiveJState feature exists on the USB module.
	PLIB_USB_ExistsLiveSingleEndedZero	Identifies whether the LiveSingleEndedZero feature exists on the USB module.
	PLIB_USB_ExistsModuleBusy	Identifies whether the ModuleBusy feature exists on the USB module.
	PLIB_USB_ExistsModulePower	Identifies whether the ModulePower feature exists on the USB module.
	PLIB_USB_ExistsNextTokenSpeed	Identifies whether the NextTokenSpeed feature exists on the USB module.
	PLIB_USB_ExistsOnChipPullup	Identifies whether the OnChipPullup feature exists on the USB module.
	PLIB_USB_ExistsOnChipTransceiver	Identifies whether the OnChipTransceiver feature exists on the USB module.
	PLIB_USB_ExistsOpModeSelect	Identifies whether the OpModeSelect feature exists on the USB module.
	PLIB_USB_ExistsOTG_ASessionValid	Identifies whether the OTG_ASessionValid feature exists on the USB module.
	PLIB_USB_ExistsOTG_BSessionEnd	Identifies whether the OTG_BSessionEnd feature exists on the USB module.
	PLIB_USB_ExistsOTG_IDPinState	Identifies whether the OTG_IDPinState feature exists on the USB module.
	PLIB_USB_ExistsOTG_Interrupt	Identifies whether the OTG_Interrupt feature exists on the USB module.
	PLIB_USB_ExistsOTG_InterruptStatus	Identifies whether the OTG_InterruptStatus feature exists on the USB module.
	PLIB_USB_ExistsOTG_LineState	Identifies whether the OTG_LineState feature exists on the USB module.
	PLIB_USB_ExistsOTG_PullUpPullDown	Identifies whether the OTG_PullUpPullDown feature exists on the USB module.
	PLIB_USB_ExistsOTG_SessionValid	Identifies whether the OTG_SessionValid feature exists on the USB module.
	PLIB_USB_ExistsOTG_VbusCharge	Identifies whether the OTG_VbusCharge feature exists on the USB module.
	PLIB_USB_ExistsOTG_VbusDischarge	Identifies whether the OTG_VbusDischarge feature exists on the USB module.
	PLIB_USB_ExistsOTG_VbusPowerOnOff	Identifies whether the OTG_VbusPowerOnOff feature exists on the USB module.
	PLIB_USB_ExistsPacketTransfer	Identifies whether the PacketTransfer feature exists on the USB module.
	PLIB_USB_ExistsPingPongMode	Identifies whether the PingPongMode feature exists on the USB module.
	PLIB_USB_ExistsResumeSignaling	Identifies whether the ResumeSignaling feature exists on the USB module.
	PLIB_USB_ExistsSleepEntryGuard	Identifies whether the SleepEntryGuard feature exists on the USB module.
	PLIB_USB_ExistsSOFThreshold	Identifies whether the SOFThreshold feature exists on the USB module.
	PLIB_USB_ExistsSpeedControl	Identifies whether the SpeedControl feature exists on the USB module.
	PLIB_USB_ExistsStartOfFrames	Identifies whether the StartOfFrames feature exists on the USB module.

	PLIB_USB_ExistsStopInIdle	Identifies whether the StopInIdle feature exists on the USB module.
	PLIB_USB_ExistsSuspend	Identifies whether the Suspend feature exists on the USB module.
	PLIB_USB_ExistsTokenEP	Identifies whether the TokenEP feature exists on the USB module.
	PLIB_USB_ExistsTokenPID	Identifies whether the TokenPID feature exists on the USB module.
	PLIB_USB_ExistsUOEMonitor	Identifies whether the UOEMonitor feature exists on the USB module.
	PLIB_USB_ExternalComparatorMode2Pin	Sets the 2-pin input configuration for VBUS comparators.
	PLIB_USB_ExternalComparatorMode3Pin	Sets the 3-pin input configuration for VBUS Comparators.
	PLIB_USB_EyePatternDisable	Disables the USB eye pattern test.
	PLIB_USB_EyePatternEnable	Enables USB eye pattern test.
	PLIB_USB_FrameNumberGet	Returns the USB frame number.
	PLIB_USB_FullSpeedDisable	Forces the USB module to operate at low speed.
	PLIB_USB_FullSpeedEnable	Enables the USB to operate at full speed.
	PLIB_USB_I2CInterfaceForExtModuleDisable	Specifies external module(s) are controlled via dedicated pins.
	PLIB_USB_I2CInterfaceForExtModuleEnable	Specifies external module(s) are controlled via the I2C interface.
	PLIB_USB_InterruptDisable	Disables a general interrupt for the USB module.
	PLIB_USB_InterruptEnable	Enables a general interrupt for the USB module.
	PLIB_USB_InterruptEnableGet	Returns the enable/disable status of general USB module interrupts
	PLIB_USB_InterruptFlagAllGet	Returns a logically ORed bit map of active general USB interrupt flags.
	PLIB_USB_InterruptFlagClear	Clears a general interrupt flag for the USB module.
	PLIB_USB_InterruptFlagGet	Tests a general interrupt flag for the USB module.
	PLIB_USB_InterruptFlagSet	Sets a general interrupt flag for the USB module.
	PLIB_USB_InterruptIsEnabled	Returns true if interrupts are enabled.
	PLIB_USB_IsBusyWithToken	Indicates whether there is a token being executed by the USB module as Host.
	PLIB_USB_JStateIsActive	Live differential receiver J State flag.
	PLIB_USB_LastTransactionDetailsGet	Returns the details of the last completed transaction.
	PLIB_USB_LastTransactionDirectionGet	Indicates the direction of the last transaction.
	PLIB_USB_LastTransactionEndPtGet	Returns the endpoint number of the last USB transfer.
	PLIB_USB_LastTransactionPingPongStateGet	Indicates whether the last transaction was to an EVEN buffer or an ODD buffer.
	PLIB_USB_ModuleIsBusy	Indicates if the USB module is not ready to be enabled.
	PLIB_USB_OnChipPullUpDisable	Disables on-chip pull-ups.
	PLIB_USB_OnChipPullUpEnable	Enables on-chip pull-ups.
	PLIB_USB_OperatingModeSelect	Selects the operating mode of the USB module.
	PLIB_USB_OTG_BSessionHasEnded	Returns the status of the B-Session End Indicator bit.
	PLIB_USB_OTG_IDPinStateIsTypeA	Returns the ID Pin state.
	PLIB_USB_OTG_InterruptDisable	Disables a USB On-The-Go (OTG) Interrupt for the USB module.
	PLIB_USB_OTG_InterruptEnable	Enables a USB On-The-Go (OTG) Interrupt for the USB module.
	PLIB_USB_OTG_InterruptFlagClear	Clears a USB On-The-Go (OTG) Interrupt flag for the USB module.
	PLIB_USB_OTG_InterruptFlagGet	Tests a USB On-The-Go (OTG) Interrupt flag for the USB module.
	PLIB_USB_OTG_InterruptFlagSet	Sets a USB On-The-Go (OTG) Interrupt flag for the USB module.
	PLIB_USB_OTG_InterruptIsEnabled	Returns whether or not interrupts are enabled.
	PLIB_USB_OTG_LineStateIsStable	Returns the status of the Line Stable Indicator bit.
	PLIB_USB_OTG_PullUpPullDownSetup	Enables or disables pull-up and pull-down resistors.
	PLIB_USB_OTG_SessionValid	Returns the status of the Session Valid Indicator bit.
	PLIB_USB_OTG_VBusChargeDisable	Disables VBUS line charge.
	PLIB_USB_OTG_VBusChargeEnable	Enables the VBUS line to be charged through a pull-up resistor.
	PLIB_USB_OTG_VBusChargeTo3V	Sets the VBUS line to charge to 3.3V.
	PLIB_USB_OTG_VBusChargeTo5V	Sets the VBUS line to charge to 5V.
	PLIB_USB_OTG_VBusDischargeDisable	Disables VBUS line discharge.
	PLIB_USB_OTG_VBusDischargeEnable	Enables VBUS line to be discharged through a resistor.
	PLIB_USB_OTG_VBusPowerOff	Turns off power on the VBUS Line.
	PLIB_USB_OTG_VBusPowerOn	Turns on power for the VBUS line.
	PLIB_USB_OTG_VBusValid	Returns the status of the A-VBUS valid indicator.
	PLIB_USB_PacketTransferDisable	Disables the Serial Interface Engine (SIE).
	PLIB_USB_PacketTransferEnable	Re-enables the Serial Interface Engine (SIE), allowing token and packet processing.

	PLIB_USB_PacketTransferIsDisabled	Indicates that a setup token has been received from the Host and that token/packet processing is disabled.
	PLIB_USB_PingPongFreeze	Resets all Ping-Pong buffer pointers to even buffers.
	PLIB_USB_PingPongModeGet	Returns the Ping-Pong Configuration setting.
	PLIB_USB_PingPongModeSelect	Selects the Ping-Pong Configuration setting.
	PLIB_USB_PingPongReset	Resets the USB peripheral internal Ping-Pong indicator to point to even buffers.
	PLIB_USB_PingPongUnfreeze	Enables Ping-Pong buffering.
	PLIB_USB_PWMCounterDisable	Disables the PWM counter used to generate the VBUS for the USB module.
	PLIB_USB_PWMCounterEnable	Enables the PWM counter used to generate the VBUS for the USB module.
	PLIB_USB_PWMDisable	Disables the PWM Generator.
	PLIB_USB_PWMEnable	Enables the PWM Generator.
	PLIB_USB_PWMPolaritiyActiveLow	Sets the PWM output to active-high and resets low.
	PLIB_USB_PWMPolarityActiveHigh	Sets the PWM output to active-low and resets high.
	PLIB_USB_ResetSignalDisable	Disables reset signaling on the USB bus.
	PLIB_USB_ResetSignalEnable	Enables reset signaling on the USB bus.
	PLIB_USB_ResumeSignalingDisable	Disables resume signaling.
	PLIB_USB_ResumeSignalingEnable	Enables resume signaling.
	PLIB_USB_SE0InProgress	Returns whether a single-ended zero event is in progress.
	PLIB_USB_SleepGuardDisable	This function disables Sleep Guard. Entry into Sleep mode is immediate.
	PLIB_USB_SleepGuardEnable	Entry into Sleep mode is blocked if bus activity is detected or if an interrupt is pending.
	PLIB_USB_SOFDisable	Disables the automatic generation of the SOF token.
	PLIB_USB_SOFEnable	Enables the automatic generation of the SOF token every 1 ms.
	PLIB_USB_SOFThresholdGet	Returns the Start-of-Frame (SOF) Count bits.
	PLIB_USB_SOFThresholdSet	Sets the Start-of-Frame (SOF) threshold value.
	PLIB_USB_StopInIdleDisable	Allows the USB module to continue operation when the device enters Idle mode.
	PLIB_USB_StopInIdleEnable	Enables USB module operation to stop when the device enters Idle mode.
	PLIB_USB_SuspendDisable	Disables USB OTG Suspend mode.
	PLIB_USB_SuspendEnable	Enables USB Suspend mode.
	PLIB_USB_TokenEPGet	Returns the specified Endpoint address.
	PLIB_USB_TokenEPSet	Sets the Endpoint address for a host transaction.
	PLIB_USB_TokenPIDGet	Returns the token transaction type.
	PLIB_USB_TokenPIDSet	Sets the token transaction type to pidValue.
	PLIB_USB_TokenSend	Sends token to the specified address.
	PLIB_USB_TokenSpeedSelect	Selects low speed or full speed for subsequent token executions.
	PLIB_USB_TransceiverDisable	Disables the on-chip transceiver
	PLIB_USB_TransceiverEnable	Enables the on-chip transceiver.
	PLIB_USB_UOEMonitorDisable	Disables the OE signal output.
	PLIB_USB_UOEMonitorEnable	Enables the OE signal output.
	PLIB_USB_VBoostDisable	Disables the On-Chip 5V Boost Regulator Circuit Disabled bit.
	PLIB_USB_VBoostEnable	Enables the On-Chip 5V Boost Regulator Circuit Enabled bit.
	PLIB_USB_VBUSComparatorDisable	Disables the on-chip VBUS Comparator.
	PLIB_USB_VBUSComparatorEnable	Enables the on-chip VBUS Comparator.
	PLIB_USB_VBUSPullUpDisable	Disables the pull-up on the VBUS pin.
	PLIB_USB_VBUSPullUpEnable	Enables the pull-up on the VBUS pin.

Macros

	Name	Description
	USB_MAX_EP_NUMBER	Maximum number of endpoints supported (not including EP0).

Description

USB Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the USB Peripheral Library.

File Name

plib_usb.h

Company

Microchip Technology Inc.

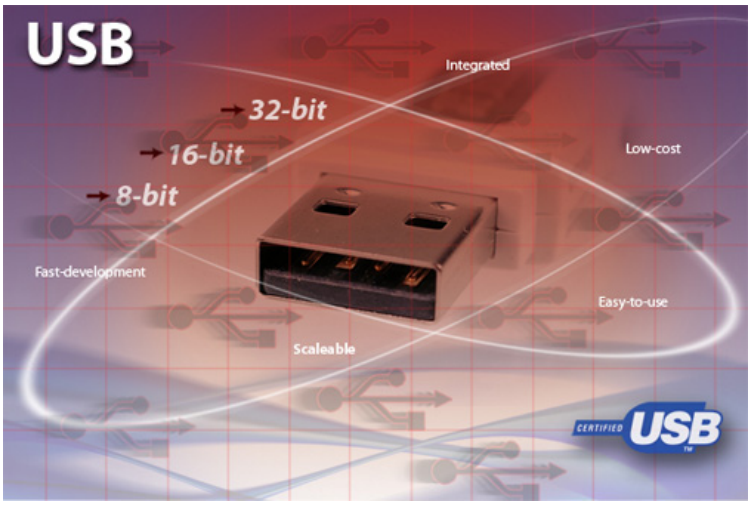
USBHS Peripheral Library

This section describes the Hi-Speed USB (USBHS) Peripheral Library.

Introduction

This library provides a low-level abstraction of the USBHS module on Microchip family of microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thus hiding differences from one microcontroller variant to another.

Description



USB Overview

USB is an asynchronous serial interface with a tiered star configuration. USB is implemented as a master/slave configuration. On a given bus, there can be multiple (up to 127) slaves (devices), but there is only one master (host). There are three possible module implementations: host, device and OTG dual role. The user should have an understanding of the USB documents available on the USB implementers web site (www.usb.org).

Features of the Hi-Speed USB (USBHS) Module

- Operates either as a function controller of a Hi-Speed/Full-Speed USB device or as the host/device in a point-to-point or multi-point communications with other USB function
- Supports OTG communications with on or more Hi-Speed, Full-Speed, or Low-Speed devices
- Provides soft connect/disconnect.
- In addition to Endpoint Zero, supports seven transmit and seven receive endpoints
- Dynamic FIFO sizing for Endpoints 1-7. (Endpoint Zero FIFO fixed at 64 bytes.) FIFOs use module-internal SRAM.
- Module-internal eight channel DMA with access to all FIFOs
- All host transaction scheduling supported in hardware
- Supports Link Power Management

Using the Library

This topic describes the basic architecture of the USBHS Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_usbhs.h`

The interface to the USBHS Peripheral Library is defined in the `plib_usbhs.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the USBHS Peripheral Library must include `peripheral.h`.

Library File:

The USBHS Peripheral Library is part of the processor-specific peripheral library archive (`.a`) file installed with the compiler. Libraries in this archive are automatically available to the linker (in the default search path) for any project built using the Microchip compiler.

Please refer to the What is MPLAB Harmony? section for how the library interacts with the framework.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the USBHS module.

Library Interface Section	Description
USBHS Setup Functions	This section provides functions to perform general USBHS peripheral setup such as functions to set USB Speed, control on-chip pull ups, etc.
Endpoints Functions	This section provides functions that allow the application to manage endpoints.
Interrupts Functions	This section provides functions that allow the application to enable, disable and query the status interrupts in the USBHS peripheral.
Device Functions	This section provides functions that are required to operate the USBHS module while in Device mode.
Host Functions	This section provides functions that are required to operate the USBHS module while in Host mode.
Status Functions	This section provides functions that read the status of the USBHS module.
VBUS Support Functions	This section provides functions that allow VBUS level monitoring and VBUS boost PWM module control.
Feature Existence Functions	This section provides functions that identify whether a particular feature exists on the USBHS module.

How the Library Works

Provides information on how the library works.

Configuring the Library

The library is configured for the supported High-Speed USB module when the processor is chosen in the MPLAB X IDE.

Library Interface

a) USBHS Setup Functions

	Name	Description
	PLIB_USBHS_HighSpeedDisable	This is function PLIB_USBHS_HighSpeedDisable.
	PLIB_USBHS_HighSpeedEnable	Sets the operation speed of the USB Module.
	PLIB_USBHS_ResetDisable	This is function PLIB_USBHS_ResetDisable.
	PLIB_USBHS_ResetEnable	This is function PLIB_USBHS_ResetEnable.
	PLIB_USBHS_ResumeDisable	This is function PLIB_USBHS_ResumeDisable.
	PLIB_USBHS_ResumeEnable	This is function PLIB_USBHS_ResumeEnable.
	PLIB_USBHS_SessionDisable	This is function PLIB_USBHS_SessionDisable.
	PLIB_USBHS_SessionEnable	This is function PLIB_USBHS_SessionEnable.
	PLIB_USBHS_SoftResetDisable	Disables soft reset.
	PLIB_USBHS_SoftResetEnable	Enables soft reset.
	PLIB_USBHS_SuspendDisable	This is function PLIB_USBHS_SuspendDisable.
	PLIB_USBHS_SuspendEnable	This is function PLIB_USBHS_SuspendEnable.
	PLIB_USBHS_DMAOperationEnable	This is function PLIB_USBHS_DMAOperationEnable.
	PLIB_USBHS_TestModeEnter	This is function PLIB_USBHS_TestModeEnter.
	PLIB_USBHS_TestModeExit	This is function PLIB_USBHS_TestModeExit.
	PLIB_USBHS_PhyIDMonitoringDisable	This is function PLIB_USBHS_PhyIDMonitoringDisable.
	PLIB_USBHS_PhyIDMonitoringEnable	This is function PLIB_USBHS_PhyIDMonitoringEnable.
	PLIB_USBHS_USBIDOverrideDisable	This is function PLIB_USBHS_USBIDOverrideDisable.

	PLIB_USBHS_USBIDOverrideEnable	This is function PLIB_USBHS_USBIDOverrideEnable.
	PLIB_USBHS_USBIDOverrideValueSet	This is function PLIB_USBHS_USBIDOverrideValueSet.
	PLIB_USBHS_IsBDevice	This is function PLIB_USBHS_IsBDevice.

b) Endpoints Functions

	Name	Description
	PLIB_USBHS_Endpoint0FIFOFlush	This is function PLIB_USBHS_Endpoint0FIFOFlush.
	PLIB_USBHS_Endpoint0SetupPacketLoad	Loads the endpoint 0 FIFO with provided setup packet and then enables the endpoint transmit.
	PLIB_USBHS_Endpoint0SetupPacketUnload	This is function PLIB_USBHS_Endpoint0SetupPacketUnload.
	PLIB_USBHS_EndpointFIFOLoad	Loads the endpoint FIFO with provided data and then enables the endpoint transmit.
	PLIB_USBHS_EndpointFIFOUnload	Unloads the endpoint FIFO.
	PLIB_USBHS_EndpointRxFIFOFlush	This is function PLIB_USBHS_EndpointRxFIFOFlush.
	PLIB_USBHS_EndpointRxRequestClear	This is function PLIB_USBHS_EndpointRxRequestClear.
	PLIB_USBHS_EndpointRxRequestEnable	This is function PLIB_USBHS_EndpointRxRequestEnable.
	PLIB_USBHS_EndpointTxFIFOFlush	This is function PLIB_USBHS_EndpointTxFIFOFlush.
	PLIB_USBHS_EP0DataEndSet	This is function PLIB_USBHS_EP0DataEndSet.
	PLIB_USBHS_EP0INHandshakeClear	This is function PLIB_USBHS_EP0INHandshakeClear.
	PLIB_USBHS_EP0INHandshakeSend	This is function PLIB_USBHS_EP0INHandshakeSend.
	PLIB_USBHS_EP0INTokenSend	This is function PLIB_USBHS_EP0INTokenSend.
	PLIB_USBHS_EP0OUTHandshakeSend	This is function PLIB_USBHS_EP0OUTHandshakeSend.
	PLIB_USBHS_EP0RxPktRdyServiced	This is function PLIB_USBHS_EP0RxPktRdyServiced.
	PLIB_USBHS_EP0RxPktRdyServicedDataEnd	This is function PLIB_USBHS_EP0RxPktRdyServicedDataEnd.
	PLIB_USBHS_EP0SentStallClear	This is function PLIB_USBHS_EP0SentStallClear.
	PLIB_USBHS_EP0SetupEndServiced	This is function PLIB_USBHS_EP0SetupEndServiced.
	PLIB_USBHS_EP0StallDisable	This is function PLIB_USBHS_EP0StallDisable.
	PLIB_USBHS_EP0StallEnable	This is function PLIB_USBHS_EP0StallEnable.
	PLIB_USBHS_EP0StatusClear	This is function PLIB_USBHS_EP0StatusClear.
	PLIB_USBHS_EP0StatusGet	This is function PLIB_USBHS_EP0StatusGet.
	PLIB_USBHS_EP0TxPktRdy	This is function PLIB_USBHS_EP0TxPktRdy.
	PLIB_USBHS_EP0TxPktRdyDataEnd	This is function PLIB_USBHS_EP0TxPktRdyDataEnd.
	PLIB_USBHS_HostRxEndpointConfigure	This is function PLIB_USBHS_HostRxEndpointConfigure.
	PLIB_USBHS_HostTxEndpointConfigure	This is function PLIB_USBHS_HostTxEndpointConfigure.
	PLIB_USBHS_RxEPINTokenSend	This is function PLIB_USBHS_RxEPINTokenSend.
	PLIB_USBHS_RxEPStatusClear	This is function PLIB_USBHS_RxEPStatusClear.
	PLIB_USBHS_RxEPStatusGet	This is function PLIB_USBHS_RxEPStatusGet.
	PLIB_USBHS_TxEPStatusClear	This is function PLIB_USBHS_TxEPStatusClear.
	PLIB_USBHS_TxEPStatusGet	This is function PLIB_USBHS_TxEPStatusGet.
	PLIB_USBHS_GetEP0CSRAddress	This is function PLIB_USBHS_GetEP0CSRAddress.
	PLIB_USBHS_GetEP0FIFOAddress	This is function PLIB_USBHS_GetEP0FIFOAddress.
	PLIB_USBHS_LoadEPInIndex	This is function PLIB_USBHS_LoadEPInIndex.

c) Interrupts Functions

	Name	Description
	PLIB_USBHS_TxInterruptDisable	Disables a TX endpoint interrupt source for the USB module.
	PLIB_USBHS_TxInterruptEnable	Enables a TX endpoint Interrupt for the USB module.
	PLIB_USBHS_GenInterruptDisable	Disables a general interrupt for the USB module.
	PLIB_USBHS_GenInterruptEnable	Enables a general interrupt for the USB module.
	PLIB_USBHS_GenInterruptFlagsGet	Gets general interrupt flags.
	PLIB_USBHS_InterruptEnableSet	Enables USB module event interrupts.
	PLIB_USBHS_DMAInterruptDisable	Disables DMA channel interrupts.
	PLIB_USBHS_DMAInterruptEnable	Enables DMA channel interrupts.
	PLIB_USBHS_DMAInterruptFlagsGet	Gets the DMA channel interrupt flags.
	PLIB_USBHS_TxInterruptFlagsGet	Gets the TX endpoint interrupt flags.
	PLIB_USBHS_RxInterruptDisable	Disables a RX endpoint interrupt for the USB module.

	PLIB_USBHS_RxInterruptEnable	Enables a RX endpoint interrupt for the USB module.
	PLIB_USBHS_RxInterruptFlagsGet	Gets RX endpoint interrupt flags.
	PLIB_USBHS_DMAInterruptGet	This is function PLIB_USBHS_DMAInterruptGet.
	PLIB_USBHS_GlobalInterruptDisable	This is function PLIB_USBHS_GlobalInterruptDisable.
	PLIB_USBHS_GlobalInterruptEnable	This is function PLIB_USBHS_GlobalInterruptEnable.

d) Device Functions

	Name	Description
	PLIB_USBHS_DeviceAddressGet	Returns the current USB device address.
	PLIB_USBHS_DeviceAddressSet	Sets the device address.
	PLIB_USBHS_DeviceAttach	This is function PLIB_USBHS_DeviceAttach.
	PLIB_USBHS_DeviceConnect	Tri-states the USB D+ and D- lines.
	PLIB_USBHS_DeviceDetach	This is function PLIB_USBHS_DeviceDetach.
	PLIB_USBHS_DeviceDisconnect	Tri-states the USB D+ and D- lines.
	PLIB_USBHS_DeviceEPFIFOLoad	This is function PLIB_USBHS_DeviceEPFIFOLoad.
	PLIB_USBHS_DeviceEPFIFOUnload	This is function PLIB_USBHS_DeviceEPFIFOUnload.
	PLIB_USBHS_DeviceRxEndpointConfigure	This is function PLIB_USBHS_DeviceRxEndpointConfigure.
	PLIB_USBHS_DeviceRxEndpointStallDisable	This is function PLIB_USBHS_DeviceRxEndpointStallDisable.
	PLIB_USBHS_DeviceRxEndpointStallEnable	This is function PLIB_USBHS_DeviceRxEndpointStallEnable.
	PLIB_USBHS_DeviceTxEndpointConfigure	This is function PLIB_USBHS_DeviceTxEndpointConfigure.
	PLIB_USBHS_DeviceTxEndpointPacketReady	This is function PLIB_USBHS_DeviceTxEndpointPacketReady.
	PLIB_USBHS_DeviceTxEndpointStallDisable	This is function PLIB_USBHS_DeviceTxEndpointStallDisable.
	PLIB_USBHS_DeviceTxEndpointStallEnable	This is function PLIB_USBHS_DeviceTxEndpointStallEnable.

e) Host Functions

	Name	Description
	PLIB_USBHS_HostRxEndpointDataToggleClear	This is function PLIB_USBHS_HostRxEndpointDataToggleClear.
	PLIB_USBHS_HostTxEndpointDataToggleClear	This is function PLIB_USBHS_HostTxEndpointDataToggleClear.

f) Status Functions

	Name	Description
	PLIB_USBHS_FullOrHighSpeedIsConnected	This is function PLIB_USBHS_FullOrHighSpeedIsConnected.
	PLIB_USBHS_HighSpeedIsConnected	This is function PLIB_USBHS_HighSpeedIsConnected.
	PLIB_USBHS_HostModeIsEnabled	This is function PLIB_USBHS_HostModeIsEnabled.
	PLIB_USBHS_ModuleSpeedGet	Returns the speed at which the module is operating.
	PLIB_USBHS_DMAErrorGet	This is function PLIB_USBHS_DMAErrorGet.
	PLIB_USBHS_GetReceiveDataCount	This is function PLIB_USBHS_GetReceiveDataCount.

g) VBUS Support Functions

	Name	Description
	PLIB_USBHS_VbusLevelGet	Returns the current VBUS level encode using the USBHS_VBUS_DETECT_LEVEL enumeration.
	PLIB_USBHS_VBUSLevelGet	This is function PLIB_USBHS_VBUSLevelGet.

h) Feature Existence Functions

	Name	Description
	PLIB_USBHS_ExistsEndpointFIFO	Identifies that the Endpoint FIFO feature exists on the Hi-Speed USB module.
	PLIB_USBHS_ExistsEndpointOperations	This is function PLIB_USBHS_ExistsEndpointOperations.
	PLIB_USBHS_ExistsEP0Status	This is function PLIB_USBHS_ExistsEP0Status.
	PLIB_USBHS_ExistsHighSpeedSupport	This is function PLIB_USBHS_ExistsHighSpeedSupport.
	PLIB_USBHS_ExistsInterrupts	This is function PLIB_USBHS_ExistsInterrupts.
	PLIB_USBHS_ExistsModuleControl	This is function PLIB_USBHS_ExistsModuleControl.
	PLIB_USBHS_ExistsRxEPStatus	This is function PLIB_USBHS_ExistsRxEPStatus.
	PLIB_USBHS_ExistsSoftReset	This is function PLIB_USBHS_ExistsSoftReset.
	PLIB_USBHS_ExistsTxEPStatus	This is function PLIB_USBHS_ExistsTxEPStatus.
	PLIB_USBHS_ExistsClockResetControl	This is function PLIB_USBHS_ExistsClockResetControl.

	PLIB_USBHS_ExistsUSBIDControl	This is function PLIB_USBHS_ExistsUSBIDControl.

i) Data Types and Constants

	Name	Description
	USBHS_CONFIGURATION	Provides the enumeration Configuration bits.
	USBHS_DATA01	Provides an enumeration data toggle for a packet.
	USBHS_DMA_ASSERT_TIMING	Provides enumeration DMA assertion timing (early versus late).
	USBHS_DMA_BURST_MODE	Provides enumeration of all DMA burst modes.
	USBHS_DMA_INTERRUPT	Provides enumeration of interrupts for DMA channels 0-7.
	USBHS_DMA_REQUEST_MODE	Used as an argument to set DMA request mode.
	USBHS_DMA_TRANSFER_MODE	Provides enumeration of all DMA transfer modes.
	USBHS_DYN_FIFO_PACKET_BUFFERING	Provides enumeration of dynamic FIFO double-packet versus single-packet buffering.
	USBHS_DYN_FIFO_SIZE	Provides enumeration of dynamic FIFO sizes.
	USBHS_ENDPOINT_DIRECTION	Used as an argument to identify an endpoint direction.
	USBHS_LPM_INTERRUPT	Provides an enumeration of LPM interrupt sources.
	USBHS_LPM_LINK_STATE	Provides enumeration requested device state after accepting an LPM transaction.
	USBHS_LPM_MODE	Provides enumeration of Link Power Management (LPM) modes.
	USBHS_OPMODES	Provides enumeration of operating modes supported by USB.
	USBHS_PKTS_PER_MICROFRAME	Provides an enumeration of the allowable isochronous packets per microframe when operating in High-Speed mode.
	USBHS_SPEED	Provides enumeration Host endpoint speeds.
	USBHS_TEST_SPEED	Used as an argument for in setting module speeds in Test mode.
	USBHS_TRANSACTION_TYPE	Provides an enumeration of transaction types.
	USBHS_TXRX_FIFO_STATE	Provides enumeration of receive and transmit FIFO states, as reported by status bits.
	USBHS_MAX_DMA_CHANNEL_NUMBER	Number of available DMA Channels.
	USBHS_MAX_EP_NUMBER	Maximum number of endpoints supported (not including EP0).

Description

This section describes the Application Programming Interface (API) functions of the USBHS Peripheral Library.

Refer to each section for a detailed description.

a) USBHS Setup Functions

PLIB_USBHS_HighSpeedDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_HighSpeedDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_HighSpeedDisable.

PLIB_USBHS_HighSpeedEnable Function

Sets the operation speed of the USB Module.

File

plib_usbhs.h

C

```
void PLIB_USBHS_HighSpeedEnable(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function sets the operation speed of the USB module.

Remarks

None.

Preconditions

None.

Example

```
// Enable the USB module for high speed support.

PLIB_USBHS_HighSpeedEnable(USBHS_ID_0, USB_SPEED_HIGH);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
speed	The operation speed of the USB module

Function

void PLIB_USBHS_ModuleSpeedSet(USBHS_MODULE_ID index, uint32_t speed)

PLIB_USBHS_ResetDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_ResetDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ResetDisable.

PLIB_USBHS_ResetEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_ResetEnable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ResetEnable.

PLIB_USBHS_ResumeDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_ResumeDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ResumeDisable.

PLIB_USBHS_ResumeEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_ResumeEnable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ResumeEnable.

PLIB_USBHS_SessionDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_SessionDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_SessionDisable.

PLIB_USBHS_SessionEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_SessionEnable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_SessionEnable.

PLIB_USBHS_SoftResetDisable Function

Disables soft reset.

File

plib_usbhs.h

C

```
void PLIB_USBHS_SoftResetDisable(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function disables soft reset.

Remarks

Valid in both Peripheral and Host mode.

Preconditions

None.

Example

```
PLIB_USBHS_SoftResetDisable(USBHS_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USBHS_SoftResetDisable(USBHS_MODULE_ID index);

PLIB_USBHS_SoftResetEnable Function

Enables soft reset.

File

plib_usbhs.h

C

```
void PLIB_USBHS_SoftResetEnable(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function enables soft reset.

Remarks

Valid in both Peripheral and Host mode.

Preconditions

None.

Example

```
PLIB_USBHS_SoftResetEnable(USBHS_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USBHS_SoftResetEnable(USBHS_MODULE_ID index);

PLIB_USBHS_SuspendDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_SuspendDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_SuspendDisable.

PLIB_USBHS_SuspendEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_SuspendEnable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_SuspendEnable.

PLIB_USBHS_DMAOperationEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DMAOperationEnable(USBHS_MODULE_ID index, uint8_t endpoint, uint8_t dmaChannel, void *
address, uint32_t count, bool direction);
```

Description

This is function PLIB_USBHS_DMAOperationEnable.

PLIB_USBHS_TestModeEnter Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_TestModeEnter(USBHS_MODULE_ID index, uint8_t testMode);
```

Description

This is function PLIB_USBHS_TestModeEnter.

PLIB_USBHS_TestModeExit Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_TestModeExit(USBHS_MODULE_ID index, uint8_t testMode);
```

Description

This is function PLIB_USBHS_TestModeExit.

PLIB_USBHS_PhyIDMonitoringDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_PhyIDMonitoringDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_PhyIDMonitoringDisable.

PLIB_USBHS_PhyIDMonitoringEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_PhyIDMonitoringEnable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_PhyIDMonitoringEnable.

PLIB_USBHS_USBIDOverrideDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_USBIDOverrideDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_USBIDOverrideDisable.

PLIB_USBHS_USBIDOverrideEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_USBIDOverrideEnable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_USBIDOverrideEnable.

PLIB_USBHS_USBIDOverrideValueSet Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_USBIDOverrideValueSet(USBHS_MODULE_ID index, USBHS_USBID_OVERRIDE_VALUE id);
```

Description

This is function PLIB_USBHS_USBIDOverrideValueSet.

PLIB_USBHS_IsBDevice Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_IsBDevice(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_IsBDevice.

b) Endpoints Functions

PLIB_USBHS_Endpoint0FIFOFlush Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_Endpoint0FIFOFlush(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_Endpoint0FIFOFlush.

PLIB_USBHS_Endpoint0SetupPacketLoad Function

Loads the endpoint 0 FIFO with provided setup packet and then enables the endpoint transmit.

File

plib_usbhs.h

C

```
void PLIB_USBHS_Endpoint0SetupPacketLoad(USBHS_MODULE_ID index, void * setupPacket, uint8_t deviceAddress,
uint8_t hubAddress, uint8_t hubPortAddress, uint32_t speed);
```

Returns

None.

Description

This function loads the endpoint 0 FIFO with provided setup packet. This operation would typically be performed at the start of a endpoint 0 control transfer. Once the FIFO is loaded the function will load the target device address, hub and hub port address and then transmit the packet.

Remarks

Valid in Host mode only. Setup packet size should be 8 bytes. Packet will always be targeted to endpoint 0 of the target device.

Preconditions

None.

Example

```
// Send a setup packet to device 7 control endpoint
// connected directly to module.

PLIB_USBHS_Endpoint0SetupPacketLoad(USBHS_ID_0, setupPacket, 7, 0,
                                                    0, USB_SPEED_HIGH);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
setupPacket	setup packet to be sent to the device
deviceAddress	USB address of the device
hubAddress	USB address of the hub if the device is connected to a hub. Should be zero otherwise.
hubPortAddress	Port number of the hub port to which the device is connected if it is connected to a hub. Should be zero otherwise.
speed	Speed of the device to which the packet should be sent.

Function

void PLIB_USBHS_Endpoint0SetupPacketLoad(USBHS_MODULE_ID index,

void * setupPacket, uint8_t deviceAddress,

uint8_t hubAddress, uint8_t hubPortAddress,

uint32_t speed)

PLIB_USBHS_Endpoint0SetupPacketUnload Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_Endpoint0SetupPacketUnload(USBHS_MODULE_ID index, void * dest);
```

Description

This is function PLIB_USBHS_Endpoint0SetupPacketUnload.

PLIB_USBHS_EndpointFIFOLoad Function

Loads the endpoint FIFO with provided data and then enables the endpoint transmit.

File

plib_usbhs.h

C

```
void PLIB_USBHS_EndpointFIFOLoad(USBHS_MODULE_ID index, uint8_t endpoint, void * source, size_t nBytes);
```

Returns

None.

Description

This function loads the endpoint FIFO with provided data. This operation would typically be performed for a endpoint transmit operation. Once the FIFO is loaded the function will enable the enable the endpoint for transmit.

Remarks

Valid in both Peripheral and Host mode.

Preconditions

None.

Example

```
// Load endpoint 1 FIFO

PLIB_USBHS_EndpointFIFOLoad(USBHS_ID_0, 1, data, 10);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
endpoint	endpoint of which FIFO needs to be loaded
source	data that should be loaded
nBytes	number of bytes to load.

Function

void PLIB_USBHS_EndpointFIFOLoad(USBHS_MODULE_ID index, uint8_t endpoint,

void * source, size_t nBytes)

PLIB_USBHS_EndpointFIFOUnload Function

Unloads the endpoint FIFO.

File

plib_usbhs.h

C

```
int PLIB_USBHS_EndpointFIFOUnload(USBHS_MODULE_ID index, uint8_t endpoint, void * dest);
```

Returns

Returns the number of functions that were read.

Description

This function unloads the endpoint FIFO. This operation would typically be performed for a endpoint receive operation. The unloaded data is stored in provided buffer.

Remarks

Valid in both Peripheral and Host mode.

Preconditions

The USB module must be configured for Device mode operation.

Example

```
// Load endpoint 1 FIFO
int count;

count = PLIB_USBHS_EndpointFIFOUnload(USBHS_ID_0, 1, dest, 10);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
endpoint	endpoint of which FIFO to be unloaded.
dest	target address where unloaded data should be stored.

Function

int PLIB_USBHS_EndpointFIFOUnload(USBHS_MODULE_ID index, uint8_t endpoint,
void * destination)

PLIB_USBHS_EndpointRxFIFOFlush Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EndpointRxFIFOFlush(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_EndpointRxFIFOFlush.

PLIB_USBHS_EndpointRxRequestClear Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EndpointRxRequestClear(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_EndpointRxRequestClear.

PLIB_USBHS_EndpointRxRequestEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EndpointRxRequestEnable(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_EndpointRxRequestEnable.

PLIB_USBHS_EndpointTxFIFOFlush Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EndpointTxFIFOFlush(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_EndpointTxFIFOFlush.

PLIB_USBHS_EP0DataEndSet Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0DataEndSet(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0DataEndSet.

PLIB_USBHS_EP0INHandshakeClear Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0INHandshakeClear(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0INHandshakeClear.

PLIB_USBHS_EP0INHandshakeSend Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0INHandshakeSend(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0INHandshakeSend.

PLIB_USBHS_EP0INTokenSend Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0INTokenSend(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0INTokenSend.

PLIB_USBHS_EP0OUTHandshakeSend Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0OUTHandshakeSend(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0OUTHandshakeSend.

PLIB_USBHS_EP0RxPktRdyServiced Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0RxPktRdyServiced(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0RxPktRdyServiced.

PLIB_USBHS_EP0RxPktRdyServicedDataEnd Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0RxPktRdyServicedDataEnd(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0RxPktRdyServicedDataEnd.

PLIB_USBHS_EP0SentStallClear Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0SentStallClear(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0SentStallClear.

PLIB_USBHS_EP0SetupEndServiced Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0SetupEndServiced(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0SetupEndServiced.

PLIB_USBHS_EP0StallDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0StallDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0StallDisable.

PLIB_USBHS_EP0StallEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0StallEnable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0StallEnable.

PLIB_USBHS_EP0StatusClear Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0StatusClear(USBHS_MODULE_ID index, USBHS_EP0_ERROR error);
```

Description

This is function PLIB_USBHS_EP0StatusClear.

PLIB_USBHS_EP0StatusGet Function

File

plib_usbhs.h

C

```
uint8_t PLIB_USBHS_EP0StatusGet(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0StatusGet.

PLIB_USBHS_EP0TxPktRdy Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0TxPktRdy(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0TxPktRdy.

PLIB_USBHS_EP0TxPktRdyDataEnd Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0TxPktRdyDataEnd(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0TxPktRdyDataEnd.

PLIB_USBHS_HostRxEndpointConfigure Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_HostRxEndpointConfigure(USBHS_MODULE_ID index, uint8_t hostEndpoint, uint32_t speed,
uint32_t pipeType, uint16_t endpointSize, uint16_t receiveFIFOAddress, uint16_t fifoSize, uint8_t
targetEndpoint, uint8_t targetDevice, uint8_t targetHub, uint8_t targetHubPort, uint8_t nakInterval);
```

Description

This is function PLIB_USBHS_HostRxEndpointConfigure.

PLIB_USBHS_HostTxEndpointConfigure Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_HostTxEndpointConfigure(USBHS_MODULE_ID index, uint8_t hostEndpoint, uint32_t speed,
uint32_t pipeType, uint16_t endpointSize, uint16_t receiveFIFOAddress, uint16_t fifoSize, uint8_t
targetEndpoint, uint8_t targetDevice, uint8_t targetHub, uint8_t targetHubPort, uint8_t nakInterval);
```

Description

This is function PLIB_USBHS_HostTxEndpointConfigure.

PLIB_USBHS_RxEPINTokenSend Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_RxEPINTokenSend(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_RxEPINTokenSend.

PLIB_USBHS_RxEPStatusClear Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_RxEPStatusClear(USBHS_MODULE_ID index, uint8_t endpoint, USBHS_RXEP_ERROR error);
```

Description

This is function PLIB_USBHS_RxEPStatusClear.

PLIB_USBHS_RxEPStatusGet Function

File

plib_usbhs.h

C

```
uint8_t PLIB_USBHS_RxEPStatusGet(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_RxEPStatusGet.

PLIB_USBHS_TxEPStatusClear Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_TxEPStatusClear(USBHS_MODULE_ID index, uint8_t endpoint, USBHS_TXEP_ERROR error);
```

Description

This is function PLIB_USBHS_TxEPStatusClear.

PLIB_USBHS_TxEPStatusGet Function

File

plib_usbhs.h

C

```
uint8_t PLIB_USBHS_TxEPStatusGet(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_TxEPStatusGet.

PLIB_USBHS_GetEP0CSRAddress Function

File

plib_usbhs.h

C

```
uint8_t * PLIB_USBHS_GetEP0CSRAddress(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_GetEP0CSRAddress.

PLIB_USBHS_GetEP0FIFOAddress Function

File

plib_usbhs.h

C

```
uint8_t * PLIB_USBHS_GetEP0FIFOAddress(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_GetEP0FIFOAddress.

PLIB_USBHS_LoadEPInIndex Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_LoadEPInIndex(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_LoadEPInIndex.

c) Interrupts Functions

PLIB_USBHS_TxInterruptDisable Function

Disables a TX endpoint interrupt source for the USB module.

File

plib_usbhs.h

C

```
void PLIB_USBHS_TxInterruptDisable(USBHS_MODULE_ID index, USBHS_EPTXRX_INTERRUPT interruptFlag);
```

Returns

None.

Description

This function disables a TX endpoint interrupt source for the USB module.

Remarks

See also PLIB_USBHS_TxInterruptEnable.

Preconditions

None.

Example

```
PLIB_USBHS_TxInterruptDisable( MY_USB_INSTANCE, USBHS_TXRXINT_EP1 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USBHS_TxInterruptDisable(USBHS_MODULE_ID index,
USBHS_EPTXRX_INTERRUPT interruptFlag)

PLIB_USBHS_TxInterruptEnable Function

Enables a TX endpoint Interrupt for the USB module.

File

plib_usbhs.h

C

```
void PLIB_USBHS_TxInterruptEnable(USBHS_MODULE_ID index, USBHS_EPTXRX_INTERRUPT interruptFlag);
```

Returns

None.

Description

This function enables the TX endpoint interrupt sources of the USB module that are used to trigger a USB interrupt.

Remarks

See also PLIB_USBHS_TxInterruptDisable.

Preconditions

None.

Example

```
PLIB_USBHS_TxInterruptEnable( MY_USB_INSTANCE, USBHS_TXRXINT_EP1 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USBHS_TxInterruptEnable(USBHS_MODULE_ID index,
USBHS_EPTXRX_INTERRUPT interruptFlag)

PLIB_USBHS_GenInterruptDisable Function

Disables a general interrupt for the USB module.

File

plib_usbhs.h

C

```
void PLIB_USBHS_GenInterruptDisable(USBHS_MODULE_ID index, USBHS_GEN_INTERRUPT interruptFlag);
```

Returns

None.

Description

This function disables a general interrupt source for the USB module.

Remarks

See also PLIB_USBHS_GenInterruptEnable.

Preconditions

None.

Example

```
PLIB_USBHS_GenInterruptDisable( MY_USB_INSTANCE, USBHS_GENINT_VBUSERR );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USBHS_GenInterruptDisable(USBHS_MODULE_ID index,
USBHS_GEN_INTERRUPT interruptFlag)

PLIB_USBHS_GenInterruptEnable Function

Enables a general interrupt for the USB module.

File

plib_usbhs.h

C

```
void PLIB_USBHS_GenInterruptEnable(USBHS_MODULE_ID index, USBHS_GEN_INTERRUPT interruptFlag);
```

Returns

None.

Description

This function enables the general interrupt sources of the USB module that are used to trigger a USB interrupt.

Remarks

See also PLIB_USBHS_GenInterruptDisable.

Preconditions

None.

Example

```
PLIB_USBHS_GenInterruptEnable( MY_USB_INSTANCE, USBHS_GENINT_VBUSERR );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USBHS_GenInterruptEnable(USBHS_MODULE_ID index,
USBHS_GEN_INTERRUPT interruptFlag)

PLIB_USBHS_GenInterruptFlagsGet Function

Gets general interrupt flags.

File

plib_usbhs.h

C

```
USBHS_GEN_INTERRUPT PLIB_USBHS_GenInterruptFlagsGet(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function gets the general interrupt flags.

Remarks

None.

Preconditions

None.

Example

```
USBHS_GEN_INTERRUPT interruptFlags;
interruptFlags = PLIB_USBHS_GenInterruptFlagsGet( MY_USB_INSTANCE );
// All interrupt flags cleared on read.

if ( interruptFlags > 0 )
    if ( interruptFlags & USBHS_GENINT_SUSPEND )
    {
       // Device has detected suspend signaling on the bus.
    }
    if ( interruptFlags & USBHS_GENINT_RESUME )
    {
        //
    }
    .
    .
    .
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USBHS_GEN_INTERRUPT PLIB_USBHS_GenInterruptFlagsGet(USBHS_MODULE_ID index)

PLIB_USBHS_InterruptEnableSet Function

Enables USB module event interrupts.

File

plib_usbhs.h

C

```
void PLIB_USBHS_InterruptEnableSet(USBHS_MODULE_ID index, USBHS_GEN_INTERRUPT generalInterrupts,
USBHS_EPTXRX_INTERRUPT transmitInterrupts, USBHS_EPTXRX_INTERRUPT receiveInterrupts);
```

Returns

None.

Description

This function enables USB module event interrupts. Combines the functionality of the PLIB_USBHS_RxInterruptEnable, PLIB_USBHS_TxInterruptEnable, and PLIB_USBHS_GenInterruptEnable functions.

Remarks

None.

Preconditions

None.

Example

```
// Enable the reset interrupt, endpoint 1 transmit interrupt
// and endpoint 2 receive interrupts

PLIB_USBHS_InterruptEnableSet (USBHS_ID_0, USBHS_GENINT_RESET,
    USBHS_TXRXINT_EP1, USBHS_TXRXINT_EP2 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
generalInterrupts	General Module interrupts.
transmitInterrupts	Transmit Endpoint Interrupts to be enabled.
receiveInterrupts	Receive Endpoint Interrupts to be enabled.

Function

void PLIB_USBHS_InterruptEnableSet(USBHS_MODULE_ID index,

USBHS_GEN_INTERRUPT generalInterrupts,

USBHS_EPTXRX_INTERRUPT transmitInterrupts,

USBHS_EPTXRX_INTERRUPT receiveInterrupts);

PLIB_USBHS_DMAInterruptDisable Function

Disables DMA channel interrupts.

File

plib_usbhs.h

C

```
void PLIB_USBHS_DMAInterruptDisable(USBHS_MODULE_ID index, USBHS_DMA_INTERRUPT nChannelNumber);
```

Returns

None.

Description

This function disables DMA Channel interrupts.

Remarks

None.

Preconditions

None.

Example

```
PLIB_USBHS_DMAInterruptDisable (USBHS_ID_0, USBHS_DMAINT_5);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
dmaChannelInterrupt	DMA channel Interrupt to disable

Function

void PLIB_USBHS_DMAInterruptDisable(USBHS_MODULE_ID index,
USBHS_DMA_INTERRUPT dmaChannelInterrupt)

PLIB_USBHS_DMAInterruptEnable Function

Enables DMA channel interrupts.

File

plib_usbhs.h

C

```
void PLIB_USBHS_DMAInterruptEnable(USBHS_MODULE_ID index, USBHS_DMA_INTERRUPT nChannelNumber);
```

Returns

None.

Description

This function enables DMA Channel interrupts.

Remarks

None.

Preconditions

None.

Example

```
PLIB_USBHS_DMAInterruptEnable (USBHS_ID_0, USBHS_DMAINT_5);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
dmaChannelInterrupt	DMA channel Interrupt to enable

Function

void PLIB_USBHS_DMAInterruptEnable(USBHS_MODULE_ID index,
USBHS_DMA_INTERRUPT dmaChannelInterrupt)

PLIB_USBHS_DMAInterruptFlagsGet Function

Gets the DMA channel interrupt flags.

File

plib_usbhs.h

C

```
USBHS_DMA_INTERRUPT PLIB_USBHS_DMAInterruptFlagsGet(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function gets the DMA channel interrupt flags.

Remarks

None.

Preconditions

None.

Example

```
USBHS_DMA_INTERRUPT interruptFlags;
interruptFlags = PLIB_USBHS_DMAInterruptFlagsGet( MY_USB_INSTANCE );
// All interrupt flags cleared on read.

if ( interruptFlags > 0 )
    if ( interruptFlags & USBHS_DMAINT_1 )
    {
        // DMA Channel 1
    }
    if (interruptFlags & USBHS_DMAINT_2)
    {
        // DMA Channel 2
    }
    .
    .
    .
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USBHS_DMA_INTERRUPT PLIB_USBHS_DMAInterruptFlagsGet(USBHS_MODULE_ID index)

PLIB_USBHS_TxInterruptFlagsGet Function

Gets the TX endpoint interrupt flags.

File

plib_usbhs.h

C

```
USBHS_EPTXRX_INTERRUPT PLIB_USBHS_TxInterruptFlagsGet(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function gets the TX endpoint interrupt flags.

Remarks

TX interrupts must first be enabled by calling PLIB_USBHS_TxInterruptEnable.

Preconditions

None.

Example

```
USBHS_EPTXRX_INTERRUPT interruptFlags;
interruptFlags = PLIB_USBHS_TxInterruptFlagsGet( MY_USB_INSTANCE );
// All interrupt flags cleared on read.

if ( interruptFlags > 0 )
    if ( interruptFlags & USBHS_TXRXINT_EP0 )
    {
       // Endpoint Zero
    }
    if ( interruptFlags & USBHS_TXRXINT_EP1 )
    {
        // Endpoint One
    }
    .
    .
    .
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USBHS_EPTXRX_INTERRUPT PLIB_USBHS_TxInterruptFlagsGet(USBHS_MODULE_ID index)

PLIB_USBHS_RxInterruptDisable Function

Disables a RX endpoint interrupt for the USB module.

File

plib_usbhs.h

C

```
void PLIB_USBHS_RxInterruptDisable(USBHS_MODULE_ID index, USBHS_EPTXRX_INTERRUPT interruptFlag);
```

Returns

None.

Description

This function disables a RX endpoint interrupt source for the USB module.

Remarks

See also PLIB_USBHS_RxInterruptEnable. USBHS_TXRXINT_EP0 is not a valid argument. For endpoint zero, use PLIB_USBHS_TxInterruptDisable.

Preconditions

None.

Example

```
PLIB_USBHS_RxInterruptDisable( MY_USB_INSTANCE, USBHS_TXRXINT_EP1 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USBHS_RxInterruptDisable(USBHS_MODULE_ID index,

USBHS_EPTXRX_INTERRUPT interruptFlag)

PLIB_USBHS_RxInterruptEnable Function

Enables a RX endpoint interrupt for the USB module.

File

plib_usbhs.h

C

```
void PLIB_USBHS_RxInterruptEnable(USBHS_MODULE_ID index, USBHS_EPTXRX_INTERRUPT interruptFlag);
```

Returns

None.

Description

This function enables RX endpoint interrupt sources of the USB module to trigger a USB interrupt.

Remarks

See also PLIB_USBHS_RxInterruptDisable. USBHS_TXRXINT_EP0 is not a valid argument. For endpoint zero use PLIB_USBHS_TxInterruptEnable.

Preconditions

None.

Example

```
PLIB_USBHS_RxInterruptEnable( MY_USB_INSTANCE, USBHS_TXRXINT_EP1 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USBHS_RxInterruptEnable(USBHS_MODULE_ID index,

USBHS_EPTXRX_INTERRUPT interruptFlag)

PLIB_USBHS_RxInterruptFlagsGet Function

Gets RX endpoint interrupt flags.

File

plib_usbhs.h

C

```
USBHS_EPTXRX_INTERRUPT PLIB_USBHS_RxInterruptFlagsGet(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function gets the RX endpoint interrupt flags.

Remarks

RX interrupts must first be enabled by calling PLIB_USBHS_RxInterruptEnable. USBHS_TXRXINT_EP0 is not a valid argument. For endpoint zero use PLIB_USBHS_TxInterruptFlagsGet.

Preconditions

None.

Example

```
USBHS_EPTXRX_INTERRUPT interruptFlags;
```

```
    interruptFlags = PLIB_USBHS_RxInterruptFlagsGet( MY_USB_INSTANCE );
    // All interrupt flags cleared on read.

    if ( interruptFlags > 0 )
        if ( interruptFlags & USBHS_TXRXINT_EP1 )
        {
           // Endpoint Zero
        }
        if ( interruptFlags & USBHS_TXRXINT_EP2 )
        {
            // Endpoint One
        }
        .
        .
        .
    }
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USBHS_EPTXRX_INTERRUPT PLIB_USBHS_RxInterruptFlagsGet(USBHS_MODULE_ID index)

PLIB_USBHS_DMAInterruptGet Function

File

plib_usbhs.h

C

```
uint8_t PLIB_USBHS_DMAInterruptGet(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_DMAInterruptGet.

PLIB_USBHS_GlobalInterruptDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_GlobalInterruptDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_GlobalInterruptDisable.

PLIB_USBHS_GlobalInterruptEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_GlobalInterruptEnable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_GlobalInterruptEnable.

d) Device Functions

PLIB_USBHS_DeviceAddressGet Function

Returns the current USB device address.

File

plib_usbhs.h

C

```
uint8_t PLIB_USBHS_DeviceAddressGet(USBHS_MODULE_ID index);
```

Returns

7-bit unsigned integer value indicating the current USB device address.

Description

This function returns the current USB device address.

Remarks

None.

Preconditions

The USB module should have been configured for Device mode operation.

Example

```
// This code example reads the current assigned USB device address.

uint8_t address;
address = PLIB_USBHS_DeviceAddressGet(USBHS_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_USBHS_DeviceAddressGet (USBHS_MODULE_ID index)

PLIB_USBHS_DeviceAddressSet Function

Sets the device address.

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceAddressSet(USBHS_MODULE_ID index, uint8_t address);
```

Returns

None.

Description

This function sets the device address. This function should be called with the address received from the host in the SET_ADDRESS request.

Remarks

None.

Preconditions

The USB module must be configured for Device mode operation.

Example

```
// This code example assigns a USB device address.

uint8_t address;
```

```
PLIB_USBHS_DeviceAddressSet(USBHS_ID_0, address);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
address	7-bit USB Device address that should be assigned to this device

Function

void PLIB_USBHS_DeviceAddressSet (USBHS_MODULE_ID index, uint8_t address)

PLIB_USBHS_DeviceAttach Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceAttach(USBHS_MODULE_ID index, uint32_t speed);
```

Description

This is function PLIB_USBHS_DeviceAttach.

PLIB_USBHS_DeviceConnect Function

Tri-states the USB D+ and D- lines.

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceConnect(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function enables the USB D+ and D- lines, which connects the device from the host.

Remarks

Only valid for Device mode.

Preconditions

The USB module must be configured for Device mode operation.

Example

```
// Disconnect the device from the host

PLIB_USBHS_DeviceConnect(USBHS_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USBHS_DeviceConnect(USBHS_MODULE_ID index)

PLIB_USBHS_DeviceDetach Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceDetach(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_DeviceDetach.

PLIB_USBHS_DeviceDisconnect Function

Tri-states the USB D+ and D- lines.

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceDisconnect(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function tri-states the USB D+ and D- lines, which disconnects the device from the host.

Remarks

Only valid for Device mode.

Preconditions

None.

Example

```
// Disconnect the device from the host

PLIB_USBHS_DeviceDisconnect(USBHS_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USBHS_DeviceDisconnect(USBHS_MODULE_ID index)

PLIB_USBHS_DeviceEPFIFOLoad Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceEPFIFOLoad(USBHS_MODULE_ID index, uint8_t endpoint, void * source, size_t nBytes);
```

Description

This is function PLIB_USBHS_DeviceEPFIFOLoad.

PLIB_USBHS_DeviceEPFIFOUnload Function

File

plib_usbhs.h

C

```
int PLIB_USBHS_DeviceEPFIFOUnload(USBHS_MODULE_ID index, uint8_t endpoint, void * dest);
```

Description

This is function PLIB_USBHS_DeviceEPFIFOUnload.

PLIB_USBHS_DeviceRxEndpointConfigure Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceRxEndpointConfigure(USBHS_MODULE_ID index, uint8_t endpoint, uint16_t endpointSize,
uint16_t fifoAddress, uint8_t fifoSize, uint32_t transferType);
```

Description

This is function PLIB_USBHS_DeviceRxEndpointConfigure.

PLIB_USBHS_DeviceRxEndpointStallDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceRxEndpointStallDisable(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_DeviceRxEndpointStallDisable.

PLIB_USBHS_DeviceRxEndpointStallEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceRxEndpointStallEnable(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_DeviceRxEndpointStallEnable.

PLIB_USBHS_DeviceTxEndpointConfigure Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceTxEndpointConfigure(USBHS_MODULE_ID index, uint8_t endpoint, uint16_t endpointSize,
uint16_t fifoAddress, uint8_t fifoSize, uint32_t transferType);
```

Description

This is function PLIB_USBHS_DeviceTxEndpointConfigure.

PLIB_USBHS_DeviceTxEndpointPacketReady Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceTxEndpointPacketReady(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_DeviceTxEndpointPacketReady.

PLIB_USBHS_DeviceTxEndpointStallDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceTxEndpointStallDisable(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_DeviceTxEndpointStallDisable.

PLIB_USBHS_DeviceTxEndpointStallEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceTxEndpointStallEnable(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_DeviceTxEndpointStallEnable.

e) Host Functions

PLIB_USBHS_HostRxEndpointDataToggleClear Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_HostRxEndpointDataToggleClear(USBHS_MODULE_ID index, uint8_t hostEndpoint);
```

Description

This is function PLIB_USBHS_HostRxEndpointDataToggleClear.

PLIB_USBHS_HostTxEndpointDataToggleClear Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_HostTxEndpointDataToggleClear(USBHS_MODULE_ID index, uint8_t hostEndpoint);
```

Description

This is function PLIB_USBHS_HostTxEndpointDataToggleClear.

f) Status Functions

PLIB_USBHS_FullOrHighSpeedIsConnected Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_FullOrHighSpeedIsConnected(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_FullOrHighSpeedIsConnected.

PLIB_USBHS_HighSpeedIsConnected Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_HighSpeedIsConnected(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_HighSpeedIsConnected.

PLIB_USBHS_HostModeIsEnabled Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_HostModeIsEnabled(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_HostModeIsEnabled.

PLIB_USBHS_ModuleSpeedGet Function

Returns the speed at which the module is operating.

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ModuleSpeedGet(USBHS_MODULE_ID index);
```

Returns

Current module operation speed on the USB.

Description

This function returns the speed at which the module is operating. In case of device mode operation, this function returns the speed at which the device attached to the host.

Remarks

None.

Preconditions

None.

Example

```
USB_SPEED speed;
speed = PLIB_USBHS_ModuleSpeedGet(USBHS_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USB_SPEED PLIB_USBHS_ModuleSpeedGet(USBHS_MODULE_ID index)

PLIB_USBHS_DMAErrorGet Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_DMAErrorGet(USBHS_MODULE_ID index, uint8_t dmaChannel);
```

Description

This is function PLIB_USBHS_DMAErrorGet.

PLIB_USBHS_GetReceiveDataCount Function

File

plib_usbhs.h

C

```
uint32_t PLIB_USBHS_GetReceiveDataCount(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_GetReceiveDataCount.

g) VBUS Support Functions

PLIB_USBHS_VbusLevelGet Function

Returns the current VBUS level encode using the USBHS_VBUS_DETECT_LEVEL enumeration.

File

plib_usbhs.h

C

```
USBHS_VBUS_LEVEL PLIB_USBHS_VbusLevelGet(USBHS_MODULE_ID index);
```

Returns

Detected VBUS level, see USBHS_VBUS_DETECT_LEVEL enumeration.

Description

Returns the current VBUS level encode using the USBHS_VBUS_DETECT_LEVEL enumeration.

Remarks

None.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USBHS_VBUS_DETECT_LEVEL PLIB_USBHS_VbusLevelGet(USBHS_MODULE_ID index)

PLIB_USBHS_VBUSLevelGet Function

File

plib_usbhs.h

C

```
USBHS_VBUS_LEVEL PLIB_USBHS_VBUSLevelGet(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_VBUSLevelGet.

h) Feature Existence Functions

PLIB_USBHS_ExistsEndpointFIFO Function

Identifies that the Endpoint FIFO feature exists on the Hi-Speed USB module.

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsEndpointFIFO(USBHS_MODULE_ID index);
```

Returns

- true - The feature is supported
- false - The feature is not supported

Description

This interface identifies that the Endpoint FIFO feature is available on the Hi-Speed USB module. When this interface returns true, these functions are supported on the device:

- PLIB_USBHS_EndpointFIFOLoad
- PLIB_USBHS_EndpointFIFOUnload

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USBHS_ExistsEndpointFIFO(USBHS_MODULE_ID index)

PLIB_USBHS_ExistsEndpointOperations Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsEndpointOperations(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsEndpointOperations.

PLIB_USBHS_ExistsEP0Status Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsEP0Status(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsEP0Status.

PLIB_USBHS_ExistsHighSpeedSupport Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsHighSpeedSupport(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsHighSpeedSupport.

PLIB_USBHS_ExistsInterrupts Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsInterrupts(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsInterrupts.

PLIB_USBHS_ExistsModuleControl Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsModuleControl(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsModuleControl.

PLIB_USBHS_ExistsRxEPStatus Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsRxEPStatus(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsRxEPStatus.

PLIB_USBHS_ExistsSoftReset Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsSoftReset(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsSoftReset.

PLIB_USBHS_ExistsTxEPStatus Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsTxEPStatus(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsTxEPStatus.

PLIB_USBHS_ExistsClockResetControl Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsClockResetControl(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsClockResetControl.

PLIB_USBHS_ExistsUSBIDControl Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsUSBIDControl(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsUSBIDControl.

i) Data Types and Constants

USBHS_CONFIGURATION Enumeration

Provides the enumeration Configuration bits.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_CONFIG_SOFTCONN,
  USBHS_CONFIG_DYNFIFOSIZE,
```

```
  USBHS_CONFIG_HBWTXISO,
  USBHS_CONFIG_HBWRXISO,
  USBHS_CONFIG_BIGENDIAN,
  USBHS_CONFIG_AUTOSPLIT,
  USBHS_CONFIG_AUTOJOIN
} USBHS_CONFIGURATION;
```

Members

Members	Description
USBHS_CONFIG_SOFTCONN	Soft connect/disconnect supported
USBHS_CONFIG_DYNFIFOSIZE	Dynamic sizing of FIFO buffers supported
USBHS_CONFIG_HBWTXISO	High bandwidth TX isochronous transfers supported
USBHS_CONFIG_HBWRXISO	High bandwidth RX isochronous transfers supported
USBHS_CONFIG_BIGENDIAN	Big Endian byte ordering supported instead of Little Endian
USBHS_CONFIG_AUTOSPLIT	Automatic splitting of bulk packets supported
USBHS_CONFIG_AUTOJOIN	Automatic combining of bulk packets supported

Description

USBHS Hardware Configuration Bits Enumeration

This data type provides the enumeration configuration bits returned by PLIB_USBHS_ConfigurationBitsGet.

Remarks

See also PLIB_USBHS_ConfigurationBitsGet.

USBHS_DATA01 Enumeration

Provides an enumeration data toggle for a packet.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_DATA0,
  USBHS_DATA1
} USBHS_DATA01;
```

Members

Members	Description
USBHS_DATA0	DATA0/1 = 0
USBHS_DATA1	DATA0/1 = 1

Description

USBHS Endpoint Data Toggle Enumeration

This data type provides an enumeration data toggle for a packet.

Remarks

None.

USBHS_DMA_ASSERT_TIMING Enumeration

Provides enumeration DMA assertion timing (early versus late).

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_DMA_ASSERT_EARLY,
  USBHS_DMA_ASSERT_LATE
} USBHS_DMA_ASSERT_TIMING;
```

Members

Members	Description
USBHS_DMA_ASSERT_EARLY	Assert DMA 8 bytes before filling FIFO
USBHS_DMA_ASSERT_LATE	Assert DMA when FIFO is full

Description

USBHS DMA Assertion Timing Enumeration

This data type provides enumeration DMA assertion timing (early versus late).

Remarks

None.

USBHS_DMA_BURST_MODE Enumeration

Provides enumeration of all DMA burst modes.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_DMA_BURST_MODE0,
  USBHS_DMA_BURST_MODE1,
  USBHS_DMA_BURST_MODE2,
  USBHS_DMA_BURST_MODE3
} USBHS_DMA_BURST_MODE;
```

Members

Members	Description
USBHS_DMA_BURST_MODE0	Burst Mode 0: Bursts of unspecified length
USBHS_DMA_BURST_MODE1	Burst Mode 1: INCR4 or unspecified length
USBHS_DMA_BURST_MODE2	Burst Mode 2: INCR8, INCR4 or unspecified length
USBHS_DMA_BURST_MODE3	Burst Mode 3: INCR16, INCR8, INCR4 or unspecified length

Description

USBHS DMA Burst Modes Enumeration

This data type provides enumeration of all DMA burst modes.

Remarks

None.

USBHS_DMA_INTERRUPT Enumeration

Provides enumeration of interrupts for DMA channels 0-7.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_DMAINT_1,
  USBHS_DMAINT_2,
  USBHS_DMAINT_3,
  USBHS_DMAINT_4,
  USBHS_DMAINT_5,
  USBHS_DMAINT_6,
  USBHS_DMAINT_7,
  USBHS_DMAINT_8,
  USBHS_DMAINT_ANY,
  USBHS_DMAINT_ALL
} USBHS_DMA_INTERRUPT;
```

Description

USBHS DMA Interrupts Enumeration

This data type provides the enumeration of interrupts for DMA channels 0-7.

Remarks

None.

USBHS_DMA_REQUEST_MODE Enumeration

Used as an argument to set DMA request mode.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_DMA_MODE0,
  USBHS_DMA_MODE1
} USBHS_DMA_REQUEST_MODE;
```

Description

USBHS DMA Request Mode Enumeration

THis data type is used as an argument to set DMA request mode. Valid only for Endpoints 1-7.

Remarks

Used by PLIB_USBHS_EPnDMARequestModeSet.

USBHS_DMA_TRANSFER_MODE Enumeration

Provides enumeration of all DMA transfer modes.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_DMA_TRANSFER_MODE0,
  USBHS_DMA_TRANSFER_MODE1
} USBHS_DMA_TRANSFER_MODE;
```

Description

USBHS DMA Transfer Modes Enumeration

This data type provides enumeration of all DMA Transfer modes.

Remarks

None.

USBHS_DYN_FIFO_PACKET_BUFFERING Enumeration

Provides enumeration of dynamic FIFO double-packet versus single-packet buffering.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_FIFO_SINGLEPKT,
  USBHS_FIFO_DOUBLEPKT
} USBHS_DYN_FIFO_PACKET_BUFFERING;
```

Description

USBHS Dynamic FIFO Double Packet versus Single Packet Buffering

This data type provides enumeration of dynamic FIFO double-packet versus single-packet buffering.

Remarks

None.

USBHS_DYN_FIFO_SIZE Enumeration

Provides enumeration of dynamic FIFO sizes.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_FIFO_SIZE_8BYTES,
  USBHS_FIFO_SIZE_16BYTES,
  USBHS_FIFO_SIZE_32BYTES,
  USBHS_FIFO_SIZE_64BYTES,
  USBHS_FIFO_SIZE_128BYTES,
  USBHS_FIFO_SIZE_256BYTES,
  USBHS_FIFO_SIZE_512BYTES,
  USBHS_FIFO_SIZE_1024BYTES,
  USBHS_FIFO_SIZE_2048BYTES,
  USBHS_FIFO_SIZE_4096BYTES
} USBHS_DYN_FIFO_SIZE;
```

Description

USBHS Dynamic FIFO Size Enumeration

This data type provides enumeration of dynamic FIFO sizes.

Remarks

FIFO size = 2^(FIFO_Size<3:0> + 3)

USBHS_ENDPOINT_DIRECTION Enumeration

Used as an argument to identify an endpoint direction.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_ENDPOINT_RX,
  USBHS_ENDPOINT_TX
} USBHS_ENDPOINT_DIRECTION;
```

Members

Members	Description
USBHS_ENDPOINT_RX	RX endpoint
USBHS_ENDPOINT_TX	TX endpoint

Description

USBHS Endpoint Direction Enumeration

This data type is used as an argument to identify an endpoint direction. Valid only for Endpoints 1-7.

Remarks

None.

USBHS_LPM_INTERRUPT Enumeration

Provides an enumeration of LPM interrupt sources.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_LPMINT_STALL,
  USBHS_LPMINT_NYET,
  USBHS_LPMINT_ACK,
  USBHS_LPMINT_NOTCOMPLETE,
  USBHS_LPMINT_RESUMED,
  USBHS_LPMINT_ERROR
} USBHS_LPM_INTERRUPT;
```

Members

Members	Description
USBHS_LPMINT_STALL	Host: Device responded with STALL. Peripheral/Device: Sent a STALL.
USBHS_LPMINT_NYET	Host: Device responded with NYET. Peripheral/Device: Sent a NYET.
USBHS_LPMINT_ACK	Host: Device responded with ACK. Peripheral/Device: Sent an ACK.
USBHS_LPMINT_NOTCOMPLETE	Host: LPM transaction failed to complete. Peripheral/Device: NYET sent because data is pending in RX FIFOs.
USBHS_LPMINT_RESUMED	USB Module has resumed operation.
USBHS_LPMINT_ERROR	Host: Received Bit Stuff or PID error. Peripheral/Device: Unsupported LinkState field received.

Description

USBHS Link Power Management (LPM) Interrupts Enumeration

This data type provides an enumeration of LPM interrupt sources.

Remarks

None.

USBHS_LPM_LINK_STATE Enumeration

Provides enumeration requested device state after accepting an LPM transaction.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_LPM_RESERVED_0,
  USBHS_LPM_L1_STATE,
  USBHS_LPM_RESERVED_2,
  USBHS_LPM_RESERVED_3,
  USBHS_LPM_RESERVED_4,
  USBHS_LPM_RESERVED_5,
  USBHS_LPM_RESERVED_6,
  USBHS_LPM_RESERVED_7,
  USBHS_LPM_RESERVED_8,
  USBHS_LPM_RESERVED_9,
  USBHS_LPM_RESERVED_A,
  USBHS_LPM_RESERVED_B,
  USBHS_LPM_RESERVED_C,
  USBHS_LPM_RESERVED_D,
  USBHS_LPM_RESERVED_E,
  USBHS_LPM_RESERVED_F
} USBHS_LPM_LINK_STATE;
```

Description

USBHS Link Power Management Requested State Enumeration

This data type provides enumeration requested device state after accepting an LPM transaction.

Remarks

Used by PLIB_USBHS_LPMRequestedLinkStateGet and PLIB_USBHS_LPMRequestedLinkStateSet.

USBHS_LPM_MODE Enumeration

Provides enumeration of Link Power Management (LPM) modes.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_LPM_DISABLED,
  USBHS_LPM_EXTENDEDNOLPM,
  USBHS_LPM_DISABLED2,
  USBHS_LPM_LPMEXTENDED
} USBHS_LPM_MODE;
```

Members

Members	Description
USBHS_LPM_DISABLED	LPM and Extended transactions not supported and will time-out
USBHS_LPM_EXTENDEDNOLPM	Extended transactions supported but LPM transactions not supported and produce STALLs
USBHS_LPM_DISABLED2	LPM and Extended transactions not supported and will timeout
USBHS_LPM_LPMEXTENDED	LPM and Extended transactions are supported

Description

USBHS Link Power Management (LPM) Mode Enumeration

This data type provides enumeration of Link Power Management (LPM) modes.

Remarks

Used by PLIB_USBHS_LPMModeSet.

USBHS_OPMODES Enumeration

Provides enumeration of operating modes supported by USB.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_OPMODE_NONE,
  USBHS_OPMODE_DEVICE,
  USBHS_OPMODE_HOST,
  USBHS_OPMODE_OTG
} USBHS_OPMODES;
```

Members

Members	Description
USBHS_OPMODE_NONE	None
USBHS_OPMODE_DEVICE	Device
USBHS_OPMODE_HOST	Host
USBHS_OPMODE_OTG	OTG

Description

USB Operating Modes Enumeration

This data type provides enumeration of the operating modes supported by the USB module.

Remarks

None.

USBHS_PKTS_PER_MICROFRAME Enumeration

Provides an enumeration of the allowable isochronous packets per microframe when operating in High-Speed mode.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_ONE_PKTS,
  USBHS_TWO_PKTS,
  USBHS_THREE_PKTS,
  USBHS_RSVD_PKTS
} USBHS_PKTS_PER_MICROFRAME;
```

Description

USBHS Iso Packets Per Microframe Enumeration

This data type provides an enumeration of the allowable isochronous packets per microframe when operating in High-Speed mode.

Remarks

Used by PLIB_USBHS_EPnPacketsInMicroFrameSet.

For Transmit Endpoints: PIC32MZ EC device SFR fields: USBIENCSR0.MULT<1:0> = USBIENCSR0<12:11>, with USBCSR3.ENDPOINT = 1,2,...7

For Receive Endpoints: MG register fields: RXMAXP.m-1 = RXMAXP<12:11>, with INDEX.SelectedEndpoint = 1,2,...7 PIC32MZ EC device SFR fields: USBIENCSR1.MULT<1:0> = USBIENCSR1<12:11>, with USBCSR3.ENDPOINT = 1,2,...7

USBHS_SPEED Enumeration

Provides enumeration Host endpoint speeds.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_LOW_SPEED,
  USBHS_FULL_SPEED,
  USBHS_HIGH_SPEED
} USBHS_SPEED;
```

Description

USBHS Endpoint Speed Enumeration

This data type provides enumeration Host endpoint speeds.

Remarks

Used by PLIB_USBHS_EPnSpeedSet.

USBHS_TEST_SPEED Enumeration

Used as an argument for in setting module speeds in Test mode.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_TEST_LOW_SPEED,
  USBHS_TEST_FULL_SPEED,
  USBHS_TEST_HIGH_SPEED
} USBHS_TEST_SPEED;
```

Description

USBHS Test Speeds Enumeration

This data type is used as an argument for setting module speeds in Test mode.

Remarks

For use with PLIB_USBHS_TestSpeedForce.

USBHS_TRANSACTION_TYPE Enumeration

Provides an enumeration of transaction types.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_TRANSACTION_CONTROL,
  USBHS_TRANSACTION_ISO,
  USBHS_TRANSACTION_BULK,
  USBHS_TRANSACTION_INTERRUPT
} USBHS_TRANSACTION_TYPE;
```

Description

USBHS Endpoint Transaction Type Enumeration

This data type provides an enumeration of transaction types.

Remarks

Used by PLIB_USBHS_EPnTransactionTypeSet

USBHS_TXRX_FIFO_STATE Enumeration

Provides enumeration of receive and transmit FIFO states, as reported by status bits.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_TX_FIFO_EMPTY,
  USBHS_TX_FIFO_NOT_EMPTY,
  USBHS_RX_FIFO_FULL,
  USBHS_RX_FIFO_NOTFULL
} USBHS_TXRX_FIFO_STATE;
```

Members

Members	Description
USBHS_TX_FIFO_EMPTY	TX FIFO Empty
USBHS_TX_FIFO_NOT_EMPTY	TX FIFO NOT Empty
USBHS_RX_FIFO_FULL	RX FIFO Full
USBHS_RX_FIFO_NOTFULL	RX FIFO NOT Full

Description

USBHS FIFO State Enumeration

This data type provides enumeration of receive and transmit FIFO states, as reported by status bits.

Remarks

None.

For Transmit Endpoints: MG register fields: TXCSRL.FIFONotEmpty = TXCSRL<1>, with INDEX.SelectedEndpoint = 1,2,...7 PIC32MZ EC device SFR fields: USBIENCSR0.FIFONE = USBIENCSR0<17>, with USBCSR3.ENDPOINT = 1,2,...7

For Receive Endpoints: MG register fields: RXCSRL.FIFOFull = RXCSRL<1>, with INDEX.SelectedEndpoint = 1,2,...7 PIC32MZ EC device SFR fields: USBIENCSR1.FIFOFULL = USBIENCSR1<17>, with USBCSR3.ENDPOINT = 1,2,...7

USBHS_MAX_DMA_CHANNEL_NUMBER Macro

Number of available DMA Channels.

File

plib_usbhs.h

C

```
#define USBHS_MAX_DMA_CHANNEL_NUMBER 8
```

Description

Number of DMA Channels

This constant defines the number of available DMA Channels.

USBHS_MAX_EP_NUMBER Macro

Maximum number of endpoints supported (not including EP0).

File

plib_usbhs.h

C

```
#define USBHS_MAX_EP_NUMBER 7
```

Description

Maximum number of endpoints

This constant defines the maximum number of endpoints supported (not including EP0).

Files

Files

Name	Description
plib_usbhs.h	HS USB PLIB Interface Header for definitions common to the Hi-Speed USB module.

Description

This section lists the source and header files used by the library.

plib_usbhs.h

HS USB PLIB Interface Header for definitions common to the Hi-Speed USB module.

Enumerations

	Name	Description
	USBHS_CONFIGURATION	Provides the enumeration Configuration bits.
	USBHS_DATA01	Provides an enumeration data toggle for a packet.
	USBHS_DMA_ASSERT_TIMING	Provides enumeration DMA assertion timing (early versus late).
	USBHS_DMA_BURST_MODE	Provides enumeration of all DMA burst modes.
	USBHS_DMA_INTERRUPT	Provides enumeration of interrupts for DMA channels 0-7.
	USBHS_DMA_REQUEST_MODE	Used as an argument to set DMA request mode.
	USBHS_DMA_TRANSFER_MODE	Provides enumeration of all DMA transfer modes.
	USBHS_DYN_FIFO_PACKET_BUFFERING	Provides enumeration of dynamic FIFO double-packet versus single-packet buffering.
	USBHS_DYN_FIFO_SIZE	Provides enumeration of dynamic FIFO sizes.
	USBHS_ENDPOINT_DIRECTION	Used as an argument to identify an endpoint direction.
	USBHS_LPM_INTERRUPT	Provides an enumeration of LPM interrupt sources.
	USBHS_LPM_LINK_STATE	Provides enumeration requested device state after accepting an LPM transaction.
	USBHS_LPM_MODE	Provides enumeration of Link Power Management (LPM) modes.
	USBHS_OPMODES	Provides enumeration of operating modes supported by USB.
	USBHS_PKTS_PER_MICROFRAME	Provides an enumeration of the allowable isochronous packets per microframe when operating in High-Speed mode.
	USBHS_SPEED	Provides enumeration Host endpoint speeds.
	USBHS_TEST_SPEED	Used as an argument for in setting module speeds in Test mode.
	USBHS_TRANSACTION_TYPE	Provides an enumeration of transaction types.
	USBHS_TXRX_FIFO_STATE	Provides enumeration of receive and transmit FIFO states, as reported by status bits.

Functions

	Name	Description
	PLIB_USBHS_DeviceAddressGet	Returns the current USB device address.
	PLIB_USBHS_DeviceAddressSet	Sets the device address.
	PLIB_USBHS_DeviceAttach	This is function PLIB_USBHS_DeviceAttach.
	PLIB_USBHS_DeviceConnect	Tri-states the USB D+ and D- lines.
	PLIB_USBHS_DeviceDetach	This is function PLIB_USBHS_DeviceDetach.
	PLIB_USBHS_DeviceDisconnect	Tri-states the USB D+ and D- lines.
	PLIB_USBHS_DeviceEPFIFOLoad	This is function PLIB_USBHS_DeviceEPFIFOLoad.
	PLIB_USBHS_DeviceEPFIFOUnload	This is function PLIB_USBHS_DeviceEPFIFOUnload.
	PLIB_USBHS_DeviceRxEndpointConfigure	This is function PLIB_USBHS_DeviceRxEndpointConfigure.
	PLIB_USBHS_DeviceRxEndpointStallDisable	This is function PLIB_USBHS_DeviceRxEndpointStallDisable.
	PLIB_USBHS_DeviceRxEndpointStallEnable	This is function PLIB_USBHS_DeviceRxEndpointStallEnable.
	PLIB_USBHS_DeviceTxEndpointConfigure	This is function PLIB_USBHS_DeviceTxEndpointConfigure.
	PLIB_USBHS_DeviceTxEndpointPacketReady	This is function PLIB_USBHS_DeviceTxEndpointPacketReady.
	PLIB_USBHS_DeviceTxEndpointStallDisable	This is function PLIB_USBHS_DeviceTxEndpointStallDisable.
	PLIB_USBHS_DeviceTxEndpointStallEnable	This is function PLIB_USBHS_DeviceTxEndpointStallEnable.
	PLIB_USBHS_DMAErrorGet	This is function PLIB_USBHS_DMAErrorGet.
	PLIB_USBHS_DMAInterruptDisable	Disables DMA channel interrupts.
	PLIB_USBHS_DMAInterruptEnable	Enables DMA channel interrupts.
	PLIB_USBHS_DMAInterruptFlagsGet	Gets the DMA channel interrupt flags.
	PLIB_USBHS_DMAInterruptGet	This is function PLIB_USBHS_DMAInterruptGet.
	PLIB_USBHS_DMAOperationEnable	This is function PLIB_USBHS_DMAOperationEnable.
	PLIB_USBHS_Endpoint0FIFOFlush	This is function PLIB_USBHS_Endpoint0FIFOFlush.
	PLIB_USBHS_Endpoint0SetupPacketLoad	Loads the endpoint 0 FIFO with provided setup packet and then enables the endpoint transmit.
	PLIB_USBHS_Endpoint0SetupPacketUnload	This is function PLIB_USBHS_Endpoint0SetupPacketUnload.
	PLIB_USBHS_EndpointFIFOLoad	Loads the endpoint FIFO with provided data and then enables the endpoint transmit.
	PLIB_USBHS_EndpointFIFOUnload	Unloads the endpoint FIFO.
	PLIB_USBHS_EndpointRxFIFOFlush	This is function PLIB_USBHS_EndpointRxFIFOFlush.
	PLIB_USBHS_EndpointRxRequestClear	This is function PLIB_USBHS_EndpointRxRequestClear.
	PLIB_USBHS_EndpointRxRequestEnable	This is function PLIB_USBHS_EndpointRxRequestEnable.
	PLIB_USBHS_EndpointTxFIFOFlush	This is function PLIB_USBHS_EndpointTxFIFOFlush.
	PLIB_USBHS_EP0DataEndSet	This is function PLIB_USBHS_EP0DataEndSet.
	PLIB_USBHS_EP0INHandshakeClear	This is function PLIB_USBHS_EP0INHandshakeClear.
	PLIB_USBHS_EP0INHandshakeSend	This is function PLIB_USBHS_EP0INHandshakeSend.
	PLIB_USBHS_EP0INTokenSend	This is function PLIB_USBHS_EP0INTokenSend.
	PLIB_USBHS_EP0OUTHandshakeSend	This is function PLIB_USBHS_EP0OUTHandshakeSend.
	PLIB_USBHS_EP0RxPktRdyServiced	This is function PLIB_USBHS_EP0RxPktRdyServiced.
	PLIB_USBHS_EP0RxPktRdyServicedDataEnd	This is function PLIB_USBHS_EP0RxPktRdyServicedDataEnd.
	PLIB_USBHS_EP0SentStallClear	This is function PLIB_USBHS_EP0SentStallClear.
	PLIB_USBHS_EP0SetupEndServiced	This is function PLIB_USBHS_EP0SetupEndServiced.
	PLIB_USBHS_EP0StallDisable	This is function PLIB_USBHS_EP0StallDisable.
	PLIB_USBHS_EP0StallEnable	This is function PLIB_USBHS_EP0StallEnable.
	PLIB_USBHS_EP0StatusClear	This is function PLIB_USBHS_EP0StatusClear.
	PLIB_USBHS_EP0StatusGet	This is function PLIB_USBHS_EP0StatusGet.
	PLIB_USBHS_EP0TxPktRdy	This is function PLIB_USBHS_EP0TxPktRdy.
	PLIB_USBHS_EP0TxPktRdyDataEnd	This is function PLIB_USBHS_EP0TxPktRdyDataEnd.
	PLIB_USBHS_ExistsClockResetControl	This is function PLIB_USBHS_ExistsClockResetControl.
	PLIB_USBHS_ExistsEndpointFIFO	Identifies that the Endpoint FIFO feature exists on the Hi-Speed USB module.
	PLIB_USBHS_ExistsEndpointOperations	This is function PLIB_USBHS_ExistsEndpointOperations.
	PLIB_USBHS_ExistsEP0Status	This is function PLIB_USBHS_ExistsEP0Status.
	PLIB_USBHS_ExistsHighSpeedSupport	This is function PLIB_USBHS_ExistsHighSpeedSupport.
	PLIB_USBHS_ExistsInterrupts	This is function PLIB_USBHS_ExistsInterrupts.

	PLIB_USBHS_ExistsModuleControl	This is function PLIB_USBHS_ExistsModuleControl.
	PLIB_USBHS_ExistsRxEPStatus	This is function PLIB_USBHS_ExistsRxEPStatus.
	PLIB_USBHS_ExistsSoftReset	This is function PLIB_USBHS_ExistsSoftReset.
	PLIB_USBHS_ExistsTxEPStatus	This is function PLIB_USBHS_ExistsTxEPStatus.
	PLIB_USBHS_ExistsUSBIDControl	This is function PLIB_USBHS_ExistsUSBIDControl.
	PLIB_USBHS_FullOrHighSpeedIsConnected	This is function PLIB_USBHS_FullOrHighSpeedIsConnected.
	PLIB_USBHS_GenInterruptDisable	Disables a general interrupt for the USB module.
	PLIB_USBHS_GenInterruptEnable	Enables a general interrupt for the USB module.
	PLIB_USBHS_GenInterruptFlagsGet	Gets general interrupt flags.
	PLIB_USBHS_GetEP0CSRAddress	This is function PLIB_USBHS_GetEP0CSRAddress.
	PLIB_USBHS_GetEP0FIFOAddress	This is function PLIB_USBHS_GetEP0FIFOAddress.
	PLIB_USBHS_GetReceiveDataCount	This is function PLIB_USBHS_GetReceiveDataCount.
	PLIB_USBHS_GlobalInterruptDisable	This is function PLIB_USBHS_GlobalInterruptDisable.
	PLIB_USBHS_GlobalInterruptEnable	This is function PLIB_USBHS_GlobalInterruptEnable.
	PLIB_USBHS_HighSpeedDisable	This is function PLIB_USBHS_HighSpeedDisable.
	PLIB_USBHS_HighSpeedEnable	Sets the operation speed of the USB Module.
	PLIB_USBHS_HighSpeedIsConnected	This is function PLIB_USBHS_HighSpeedIsConnected.
	PLIB_USBHS_HostModeIsEnabled	This is function PLIB_USBHS_HostModeIsEnabled.
	PLIB_USBHS_HostRxEndpointConfigure	This is function PLIB_USBHS_HostRxEndpointConfigure.
	PLIB_USBHS_HostRxEndpointDataToggleClear	This is function PLIB_USBHS_HostRxEndpointDataToggleClear.
	PLIB_USBHS_HostTxEndpointConfigure	This is function PLIB_USBHS_HostTxEndpointConfigure.
	PLIB_USBHS_HostTxEndpointDataToggleClear	This is function PLIB_USBHS_HostTxEndpointDataToggleClear.
	PLIB_USBHS_InterruptEnableSet	Enables USB module event interrupts.
	PLIB_USBHS_IsBDevice	This is function PLIB_USBHS_IsBDevice.
	PLIB_USBHS_LoadEPInIndex	This is function PLIB_USBHS_LoadEPInIndex.
	PLIB_USBHS_ModuleSpeedGet	Returns the speed at which the module is operating.
	PLIB_USBHS_PhyIDMonitoringDisable	This is function PLIB_USBHS_PhyIDMonitoringDisable.
	PLIB_USBHS_PhyIDMonitoringEnable	This is function PLIB_USBHS_PhyIDMonitoringEnable.
	PLIB_USBHS_ResetDisable	This is function PLIB_USBHS_ResetDisable.
	PLIB_USBHS_ResetEnable	This is function PLIB_USBHS_ResetEnable.
	PLIB_USBHS_ResumeDisable	This is function PLIB_USBHS_ResumeDisable.
	PLIB_USBHS_ResumeEnable	This is function PLIB_USBHS_ResumeEnable.
	PLIB_USBHS_RxEPINTokenSend	This is function PLIB_USBHS_RxEPINTokenSend.
	PLIB_USBHS_RxEPStatusClear	This is function PLIB_USBHS_RxEPStatusClear.
	PLIB_USBHS_RxEPStatusGet	This is function PLIB_USBHS_RxEPStatusGet.
	PLIB_USBHS_RxInterruptDisable	Disables a RX endpoint interrupt for the USB module.
	PLIB_USBHS_RxInterruptEnable	Enables a RX endpoint interrupt for the USB module.
	PLIB_USBHS_RxInterruptFlagsGet	Gets RX endpoint interrupt flags.
	PLIB_USBHS_SessionDisable	This is function PLIB_USBHS_SessionDisable.
	PLIB_USBHS_SessionEnable	This is function PLIB_USBHS_SessionEnable.
	PLIB_USBHS_SoftResetDisable	Disables soft reset.
	PLIB_USBHS_SoftResetEnable	Enables soft reset.
	PLIB_USBHS_SuspendDisable	This is function PLIB_USBHS_SuspendDisable.
	PLIB_USBHS_SuspendEnable	This is function PLIB_USBHS_SuspendEnable.
	PLIB_USBHS_TestModeEnter	This is function PLIB_USBHS_TestModeEnter.
	PLIB_USBHS_TestModeExit	This is function PLIB_USBHS_TestModeExit.
	PLIB_USBHS_TxEPStatusClear	This is function PLIB_USBHS_TxEPStatusClear.
	PLIB_USBHS_TxEPStatusGet	This is function PLIB_USBHS_TxEPStatusGet.
	PLIB_USBHS_TxInterruptDisable	Disables a TX endpoint interrupt source for the USB module.
	PLIB_USBHS_TxInterruptEnable	Enables a TX endpoint Interrupt for the USB module.
	PLIB_USBHS_TxInterruptFlagsGet	Gets the TX endpoint interrupt flags.
	PLIB_USBHS_USBIDOverrideDisable	This is function PLIB_USBHS_USBIDOverrideDisable.
	PLIB_USBHS_USBIDOverrideEnable	This is function PLIB_USBHS_USBIDOverrideEnable.
	PLIB_USBHS_USBIDOverrideValueSet	This is function PLIB_USBHS_USBIDOverrideValueSet.

	PLIB_USBHS_VbusLevelGet	Returns the current VBUS level encode using the USBHS_VBUS_DETECT_LEVEL enumeration.
	PLIB_USBHS_VBUSLevelGet	This is function PLIB_USBHS_VBUSLevelGet.

Macros

	Name	Description
	USBHS_MAX_DMA_CHANNEL_NUMBER	Number of available DMA Channels.
	USBHS_MAX_EP_NUMBER	Maximum number of endpoints supported (not including EP0).

Description

Hi-Speed USB (HS USB) Module Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the USB PLIB for families of Microchip microcontrollers that feature the Hi-Speed USB module.

Remarks

Required to access the High Speed USB Module registers.

File Name

plib_usbhs.h

Company

Microchip Technology Inc.

Watchdog Timer Peripheral Library

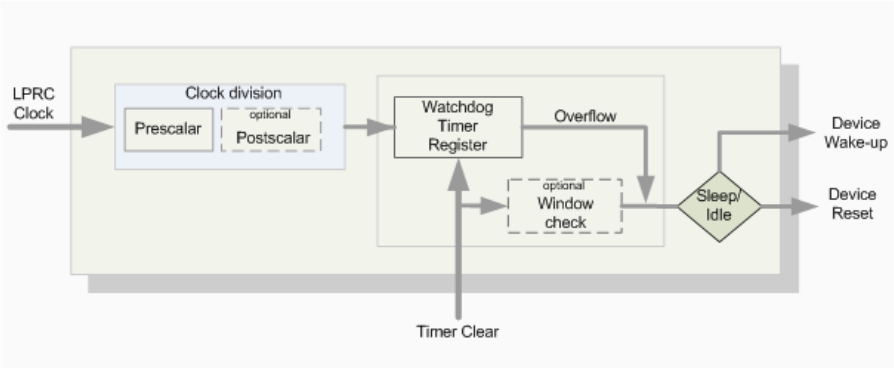
This section describes the Watchdog Timer (WDT) Peripheral Library.

Introduction

This library provides a low-level abstraction of the WDT Peripheral Library that is available on the Microchip family of microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, there by abstracting differences from one microcontroller variant to another.

Description

The primary function of the Watchdog Timer (WDT) is to reset the microcontroller, in the event of a software malfunction, by resetting the device if it has not been cleared by software. To ensure that application does not hang, the application is supposed to reset the timer periodically. It can also be used to wake the device from Sleep or Idle mode. The WDT is a free-running timer, which uses the Low-Power RC (LPRC) Oscillator and requires no external components. Therefore, the WDT will continue to operate even if the system's primary clock source is stopped.



Using the Library

This topic describes the basic architecture of the WDT Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_wdt.h`

The interface to the WDT Peripheral Library is defined in the `plib_wdt.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the WDT Peripheral Library must include `peripheral.h`.

Library File:

The WDT Peripheral Library archive (`.a`) file is installed with MPLAB Harmony.

Please refer to the What is MPLAB Harmony? section for information on how the library interacts with the framework.

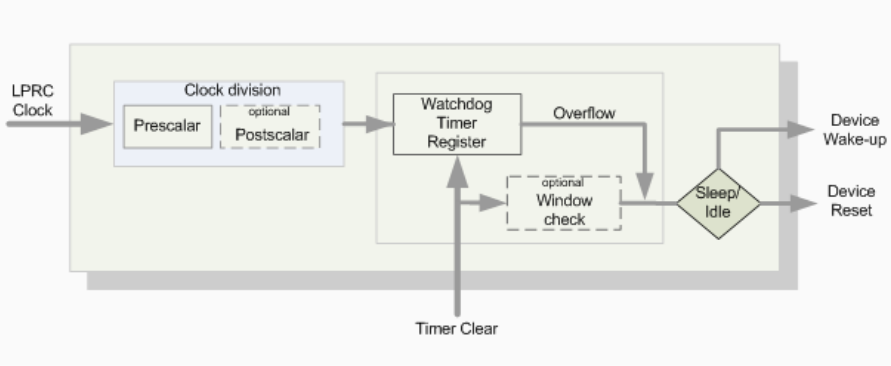
Hardware Abstraction Model

This library provides the low-level abstraction of the *Watchdog timer* module on the Microchip family of microcontrollers with a convenient C language interface. This topic describes how that abstraction is modeled in the software and introduces the library interface.

Note: The interface provided is a superset of all of the functionality of the available Watchdog Timer modules on the device. Please refer to the **"Watchdog Timer"** chapter in the specific device data sheet or the family reference manual section specified in that chapter to determine the set of functions that are supported for each Watchdog Timer module on your device.

Description

Watchdog Timer Software Abstraction Block Diagram



The WDT uses the internal Low-Power RC (LPRC) Oscillator as the clock source. The clock is divided by the configured prescaler value. There may be one more postscaler divisors. The divided clock is then used to increment a counter. The WDT module uses the watchdog register as a timer. If there is no reset signal from the software and if the counter overflows, this results in a reset in normal mode. In the case of Sleep or Idle mode, the overflow will result in a device wake-up.

For Windowed mode, resetting the counter when the count is not in the specified window will also lead to a reset. If the device is in Sleep or Idle mode, the reset signal will be used to wake-up the device.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the WDT module

Library Interface Section	Description
General Configuration Functions	This includes module enable, module disable, watchdog timer window enable, watchdog timer window disable and the timer reset routines.
General Status Functions	Status routines for the WDT.

How the Library Works

This section describes how the Watchdog Timer Peripheral Library works.

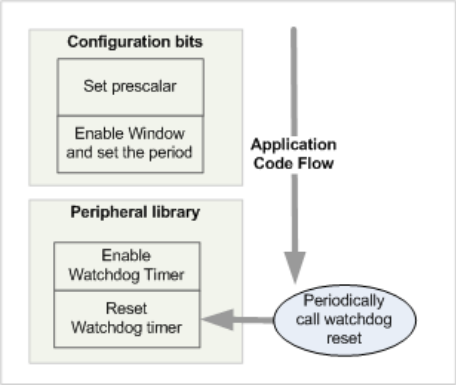
Description

Initializing the WDT module involves these processes.

- Selecting the postscaler
- Enabling the WDT using PLIB_WDT_Enable
- Selecting the window size if the application wants the WDT in Windowed mode using PLIB_WDT_WindowEnable

Note: Selecting the postscaler and window size should be done through the Configuration bits.

The application should periodically clear the timer once it is enabled; otherwise, a time-out will lead to a device Reset. Use PLIB_WDT_TimerClear to clear the WDT. A timer clear before a time-out may also lead to a reset in Windowed mode. The user application can clear the window only in the allowed window. Refer to the specific device data sheet to determine the allowed window period for your device.



Example

```
/*************************************************************
* This code fragment assumes the WDT is not enabled through   *
* device configuration bits. The Postscaler value must be set *
* through the device configuration and window size should be  *
* set if applicable                                           *
*************************************************/

/* Initializing the watchdog involves  */
PLIB_WDT_Enable(WDT_ID_0);

//Application loop
while(1)
{
    PLIB_WDT_TimerClear(WDT_ID_0);

    //user code
}
```

Note: Refer to the specific device data sheet for information on the allowed window periods for your device and other Configuration bit settings.

Configuring the Library

The library is configured for the supported Watchdog Timer module when the processor is chosen in the MPLAB X IDE.

Library Interface

a) General Configuration Functions

	Name	Description
	PLIB_WDT_Disable	Disables the WDT module.
	PLIB_WDT_Enable	Enables the WDT module.
	PLIB_WDT_WindowDisable	Disables the WDT Windowed mode.
	PLIB_WDT_WindowEnable	Enables the WDT Window mode.
	PLIB_WDT_TimerClear	Resets the WDT module.

b) General Status Functions

	Name	Description
	PLIB_WDT_IsEnabled	Returns the watchdog timer on/off(enable/disable) status.
	PLIB_WDT_PostscalerValueGet	Returns the WDT postscaler value.
	PLIB_WDT_SleepModePostscalerValueGet	Returns the WDT Sleep Mode postscaler value.

c) Feature Existence Functions

	Name	Description
	PLIB_WDT_ExistsEnableControl	Identifies whether the EnableControl feature exists on the WDT module.
	PLIB_WDT_ExistsPostscalerValue	Identifies whether the PostscalerValue feature exists on the WDT module.
	PLIB_WDT_ExistsTimerClear	Identifies whether the TimerClear feature exists on the WDT module.

	PLIB_WDT_ExistsWindowEnable	Identifies whether the WindowEnable feature exists on the WDT module.
	PLIB_WDT_ExistsSleepModePostscalerValue	Identifies whether the SleepModePostscalerValue feature exists on the WDT module.

d) Data Types and Constants

	Name	Description
	WDT_MODULE_ID	Identifies the supported Watchdog Timer modules.

Description

This section describes the Application Programming Interface (API) functions of the Watchdog Timer Peripheral Library.

Refer to each section for a detailed description.

a) General Configuration Functions

PLIB_WDT_Disable Function

Disables the WDT module.

File

plib_wdt.h

C

```
void PLIB_WDT_Disable(WDT_MODULE_ID index);
```

Returns

None.

Description

This function disables the WDT module if it is enabled in software.

Remarks

This function will not disable the WDT module if it is enabled through its Configuration bits.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_WDT_ExistsEnableControl in your application to determine whether this feature is available.

Preconditions

The WDT module must be enabled through software.

Example

```
PLIB_WDT_Disable ( WDT_ID_0 );
```

Parameters

Parameters	Description
index	Identifies the desired WDT module

Function

void PLIB_WDT_Disable (WDT_MODULE_ID index)

PLIB_WDT_Enable Function

Enables the WDT module.

File

plib_wdt.h

C

```
void PLIB_WDT_Enable(WDT_MODULE_ID index);
```

Returns

None.

Description

This function enables the WDT module. If it is already enabled through the Configuration bits, it will keep it enabled.

Remarks

Calling this function is not necessary if it is enabled through its Configuration bits.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_WDT_ExistsEnableControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_WDT_Enable ( WDT_ID_0 );
```

Parameters

Parameters	Description
index	Identifies the desired WDT module

Function

void PLIB_WDT_Enable (WDT_MODULE_ID index)

PLIB_WDT_WindowDisable Function

Disables the WDT Windowed mode.

File

plib_wdt.h

C

```
void PLIB_WDT_WindowDisable(WDT_MODULE_ID index);
```

Returns

None.

Description

This function disables the WDT Windowed mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_WDT_ExistsWindowEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_WDT_WindowDisable ( WDT_ID_0 );
```

Parameters

Parameters	Description
index	Identifies the desired WDT module

Function

void PLIB_WDT_WindowDisable (WDT_MODULE_ID index)

PLIB_WDT_WindowEnable Function

Enables the WDT Window mode.

File

plib_wdt.h

C

```
void PLIB_WDT_WindowEnable(WDT_MODULE_ID index);
```

Returns

None.

Description

This function enables the WDT Windowed mode.

Remarks

The window size must be set through the Configuration bits.

The example code doesn't include the settings that should be done through the Configuration bits.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_WDT_ExistsWindowEnable in your application to determine whether this feature is available.

Preconditions

The window size must be set through the Configuration bits.

Example

```
PLIB_WDT_WindowEnable ( WDT_ID_0 );
PLIB_WDT_Enable ( WDT_ID_0 );
```

Parameters

Parameters	Description
index	Identifies the desired WDT module

Function

void PLIB_WDT_WindowEnable (WDT_MODULE_ID index)

PLIB_WDT_TimerClear Function

Resets the WDT module.

File

plib_wdt.h

C

```
void PLIB_WDT_TimerClear(WDT_MODULE_ID index);
```

Returns

None.

Description

This function resets the WDT module. The WDT module should be cleared periodically before the count crosses and forces the device to reset.

Remarks

Resetting the device before the count reaches the window will cause a reset in Windowed mode.

The example code doesn't include the settings that should be done through the Configuration bits.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_WDT_ExistsTimerClear in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_WDT_Enable ( WDT_ID_0 );

//Application loop
```

```
while(1)
{
    PLIB_WDT_TimerClear ( WDT_ID_0 );
    //user code
}
```

Parameters

Parameters	Description
index	Identifies the desired WDT module

Function

void PLIB_WDT_TimerClear (WDT_MODULE_ID index)

b) General Status Functions

PLIB_WDT_IsEnabled Function

Returns the watchdog timer on/off(enable/disable) status.

File

plib_wdt.h

C

```
bool PLIB_WDT_IsEnabled(WDT_MODULE_ID index);
```

Returns

- true - If the watchdog timer is on
- false - If the watchdog timer is off

Description

Returns the 'true', if the watchdog timer is already ON. Otherwise returns 'false'.

Remarks

This function returns 'true' if the device is enabled either though the Configuration bits or in the software.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_WDT_ExistsEnableControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if (PLIB_WDT_IsEnabled ( WDT_ID_0 ) )
{
    //Do some action
}
```

Parameters

Parameters	Description
index	Identifies the desired WDT module

Function

bool PLIB_WDT_IsEnabled (WDT_MODULE_ID index)

PLIB_WDT_PostscalerValueGet Function

Returns the WDT postscaler value.

File

plib_wdt.h

C

```
char PLIB_WDT_PostscalerValueGet(WDT_MODULE_ID index);
```

Returns

The postscaler value.

Description

This function returns the WDT postscaler value. The value will correspond to a division factor.

Remarks

The value returned will be right-aligned.

Refer to the specific device data sheet to get the division factor corresponding to the value.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_WDT_ExistsPostscalerValue in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t value;

PLIB_WDT_Enable ( WDT_ID_0 );
value = PLIB_WDT_PostscalerValueGet ( WDT_ID_0 );
```

Parameters

Parameters	Description
index	Identifies the desired WDT module

Function

char PLIB_WDT_PostscalerValueGet (WDT_MODULE_ID index)

PLIB_WDT_SleepModePostscalerValueGet Function

Returns the WDT Sleep Mode postscaler value.

File

plib_wdt.h

C

```
char PLIB_WDT_SleepModePostscalerValueGet(WDT_MODULE_ID index);
```

Returns

The Sleep Mode postscaler value.

Description

This function returns the WDT postscaler value in Sleep Mode. The value will correspond to a division factor.

Remarks

The value returned will be right-aligned.

Refer to the specific device data sheet to get the division factor corresponding to the value.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_WDT_ExistsSleepModePostscalerValue in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t value;
value = PLIB_WDT_SleepModePostscalerValueGet ( WDT_ID_0 );
```

Parameters

Parameters	Description
index	Identifies the desired WDT module

Function

char PLIB_WDT_SleepModePostscalerValueGet (WDT_MODULE_ID index)

c) Feature Existence Functions

PLIB_WDT_ExistsEnableControl Function

Identifies whether the EnableControl feature exists on the WDT module.

File

plib_wdt.h

C

```
bool PLIB_WDT_ExistsEnableControl(WDT_MODULE_ID index);
```

Returns

Existence of the EnableControl feature:

- true - When EnableControl feature is supported on the device
- false - When EnableControl feature is not supported on the device

Description

This function identifies whether the EnableControl feature is available on the WDT module. When this function returns true, these functions are supported on the device:

- PLIB_WDT_Enable
- PLIB_WDT_Disable
- PLIB_WDT_IsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_WDT_ExistsEnableControl(WDT_MODULE_ID index)

PLIB_WDT_ExistsPostscalerValue Function

Identifies whether the PostscalerValue feature exists on the WDT module.

File

plib_wdt.h

C

```
bool PLIB_WDT_ExistsPostscalerValue(WDT_MODULE_ID index);
```

Returns

- true - The PostscalerValue feature is supported on the device
- false - The PostscalerValue feature is not supported on the device

Description

This function identifies whether the PostscalerValue feature is available on the WDT module. When this function returns true, this function is supported on the device:

- PLIB_WDT_PostscalerValueGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_WDT_ExistsPostscalerValue(WDT_MODULE_ID index)

PLIB_WDT_ExistsTimerClear Function

Identifies whether the TimerClear feature exists on the WDT module.

File

plib_wdt.h

C

```
bool PLIB_WDT_ExistsTimerClear(WDT_MODULE_ID index);
```

Returns

- true - The TimerClear feature is supported on the device
- false - The TimerClear feature is not supported on the device

Description

This function identifies whether the TimerClear feature is available on the WDT module. When this function returns true, this function is supported on the device:

- PLIB_WDT_TimerClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_WDT_ExistsTimerClear(WDT_MODULE_ID index)

PLIB_WDT_ExistsWindowEnable Function

Identifies whether the WindowEnable feature exists on the WDT module.

File

plib_wdt.h

C

```
bool PLIB_WDT_ExistsWindowEnable(WDT_MODULE_ID index);
```

Returns

- true - The WindowEnable feature is supported on the device
- false - The WindowEnable feature is not supported on the device

Description

This function identifies whether the WindowEnable feature is available on the WDT module. When this function returns true, these functions are supported on the device:

- PLIB_WDT_WindowEnable
- PLIB_WDT_WindowDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_WDT_ExistsWindowEnable(WDT_MODULE_ID index)

PLIB_WDT_ExistsSleepModePostscalerValue Function

Identifies whether the SleepModePostscalerValue feature exists on the WDT module.

File

plib_wdt.h

C

```
bool PLIB_WDT_ExistsSleepModePostscalerValue(WDT_MODULE_ID index);
```

Returns

- true - The SleepModePostscalerValue feature is supported on the device
- false - The SleepModePostscalerValue feature is not supported on the device

Description

This function identifies whether the SleepModePostscalerValue feature is available on the WDT module. When this function returns true, this function is supported on the device:

- PLIB_WDT_SleepModePostscalerValueGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_WDT_ExistsSleepModePostscalerValue(WDT_MODULE_ID index)

d) Data Types and Constants

WDT_MODULE_ID Enumeration

Identifies the supported Watchdog Timer modules.

File

plib_wdt_help.h

C

```
typedef enum {
  WDT_ID_0,
  WDT_NUMBER_OF_MODULES
} WDT_MODULE_ID;
```

Members

Members	Description
WDT_ID_0	WDT Module 1 ID
WDT_NUMBER_OF_MODULES	Number of available WDT modules.

Description

Watchdog Timer (WDT) Module ID

This enumeration identifies the available Watchdog Timer modules.

Remarks

The caller should not rely on the specific numbers assigned to any of these values as they may change from one processor to the next.

Files

Files

Name	Description
plib_wdt.h	Watchdog Timer (WDT) Peripheral Library interface header for Watchdog Timer common definitions.
plib_wdt_help.h	

Description

This section lists the source and header files used by the library.

plib_wdt.h

Watchdog Timer (WDT) Peripheral Library interface header for Watchdog Timer common definitions.

Functions

	Name	Description
	PLIB_WDT_Disable	Disables the WDT module.
	PLIB_WDT_Enable	Enables the WDT module.
	PLIB_WDT_ExistsEnableControl	Identifies whether the EnableControl feature exists on the WDT module.
	PLIB_WDT_ExistsPostscalerValue	Identifies whether the PostscalerValue feature exists on the WDT module.
	PLIB_WDT_ExistsSleepModePostscalerValue	Identifies whether the SleepModePostscalerValue feature exists on the WDT module.
	PLIB_WDT_ExistsTimerClear	Identifies whether the TimerClear feature exists on the WDT module.
	PLIB_WDT_ExistsWindowEnable	Identifies whether the WindowEnable feature exists on the WDT module.
	PLIB_WDT_IsEnabled	Returns the watchdog timer on/off(enable/disable) status.
	PLIB_WDT_PostscalerValueGet	Returns the WDT postscaler value.
	PLIB_WDT_SleepModePostscalerValueGet	Returns the WDT Sleep Mode postscaler value.
	PLIB_WDT_TimerClear	Resets the WDT module.
	PLIB_WDT_WindowDisable	Disables the WDT Windowed mode.
	PLIB_WDT_WindowEnable	Enables the WDT Window mode.

Description

Watchdog Timer (WDT) Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the Watchdog Timer Peripheral Library for all families of Microchip microcontrollers. The definitions in this file are common to the Watchdog Timer peripheral.

File Name

plib_wdt.h

Company

Microchip Technology Inc.

plib_wdt_help.h

Enumerations

	Name	Description
	WDT_MODULE_ID	Identifies the supported Watchdog Timer modules.

Section

Data Types & Constants

Sample Library Help

This section describes the Sample Library that is available in MPLAB Harmony.

Introduction

This library provides a simple example of a MPLAB Harmony module.

Description

The Sample Library provides a simple example of a MPLAB Harmony module; however, its actual functionality is very limited and is not suitable for a practical application. The Sample Library provides an interface function to accept a single integer data value, another to see if the module currently holds any data, and a third to obtain any data currently held. The library can only hold up to two integer values at any given time.

Using the Library

This topic describes the basic architecture of the Sample Library and provides information and examples on its use.

Description

The interface to the Sample Library is defined in the `sample_module.h` header file.

Any C language source (`.c`) file that uses the Sample Library must include `sample_module.h`.

Library Overview

This section provides an overview of the Sample Library.

Description

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Sample Library.

Library Interface Section	Description
System Interface Functions	Functions used by the MPLAB Harmony system configuration to initialize and maintain the sample library module.
Client Interface Functions	Functions used by client modules and applications to interact with the Sample module.
Data Types and Constants	This section describes the various data types utilized in the Sample module interface.

How the Library Works

This section provides information on how the Sample Library works.

Core Functionality

Provides information on the core functionality of the Sample Library.

Description

The primary purpose of the Sample Library is to serve as an example of a dynamic MPLAB Harmony module (similar to a middleware library module). The library implements the system interface functions normally supported by a MPLAB Harmony module and provides a simple client-level interface to store and retrieve an integer data value. The library can hold up to two integer values per instance of the library. And, while it has no associated hardware or interrupts, the library can be used in an interrupt-driven configuration utilizing a timer (or other appropriate peripheral) providing it is appropriately configured and initialized.

Configuring the Library

Macros

	Name	Description
	SAMPLE_MODULE_INTERRUPT_MODE	Determines whether or not the sample module will support interrupt-driven execution mode.
	SAMPLE_MODULE_INSTANCES_NUMBER	Defines how many instances of the sample module are supported.
	SAMPLE_MODULE_TIMEOUT	Defines OSAL mutex timeout for Sample module (in milliseconds).

Description

The configuration of the Sample Library is based on the file `system_config.h`.

This header file contains the configuration selections for the Sample Library. Based on the selections made, the Sample Library may support the selected features.

This header can be placed anywhere, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

SAMPLE_MODULE_INTERRUPT_MODE Macro

Determines whether or not the sample module will support interrupt-driven execution mode.

File

sample_module_config_template.h

C

```
#define SAMPLE_MODULE_INTERRUPT_MODE false
```

Description

Sample Module, Interrupt Mode

This macro determines whether or not the sample module will support interrupt interrupt driven execution. If defined as true, then the sample module will enable, disable, and clear the interrupt source identified in the SAMPLE_MODULE_INIT_DATA structure. Otherwise, it shoud be defined as false and the module will only support polled operation.

SAMPLE_MODULE_INSTANCES_NUMBER Macro

Defines how many instances of the sample module are supported.

File

sample_module_config_template.h

C

```
#define SAMPLE_MODULE_INSTANCES_NUMBER 2
```

Description

Sample Module, Number of Instances

This macro defines how many instances of the sample module are supported.

Remarks

Defaults to 1 and displays a build warning if not specified..

SAMPLE_MODULE_TIMEOUT Macro

Defines OSAL mutex timeout for Sample module (in milliseconds).

File

sample_module_config_template.h

C

```
#define SAMPLE_MODULE_TIMEOUT 100
```

Description

Sample Module, Timeout

This macro defines how many milliseconds the sample module will block, waiting to obtain a mutex, when accessing its internal shared resources. This is only utilized in interrupt-driven modes, but needs to be defined to build correclty.

Remarks

Used by OSAL_MUTEX_Lock.

Building the Library

This section lists the files that are available in the Sample Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/sample`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/sample_module.h`	This file provides the interface definitions of the Sample Library.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/sample_module.c`	Sample Library implementation.

Optional File(s)

There are no optional files for the Sample Library.

Module Dependencies

The Sample Library is dependent upon the following libraries and header files.

- Interrupt System Service Library
- Operating System Abstraction Layer (OSAL)
- sys_common.h
- sys_module.h

Library Interface

a) System Interface Functions

	Name	Description
	SAMPLE_Initialize	Initializes the sample module.
	SAMPLE_Reinitialize	Reinitializes the sample module and refreshes any associated internal settings.
	SAMPLE_Deinitialize	Deinitializes the specified instance of the sample module.
	SAMPLE_Tasks	Maintains the sample module instance's state machine.
	SAMPLE_Status	Provides the current status of the sample module instance.

b) Client Interface Functions

	Name	Description
	SAMPLE_DataGive	Gives data to the sample module.
	SAMPLE_DataGet	Gets data from the sample module.
	SAMPLE_DataStatus	Identifies the current status of the data processed by the module.

c) Data Types and Constants

	Name	Description
	SAMPLE_INDEX_0	Labels for module index numbers.
	SAMPLE_INDEX_1	This is macro SAMPLE_INDEX_1.
	SAMPLE_MODULE_DATA_STATUS	Possible data processing states.
	SAMPLE_MODULE_INIT_DATA	Data necessary to initialize the sample module.

	_sample_module_data_status	Possible data processing states.
	_sample_module_init_data	Data necessary to initialize the sample module.

Description

This section describes the APIs of the Sample Library. Refer to each section for a description.

a) System Interface Functions

SAMPLE_Initialize Function

Initializes the sample module.

File

sample_module.h

C

```
SYS_MODULE_OBJ SAMPLE_Initialize(const SYS_MODULE_INDEX index, const SYS_MODULE_INIT * const init);
```

Returns

If successful, returns a valid handle to a system module object. Otherwise, it returns SYS_MODULE_OBJ_INVALID. The returned object handle must be passed as an argument to SAMPLE_Reinitialize, SAMPLE_Deinitialize, SAMPLE_Tasks and SAMPLE_Status routines.

Description

This routine initializes the sample module, making it ready for clients to open and use it.

Remarks

This routine must be called before any other sample module routine is called.

This routine should only be called once during system initialization unless SAMPLE_Deinitialize is called to deinitialize the module instance.

This routine will NEVER block for internal state changes. If the operation requires time to complete, it will be reported by the SAMPLE_Status operation. The system can use SAMPLE_Status to find out when the associated instance of the sample module is in a ready state.

Preconditions

None.

Example

```
SAMPLE_MODULE_INIT_DATA init;
SYS_MODULE_OBJ          obj;

// Populate the sample initialization structure
init.sys.powerState     = SYS_MODULE_POWER_RUN_FULL;
init.dataSome           = 42;

// Initialize the first instance of the sample module.
obj = SAMPLE_Initialize(SAMPLE_INDEX_0, (SYS_MODULE_INIT *)&init);
if (SYS_MODULE_OBJ_INVALID == obj)
{
    // Handle failure
}
```

Parameters

Parameters	Description
index	Index for the module instance to be initialized
init	Pointer to a data structure containing any data necessary to initialize the module.

Function

SYS_MODULE_OBJ SAMPLE_Initialize(const SYS_MODULE_INDEX index,
const SYS_MODULE_INIT * const init)

SAMPLE_Reinitialize Function

Reinitializes the sample module and refreshes any associated internal settings.

File

sample_module.h

C

```
void SAMPLE_Reinitialize(SYS_MODULE_OBJ object, const SYS_MODULE_INIT * const init);
```

Returns

None

Description

This routine reinitializes the sample module and refreshes any associated settings using the initialization data given. However, it will not interrupt ongoing client operations.

Remarks

This function can be called multiple times to reinitialize the module.

This operation can be used to refresh any supported internal settings as specified by the initialization data or to change the power state of the module.

This routine will NEVER block for internal state changes. If the operation requires time to compete, it will be reported by the SAMPLE_Status operation. The system can use SAMPLE_Status to find out when the specified sample module instance is in a ready state.

Preconditions

Function SAMPLE_Initialize must have been called before calling this routine and a valid SYS_MODULE_OBJ must have been returned.

Example

```
SYS_MODULE_OBJ          obj;    // Returned from SAMPLE_Initialize
SAMPLE_MODULE_INIT_DATA init;
SYS_STATUS              status;

// Populate the sample initialization structure
init.sys.powerState     = SYS_MODULE_POWER_SLEEP;
init.dataSome           = 0;

SAMPLE_Reinitialize(obj, (SYS_MODULE_INIT*)&init);

status = SAMPLE_Status(obj);
if (SYS_STATUS_BUSY == status)
{
    // Check again later to ensure the driver is ready
}
else if (SYS_STATUS_ERROR >= status)
{
    // Handle error
}
```

Parameters

Parameters	Description
object	Sample module object handle, returned from the SAMPLE_Initialize routine
init	Pointer to the initialization data structure

Function

void SAMPLE_Reinitialize(SYS_MODULE_OBJ object,
const SYS_MODULE_INIT * const init)

SAMPLE_Deinitialize Function

Deinitializes the specified instance of the sample module.

File

sample_module.h

C

```
void SAMPLE_Deinitialize(SYS_MODULE_OBJ object);
```

Returns

None.

Description

Deinitializes the specified instance of the sample module, disabling its operation. Invalidates all the internal data and client operations.

Remarks

Once the Initialize operation has been called, the Deinitialize operation must be called before the Initialize operation can be called again.

This routine will NEVER block waiting for internal state changes. If the operation requires time to complete, it will be reported by the SAMPLE_Status operation. The system can to use SAMPLE_Status to find out when the module is in the SYS_STATUS_UNINITIALIZED state.

Preconditions

Function SAMPLE_Initialize must have been called before calling this routine and a valid SYS_MODULE_OBJ handle must have been returned.

Example

```
SYS_MODULE_OBJ      object;     //  Returned from SAMPLE_Initialize
SYS_STATUS          status;

SAMPLE_Deinitialize(object);

status = SAMPLE_Status(object);
if (SYS_MODULE_DEINITIALIZED == status)
{
    // Check again later if you need to know when the sample module
    // instance has been deinitialized.
}
```

Parameters

Parameters	Description
object	Sample module instance's object handle, returned from the SAMPLE_Initialize routine.

Function

void SAMPLE_Deinitialize (SYS_MODULE_OBJ object)

SAMPLE_Tasks Function

Maintains the sample module instance's state machine.

File

sample_module.h

C

```
void SAMPLE_Tasks(SYS_MODULE_OBJ object);
```

Returns

None.

Description

This routine is used to maintain the sample module instance's internal state machine.

Remarks

This routine should not be called directly a client of the sample module. It is called by the system's Tasks routine (SYS_Tasks) or by an appropriate ISR.

This routine may execute in an ISR context and will never block or access any resources that may cause it to block.

Preconditions

The SAMPLE_Initialize routine must have been called for the specified SAMPLE module instance.

Example

```
SYS_MODULE_OBJ      object;     // Returned from SAMPLE_Initialize

while (true)
{
    SAMPLE_Tasks (object);

    // Do other tasks
}
```

Parameters

Parameters	Description
object	Object handle for the specified sample module instance (returned from SAMPLE_Initialize).

Function

void SAMPLE_Tasks(SYS_MODULE_OBJ object)

SAMPLE_Status Function

Provides the current status of the sample module instance.

File

sample_module.h

C

```
SYS_STATUS SAMPLE_Status(SYS_MODULE_OBJ object);
```

Returns

- SYS_STATUS_ERROR - Indicates that the module instance is in an error state. Note: Any value less than SYS_STATUS_ERROR is also an error state.
- SYS_STATUS_UNINITIALIZED - Indicates that the driver has been deinitialized.

Description

This routine provides the current status of the sample module instance.

Remarks

This value is greater than SYS_STATUS_ERROR

- SYS_STATUS_BUSY - Indicates that the module instance is busy with a previous system level operation and cannot start another
- SYS_STATUS_READY - Indicates that the module instance is running and ready to begin another system level operation.

Any value greater than SYS_STATUS_READY is also a normal running state in which the module is ready to accept new operations

The this operation can be used to determine when any of the system operations have completed.

If the status operation returns SYS_STATUS_BUSY, the a previous operation has not yet completed. Once the status operation returns SYS_STATUS_READY, any previous operations have completed.

The value of SYS_STATUS_ERROR is negative (-1). Any value less than that is also an error state.

This routine will NEVER block waiting for an internal state change.

If the Status operation returns an error value, the error may be cleared by calling the reinitialize operation. If that fails, the deinitialize operation will need to be called, followed by the initialize operation to return to normal operations.

Preconditions

Function SAMPLE_Initialize must have been called before calling this function.

Example

```
SYS_MODULE_OBJ      object;     // Returned from SAMPLE_Initialize
SYS_STATUS          status;

status = SAMPLE_Status(object);
else if (SYS_STATUS_ERROR >= status)
{
    // Handle error
```

```
}
```

Parameters

Parameters	Description
object	Sample module instance's object handle, returned from the SAMPLE_Initialize routine.

Function

SYS_STATUS SAMPLE_Status (SYS_MODULE_OBJ object)

b) Client Interface Functions

SAMPLE_DataGive Function

Gives data to the sample module.

File

sample_module.h

C

```
bool SAMPLE_DataGive(const SYS_MODULE_INDEX index, int data);
```

Returns

- true - If successful.
- false - If an error occurred.

Description

This function gives data to the sample module.

Remarks

Any data value given to the sample module will be available via the SAMPLE_DataGet function later, after the sample module state machine is ready to give it back.

Preconditions

The sample module should be initialized before calling this API function.

Example

```
if (SAMPLE_DataGive(SAMPLE_INDEX_0, 42))
{
    // Data given
}
```

Parameters

Parameters	Description
index	Index of the desired module instance.
data	Data value to give to the sample module.

Function

bool SAMPLE_DataGive (const SYS_MODULE_INDEX index, int data)

SAMPLE_DataGet Function

Gets data from the sample module.

File

sample_module.h

C

```
bool SAMPLE_DataGet(const SYS_MODULE_INDEX index, int * data);
```

Returns

- true - If successful.
- false - If an error occurred. If an error occurs, the variable pointed to by pData is not updated.

Description

This function gets data from the sample module. If no data has been given to the sample module yet, it will return a failure

Remarks

Any data value given to the sample module by the SAMPLE_DataGive function will be available via this function later, after the sample module state machine is ready to give it back.

Preconditions

The sample module should be initialized before calling this API function.

Example

```
int data;

if (SAMPLE_DataGet(SAMPLE_INDEX_0, &data))
{
    // Data valid
}
```

Parameters

Parameters	Description
index	Index of the desired module instance.
pData	Pointer to the variable to receive the data value.

Function

bool SAMPLE_DataGet (const SYS_MODULE_INDEX index, int *pData)

SAMPLE_DataStatus Function

Identifies the current status of the data processed by the module.

File

sample_module.h

C

```
SAMPLE_MODULE_DATA_STATUS SAMPLE_DataStatus(const SYS_MODULE_INDEX index);
```

Returns

- SAMPLE_MODULE_DATA_NONE - If the sample module has no data to give.
- SAMPLE_MODULE_DATA_BUSY - If the sample module is busy processing and will have data available soon.
- SAMPLE_MODULE_DATA_AVAILABLE - If the sample module has data available.

Description

This function identifies the current status of the data processed by the module.

Remarks

In a polled "super-loop" system, you cannot poll this function waiting for the sample module to change status from SAMPLE_MODULE_DATA_BUSY to SAMPLE_MODULE_DATA_AVAILABLE. The loop must be allowed to continue so that the sample module can finish processing the data before it will become available.

Preconditions

The sample module must be initialized before calling this API function.

Example

```
if (SAMPLE_MODULE_DATA_BUSY == SAMPLE_DataStatus(SAMPLE_INDEX_0))
{
    // Check again later.
}
```

Parameters

Parameters	Description
index	Index of the desired module instance.

Function

SAMPLE_MODULE_DATA_STATUS SAMPLE_DataStatus (const SYS_MODULE_INDEX index)

c) Data Types and Constants

SAMPLE_INDEX_0 Macro

Labels for module index numbers.

File

sample_module.h

C

```
#define SAMPLE_INDEX_0 0
```

Description

Module Instance Indexes

The following symbolic labels can be used in place of numeric literals to identify module indexes.

SAMPLE_INDEX_1 Macro

File

sample_module.h

C

```
#define SAMPLE_INDEX_1 1
```

Description

This is macro SAMPLE_INDEX_1.

SAMPLE_MODULE_DATA_STATUS Enumeration

Possible data processing states.

File

sample_module.h

C

```
typedef enum _sample_module_data_status {
  SAMPLE_MODULE_DATA_NONE = 0,
  SAMPLE_MODULE_DATA_BUSY,
  SAMPLE_MODULE_DATA_AVAILABLE
} SAMPLE_MODULE_DATA_STATUS;
```

Members

Members	Description
SAMPLE_MODULE_DATA_NONE = 0	Indicates that the sample module has no data available.
SAMPLE_MODULE_DATA_BUSY	Indicates that the sample module is busy processing and will have data available soon.
SAMPLE_MODULE_DATA_AVAILABLE	Indicates that the sample module has available data.

Description

Sample Module Data Status

This enumeration defines the possible data processing states of the sample module.

Remarks

This status is provided by the SAMPLE_DataStatus function..

SAMPLE_MODULE_INIT_DATA Structure

Data necessary to initialize the sample module.

File

sample_module.h

C

```
typedef struct _sample_module_init_data {
  SYS_MODULE_INIT moduleInit;
  int dataSome;
  TMR_MODULE_ID tmr;
  TMR_PRESCALE prescale;
  uint16_t period;
  INT_SOURCE interrupt;
  INT_VECTOR vector;
  INT_PRIORITY_LEVEL priority;
  INT_SUBPRIORITY_LEVEL subpriority;
} SAMPLE_MODULE_INIT_DATA;
```

Members

Members	Description
SYS_MODULE_INIT moduleInit;	Standard system module init data.
int dataSome;	Some initialization data.
TMR_MODULE_ID tmr;	Timer used in interrupt-driven configurations.
TMR_PRESCALE prescale;	Timer prescaler setting.
uint16_t period;	Timer period setting.
INT_SOURCE interrupt;	Timer interrupt source.
INT_VECTOR vector;	Timer interrupt vector.
INT_PRIORITY_LEVEL priority;	Timer interrupt priority.
INT_SUBPRIORITY_LEVEL subpriority;	Timer interrupt subpriority.

Description

Sample Module Initialization Data

This data structure contains data necessary to initialize an instance of the sample module.

Remarks

A pointer to a persistent copy of this structure must be passed into the SAMPLE_Initialize function.

Files

Files

Name	Description
sample_module.h	Sample of a MPLAB Harmony library module.
sample_module_config_template.h	Sample module configuration templates.

Description

This section lists the source and header files used by the SAMPLE Library.

sample_module.h

Sample of a MPLAB Harmony library module.

Enumerations

	Name	Description
	_sample_module_data_status	Possible data processing states.

	SAMPLE_MODULE_DATA_STATUS	Possible data processing states.

Functions

	Name	Description
	SAMPLE_DataGet	Gets data from the sample module.
	SAMPLE_DataGive	Gives data to the sample module.
	SAMPLE_DataStatus	Identifies the current status of the data processed by the module.
	SAMPLE_Deinitialize	Deinitializes the specified instance of the sample module.
	SAMPLE_Initialize	Initializes the sample module.
	SAMPLE_Reinitialize	Reinitializes the sample module and refreshes any associated internal settings.
	SAMPLE_Status	Provides the current status of the sample module instance.
	SAMPLE_Tasks	Maintains the sample module instance's state machine.

Macros

	Name	Description
	SAMPLE_INDEX_0	Labels for module index numbers.
	SAMPLE_INDEX_1	This is macro SAMPLE_INDEX_1.

Structures

	Name	Description
	_sample_module_init_data	Data necessary to initialize the sample module.
	SAMPLE_MODULE_INIT_DATA	Data necessary to initialize the sample module.

Description

MPLAB Harmony Sample Library Module Interface Header

This is a sample of a MPLAB Harmony library interface module. This file defines the system and application interface.

File Name

sample_module.h

Company

Microchip Technology Inc.

sample_module_config_template.h

Sample module configuration templates.

Macros

	Name	Description
	SAMPLE_MODULE_INSTANCES_NUMBER	Defines how many instances of the sample module are supported.
	SAMPLE_MODULE_INTERRUPT_MODE	Determines whether or not the sample module will support interrupt-driven execution mode.
	SAMPLE_MODULE_TIMEOUT	Defines OSAL mutex timeout for Sample module (in milliseconds).

Description

Sample Module Configuration Templates

This file contains examples of constants to configure the sample module.

File Name

sample_module_config_template.h

Microchip Technology Inc.

System Service Libraries Help

This section provides descriptions of the System Service libraries that are available in MPLAB Harmony.

System Service Overview

This section provides an overview of the System Service libraries that are available in MPLAB Harmony.

Introduction

Describes system services provided by MPLAB Harmony.

Description

MPLAB Harmony provides system service libraries to support common functionality and manage resources that are shared by multiple drivers, libraries, and other modules.

A system service encapsulates code that manages a shared resource or implements a common capability in a single location so that it does not need to be replicated by individual drivers and libraries. This feature eliminates duplicated code and creates consistency across all modules, and also helps to eliminate potential conflicts and complex configuration issues and runtime interactions, resulting in a smaller and simpler overall solution.

System services may directly manage one or more peripherals or core processor capabilities by utilizing peripheral libraries, special function registers, special CPU instructions, or coprocessor registers. Some system services may utilize drivers, other system services, or even entire middleware stacks to share or emulate a common resource.

System services may be implemented statically (possibly generated by the MPLAB Harmony Configurator (MHC)) or dynamically to support multiple channels and instances like a driver. However, system services will not normally provide common *Open* and *Close* functions like a device driver.

In general, the distinguishing feature of a system service is that it implements a common capability that would otherwise "cut horizontally" across multiple modules in a system, causing interoperability and compatibility conflicts if the capability were implemented by other libraries.

System service functions use the following naming convention:

`SYS_<module-abbreviation>_[<feature-short-name>]<operation>`

Where,

- `SYS_` indicates that this is a system service function
- `<module-abbreviation>` is the abbreviated name of the system service module to which this function belongs
- `[<feature-short-name>]` is an optional short (or shortened) name that identifies the feature of the associated system service module to which this function refers. The feature short name will appear in the name of all functions that interact with or provide access to that particular feature.
- `<operation>` is a verb that identifies the action taken by the function

For example, SYS_TMR_AlarmSet, where:

- `<module-abbreviation>` = `TMR`, which indicates that this is a Timer System Service function
- `<feature-short-name>` = `Alarm`, which indicates that this function controls the alarm feature of the Timer System Service
- `<operation>` = `Set`, which indicates that this function sets the value of the alarm feature of the Timer System Service, as indicated by the function's parameters (not shown above).

System State Machine

Describes the MPLAB Harmony main function and system-wide state machine.

Description

In its most basic configuration, a MPLAB Harmony system operates in a single polled *super* loop that is implemented in the project's *main* function (in the `<project-name>/firmware/src/main.c` file) that is generated by the MHC, as shown in the following example. The *main* function calls two system-wide state machine functions, SYS_Initialize and SYS_Tasks that are also generated by the MHC to initialize and run the system.

MPLAB Harmony "main" Function

```
MAIN_RETURN main ( void )
{
    SYS_Initialize(NULL);

    while(true)
    {
        SYS_Tasks();
    }
```

```
    return(EXIT_FAILURE);
}
```

The SYS_Initialize function calls the initialization functions for all library and application modules that are used in the system to place them in their initial states. Each module's initialization function must prepare the module so it is safe to call its *Tasks* function(s). The SYS_Initialize function's implementation (and necessary support code) is generated by the MHC in the `<project-name>/firmware/src/system_config/<configuration-name>/system_init.c` file.

After initializing all modules, the *main* function contains the system-wide super loop that executes continuously until the system is powered off or reset. Inside the super loop, the *main* function calls the SYS_Tasks function. This function in turn calls the *Tasks* functions for any library or application modules whose state machines operate in a polled manner in the system. Of course, those state machines must first have been initialized by a prior call to their initialization functions by the SYS_Initialize function. The SYS_Task function's implementation is also generated by the MHC, but it is contained in the `<project-name>/firmware/src/system_config/<configuration-name>/system_tasks.c` file.

The polled super loop configuration described above is the most basic configuration of a MPLAB Harmony project. However, a single MPLAB Harmony project can have multiple configurations and different configurations may change modules so that they operate either polled or interrupt driven or in an RTOS thread. However, regardless of the configuration selected, the *main* function does not normally change.

MPLAB Harmony Documentation Volumes

For further information on MPLAB Harmony configurations and execution models, refer to the following MPLAB Harmony documentation.

- Volume I: Getting Started with MPLAB Harmony
- Volume II: MPLAB Harmony Configurator (MHC)
- Volume III: MPLAB Harmony Development

Note: Although the MPLAB Harmony *main* function and system state machine functions (and other system configuration code) are generated as part of a MPLAB Harmony project for your convenience, these files are unique to your project and can be modified or implemented by other means if so desired, or even removed from the project to create a binary library (`.a` file) containing all configured MPLAB Harmony libraries. Refer to the *"MPLAB® X IDE User's Guide"* (DS50002027) and the *"MPLAB® XC32 C/C++ Compiler User's Guide"* (DS50001686) for information on creating library projects.

MPLAB Harmony Module System Interface

Describes the MPLAB Harmony module system interface and provides usage examples.

Description

To support the system-wide state machine (see System State Machine), an MPLAB Harmony module must provide an initialization function and a *Tasks* function. In addition, a MPLAB Harmony module may (optionally) provide deinitialization, reinitialization, and status functions. This set of functions is considered the module's "system interface". The system state machine, system scheduler, or any other system-management code uses a module's system interface to initialize, run, and otherwise control the execution of a module in the MPLAB Harmony system.

To define the calling signature of these system interface functions, the `sys_module.h` header defines function pointer data types for each. These data types could be used to develop a dynamic system with capabilities beyond the basic system state machine, such as dynamic task registration, power management, advanced schedulers, or even your own operating system.

The following examples show how the system interface could be used to create a simple dynamic polled system tasks scheduler.

Example Dynamic System Data Structures

```
typedef struct _system_module_interface
{
    SYS_MODULE_INITIALIZE_ROUTINE   initialize;
    SYS_MODULE_TASKS_ROUTINE        tasks;
    SYS_MODULE_REINITIALIZE_ROUTINE reinitialize;
    SYS_MODULE_DEINITIALIZE_ROUTINE deinitialize;
    SYS_MODULE_STATUS_ROUTINE       status;

} SYSTEM_MODULE_INTERFACE;

typedef struct _system_module_data
{
    SYSTEM_MODULE_INTERFACE function;
    SYS_MODULE_INDEX        index;
    SYS_MODULE_INIT        *initData;
    SYS_MODULE_OBJ          obj;
    SYS_STATUS              status;
    uint8_t                 powerState;

} SYSTEM_MODULE_DATA;
```

```
SYSTEM_MODULE_DATA gModules[CONFIG_NUMBER_OF_MODULES];
```

In the previous example code, the SYSTEM_MODULE_INTERFACE structure contains pointers to all of a module's system interface functions. This structure could be filled in with pointers to a module's system interface functions and a pointer to the structure passed into a dynamic module registration function, along with the module index number and a pointer to any initialization data required by the module. The following example shows how this dynamic registration function might appear.

Example Dynamic Module Registration Function

```
bool SYS_ModuleRegister ( SYSTEM_MODULE_DATA *module,
                          SYS_MODULE_INDEX    index,
                          SYS_MODULE_INIT    *iniData )
{
    SYSTEM_MODULE_DATA  module;
    int                 i;
    bool                success = false;

    for (i=0; i < CONFIG_NUMBER_OF_MODULES; i++)
    {
        if (gModules[i].function.initialize != NULL)
        {
            module = &gModules[i];
        }
    }

    if (i < CONFIG_NUMBER_OF_MODULES)
    {
        module->function.initialize     = module->initialize;
        module->function.tasks          = module->tasks;
        module->function.reinitialize   = module->reinitialize;
        module->function.deinitialize   = module->deinitialize;
        module->function.status         = module->status;

        module->index       = index;
        module->initData    = initData;
        module->obj         = SYS_MODULE_OBJ_INVALID;
        module->status      = SYS_STATUS_UNINITIALIZED;
        module->powerState  = SYS_MODULE_POWER_RUN_FULL;

        success = true;
    }

    return success;
}
```

The SYS_ModuleRegister function could then scan a system-global array (`gModules`, from the previous system data structures example) to find an empty SYSTEM_MODULE_DATA structure (using the initialization function pointer as a "flag" to indicate if the structure is in use or not), copy the newly registered module's interface and other data into the structure, and initialize the other members of the structure.

Once all modules to be used have been similarly registered, the entire system could be initialized when desired by calling a SYS_InitializeDynamic function implementation, similar to the following example.

Example Dynamic System Initialization Function

```
void SYS_InitializeDynamic ( void *data )
{
    SYSTEM_MODULE_DATA  module = (SYSTEM_MODULE_DATA *)data;
    int                 i;

    for (i=0; i < CONFIG_NUMBER_OF_MODULES; i++)
    {
        if (module->function.initialize != NULL)
        {
            module->obj = module->function.initialize(module->index,
                                                      module->initData);

            module->status     = SYS_STATUS_BUSY;
            module->powerState = SYS_MODULE_POWER_RUN_FULL;

            if (module->obj == SYS_MODULE_OBJ_INVALID)
            {
                module->function.initialize = NULL;
            }
```

```
        }
    }
}
```

The previous SYS_InitializeDynamic example function iterates through the global array of module data structures, calling the initialization functions for any modules that have been registered and skipping over any structures that have no module registered (again using the required initialization function pointer as a sort of flag). If a module's initialization function successfully initializes the module it returns a valid module object handle, which the dynamic system initialization function captures in the module's data structure so it can call the module's other system interface routines. If the module is not successfully initialized, the object handle reported will be invalid (SYS_MODULE_OBJECT_INVALID) and the module is deregistered by nulling the pointer to the initialization function.

Once the system has been initialized, a dynamic tasks function like the following example would also iterate through the module data array and call the tasks functions for each module registered.

Example Dynamic System Tasks Function

```
void SYS_TasksDynamic ( void *data )
{
    SYSTEM_MODULE_DATA  module = (SYSTEM_MODULE_DATA *)data;
    int                 i;

    for (i=0; i < CONFIG_NUMBER_OF_MODULES; i++)
    {
        if (module->function.initialize != NULL &&
            module->function.tasks      != NULL )
        {
            if (module->status(module->obj) >= SYS_STATUS_UNINITIALIZED)
            {
                module->function.tasks(module->obj);
            }
            else
            {
                module->function.deinitialize(module->obj);
                module->function.initialize = NULL;
            }
        }
    }
}
```

After calling a module's *Tasks* function, the previous example checks the module's status by calling its *Status* function. If the module reports an error status (any status less than SYS_STATUS_UNINITIALIZED), the module is deinitialized by calling its *Deinitialize* function and deregistered by nulling out the *Initialize* function pointer.

Please note that the example code provided is for informational purposes only, and is used to describe the purpose and usage of the MPLAB Harmony module system interface. A real dynamic tasks scheduler would need to deal with additional complexities. For example, MPLAB Harmony modules may have zero or more *Tasks* functions (only the initialization function is absolutely required). Therefore, a single tasks-function pointer would not be sufficient. The previous example demonstrates usage of the system status and power state data, but it does not actually update or manage these items. Also, this example does not demonstrate the usage of a module's reinitialization function. This function allows a module to provide a way to change its initial parameters while the module is active (after it has been initialized) without disrupting active clients of the module. *However, at the time of this writing, most MPLAB Harmony modules do not implement this function, so this capability is not usually available.*

Using the SYS_ASSERT Macro

Describes the purpose and usage of the system assertion macro.

Description

The SYS_ASSERT macro is a testing and debugging tool used throughout MPLAB Harmony libraries to verify (or assert) critical assumptions before any action is taken on them. However, it is not usually desirable to have these tests in production code because system assertion failures are normally fatal events that stop current execution, either hanging or resetting the system because it is not safe to continue. Also, even if the tests pass, they would add significant overhead, affecting code size and execution time. To avoid these issues, the default implementation of this macro is empty to eliminate the assertion tests and failure messages from the build, as shown in the following example.

Default SYS_ASSERT Macro Definition

```
#define SYS_ASSERT(test,message)
```

Conversely, when developing, debugging, and testing a project, having SYS_ASSERT statements in the code (particularly in library code) can be very helpful. This macro is used to check key parameter values and intermediate results and provide messages that explain the consequences that occur when they don't match what was expected when the library was implemented. A SYS_ASSERT failure during testing may save significant time spent debugging a MPLAB Harmony library only to find that a configuration setting or value passed into a library was incorrect or unexpected.

The SYS_ASSERT macro provides a convenient way to obtain the desired behavior when an assertion fails. In production code, simply accept the default definition that disposes of the assertion test code and the failure message. If things go wrong during testing, either enable a predefined

implementation of this macro or define it in any way that is convenient for the current application.

One particularly useful definition of the SYS_ASSERT macro is to execute a hard-coded breakpoint instruction if the assertion fails, as shown in the following example.

Example SYS_ASSERT Macro Breakpoint Definition

```
#define SYS_ASSERT(test, message) \
            do{ if(!(test)) SYS_DEBUG_Breakpoint(); }while(true)
```

When using the previous definition, if the assertion test fails, the processor will reach a hard-coded breakpoint and execution will stop in the debugger at the SYS_ASSERT call. This behavior identifies the point in the source code where the assertion call failed. Then, the assertion call conveniently provides an explanation of what the failure means in the associated message string. A system assertion failure is a catastrophic failure, so the `do... while` loop hangs the system to prevent execution of code under an invalid assumption that may cause incorrect behavior or even damage to the system. It is also a way to guarantee that the `if` statement is correctly interpreted by the compiler and not accidentally associated with a following `else` statement.

Another useful implementation of the SYS_ASSERT macro might use the Debug System Service to display the message, as shown in the following example.

Example SYS_ASSERT Macro Definition Using Debug Message Service

```
#define SYS_ASSERT(test, message) \
            do{ if(!(test)) \
                    SYS_DEBUG_MESSAGE(SYS_ERROR_FATAL,(message)); \
            }while(false)
```

The previous definition will display the assertion failure message using whatever method the SYS_DEBUG service is configured to use. However, it has the drawback that it does not hang the system (because the message service may need to continue running), so incorrect or unsafe behavior may result.

It is also possible to combine these two example definitions, which is particularly useful if the debug message service is configured to use the debugger's output window, or to create any another definition that is more useful for a given situation.

Obtaining System Version Information

Describes the purpose and usage of the system version functions.

Description

It is possible to programmatically obtain the version information for the release of MPLAB Harmony using the SYS_Version group of functions. For example, once the Debug System Service has been initialized and is running, the following code would retrieve the current version number and display it on the configured debug console if it were lower than a given value.

Example Version Function Usage

```
#define REQUIRED_VERSION 10700

if (SYS_VersionGet() < REQUIRED_VERSION)
{
    SYS_DEBUG_MESSAGE( SYS_ERROR_WARNING, "Version %s is too low",
                       SYS_VersionStrGet() );
}
```

In the previous example, the SYS_VersionGet function is used to get the numeric representation of the version number so that it can be easily compared to a known value and the SYS_VersionStrGet is used to get a string representation of it for displaying on the debug console.

Library Interface

Data Types and Constants

	Name	Description
	MAIN_RETURN_CODES	Defines return codes for "main".
	SYS_MODULE_DEINITIALIZE_ROUTINE	Pointer to a routine that deinitializes a system module (driver, library, or system-maintained application).
	SYS_MODULE_INDEX	Identifies which instance of a system module should be initialized or opened.
	SYS_MODULE_INIT	Initializes a module (including device drivers) in a current power status as requested by the system or power manager.
	SYS_MODULE_INITIALIZE_ROUTINE	Pointer to a routine that initializes a system module (driver, library, or system-maintained application).
	SYS_MODULE_OBJ	Handle to an instance of a system module.
	SYS_MODULE_REINITIALIZE_ROUTINE	Pointer to a routine that reinitializes a system module (driver, library, or system-maintained application)
	SYS_MODULE_STATUS_ROUTINE	Pointer to a routine that gets the current status of a system module (driver, library, or system-maintained application).

	SYS_MODULE_TASKS_ROUTINE	Pointer to a routine that performs the tasks necessary to maintain a state machine in a module system module (driver, library, or system-maintained application).
	SYS_STATUS	Identifies the current status/state of a system module (including device drivers).
	MAIN_RETURN_CODE	Casts the given value to the correct type for the return code from "main".
	SYS_MODULE_OBJ_INVALID	Object handle value returned if unable to initialize the requested instance of a system module.
	SYS_MODULE_OBJ_STATIC	Object handle value returned by static modules.
	SYS_MODULE_POWER_IDLE_RUN	Module power-state idle-run state code.
	SYS_MODULE_POWER_IDLE_STOP	Module power-state idle-stop state code.
	SYS_MODULE_POWER_OFF	Module power-state power off state code.
	SYS_MODULE_POWER_RUN_FULL	Module power-state run-full state code.
	SYS_MODULE_POWER_SLEEP	Module power-state sleep state code.

Main Function Support Macro

	Name	Description
	MAIN_RETURN	Defines the correct return type for the "main" routine.

System Assert Macro

	Name	Description
	SYS_ASSERT	Implements default system assert routine, asserts that "test" is true.

System State Machine Functions

	Name	Description
	SYS_Tasks	Function that performs all polled system tasks.
	SYS_Initialize	Initializes the board, services, drivers, and other modules

Version Functions

	Name	Description
	SYS_VersionGet	Gets SYS_COMMON version in numerical format.
	SYS_VersionStrGet	Gets SYS_COMMON version in string format.

Description

This section describes the APIs of the System Service Library.

Refer to each section for a detailed description.

Main Function Support Macro

MAIN_RETURN Macro

Defines the correct return type for the "main" routine.

File

sys_common.h

C

```
#define MAIN_RETURN void
```

Description

Main Function Return Type

This macro defines the correct return type for the "main" routine for the selected Microchip microcontroller family.

Remarks

The main function return type may change, depending upon which family of Microchip microcontrollers is chosen. Refer to the user documentation for the C-language compiler in use for more information.

Example

```
MAIN_RETURN main ( void )
{
```

```
    // Initialize the system
    SYS_Initialize(...);

    // Main Loop
    while(true)
    {
        SYS_Tasks();
    }

    return MAIN_RETURN_CODE(MAIN_RETURN_SUCCESS);
}
```

System Assert Macro

SYS_ASSERT Macro

Implements default system assert routine, asserts that "test" is true.

File

sys_common.h

C

```
#define SYS_ASSERT(test,message)
```

Returns

None. Normally hangs in a loop, depending on the implementation to which it is mapped.

Description

This macro implements the default system assert routine that asserts that the provided boolean test is true.

Remarks

Can be overridden as desired by defining your own SYS_ASSERT macro before including system.h.

The default definition removes this macro from all code because it adds significant size to all projects. The most efficient use is to enable it in individual libraries and build them separately for debugging.

Preconditions

None, depending on the implementation to which this macro is mapped.

Example

```
void MyFunc ( int *pointer )
{
    SYS_ASSERT(NULL != pointer, "NULL Pointer passed to MyFunc");

    Do something with pointer.
}
```

Parameters

Parameters	Description
test	This is an expression that resolves to a boolean value (zero=false, non-zero=true)
message	This is a NULL-terminated ASCII character string that can be displayed on a debug output terminal if "test" is false (if supported).

Function

void SYS_ASSERT (bool test, char *message)

System State Machine Functions

SYS_Tasks Function

Function that performs all polled system tasks.

File

sys_module.h

C

```
void SYS_Tasks();
```

Returns

None.

Description

System Tasks Function

This function performs all polled system tasks by calling the state machine "tasks" functions for all polled modules in the system, including drivers, services, middleware and applications.

Remarks

If the module is interrupt driven, the system will call this routine from an interrupt context.

Preconditions

The SYS_Initialize function must have been called and completed.

Example

```
SYS_Initialize ( NULL );

while ( true )
{
    SYS_Tasks ( );
}
```

Function

void SYS_Tasks (void);

SYS_Initialize Function

Initializes the board, services, drivers, and other modules

File

sys_init.h

C

```
void SYS_Initialize(void * data);
```

Returns

None.

Description

This function initializes the board, services, drivers, and other modules as configured at build time. It should be called almost immediately after entering the "main" function.

Remarks

Basic System Initialization Sequence:

1. Initialize core processor services.
2. Initialize board support package.
3. Initialize RTOS (if utilized).
4. Initialize drivers.
5. Initialize system services.
6. Initialize middleware.
7. Initialize application(s).

This function may be overridden and implemented as desired as long as it appropriately initializes all necessary board, services, and modules.

Most MPLAB Harmony libraries are designed so that the order in which they are initialized is not important. However, core processor services and board support packgage initialization should be completed before any other initialization takes place and RTOS initialization (if utilized) shoudl take palce before drivers, system services and middleware are initialized. Applications should be initialized last.

Preconditions

The C-language run-time environment and stack must have been initialized.

Example

```
int main ( void )
{
    SYS_Initialize(NULL);

    while (true)
    {
        SYS_Tasks();
    }
}
```

Parameters

Parameters	Description
data	Pointer to any system initialization data required. Normally passed as NULL for static system implementations.

Function

void SYS_Initialize (void *data)

Version Functions

SYS_VersionGet Macro

Gets SYS_COMMON version in numerical format.

File

sys_common.h

C

```
#define SYS_VersionGet( void ) SYS_VERSION
```

Returns

Current driver version in numerical format.

Description

This routine gets the SYS_COMMON version. The version is encoded as major * 10000 + minor * 100 + patch. The string version can be obtained using SYS_VersionStrGet()

Function

SYS_VersionGet(void)

SYS_VersionStrGet Macro

Gets SYS_COMMON version in string format.

File

sys_common.h

C

```
#define SYS_VersionStrGet( void ) SYS_VERSION_STR
```

Returns

Current SYS_COMMON version in the string format.

Description

Macro: char * SYS_VersionStrGet (void)

This routine gets the SYS_COMMON version in string format. The version is returned as major.minor.path[type], where type is optional. The

numerical version can be obtained using SYS_VersionGet()

Remarks

None.

Data Types and Constants

MAIN_RETURN_CODES Enumeration

Defines return codes for "main".

File

sys_common.h

C

```
typedef enum {
  MAIN_RETURN_FAILURE = -1,
  MAIN_RETURN_SUCCESS = 0
} MAIN_RETURN_CODES;
```

Description

Main Routine Codes Enumeration

This enumeration provides a predefined list of return codes for the main function. These codes can be passed into the MAIN_RETURN_CODE macro to convert them to the appropriate type (or discard them if not needed) for the Microchip C-language compiler in use.

Remarks

The main function return type may change, depending upon which family of Microchip microcontrollers is chosen. Refer to the user documentation for the C-language compiler in use for more information.

Example

```
MAIN_RETURN main ( void )
{
    SYS_Initialize(...);

    while(true)
    {
        SYS_Tasks();
    }

    return MAIN_RETURN_CODE(MAIN_RETURN_SUCCESS);
}
```

SYS_MODULE_DEINITIALIZE_ROUTINE Type

Pointer to a routine that deinitializes a system module (driver, library, or system-maintained application).

File

sys_module.h

C

```
typedef void (* SYS_MODULE_DEINITIALIZE_ROUTINE)(SYS_MODULE_OBJ object);
```

Returns

None.

Description

System Module Deinitialization Routine Pointer. This data type is a pointer to a routine that deinitializes a system module (driver, library, or system-maintained application).

Remarks

If the module instance has to be used again, the module's "initialize" function must first be called.

Preconditions

The low-level board initialization must have (and will be) completed and the module's initialization routine will have been called before the system will call the deinitialization routine for any modules.

Example

None.

Parameters

Parameters	Description
object	Handle to the module instance

Function

void (* SYS_MODULE_DEINITIALIZE_ROUTINE) (SYS_MODULE_OBJ object)

SYS_MODULE_INDEX Type

Identifies which instance of a system module should be initialized or opened.

File

sys_module.h

C

```
typedef unsigned short int SYS_MODULE_INDEX;
```

Description

System Module Index

This data type identifies to which instance of a system module a call to that module's "Initialize" and "Open" routines refers.

Remarks

Each individual module will usually define macro names for the index values it supports (e.g., DRV_TMR_INDEX_1, DRV_TMR_INDEX_2, ...).

SYS_MODULE_INIT Union

Initializes a module (including device drivers) in a current power status as requested by the system or power manager.

File

sys_module.h

C

```
typedef union {
  uint8_t value;
  struct {
    uint8_t powerState : 4;
    uint8_t reserved : 4;
  } sys;
} SYS_MODULE_INIT;
```

Members

Members	Description
uint8_t powerState : 4;	Requested power state
uint8_t reserved : 4;	Module-definable field, module-specific usage

Description

System Module Init

This structure provides the necessary data to initialize or reinitialize a module (including device drivers) into a requested power state. The structure can be extended in a module specific way as to carry module specific initialization data.

Remarks

This structure is used in the device driver routines DRV__Initialize and DRV__Reinitialize that are defined by each device driver.

The "powerState" member has several predefined values (shown below). All other available values (within the 4-bit field) are available for

module-specific meaning.

Predefined powerState Values:

- 0. SYS_MODULE_POWER_OFF - Module power-state power off state code
- 1. SYS_MODULE_POWER_SLEEP - Module power-state sleep state code
- 2. SYS_MODULE_POWER_IDLE_STOP - Module power-state idle-stop state code
- 3. SYS_MODULE_POWER_IDLE_RUN - Module power-state idle-run state code
- 4. through 14. - Module-specific meaning
- 15. SYS_MODULE_POWER_RUN_FULL - Module power-state run-full state code

SYS_MODULE_INITIALIZE_ROUTINE Type

Pointer to a routine that initializes a system module (driver, library, or system-maintained application).

File

sys_module.h

C

```
typedef SYS_MODULE_OBJ (* SYS_MODULE_INITIALIZE_ROUTINE)(const SYS_MODULE_INDEX index, const
SYS_MODULE_INIT * const init);
```

Returns

A handle to the instance of the system module that was initialized. This handle is a necessary parameter to all of the other system-module level routines for that module.

Description

System Module Initialization Routine Pointer

This data type is a pointer to a routine that initializes a system module (driver, library, or system-maintained application).

Remarks

This function will only be called once during system initialization.

Preconditions

The low-level board initialization must have (and will be) completed before the system will call the initialization routine for any modules.

Parameters

Parameters	Description
index	Identifier for the module instance to be initialized
init	Pointer to the data structure containing any data necessary to initialize the module. This pointer may be null if no data is required and default initialization is to be used.

Function

SYS_MODULE_OBJ (* SYS_MODULE_INITIALIZE_ROUTINE) (
const SYS_MODULE_INDEX index,
const SYS_MODULE_INIT * const init)

SYS_MODULE_OBJ Type

Handle to an instance of a system module.

File

sys_module.h

C

```
typedef uintptr_t SYS_MODULE_OBJ;
```

Description

System Module Object

This data type is a handle to a specific instance of a system module (such as a device driver).

Remarks

Code outside of a specific module should consider this as an opaque type (much like a void *). Do not make any assumptions about base type as

it may change in the future or about the value stored in a variable of this type.

SYS_MODULE_REINITIALIZE_ROUTINE Type

Pointer to a routine that reinitializes a system module (driver, library, or system-maintained application)

File

sys_module.h

C

```
typedef void (* SYS_MODULE_REINITIALIZE_ROUTINE)(SYS_MODULE_OBJ object, const SYS_MODULE_INIT * const init);
```

Returns

None.

Description

System Module Reinitialization Routine Pointer

This data type is a pointer to a routine that reinitializes a system module (driver, library, or system-maintained application).

Remarks

This operation uses the same initialization data structure as the Initialize operation.

This operation can be used to change the power state of a module.

This operation can also be used to refresh the hardware state as defined by the initialization data, thus it must guarantee that all hardware state has been refreshed.

This function can be called multiple times to reinitialize the module.

Preconditions

The low-level board initialization must have (and will be) completed and the module's initialization routine will have been called before the system will call the reinitialization routine for any modules.

Example

None.

Parameters

Parameters	Description
object	Handle to the module instance
init	Pointer to the data structure containing any data necessary to initialize the module. This pointer may be null if no data is required and default initialization is to be used.

Function

void (* SYS_MODULE_REINITIALIZE_ROUTINE) (SYS_MODULE_OBJ object,
const SYS_MODULE_INIT * const init)

SYS_MODULE_STATUS_ROUTINE Type

Pointer to a routine that gets the current status of a system module (driver, library, or system-maintained application).

File

sys_module.h

C

```
typedef SYS_STATUS (* SYS_MODULE_STATUS_ROUTINE)(SYS_MODULE_OBJ object);
```

Returns

One of the possible status codes from SYS_STATUS

Description

System Module Status Routine Pointer

This data type is a pointer to a routine that gets the current status of a system module (driver, library, or system-maintained application).

Remarks

A module's status operation can be used to determine when any of the other module level operations has completed as well as to obtain general status of the module. The value returned by the status routine will be checked after calling any of the module operations to find out when they have completed.

If the status operation returns SYS_STATUS_BUSY, the previous operation has not yet completed. Once the status operation returns SYS_STATUS_READY, any previous operations have completed.

The value of SYS_STATUS_ERROR is negative (-1). A module may define module-specific error values of less or equal SYS_STATUS_ERROR_EXTENDED (-10).

The status function must NEVER block.

If the status operation returns an error value, the error may be cleared by calling the reinitialize operation. If that fails, the deinitialize operation will need to be called, followed by the initialize operation to return to normal operations.

Preconditions

The low-level board initialization must have (and will be) completed and the module's initialization routine will have been called before the system will call the status routine for any modules.

Example

None.

Parameters

Parameters	Description
object	Handle to the module instance

Function

SYS_STATUS (* SYS_MODULE_STATUS_ROUTINE) (SYS_MODULE_OBJ object)

SYS_MODULE_TASKS_ROUTINE Type

Pointer to a routine that performs the tasks necessary to maintain a state machine in a module system module (driver, library, or system-maintained application).

File

sys_module.h

C

```
typedef void (* SYS_MODULE_TASKS_ROUTINE)(SYS_MODULE_OBJ object);
```

Returns

None.

Description

System Module Tasks Routine Pointer

This data type is a pointer to a routine that performs the tasks necessary to maintain a state machine in a module system module (driver, library, or system-maintained application).

Remarks

If the module is interrupt driven, the system will call this routine from an interrupt context.

Preconditions

The low-level board initialization must have (and will be) completed and the module's initialization routine will have been called before the system will call the deinitialization routine for any modules.

Example

None.

Parameters

Parameters	Description
object	Handle to the module instance

Function

void (* SYS_MODULE_TASKS_ROUTINE) (SYS_MODULE_OBJ object)

SYS_STATUS Enumeration

Identifies the current status/state of a system module (including device drivers).

File

sys_module.h

C

```
typedef enum {
  SYS_STATUS_ERROR_EXTENDED = -10,
  SYS_STATUS_ERROR = -1,
  SYS_STATUS_UNINITIALIZED = 0,
  SYS_STATUS_BUSY = 1,
  SYS_STATUS_READY = 2,
  SYS_STATUS_READY_EXTENDED = 10
} SYS_STATUS;
```

Members

Members	Description
SYS_STATUS_ERROR_EXTENDED = -10	Indicates that a non-system defined error has occurred. The caller must call the extended status routine for the module in question to identify the error.
SYS_STATUS_ERROR = -1	An unspecified error has occurred.
SYS_STATUS_UNINITIALIZED = 0	The module has not yet been initialized
SYS_STATUS_BUSY = 1	An operation is currently in progress
SYS_STATUS_READY = 2	Any previous operations have succeeded and the module is ready for additional operations
SYS_STATUS_READY_EXTENDED = 10	Indicates that the module is in a non-system defined ready/run state. The caller must call the extended status routine for the module in question to identify the state.

Description

System Module Status

This enumeration identifies the current status/state of a system module (including device drivers).

Remarks

This enumeration is the return type for the system-level status routine defined by each device driver or system module (for example, DRV_I2C_Status).

MAIN_RETURN_CODE Macro

Casts the given value to the correct type for the return code from "main".

File

sys_common.h

C

```
#define MAIN_RETURN_CODE(c)
```

Description

Main Routine Code Macro

This macro cases the given value to the correct type for the return code from the main function.

Remarks

The main function return type may change, depending upon which family of Microchip microcontrollers is chosen. Refer to the user documentation for the C-language compiler in use for more information.

Example

```
MAIN_RETURN main ( void )
{
    // Initialize the system
    SYS_Initialize(...);

    // Main Loop
    while(true)
```

```
    {
        SYS_Tasks();
    }

    return MAIN_RETURN_CODE(MAIN_RETURN_SUCCESS);
}
```

SYS_MODULE_OBJ_INVALID Macro

Object handle value returned if unable to initialize the requested instance of a system module.

File

sys_module.h

C

```
#define SYS_MODULE_OBJ_INVALID ((SYS_MODULE_OBJ) -1 )
```

Description

System Module Object Invalid

This is the object handle value returned if unable to initialize the requested instance of a system module.

Remarks

Do not rely on the actual value of this constant. It may change in future implementations.

SYS_MODULE_OBJ_STATIC Macro

Object handle value returned by static modules.

File

sys_module.h

C

```
#define SYS_MODULE_OBJ_STATIC ((SYS_MODULE_OBJ) 0 )
```

Description

System Module Object Static

This is the object handle value returned by static system modules.

Remarks

Do not rely on the actual value of this constant. It may change in future implementations.

SYS_MODULE_POWER_IDLE_RUN Macro

Module power-state idle-run state code.

File

sys_module.h

C

```
#define SYS_MODULE_POWER_IDLE_RUN 3
```

Description

System Module Power Idle-Run State

This value identifies the current power status/state of a system module (including device drivers). It is used to indicate that the module should prepare to enter an idle-run state.

Remarks

An idle-run state indicates that the core CPU clock may be stopped, but the module's peripheral clock may continue running and peripheral operations may continue as long as no code needs to be executed. If code needs to execute, the module must cause an interrupt.

This value is passed in the powerState field of the SYS_MODULE_INIT structure that takes part in all modules initialization and reinitialization.

The power state codes between SYS_MODULE_POWER_IDLE_RUN (with a value of 3) and SYS_MODULE_POWER_RUN_FULL (with a value of 15) are available for module-specific definition and usage.

SYS_MODULE_POWER_IDLE_STOP Macro

Module power-state idle-stop state code.

File

sys_module.h

C

```
#define SYS_MODULE_POWER_IDLE_STOP 2
```

Description

System Module Power Idle-Stop State

This value identifies the current power status/state of a system module (including device drivers). It is used to indicate that the module should prepare to enter an idle-stop state.

Remarks

An idle-stop state indicates that the core CPU clock may be stopped, but the module's peripheral clock may continue running. However, the peripheral should prepare to stop operations when the idle state is entered.

This value is passed in the powerState field of the SYS_MODULE_INIT structure that takes part in all modules initialization and reinitialization.

The power state codes between SYS_MODULE_POWER_IDLE_RUN (with a value of 3) and SYS_MODULE_POWER_RUN_FULL (with a value of 15) are available for module-specific definition and usage.

SYS_MODULE_POWER_OFF Macro

Module power-state power off state code.

File

sys_module.h

C

```
#define SYS_MODULE_POWER_OFF 0
```

Description

System Module Power Off State

This value identifies the current power status/state of a system module (including device drivers). It is used to indicate that the module should prepare to enter a full power-off state.

Remarks

A power off state indicates that power may be completely removed (0 Volts).

This value is passed in the powerState field of the SYS_MODULE_INIT structure that takes part in all modules initialization and reinitialization.

The power state codes between SYS_MODULE_POWER_IDLE_RUN (with a value of 3) and SYS_MODULE_POWER_RUN_FULL (with a value of 15) are available for module-specific definition and usage.

SYS_MODULE_POWER_RUN_FULL Macro

Module power-state run-full state code.

File

sys_module.h

C

```
#define SYS_MODULE_POWER_RUN_FULL 15
```

Description

System Module Power Run-Full State. This value identifies the current power status/state of a system module (including device drivers). It is used to indicate that the module should prepare to enter an run-full state.

Remarks

An run-full state indicates that the core CPU and peripheral clocks are operational at their normal configured speed and the module should be ready for normal operation.

This value is passed in the powerState field of the SYS_MODULE_INIT structure that takes part in all modules initialization and reinitialization.

The power state codes between SYS_MODULE_POWER_IDLE_RUN (with a value of 3) and SYS_MODULE_POWER_RUN_FULL (with a value of 15) are available for module-specific definition and usage.

SYS_MODULE_POWER_SLEEP Macro

Module power-state sleep state code.

File

sys_module.h

C

```
#define SYS_MODULE_POWER_SLEEP 1
```

Description

System Module Power Sleep State

This value identifies the current power status/state of a system module (including device drivers). It is used to indicate that the module should prepare to enter a sleep state.

Remarks

A Sleep state indicates that the core CPU and peripheral clocks may be stopped and no code will execute and any module hardware will be stopped.

This value is passed in the powerState field of the SYS_MODULE_INIT structure that takes part in all modules initialization and reinitialization.

The power state codes between SYS_MODULE_POWER_IDLE_RUN (with a value of 3) and SYS_MODULE_POWER_RUN_FULL (with a value of 15) are available for module-specific definition and usage.

System Module Header

This file defines definitions and interfaces related to system modules.

Remarks

This file is included via "system.h" and does not normally need to be included directly.

File Name

sys_module.h

Company

Microchip Technology Inc.

system.h

Top level common system services library interface header.

Description

System Services Library Interface Header

This file is the top level common system services library interface header. It defines (or includes files that define) the common system service types, prototypes, and other definitions that are commonly used by MPLAB Harmony libraries and system services.

System services provide common functionality that would otherwise need to be duplicated by multiple other modules or that would force them to interact in complex and hard to manage ways. System services eliminate conflicts by controlling access shared resources.

Remarks

The parent directory to the "system" directory should be added to the compiler's search path for header files such that the following include statment will successfully include this file.

#include "system/system.h"

Clock System Service Library

This section describes the Clock System Service Library.

Introduction

This library provides an interface to manage the Oscillator module on the Microchip family of microcontrollers during Execution time using the Clock System Service Library.

Description

The Clock System Service can be configured to run in either Static mode or Dynamic mode via the MPLAB Harmony Configurator. In Static mode,

the service will configure the Oscillator module to the user-desired system clock frequency, peripheral bus clock frequency, reference bus clock frequency, and USB PLL clock frequency. These settings are set at initialization and are designed to remain the same for the duration of run-time. In Dynamic mode, the service will also set all of these frequencies at initialization; however it offers the function support to allow users to change the system clock frequency, peripheral bus frequency, and if the device supports it, the reference clock frequency.

Design Recommendations

If performance and small code size are critical, and there is no requirement to change the clock speed, the recommendation is to use Static mode. If there is a need to change the system, peripheral, or reference clock frequencies during run-time, the recommendation is to use Dynamic mode.

Configuration

The Oscillator is the heart of the microcontroller, which provides the clock on which the core and the peripherals run. For all of the oscillators present on a Microchip microcontroller, two types of configurations exist:

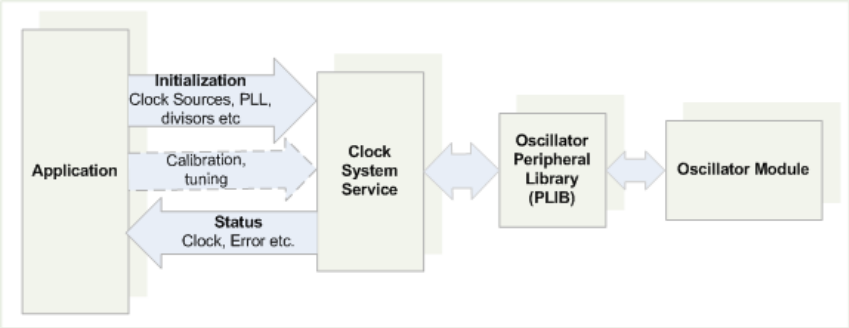
- Through Configuration bits
- At Execution time

Configuring the oscillator through the Configuration bits is a one-time process that it is done during the programming of the device. This one-time configuration is programmed in the code memory. The Execution time configuration provides features that are allowed to be changed during code execution. The Clock System Service Library provides functions the Execution time configurable features of the Oscillator module.

The Oscillator module supports the CPU and other peripherals by providing the clock. Therefore, there is more initialization and little or no run-time operations. The run-time operations set the system clock or any other output clocks. If the application needs to make any initialization changes, they can be done at run-time.

The Oscillator module as a whole is a group of oscillators. These are provided for the application to choose the correct oscillator for the application. It is important to wisely choose the oscillator and the frequency at which the CPU and the other peripherals should run in power-critical environments.

The following figure illustrates the interaction of the Clock System Service Library.



Using the Library

This topic describes the basic architecture of the Clock System Service and provides information and examples on its use.

Description

Interface Header File: `sys_osc.h`

The interface to the Clock System Service is defined in the `sys_osc.h` header file, which is included by the `sys.h` header file.

Any C language source (`.c`) file that uses the Clock System Service must include `sys.h`.

Abstraction Model

This library provides a low-level abstraction of the Clock System Service Library. This topic describes how that abstraction is modeled in software and introduces the library's interface.

Description

To understand the Oscillator module and how each of its feature is mapped in this library, it is important to understand the following terminologies.

Oscillators/Clock Sources

A clock source is hardware that generates oscillations. This may be internal or external.

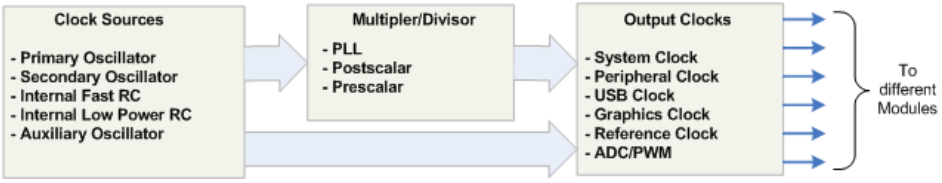
Divisor and Multiplier/PLL

These are hardware modules that can scale the clock. The rate at which the scaling is done may be fixed or configurable.

Clocks

Clock outputs are output lines from the Oscillator module, which may route to different modules of the device or to the CPU (the system clock).

The following diagram provides a simplified explanation and the relationship between the previously mentioned terms. In most cases, there are multiple clock source options available for each of the clock outputs. However, not all clock sources are available for all output clocks. Scaling is an optional feature in most cases.



Library Overview

Please refer to the System Service Introduction for a detailed description of MPLAB Harmony system services.

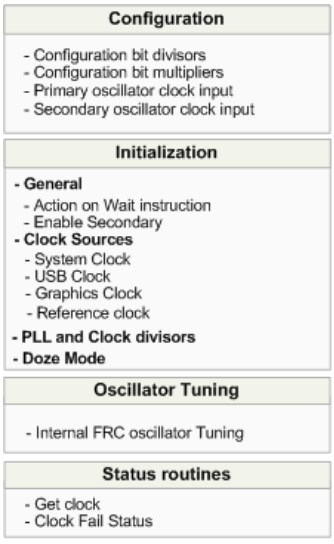
The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Clock System Service module.

Library Interface Section	Description
System Clock Functions	Provides functions to set and get the system clock frequency.
Peripheral Clock Functions	Provides functions to set and get the peripheral clock frequency.
Reference Clock Functions	Provides functions to set up the reference clock, and set and get the reference clock frequency.
Clock Failure Functions	Provides functions to allow registration of a callback function that will be triggered on a clock failure and to inform the user on a clock failure by invoking the registered call back function.
Initialization Functions	Provides an initialization routine to configure the module at the start-up of the system and reinitialization if the application wants to change any of the initialization settings.

How the Library Works

The following diagram shows the flow of an application call to the Clock System Service Library.

Refer to the System Services Introduction section for information on how the system services operate in a system.



Initialization

Provides information and code examples for initializing the Oscillator.

Description

The Oscillator is a module with little or no run-time operations. Therefore, the application must do most of the configurations at the time of system initialization even though it is allowed to change the clock frequency at run-time.

The Oscillator needs some time to settle. Therefore, it is recommended to perform the oscillator initialization before initializing other modules. Check for the oscillator status once all of the initializations are complete and before the application task routine takes control.

Note: Not all devices require all of the initialization parameters of the structure. Refer to the specific device data sheet to determine which features are available for your device.

Clock is Set Through Configuration bits

In most cases, setting the clock is done through Configuration bits. Therefore, what the application expects from the Clock System Service Library is to provide all of the clock frequency values on a function call. To use the Clock System Service in this way, call the SYS_CLK_Initialize function by passing a NULL to it, as shown in the following code example. The function reads the registers and will initialize its internal data structure.

```
SYS_CLK_Initialize ( NULL );
//As per my setting, the system clock should be 80 MHz
If ( SYS_CLK_SystemFrequencyGet ( )  != 80000000 )
{
     //Something is wrong, check the Configuration bit settings
}
```

Alter the Configuration bit Setting

To alter the settings made in the Configuration bit, pass the structure to the SYS_CLK_Initialize function.

```
SYS_CLK_INIT generalInit;

// Populate the oscillator initialization structure
generalInit.systemClockSource = SYS_CLK_SOURCE_FRC_SYSPLL;
generalInit.systemClockFrequencyHz = 30000000;
generalInit.onWaitInstruction = OSC_ON_WAIT_SLEEP;
generalInit.secondaryOscKeepEnabled = true;
SYS_CLK_Initialize (&generalInit);
```

Changing the Clock

Provides information on changing the clock.

Description

The module initializes only the system clock as part of the SYS_CLK_Initialize function. All other clocks including the peripheral clock must be set by calling specific functions.

Changing the System Clock

Changing the system clock is done using the SYS_CLK_SystemFrequencySet function, which expects the clock source and the frequency as arguments. If the clock source is a PLL-based source, a flag is provided so that a user can chose whether to wait until the operation is complete or just trigger the change and exit. The function will return zero if the requested clock is not achievable.

Changing the Peripheral Clock

Changing the Peripheral clock is done using the SYS_CLK_PeripheralFrequencySet function, which expects the clock source and the frequency as arguments. The function will return zero if the requested clock is not achievable. When this occurs, call the SYS_CLK_ PeripheralClosestFrequencyGet function by passing the bus number to it, to determine the closest possible clock.

```
switch ( clockState )
{
case 1:
SYS_CLK_PeripheralFrequencySet ( CLK_BUS_PERIPHERAL_1, CLK_SOURCE_PERIPHERAL_SYSTEMCLK, 8000000, true );

clockState++;

break;

case 2:
if ( SYS_CLK_PeripheralOperationStatus ( CLK_BUS_PERIPHERAL_1 ) == SYS_CLK_OPERATION_COMPLETE )
{
//Peripheral clock setting is completed
clockState++;
}
break;
}
```

Changing/Setting the Reference Clock

Changing or setting the reference clock is done using two functions. Set the module's response to Sleep and Idle mode using the function SYS_CLK_ReferenceClockSetup. Use the SYS_CLK_ReferenceFrequencySet function to set the clock out, which expects the clock source and the frequency as arguments. The function will return zero if the requested clock is not achievable. When this occurs, call the SYS_CLK_ ReferenceClosestFrequencyGet function by passing the bus number to it, to determine the closest possible clock.

```
uint32_t achievedFrequencyHz;
```

```
//I want 200 kHz as output
achievedFrequencyHz = SYS_CLK_ReferenceFrequencySet ( CLK_BUS_REFERENCE_3, CLK_SOURCE_REF_FRC, 200000, true
);

if ( achievedFrequencyHz != 0 )
{
        //Frequency successfully set
}
```

Using Status Functions

Provides a code example to check the clock output.

Description

Checking the Clock Output

The following code provides an example of checking the clock output.

```
uint32_t usbClockOutputHz;
unsigned long sysClockOutputHz;
unsigned long peripheralClockHz;
uint32_t sysClockHz;

    sysClockHz = SYS_CLK_SystemFrequencyGet ( );

    peripheralClockHz = SYS_CLK_PeripheralFrequencyGet ( CLK_BUS_PERIPHERAL_1);
    usbClockOutputHz = SYS_CLK_USBClockFrequencyGet ( CLK_BUS_USB_1 );

    sysClockOutputHz = SYS_CLK_ReferenceFrequencyGet ( CLK_BUS_REFERENCE_1 );
```

Oscillator Tuning

Provides information on tuning the Oscillator.

Description

Oscillator tuning will help compensate for temperature effects on the FRC frequency over a wide range of temperatures. The tuning step size is an approximation; the application is supposed to try different values to achieve the best result. In some devices, there are different tuning modes available.

Direct Number Method

```
//Software must unlock before the start of the tuning.
SYS_OSC_FRCTUNING_DATA tuningInput;
OSC_FRC_TUNING_VALUE tuningValue = OSC_TUNE_TO_CENTRAL_FREQ_PLUS_0_86;

tuningInput.tuningMode = OSC_TUNING_USING_NUMBER;
tuningInput.tuningData = &tuningValue;
SYS_OSC_FRCTuningSet(&tuningInput);
```

Sequential Dithering

To get the Sequential Dithering working, the application is supposed to set the value in seven sequencers and also in the tuning register. Next, the PWM module is configured and the period and pulse width are set. The Oscillator module generates frequencies corresponding to the value specified in these registers in every eighth PWM cycle.

```
//Software must unlock before the start of the tuning.
SYS_OSC_FRCTUNING_DATA tuningInput;
OSC_FRC_TUNING_VALUE tuningValue[8];

//Initialize with tuning values
tuningValue[0] = OSC_TUNE_TO_CENTRAL_MINUS_2_25_PERC;
tuningValue[1] = OSC_TUNE_TO_CENTRAL_MINUS_1_5_PERC;
tuningValue[2] = OSC_TUNE_TO_CENTRAL_MINUS_0_375_PERC;
tuningValue[3] = OSC_TUNE_TO_CENTRAL_PLUS_0_43_PERC;
tuningValue[4] = OSC_TUNE_TO_CENTRAL_PLUS_1_29_PERC;
tuningValue[5] = OSC_TUNE_TO_CENTRAL_PLUS_2_54_PERC;
tuningValue[6] = OSC_TUNE_TO_CENTRAL_MINUS_3_PERC;
tuningValue[7] = OSC_TUNE_TO_CENTRAL_MINUS_3_PERC;

tuningInput.tuningMode = OSC_TUNING_SEQ_DITHER;
```

```
tuningInput.tuningData = tuningValue;
SYS_OSC_FRCTuningSet(&tuningInput);
```

Pseudo-Random Number

In this method, select the tuning mode. Next, configure the PWM module and set the period and pulse width. The Oscillator system generates a 4-bit number based on a pseudo-random number generation algorithm. The Oscillator system then uses this value to tune the FRC oscillator. The module will generate different frequencies corresponding to the generated pseudo-random numbers every eighth PWM cycle.

```
//Software must unlock before the start of the tuning.
SYS_OSC_FRCTUNING_DATA tuningInput;
OSC_FRC_TUNING_VALUE tuningValue = 0x7FFF;

tuningInput.tuningMode = OSC_TUNING_PSEUDO_RANDOM;
tuningInput.tuningData = &tuningValue;
SYS_OSC_FRCTuningSet(&tuningInput);
```

Configuring the Library

Macros

	Name	Description
	SYS_CLK_CONFIG_FREQ_ERROR_LIMIT	Sets the allowed frequency configuration error Hertz.
	SYS_CLK_CONFIG_PRIMARY_XTAL	Gives the Primary oscillator input frequency. This is from the hardware and not the output required frequency.
	SYS_CLK_CONFIG_SECONDARY_XTAL	Gives the Secondary oscillator input frequency. This is from the hardware and not the output required frequency.
	SYS_CLK_CONFIG_SYSPLL_INP_DIVISOR	Gives the System PLL input divisor configured through configuration bits. For some of the devices, the system PLL input divisor is not accessible through software. So use this macro to inform the System service about the input divisor.
	SYS_CLK_CONFIGBIT_USBPLL_DIVISOR	Gives the Oscillator USB clock divisor.
	SYS_CLK_CONFIGBIT_USBPLL_ENABLE	Defines the status of the USB PLL.
	SYS_CLK_CONFIG_EXTERNAL_CLOCK	Gives the clock that is provided on the Reference clock output pin.
	SYS_CLK_UPLL_BEFORE_DIV2_FREQ	Defines the value of the USB clock for the devices which does not have a software controllable USB clock.

Description

The configuration of the Clock System Service Library is based on the file `system_config.h`.

This header file contains the configuration selection for the Clock System Service Library. Based on the selections made, the Clock System Service Library may support the selected features. These configuration settings will apply to all instances of the Clock System Service Library.

This header can be placed anywhere, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

SYS_CLK_CONFIG_FREQ_ERROR_LIMIT Macro

Sets the allowed frequency configuration error Hertz.

File

sys_clk_config_template.h

C

```
#define SYS_CLK_CONFIG_FREQ_ERROR_LIMIT 10
```

Description

Frequency Configuration error

This macro sets the allowed frequency error in Hertz.

Remarks

None.

SYS_CLK_CONFIG_PRIMARY_XTAL Macro

Gives the Primary oscillator input frequency. This is from the hardware and not the output required frequency.

File

sys_clk_config_template.h

C

```
#define SYS_CLK_CONFIG_PRIMARY_XTAL 8000000L
```

Description

Primary Oscillator clock input frequency

This macro gives the Primary Oscillator clock input frequency.

Remarks

Find this out by checking the hardware. examine the crystal connected to the Primary Oscillator input pin.

SYS_CLK_CONFIG_SECONDARY_XTAL Macro

Gives the Secondary oscillator input frequency. This is from the hardware and not the output required frequency.

File

sys_clk_config_template.h

C

```
#define SYS_CLK_CONFIG_SECONDARY_XTAL 8000000
```

Description

Secondary Oscillator clock input frequency

This macro gives the Secondary Oscillator clock input frequency.

Remarks

Find this out by checking the hardware. examine the crystal connected to the Secondary Oscillator input pin.

SYS_CLK_CONFIG_SYSPLL_INP_DIVISOR Macro

Gives the System PLL input divisor configured through configuration bits. For some of the devices, the system PLL input divisor is not accessible through software. So use this macro to inform the System service about the input divisor.

File

sys_clk_config_template.h

C

```
#define SYS_CLK_CONFIG_SYSPLL_INP_DIVISOR 2
```

Description

System PLL input divisor configured through configuration bits

Gives the System PLL input divisor configured through configuration bits. For some of the devices, the system PLL input divisor is not accessible through software. So use this macro to inform the System service about the input divisor. In case of some devices PLL expects its input frequency to be in a specific range. So it is important to set the input divisor get the right input frequency.

Remarks

This must be changed every time you change the System PLL input divisor through the configuration bits.

SYS_CLK_CONFIGBIT_USBPLL_DIVISOR Macro

Gives the Oscillator USB clock divisor.

File

sys_clk_config_template.h

C

```
#define SYS_CLK_CONFIGBIT_USBPLL_DIVISOR 2
```

Description

Oscillator USB clock divisor configured through configuration bits

This macro sets up the Oscillator USB clock divisor. Use OSC_CONFIGBITS_PLLIDIV to select the configuration.

Remarks

This must be changed every time you change the USB PLL divisor through the configuration bits.

SYS_CLK_CONFIGBIT_USBPLL_ENABLE Macro

Defines the status of the USB PLL.

File

sys_clk_config_template.h

C

```
#define SYS_CLK_CONFIGBIT_USBPLL_ENABLE true
```

Description

System clock PLL enable configuration

Setting this macro to 'true' states that USB PLL is enabled through the Configuration bits.

Remarks

This must be changed every time you enable/disable the USB PLL through the configuration bits.

SYS_CLK_CONFIG_EXTERNAL_CLOCK Macro

Gives the clock that is provided on the Reference clock output pin.

File

sys_clk_config_template.h

C

```
#define SYS_CLK_CONFIG_EXTERNAL_CLOCK 4000000
```

Description

External clock frequency

This macro gives the clock that is provided on the Reference clock output pin.

Remarks

None.

SYS_CLK_UPLL_BEFORE_DIV2_FREQ Macro

Defines the value of the USB clock for the devices which does not have a software controllable USB clock.

File

sys_clk_config_template.h

C

```
#define SYS_CLK_UPLL_BEFORE_DIV2_FREQ 48000000
```

Description

USB clock frequency

Defines the value of the USB clock for the devices which does not have a software controllable USB clock(Fully controlled through configuration bits).

Remarks

None.

Building the Library

This section lists the files that are available in the Clock System Service Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/system/clk`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
sys_clk.h	Clock System Service Library API header file.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/sys_clk.c	Clock System Service Library implementation.
/src/sys_clk_pic32mx.c /src/sys_clk_pic32mx.h	System clock implementation specific to PIC32MX devices.
/src/sys_clk_pic32mz.c /src/sys_clk_pic32mz.h	System clock implementation specific to PIC32MZ devices.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The Clock System Service is not dependent upon other modules.

Library Interface

a) System Clock Functions

	Name	Description
	SYS_CLK_SystemFrequencyGet	Gets the system clock frequency in Hertz. **Implementation:** Static/Dynamic
	SYS_CLK_SystemFrequencySet	Configures the System clock of the device to the value specified. **Implementation:** Dynamic

b) Peripheral Clock Functions

	Name	Description
	SYS_CLK_PeripheralFrequencyGet	Gets the selected clock peripheral bus frequency in Hertz. **Implementation:** Static/Dynamic
	SYS_CLK_PeripheralFrequencySet	Configures the peripheral clock of the device to the value specified. **Implementation:** Dynamic

c) Reference Clock Functions

	Name	Description
	SYS_CLK_ReferenceClockSetup	Configures the reference clock of the device to the value specified. **Implementation:** Dynamic

	SYS_CLK_ReferenceFrequencySet	Configures the reference clock of the device to the value specified. **Implementation:** Dynamic
	SYS_CLK_ReferenceFrequencyGet	Gets the selected Reference clock bus frequency in Hertz. **Implementation:** Static/Dynamic

d) Clock Failure Functions

	Name	Description
	SYS_CLK_ClockFailureCallbackRegister	Allows registration of a call back function that will be triggered on a clock failure. **Implementation:** Dynamic
	SYS_CLK_TaskError	Informs the user on a clock failure by invoking the registered call back function. **Implementation:** Dynamic

e) Initialization Functions

	Name	Description
	SYS_CLK_Initialize	Initializes hardware and internal data structure of the System Clock. **Implementation:** Static/Dynamic

f) Secondary Oscillator Functions

	Name	Description
	SYS_CLK_SecondaryOscillatorDisable	Disables the secondary oscillator. **Implementation:** Static/Dynamic
	SYS_CLK_SecondaryOscillatorEnable	Enables the secondary oscillator. **Implementation:** Static/Dynamic
	SYS_CLK_SecondaryOscillatorIsEnabled	Identifies whether secondary oscillator is enabled or disabled. **Implementation:** Static/Dynamic

g) Data Types and Constants

	Name	Description
	SYS_CLK_INIT	Defines the data required to initialize the Oscillator for the Clock System Service.
	CLK_BUSES_PERIPHERAL	Lists the available peripheral clock buses.
	CLK_BUSES_REFERENCE	Lists the available reference clock buses.
	CLK_SOURCES_PERIPHERAL	Lists the available clock sources for the peripheral clock.
	CLK_SOURCES_REFERENCE	Lists the available clock sources for the Reference clock.
	CLK_SOURCES_SYSTEM	Lists the available clock sources for the system clock.
	SYS_CLK_ERROR_HANDLER	Pointer to a CLK System service SYS_CLK_ClockFailureCallbackRegister function.
	SYS_CLK_REFERENCE_SETUP	Defines the data required to initialize the Oscillator for the Clock System Service.
	SYS_CLK_STATUS	Lists all the possible status of a system clock operation.
	SYS_CLK_FRCTune	This function is used for direct value based FRC oscillator tuning. **Implementation:** Dynamic
	SYS_CLK_FRC_TUNING_TYPE	Defines the data type for tuning the FRC Oscillator.

Description

This section describes the APIs of the Clock System Service Library.

Refer to each section for a detailed description.

a) System Clock Functions

SYS_CLK_SystemFrequencyGet Function

Gets the system clock frequency in Hertz.

Implementation: Static/Dynamic

File

sys_clk.h

C

```
uint32_t SYS_CLK_SystemFrequencyGet();
```

Returns

System clock frequency in Hertz.

Description

This function gets the System clock frequency in Hertz.

Preconditions

The SYS_CLK_Initialize function should be called before calling this API.

Example

```
uint32_t sysClockHz;

sysClockHz = SYS_CLK_SystemFrequencyGet ( );
```

Function

uint32_t SYS_CLK_SystemFrequencyGet (void)

SYS_CLK_SystemFrequencySet Function

Configures the System clock of the device to the value specified.

Implementation: Dynamic

File

sys_clk.h

C

```
uint32_t SYS_CLK_SystemFrequencySet(CLK_SOURCES_SYSTEM systemSource, uint32_t systemClockHz, bool
waitUntilComplete);
```

Returns

'Zero' on an unsuccessful operation. Configured system clock frequency on successful operation.

Description

This function configures the clock multipliers and divisors to achieve requested System clock frequency. Initially it checks the difference between the requested value and possible value. If it is not within 'SYS_CLK_CONFIG_FREQ_ERROR_LIMIT', the registers values will not be changed and a value '0' will be returned to let user know that the operation was unsuccessful. If the value requested is acceptable, then it writes to the oscillator registers and return with the newly set frequency.

Remarks

Getting the new frequency doesn't mean that the operation is complete if the API is not called to 'wait until' the operation is complete. The API will return with the possible value immediately. The actual hardware switching may take longer. Use SYS_CLK_SystemClockStatus function to get the status of completion.

Calling this API is only necessary to change the system clock. Use SYS_CLK_Initialize function to set up the system clock initially.

Preconditions

The SYS_CLK_Initialize function should be called before calling this API. To change the clock source, clock switching must be enabled through 'configuration bits'.

Example

```
uint32_t achievedFrequencyHz;

// ******** Blocking call******
achievedFrequencyHz = SYS_CLK_SystemFrequencySet (
    SYS_CLK_SOURCE_PRIMARY, 8000000, true );

if ( achievedFrequencyHz != 0 )
{
    //Clock setting complete
}
```

Parameters

Parameters	Description
systemSource	Clock source means the path of the clock signal. One of the possible value from CLK_SOURCES_SYSTEM enum. See the block diagram in the data sheet to get an idea.
systemClockHz	Required System Clock frequency in Hertz.
waitUntilComplete	Passing this parameter as 'true' will make until the actual hardware operation is complete.

Function

uint32_t SYS_CLK_SystemFrequencySet (CLK_SOURCES_SYSTEM systemSource,
uint32_t systemClockHz, bool waitUntilComplete)

b) Peripheral Clock Functions

SYS_CLK_PeripheralFrequencyGet Function

Gets the selected clock peripheral bus frequency in Hertz.

Implementation: Static/Dynamic

File

sys_clk.h

C

```
uint32_t SYS_CLK_PeripheralFrequencyGet(CLK_BUSES_PERIPHERAL peripheralBus);
```

Returns

Clock frequency in Hertz.

Description

This function gets the selected peripheral bus clock frequency in Hertz.

Remarks

Most devices do not have multiple peripheral clock buses. In those instances, pass CLK_USB_PERIPHERAL_1 as the bus number.

Preconditions

The SYS_CLK_Initialize function should be called before calling this API.

Example

```
unsigned long peripheralClockHz;

peripheralClockHz = SYS_CLK_PeripheralFrequencyGet ( CLK_BUS_PERIPHERAL_5 );
```

Parameters

Parameters	Description
peripheralBus	Reference clock bus selection. One of the possible value from CLK_BUSES_PERIPHERAL enum. For devices that do not have multiple clock channels for Reference clock, CLK_BUS_PERIPHERAL_1 should be the selection.

Function

uint32_t SYS_CLK_PeripheralFrequencyGet (CLK_BUSES_PERIPHERAL peripheralBus)

SYS_CLK_PeripheralFrequencySet Function

Configures the peripheral clock of the device to the value specified.

Implementation: Dynamic

File

sys_clk.h

C

```
uint32_t SYS_CLK_PeripheralFrequencySet(CLK_BUSES_PERIPHERAL peripheralBus, CLK_SOURCES_PERIPHERAL
peripheralSource, uint32_t peripheralClockHz, bool waitUntilComplete);
```

Returns

None.

Description

This function configures the clock multipliers and divisors to achieve requested Peripheral clock frequency. Initially it checks the difference between the requested value and possible value. If it is not within 'SYS_CLK_CONFIG_FREQ_ERROR_LIMIT', the registers values will not be changed and a value '0' will be returned to let user know that the operation was unsuccessful. If the value requested is acceptable, then it writes to the oscillator registers and return with the newly set frequency. If the operation is a failure, SYS_CLK_PeripheralClosestFrequencyGet function will give the closest possible frequency. If the closest possible value is acceptable, user can reconfigure with that value.

Remarks

Most devices do not have multiple Peripheral clock buses. In those instances, pass CLK_BUS_PERIPHERAL_1 as the bus number.

Preconditions

The SYS_CLK_Initialize function should be called before calling this API.

Example

```
uint32_t achievedFrequencyHz;

//Example for MX, single peripheral bus
achievedFrequencyHz = SYS_CLK_PeripheralFrequencySet ( CLK_BUS_PERIPHERAL_1,
    CLK_SOURCE_PERIPHERAL_SYSTEMCLK, 8000000, true );

if ( achievedFrequencyHz !=  0 )
{
    //Frequency successfully set
}

//Example for MZ, multiple peripheral buses
achievedFrequencyHz = SYS_CLK_PeripheralFrequencySet ( CLK_BUS_PERIPHERAL_4,
    CLK_SOURCE_PERIPHERAL_SYSTEMCLK, 8000000, true );

if ( achievedFrequencyHz !=  0 )
{
    //Frequency successfully set
}
```

Parameters

Parameters	Description
peripheralBus	Peripheral bus selection. One of the possible value from CLK_BUSES_PERIPHERAL enum. For devices that do not have multiple clock channels for Peripheral clock, CLK_BUS_PERIPHERAL_1 should be the selection.
peripheralSource	Clock source means the path of the clock signal. One of the possible value from CLK_SOURCES_PERIPHERAL enum. See the block diagram in the data sheet to get an idea.
peripheralClockHz	Clock frequency in Hertz.
waitUntilComplete	Passing this parameter as 'true' will make until the actual hardware operation is complete.

Function

uint32_t SYS_CLK_PeripheralFrequencySet (CLK_BUSES_PERIPHERAL peripheralBus,
CLK_SOURCES_PERIPHERAL peripheralSource, uint32_t peripheralClockHz,
bool waitUntilComplete)

c) Reference Clock Functions

SYS_CLK_ReferenceClockSetup Function

Configures the reference clock of the device to the value specified.

Implementation: Dynamic

File

sys_clk.h

C

```
void SYS_CLK_ReferenceClockSetup(CLK_BUSES_REFERENCE referenceBus, SYS_CLK_REFERENCE_SETUP * refSetup);
```

Returns

None.

Description

This function configures the clock multipliers and divisors to achieve requested Reference clock frequency. Initially it checks the difference between the requested value and possible value. If it is not within 'SYS_CLK_CONFIG_FREQ_ERROR_LIMIT', the registers values will not be changed and a value '0' will be returned to let user know that the operation was unsuccessful. If the value requested is acceptable, then it writes to the oscillator registers and return with the newly set frequency. If the operation is a failure, SYS_CLK_ReferenceClosestFrequencyGet function will give the closest possible frequency. If the closest possible value is acceptable, user can reconfigure with that value.

Remarks

Most devices do not have multiple reference clock buses. In those instances, pass CLK_BUS_REFERENCE_1 as the bus number.

Preconditions

The SYS_CLK_Initialize function should be called before calling this API.

Example

```
SYS_CLK_REFERENCE_SETUP refSetup;

refSetup.suspendInSleep = true;
refSetup.stopInIdle = true;

SYS_CLK_ReferenceClockSetup ( ( CLK_BUS_REFERENCE_3, &refSetup );
```

Parameters

Parameters	Description
referenceBus	Reference clock bus selection. One of the possible value from CLK_BUSES_REFERENCE enum. For devices that do not have multiple clock channels for Reference clock, CLK_BUS_REFERENCE_1 should be the selection.
refSetup	A structure which holds the reference oscillator configuration.

Function

void SYS_CLK_ReferenceClockSetup (CLK_BUSES_REFERENCE referenceBus,
SYS_CLK_REFERENCE_SETUP refSetup)

SYS_CLK_ReferenceFrequencySet Function

Configures the reference clock of the device to the value specified.

Implementation: Dynamic

File

sys_clk.h

C

```
uint32_t SYS_CLK_ReferenceFrequencySet(CLK_BUSES_REFERENCE referenceBus, CLK_SOURCES_REFERENCE
referenceSource, uint32_t referenceClockHz, bool waitUntilComplete);
```

Returns

None.

Description

This function configures the clock multipliers and divisors to achieve requested Reference clock frequency. Initially it checks the difference between the requested value and possible value. If it is not within 'SYS_CLK_CONFIG_FREQ_ERROR_LIMIT', the registers values will not be changed and a value '0' will be returned to let user know that the operation was unsuccessful. If the value requested is acceptable, then it writes to the oscillator registers and return with the newly set frequency. If the operation is a failure, SYS_CLK_ReferenceClosestFrequencyGet function will

give the closest possible frequency. If the closest possible value is acceptable, user can reconfigure with that value.

Remarks

Most devices do not have multiple reference clock buses. In those instances, pass CLK_BUS_REFERENCE_1 as the bus number.

Preconditions

The SYS_CLK_Initialize function should be called before calling this API. To change the clock source clock switching must be enabled through 'configuration bits'.

Example

```
uint32_t achievedFrequencyHz;

//I want 200 KHz as output
achievedFrequencyHz = SYS_CLK_ReferenceFrequencySet ( CLK_BUS_REFERENCE_3,
    CLK_SOURCE_REF_FRC, 200000, true );

if ( achievedFrequencyHz != 0 )
{
    //Frequency successfully set
}
```

Parameters

Parameters	Description
referenceBus	Reference clock bus selection. One of the possible value from CLK_BUSES_REFERENCE enum. For devices that do not have multiple clock channels for Reference clock, CLK_BUS_REFERENCE_1 should be the selection.
referenceSource	Clock source means the path of the clock signal. One of the possible value from CLK_SOURCES_REFERENCE enum. See the block diagram in the data sheet to get an idea.
referenceClockHz	Clock frequency in Hertz.
waitUntilComplete	Passing this parameter as 'true' will make until the actual hardware operation is complete.

Function

uint32_t SYS_CLK_ReferenceFrequencySet (CLK_BUSES_REFERENCE referenceBus,
CLK_SOURCES_REFERENCE referenceSource, uint32_t referenceClockHz,
bool waitUntilComplete)

SYS_CLK_ReferenceFrequencyGet Function

Gets the selected Reference clock bus frequency in Hertz.

Implementation: Static/Dynamic

File

sys_clk.h

C

```
uint32_t SYS_CLK_ReferenceFrequencyGet(CLK_BUSES_REFERENCE referenceBus);
```

Returns

Clock frequency in Hertz.

Description

This function gets frequency of the selected Reference clock bus in Hertz.

Remarks

None.

Preconditions

The SYS_CLK_Initialize function should be called before calling this API.

Example

```
unsigned long sysClockOutputHz;

sysClockOutputHz = SYS_CLK_ReferenceFrequencyGet ( CLK_BUS_REFERENCE_3 );
```

Parameters

Parameters	Description
peripheralBus	Reference clock bus selection. One of the possible value from CLK_BUSES_REFERENCE enum. For devices that do not have multiple clock channels for Reference clock, CLK_BUS_REFERENCE_1 should be the selection.

Function

uint32_t SYS_CLK_ReferenceFrequencyGet (CLK_BUSES_REFERENCE referenceBus)

d) Clock Failure Functions

SYS_CLK_ClockFailureCallbackRegister Function

Allows registration of a call back function that will be triggered on a clock failure.

Implementation: Dynamic

File

sys_clk.h

C

```
void SYS_CLK_ClockFailureCallbackRegister(SYS_CLK_ERROR_HANDLER callback);
```

Returns

None.

Description

This function allows registration of a callback function that will be triggered on a clock failure.

Remarks

This function is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
SYS_CLK_ClockFailureCallbackRegister ( &ErrorHandle );

void ErrorHandle (void)
{
    //Handle the error.
}
```

Parameters

Parameters	Description
callback	Address of a callback function of type 'SYS_CLK_ERROR_HANDLER'.

Function

void SYS_CLK_ClockFailureCallbackRegister (SYS_CLK_ERROR_HANDLER callback)

SYS_CLK_TaskError Function

Informs the user on a clock failure by invoking the registered call back function.

Implementation: Dynamic

File

sys_clk.h

C

```
void SYS_CLK_TaskError();
```

Returns

None.

Description

This function informs the user on a clock failure by invoking the registered call back function. This must be called from the Fail Safe Clock Monitor (FSCM) interrupt service routine.

Remarks

None.

Preconditions

None.

Example

```
void clockMonitorISR ( void )
{
    SYS_CLK_TaskError ( void );
}
```

Parameters

Parameters	Description
index	Identifies the desired System Clock

Function

void SYS_CLK_TaskError (void)

e) Initialization Functions

SYS_CLK_Initialize Function

Initializes hardware and internal data structure of the System Clock.

Implementation: Static/Dynamic

File

sys_clk.h

C

```
void SYS_CLK_Initialize(const SYS_CLK_INIT * clkInit);
```

Returns

None.

Description

This function initializes the hardware and internal data structure of System Clock Service.

Remarks

This is API must be be called at the time of system initialization to initialize the oscillator. Call this again to change any of the initialization settings.

If the frequency settings are already done through the 'configuration bits', call this API by passing 'NULL' to it. In any case calling this API is necessary get the internal data structures updated.

To change the clock source clock switching must be enabled through 'configuration bits'.

Preconditions

None.

Example

```
//Example 1: Do not alter the configuration bit settings
SYS_CLK_Initialize ( NULL );

//Example 2: Want to change the configuration bit settings
SYS_CLK_INIT generalInit;
```

```
// Populate the oscillator initialization structure
generalInit.systemClockSource = SYS_CLK_SOURCE_FRC_SYSPLL;
generalInit.systemClockFrequencyHz = 30000000;
generalInit.onWaitInstruction = OSC_ON_WAIT_SLEEP;
generalInit.secondaryOscKeepEnabled = true;
SYS_CLK_Initialize (&generalInit);

//Wait until complete
while ( SYS_CLK_SystemOperationStatus ( ) !=  SYS_CLK_OPERATION_COMPLETE );

//Configuration success
```

Parameters

Parameters	Description
clkInit	Pointer to a data structure containing any data necessary to initialize the System Clock. This pointer can be NULL if no data is required as static overrides have been provided.

Function

void SYS_CLK_Initialize (const SYS_CLK_INIT * clkInit)

f) Secondary Oscillator Functions

SYS_CLK_SecondaryOscillatorDisable Function

Disables the secondary oscillator.

Implementation: Static/Dynamic

File

sys_clk.h

C

```
void SYS_CLK_SecondaryOscillatorDisable();
```

Returns

None.

Description

This function disables the secondary oscillator.

Remarks

None.

Preconditions

The SYS_CLK_Initialize function should be called before calling this API.

Example

```
SYS_CLK_SecondaryOscillatorDisable ( );
```

Function

void SYS_CLK_SecondaryOscillatorDisable (void)

SYS_CLK_SecondaryOscillatorEnable Function

Enables the secondary oscillator.

Implementation: Static/Dynamic

File

sys_clk.h

C

```
void SYS_CLK_SecondaryOscillatorEnable();
```

Returns

None.

Description

This function enables secondary oscillator which can be used as a clock source for peripherals like RTCC, Timer etc.. The SOSC requires a warm-up period of 1024 before it can be used as a clock source.

Remarks

None.

Preconditions

The SYS_CLK_Initialize function should be called before calling this API.

Example

```
SYS_CLK_SecondaryOscillatorEnable ( );
```

Function

void SYS_CLK_SecondaryOscillatorEnable (void)

SYS_CLK_SecondaryOscillatorIsEnabled Function

Identifies whether secondary oscillator is enabled or disabled.

Implementation: Static/Dynamic

File

sys_clk.h

C

```
bool SYS_CLK_SecondaryOscillatorIsEnabled();
```

Returns

true - If Secondary oscillator is enabled. false - If Secondary oscillator is disabled.

Description

This function identifies whether the secondary oscillator is enabled or disabled.

Remarks

None.

Preconditions

The SYS_CLK_Initialize function should be called before calling this API.

Example

```
bool status;

status = SYS_CLK_SecondaryOscillatorIsEnabled ( );
```

Function

bool SYS_CLK_SecondaryOscillatorIsEnabled (void)

g) Data Types and Constants

SYS_CLK_INIT Structure

Defines the data required to initialize the Oscillator for the Clock System Service.

File

sys_clk.h

C

```
typedef struct {
  SYS_MODULE_INIT moduleInit;
  CLK_SOURCES_SYSTEM systemClockSource;
  uint32_t systemClockFrequencyHz;
  bool waitTillComplete;
  bool secondaryOscKeepEnabled;
  OSC_OPERATION_ON_WAIT onWaitInstruction;
} SYS_CLK_INIT;
```

Members

Members	Description
SYS_MODULE_INIT moduleInit;	System module initialization
CLK_SOURCES_SYSTEM systemClockSource;	Initializations for System clock
uint32_t systemClockFrequencyHz;	Set the System clock frequency
bool waitTillComplete;	Wait until the clock switch operation is completed
bool secondaryOscKeepEnabled;	Even though the secondary oscillator is not used, keeping the oscillator running, allows a fast switch to the lower system clock for low-power operation
OSC_OPERATION_ON_WAIT onWaitInstruction;	System action on a 'Wait' instruction

Description

Clock System Service Reference Oscillator initialization data

This structure defines the data required to initialize the Oscillator for the Clock System Service.

Remarks

This structure only includes the necessary settings for the clock module. Other features like USB clock and reference clock are considered to be optional and not every system will use it. There are dedicated APIs for configuring those.

CLK_BUSES_PERIPHERAL Enumeration

Lists the available peripheral clock buses.

File

sys_clk.h

C

```
typedef enum {
  CLK_BUS_PERIPHERAL_1 = 0x00,
  CLK_BUS_PERIPHERAL_2 = 0x01,
  CLK_BUS_PERIPHERAL_3 = 0x02,
  CLK_BUS_PERIPHERAL_4 = 0x03,
  CLK_BUS_PERIPHERAL_5 = 0x04,
  CLK_BUS_PERIPHERAL_6 = 0x05,
  CLK_BUS_PERIPHERAL_7 = 0x06,
  CLK_BUS_PERIPHERAL_8 = 0x07
} CLK_BUSES_PERIPHERAL;
```

Members

Members	Description
CLK_BUS_PERIPHERAL_1 = 0x00	Select peripheral bus 1. This should be the selection for the devices which doesn't have multiple peripheral buses
CLK_BUS_PERIPHERAL_2 = 0x01	Select peripheral bus 2
CLK_BUS_PERIPHERAL_3 = 0x02	Select peripheral bus 3
CLK_BUS_PERIPHERAL_4 = 0x03	Select peripheral bus 4
CLK_BUS_PERIPHERAL_5 = 0x04	Select peripheral bus 5
CLK_BUS_PERIPHERAL_6 = 0x05	Select peripheral bus 6
CLK_BUS_PERIPHERAL_7 = 0x06	Select peripheral bus 7
CLK_BUS_PERIPHERAL_8 = 0x07	Select peripheral bus 8

Description

Peripherals Clock Buses enumeration

This enumeration lists all of the available peripheral clock buses. This is used by the SYS_CLK_PeripheralFrequencyGet and SYS_CLK_PeripheralFrequencySet functions.

Remarks

The system service covers a wide range of devices. Not all the elements listed in here will be relevant for the your device.

CLK_BUSES_REFERENCE Enumeration

Lists the available reference clock buses.

File

sys_clk.h

C

```
typedef enum {
  CLK_BUS_REFERENCE_1 = 0x00,
  CLK_BUS_REFERENCE_2 = 0x01,
  CLK_BUS_REFERENCE_3 = 0x02,
  CLK_BUS_REFERENCE_4 = 0x03,
  CLK_BUS_REFERENCE_5 = 0x04
} CLK_BUSES_REFERENCE;
```

Members

Members	Description
CLK_BUS_REFERENCE_1 = 0x00	Select Reference bus 1. This should be the selection for the devices which doesn't have multiple Reference buses
CLK_BUS_REFERENCE_2 = 0x01	Select Reference bus 2
CLK_BUS_REFERENCE_3 = 0x02	Select Reference bus 3
CLK_BUS_REFERENCE_4 = 0x03	Select Reference bus 4
CLK_BUS_REFERENCE_5 = 0x04	Select Reference bus 5

Description

Reference Clock Buses enumeration

This enumeration lists all of the available Reference clock buses. This is used by the SYS_CLK_ReferenceFrequencyGet and SYS_CLK_ReferenceFrequencySet functions.

Remarks

The system service covers a wide range of devices. Not all the elements listed in here will be relevant for the your device.

CLK_SOURCES_PERIPHERAL Enumeration

Lists the available clock sources for the peripheral clock.

File

sys_clk.h

C

```
typedef enum {
  CLK_SOURCE_PERIPHERAL_SYSTEMCLK
} CLK_SOURCES_PERIPHERAL;
```

Members

Members	Description
CLK_SOURCE_PERIPHERAL_SYSTEMCLK	Source of clock is system clock

Description

Peripheral clock sources enumeration

This enumeration lists all the available peripheral clock sources. This is used by the SYS_CLK_PeripheralFrequencySet function.

Remarks

None.

CLK_SOURCES_REFERENCE Enumeration

Lists the available clock sources for the Reference clock.

File

sys_clk.h

C

```
typedef enum {
  CLK_SOURCE_REF_SYSTEMCLK,
  CLK_SOURCE_REF_PBCLK_BUS1,
  CLK_SOURCE_REF_PRIMARY,
  CLK_SOURCE_REF_FRC,
  CLK_SOURCE_REF_LPRC,
  CLK_SOURCE_REF_SECONDARY,
  CLK_SOURCE_REF_USBPLL_OUT,
  CLK_SOURCE_REF_SYSPLL_OUT,
  CLK_SOURCE_REF_EXTERNAL,
  CLK_SOURCE_REF_BFRC
} CLK_SOURCES_REFERENCE;
```

Members

Members	Description
CLK_SOURCE_REF_SYSTEMCLK	Source of Reference clock is System clock
CLK_SOURCE_REF_PBCLK_BUS1	Source of Reference clock is Peripheral clock
CLK_SOURCE_REF_PRIMARY	Source of Reference clock is Primary oscillator
CLK_SOURCE_REF_FRC	Source of Reference clock is Fast RC oscillator
CLK_SOURCE_REF_LPRC	Source of Reference clock is Low power RC oscillator
CLK_SOURCE_REF_SECONDARY	Source of Reference clock is Secondary oscillator
CLK_SOURCE_REF_USBPLL_OUT	Source of clock is output of USB PLL This is used only for the Reference clock.
CLK_SOURCE_REF_SYSPLL_OUT	Source of clock is the output of System PLL. Input to the system PLL may be Primary or FRC
CLK_SOURCE_REF_EXTERNAL	Source of clock is external(from the pin)
CLK_SOURCE_REF_BFRC	Source of Reference clock is backup Fast RC oscillator

Description

Reference clock sources enumeration

This enumeration lists all the available peripheral clock sources. This is used by the SYS_CLK_ReferenceFrequencySet function.

Remarks

None.

CLK_SOURCES_SYSTEM Enumeration

Lists the available clock sources for the system clock.

File

sys_clk.h

C

```
typedef enum {
  SYS_CLK_SOURCE_FRC,
  SYS_CLK_SOURCE_FRC_SYSPLL,
  SYS_CLK_SOURCE_PRIMARY,
  SYS_CLK_SOURCE_PRIMARY_SYSPLL,
  SYS_CLK_SOURCE_SECONDARY,
  SYS_CLK_SOURCE_LPRC,
  SYS_CLK_SOURCE_FRC_BY_16,
  SYS_CLK_SOURCE_FRC_BY_DIV
} CLK_SOURCES_SYSTEM;
```

Members

Members	Description
SYS_CLK_SOURCE_FRC	Source of clock is internal fast RC
SYS_CLK_SOURCE_FRC_SYSPLL	Source of clock is internal fast RC multiplied by system PLL
SYS_CLK_SOURCE_PRIMARY	Source of clock is primary oscillator
SYS_CLK_SOURCE_PRIMARY_SYSPLL	Source of clock is primary oscillator multiplied by the System PLL value and divided by the divisor configured by software
SYS_CLK_SOURCE_SECONDARY	Source of clock is secondary oscillator
SYS_CLK_SOURCE_LPRC	Source of clock is internal low power RC
SYS_CLK_SOURCE_FRC_BY_16	Source of clock is internal fast RC divided by the divisor configured in software
SYS_CLK_SOURCE_FRC_BY_DIV	Source of clock is internal fast RC divided by the divisor configured in software

Description

System Clock sources enumeration

This enumeration lists all the available clock sources for the system clock. This is used by the SYS_CLK_INIT structure.

Remarks

None.

SYS_CLK_ERROR_HANDLER Type

Pointer to a CLK System service SYS_CLK_ClockFailureCallbackRegister function.

File

sys_clk.h

C

```
typedef void (* SYS_CLK_ERROR_HANDLER)(CLK_SOURCES_SYSTEM systemSource, uint32_t systemFrequencyHz);
```

Returns

None.

Description

CLK System Service Error Handler Function Pointer

This data type defines the type of the CLK System Service Error Handler callback function. The parameters are described here and a partial example implementation is provided. On a clock failure, the device will switch its clock source to the FRC clock. By registering the callback function user will get the current System clock source and the clock frequency. User can use this information to try switching back.

Remarks

None.

Example

```
void SYS_CLK_ClockFailureCallbackRegister(  errorHandler );

errorHandler ( CLK_SOURCES_SYSTEM systemSource, uint32_t systemFrequencyHz )
{
    //Log a warning
    //Try switching back to the old source
}
```

Parameters

Parameters	Description
systemSource	System clock source.
systemFrequencyHz	System clock frequency in hertz.

SYS_CLK_REFERENCE_SETUP Structure

Defines the data required to initialize the Oscillator for the Clock System Service.

File

sys_clk.h

C

```
typedef struct {
  bool suspendInSleep;
  bool stopInIdle;
} SYS_CLK_REFERENCE_SETUP;
```

Members

Members	Description
bool suspendInSleep;	Reference clock module should be stop its operation in 'Sleep' mode
bool stopInIdle;	Reference clock module should be stop its operation in 'Idle' mode

Description

Clock System Service Reference Oscillator initialization data

This structure defines the data required to initialize the Oscillator for the Clock System Service.

Remarks

This structure only includes the necessary settings for the clock module. Other features like USB clock and reference clock are considered to be optional and not every system will use it. There are dedicated APIs for configuring those.

SYS_CLK_STATUS Enumeration

Lists all the possible status of a system clock operation.

File

sys_clk.h

C

```
typedef enum {
  SYS_CLK_OPERATION_COMPLETE,
  SYS_CLK_OPERATION_IN_PROGRESS,
  SYS_CLK_OPERATION_FAIL_SWITCHING_DISABLED,
  SYS_CLK_OPERATION_FAIL_NOT_ACHIEVABLE,
  SYS_CLK_OPERATION_FAIL_REGISTER_NOT_READY,
  SYS_CLK_OPERATION_FAIL_USBPLL_NOT_ENABLED,
  SYS_CLK_OPERATION_FAIL_PLL_LOCK_TIMEOUT,
  SYS_CLK_PLL_INVALID_INP_FREQUENCY
} SYS_CLK_STATUS;
```

Members

Members	Description
SYS_CLK_OPERATION_COMPLETE	The last operation was successful
SYS_CLK_OPERATION_IN_PROGRESS	Operation started, may be PLL is not yet locked
SYS_CLK_OPERATION_FAIL_SWITCHING_DISABLED	The last operation was not successful, Clock switching is not enabled through configuration bits
SYS_CLK_OPERATION_FAIL_NOT_ACHIEVABLE	The last operation was not successful, requested frequency is not achievable
SYS_CLK_OPERATION_FAIL_REGISTER_NOT_READY	The last operation was not successful, register is not ready to take the new value
SYS_CLK_OPERATION_FAIL_USBPLL_NOT_ENABLED	The last operation was not successful, USB PLL is not enabled in through the 'configuration bits'. The same must be update in system_config.h
SYS_CLK_OPERATION_FAIL_PLL_LOCK_TIMEOUT	PLL Lock time out. A restart is the only option
SYS_CLK_PLL_INVALID_INP_FREQUENCY	PLL cannot work with the current input clock frequency, adjust the clock input or the input divisor. Check the device data sheet to know the PLL input requirement

Description

System clock operation status

This enumeration lists all the possible status of a system clock operation.

Remarks

None.

SYS_CLK_FRCTune Function

This function is used for direct value based FRC oscillator tuning.

Implementation: Dynamic

File

sys_clk.h

C

```
void SYS_CLK_FRCTune(SYS_CLK_FRC_TUNING_TYPE tuningData);
```

Returns

None.

Description

This function tunes the FRC as per the given value. FRC tuning functionality has been provided to help customers compensate for temperature effects on the FRC frequency over a wide range of temperatures.

Remarks

The tuning step size is an approximation, and is neither characterized, nor tested.

This API can only be used with devices that support direct value based FRC tuning. Refer to the specific device data sheet to determine whether this feature exists for your device.

Preconditions

The device selected must support the oscillator tuning feature.

Example

```
SYS_CLK_FRCTune ( ox30 );
```

Parameters

Parameters	Description
tuningData	One of the possible value of Tuning. Refer to the specific device data sheet for possible values.

Function

void SYS_CLK_FRCTune (SYS_CLK_FRC_TUNING_TYPE tuningData)

SYS_CLK_FRC_TUNING_TYPE Type

Defines the data type for tuning the FRC Oscillator.

File

sys_clk.h

C

```
typedef unsigned int SYS_CLK_FRC_TUNING_TYPE;
```

Description

Clock module FRC tuning type

This structure defines the data type to tune the FRC Oscillator.

Remarks

None.

Files

Files

Name	Description
sys_clk.h	Clock system service interface header.

sys_clk_config_template.h	Clock System Service configuration templates.

Description

This section lists the source and header files used by the library.

sys_clk.h

Clock system service interface header.

Enumerations

	Name	Description
	CLK_BUSES_PERIPHERAL	Lists the available peripheral clock buses.
	CLK_BUSES_REFERENCE	Lists the available reference clock buses.
	CLK_SOURCES_PERIPHERAL	Lists the available clock sources for the peripheral clock.
	CLK_SOURCES_REFERENCE	Lists the available clock sources for the Reference clock.
	CLK_SOURCES_SYSTEM	Lists the available clock sources for the system clock.
	SYS_CLK_STATUS	Lists all the possible status of a system clock operation.

Functions

	Name	Description
	SYS_CLK_ClockFailureCallbackRegister	Allows registration of a call back function that will be triggered on a clock failure. **Implementation:** Dynamic
	SYS_CLK_FRCTune	This function is used for direct value based FRC oscillator tuning. **Implementation:** Dynamic
	SYS_CLK_Initialize	Initializes hardware and internal data structure of the System Clock. **Implementation:** Static/Dynamic
	SYS_CLK_PeripheralFrequencyGet	Gets the selected clock peripheral bus frequency in Hertz. **Implementation:** Static/Dynamic
	SYS_CLK_PeripheralFrequencySet	Configures the peripheral clock of the device to the value specified. **Implementation:** Dynamic
	SYS_CLK_ReferenceClockSetup	Configures the reference clock of the device to the value specified. **Implementation:** Dynamic
	SYS_CLK_ReferenceFrequencyGet	Gets the selected Reference clock bus frequency in Hertz. **Implementation:** Static/Dynamic
	SYS_CLK_ReferenceFrequencySet	Configures the reference clock of the device to the value specified. **Implementation:** Dynamic
	SYS_CLK_SecondaryOscillatorDisable	Disables the secondary oscillator. **Implementation:** Static/Dynamic
	SYS_CLK_SecondaryOscillatorEnable	Enables the secondary oscillator. **Implementation:** Static/Dynamic
	SYS_CLK_SecondaryOscillatorIsEnabled	Identifies whether secondary oscillator is enabled or disabled. **Implementation:** Static/Dynamic
	SYS_CLK_SystemFrequencyGet	Gets the system clock frequency in Hertz. **Implementation:** Static/Dynamic
	SYS_CLK_SystemFrequencySet	Configures the System clock of the device to the value specified. **Implementation:** Dynamic
	SYS_CLK_TaskError	Informs the user on a clock failure by invoking the registered call back function. **Implementation:** Dynamic

Structures

	Name	Description
	SYS_CLK_INIT	Defines the data required to initialize the Oscillator for the Clock System Service.
	SYS_CLK_REFERENCE_SETUP	Defines the data required to initialize the Oscillator for the Clock System Service.

Types

	Name	Description
	SYS_CLK_ERROR_HANDLER	Pointer to a CLK System service SYS_CLK_ClockFailureCallbackRegister function.
	SYS_CLK_FRC_TUNING_TYPE	Defines the data type for tuning the FRC Oscillator.

Description

Clock System Service Interface Definition

This file contains the interface definition for the Clock System Service. It provides a way to interact with the Clock subsystem to manage the timing requests supported by the system.

File Name

sys_clk.h

Company

Microchip Technology Inc.

sys_clk_config_template.h

Clock System Service configuration templates.

Macros

	Name	Description
	SYS_CLK_CONFIG_EXTERNAL_CLOCK	Gives the clock that is provided on the Reference clock output pin.
	SYS_CLK_CONFIG_FREQ_ERROR_LIMIT	Sets the allowed frequency configuration error Hertz.
	SYS_CLK_CONFIG_PRIMARY_XTAL	Gives the Primary oscillator input frequency. This is from the hardware and not the output required frequency.
	SYS_CLK_CONFIG_SECONDARY_XTAL	Gives the Secondary oscillator input frequency. This is from the hardware and not the output required frequency.
	SYS_CLK_CONFIG_SYSPLL_INP_DIVISOR	Gives the System PLL input divisor configured through configuration bits. For some of the devices, the system PLL input divisor is not accessible through software. So use this macro to inform the System service about the input divisor.
	SYS_CLK_CONFIGBIT_USBPLL_DIVISOR	Gives the Oscillator USB clock divisor.
	SYS_CLK_CONFIGBIT_USBPLL_ENABLE	Defines the status of the USB PLL.
	SYS_CLK_UPLL_BEFORE_DIV2_FREQ	Defines the value of the USB clock for the devices which does not have a software controllable USB clock.

Description

Clock System Service Configuration Templates

This file contains constants to configure the Clock System Service.

File Name

Microchip Technology Inc.

Command Processor System Service Library

This section describes the Command Processor System Service Library.

Introduction

This library provides an abstraction of the Command Processor System Service Library that is available on the Microchip family of PIC32 microcontrollers with a convenient C language interface. It provides the framework for a command console that can support commands from multiple client sources.

Description

The Command Processor System Service provides the developer with simple APIs to implement a command console. The console may support commands from one or more client software modules.

Using the Library

This topic describes the basic architecture of the Command Processor System Service Library and provides information and examples on its use.

Description

Interface Header File: `sys_command.h`

The interface to the Command Processor System Service library is defined in the `sys_command.h` header file.

Please refer to the What is MPLAB Harmony? section for how the Command Processor System Service interacts with the framework.

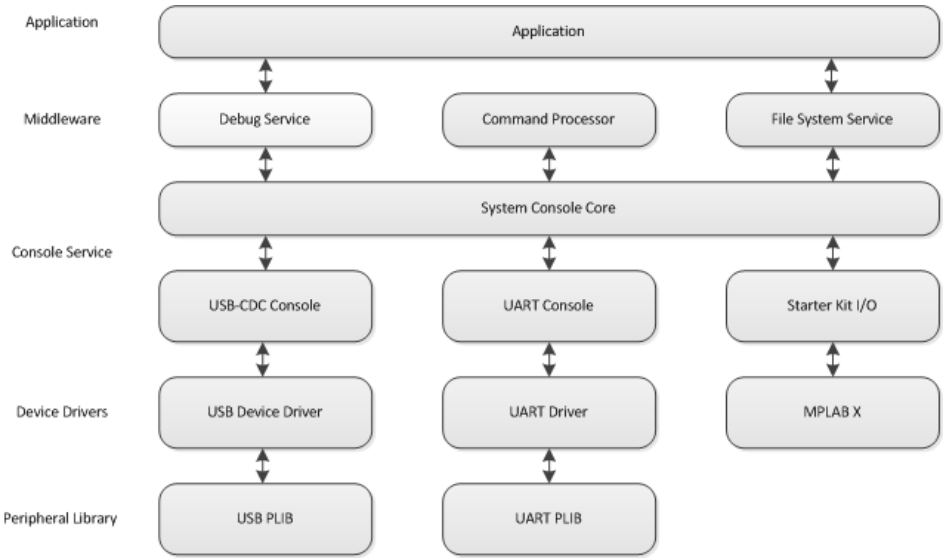
Abstraction Model

This topic provides a description of the software abstraction for the Command Processor System Service.

Description

The Command Processor System Service Library is a collection of operations specific to supporting user input commands. The commands can be uniquely native to each client service and can be dynamically added. The library can support multiple client services at once.

The Command Processor System Service is a module that works closely with the Console System Service to present a user interface command prompt.



Library Overview

Refer to the section System Services Introduction for how the system services operates in a system.

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Device Control module.

Library Interface Section	Description
System Interaction Functions	Provides system module APIs. Service initialization, deinitialization, reinitialization and status functions.
Core Functionality Functions	State Machine and control functions.
Data Types and Constants	Enumerations, structures, and constants.

How the Library Works

System Interaction

Initialization and Reinitialization

Initialization of the Command Processor System Service initializes the status of the module and sets the state of the internal state machine.

The Command Processor Status and Tasks routines are required for the normal operation of the service.

Core Functionality

Adding Commands

The Command Processor System Service will accept commands dynamically during run-time through the follow interface:

```
SYS_COMMAND_ADDGRP(const _SYS_CMD_DCPT* pCmdTbl, int nCmds, const char*
                   groupName, const char* menuStr)
```

Command Prompt

In conjunction with the Console System Service, the Command Processor System Service provides the user with an ASCII command prompt. It will interpret the commands entered at the prompt and process accordingly. It also supports command history, as well as command help.

Configuring the Library

The configuration of the Command Processor System Service is based on the file `system_config.h`.

This header file contains the configuration selection for the Device Control system service. Based on the selections made, the Device Control System Service Library may support the selected features. These configuration settings will apply to all instances of the Device Control System Service.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

Building the Library

This section lists the files that are available in the Command Processor System Service Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/system/command`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
sys_command.h	Command Processor System Service Library API header file.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/sys_command.c	Command Processor System Service Library implementation.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The Command Processor System Service is dependent on the following library:

- Console System Service Library

Library Interface

a) System Interaction Functions

	Name	Description
	SYS_CMD_Initialize	Initializes data for the instance of the Command Processor module.
	SYS_CMD_DELETE	Removes CMDIO parameters from the Command Processor System Service console.
	SYS_CMD_ADDGRP	Allows clients to add command process to the Command Processor System Service.
	SYS_CMD_MESSAGE	Outputs a message to the Command Processor System Service console.
	SYS_CMD_PRINT	Outputs a printout to the Command Processor System Service console.
	SYS_CMD_READY_TO_READ	Allows upper layer application to confirm that the command module is ready to accept command input
	SYS_CMD_READY_TO_WRITE	Allows upper layer application to confirm that the command module is ready to write output to the Console System Service.
	SYS_CMD_Tasks	Maintains the Command Processor System Service's internal state machine.
	SYS_CMD_RegisterCallback	Registers a callback function with the command service that will be executed when the lower layer read or write queue is empty.

b) Command I/O Functions

	Name	Description
	SYS_CMDIO_GET_HANDLE	Gets the CMDIO Handle base via index.
	SYS_CMDIO_ADD	Adds CMDIO parameters to the Command Processor System Service console.

c) Data Types and Constants

	Name	Description
	_promptStr	prompt string
	COMMAND_HISTORY_DEPTH	Command Processor System Service Maximum Depth of Command History.
	ESC_SEQ_SIZE	standard VT100 escape sequences
	LINE_TERM	line terminator
	MAX_CMD_ARGS	Command Processor System Service Maximum Number of Argument definitions.
	MAX_CMD_GROUP	Command Processor System Service Maximum Number of Command Group definitions.
	SYS_CMD_MAX_LENGTH	Command Processor System Service Command Buffer Maximum Length definition.
	SYS_CMD_READ_BUFFER_SIZE	Command Processor System Service Read Buffer Size definition.
	SYS_CMD_DEVICE_NODE	Defines the data structure to store each command instance.
	SYS_CMD_INIT	Identifies the system command initialize structure.
	SYS_CMD_API	Identifies the Command API structure.
	SYS_CMD_DATA_RDY_FNC	Identifies a data available function API.
	SYS_CMD_DESCRIPTOR	a simple command descriptor
	SYS_CMD_DESCRIPTOR_TABLE	table containing the supported commands
	SYS_CMD_DEVICE_LIST	Defines the list structure to store a list of command instances.
	SYS_CMD_FNC	Identifies the command process function API.
	SYS_CMD_GETC_FNC	Identifies a get single character function API.
	SYS_CMD_HANDLE	Identifies a particular Command I/O instance.
	SYS_CMD_INIT_DATA	Defines the data structure to store each command.
	SYS_CMD_MSG_FNC	Identifies a message function API.
	SYS_CMD_PRINT_FNC	Identifies a print function API.
	SYS_CMD_PUTC_FNC	Identifies a single character print function API.
	SYS_CMD_READC_FNC	Identifies a read single character function API.
	SYS_CMD_STATE	Defines the various states that can be achieved by a Command instance.
	SYS_CMD_CONSOLE_IO_PARAM	Defines whether the command module is single character or full command read
	SYS_CMD_BUFFER_DMA_READY	Define this for MX #define SYS_CMD_BUFFER_DMA_READY __attribute__((coherent)) __attribute__((aligned(4))) //Define this for MZ
	SYS_CONSOLE_MESSAGE	ifdef SYS_CONSOLE_REMOVE_APIS
	SYS_CONSOLE_PRINT	This is macro SYS_CONSOLE_PRINT.
	SYS_CMD_DEVICE_MAX_INSTANCES	This is macro SYS_CMD_DEVICE_MAX_INSTANCES.
	SYS_CMD_MESSAGE	This is macro SYS_CMD_MESSAGE.

	SYS_CMD_PRINT	This is macro SYS_CMD_PRINT.
	SYS_CMD_CallbackFunction	Command Callback Function Handle.
	SYS_CMD_EVENT	Identifies the Command Event Types

Description

This section describes the APIs of the Command Processor System Service Library.

Refer to each section for a detailed description.

a) System Interaction Functions

SYS_CMD_Initialize Function

Initializes data for the instance of the Command Processor module.

File

sys_command.h

C

```
bool SYS_CMD_Initialize(const SYS_MODULE_INIT * const init);
```

Returns

- true - Indicates success
- false - Indicates an error occurred

Description

This function initializes the Command Processor module. It also initializes any internal data structures.

Remarks

This routine should only be called once during system initialization.

Preconditions

None.

Parameters

Parameters	Description
init	Pointer to a data structure containing any data necessary to initialize the sys command. This pointer may be null if no data is required because static overrides have been provided.

Function

bool SYS_CMD_Initialize(const SYS_MODULE_INIT * const init)

SYS_CMD_DELETE Function

Removes CMDIO parameters from the Command Processor System Service console.

File

sys_command.h

C

```
bool SYS_CMD_DELETE(SYS_CMD_DEVICE_NODE* pDevNode);
```

Returns

None.

Description

This function removes CMDIO parameters from the Command Processor System Service console.

Remarks

None.

Preconditions

SYS_CMD_Initialize was successfully run once.

Function

bool SYS_CMD_DELETE(SYS_CMD_DEVICE_NODE* pDevNode);

SYS_CMD_ADDGRP Function

Allows clients to add command process to the Command Processor System Service.

File

sys_command.h

C

```
bool SYS_CMD_ADDGRP(const SYS_CMD_DESCRIPTOR* pCmdTbl, int nCmds, const char* groupName, const char* menuStr);
```

Returns

- true - Indicates success
- false - Indicates an error occurred

Description

Client modules may call this function to add command process to the Command Processor System Service.

Remarks

None.

Preconditions

SYS_CMD_Initialize was successfully run once.

Example

static const SYS_CMD_DESCRIPTOR cmdTbl[]= { {"command_as_typed_at_the_prompt", _Function_Name_That_Supports_The_Command, ": Helpful description of the command for the user"}, };

bool APP_AddCommandFunction() { if (!SYS_CMD_ADDGRP(cmdTbl, sizeof(cmdTbl)/sizeof(*cmdTbl), "Command Group Name", ": Command Group Description")) { return false; } return true; }

Function

bool SYS_CMD_ADDGRP(const SYS_CMD_DESCRIPTOR* pCmdTbl, int nCmds,

const char* groupName,

const char* menuStr)

SYS_CMD_MESSAGE Function

Outputs a message to the Command Processor System Service console.

File

sys_command.h

C

```
void SYS_CMD_MESSAGE(const char* message);
```

Returns

None.

Description

This function outputs a message to the Command Processor System Service console.

Remarks

None.

Preconditions

SYS_CMD_Initialize was successfully run once.

Function

void SYS_CMD_MESSAGE (const char* message)

SYS_CMD_PRINT Function

Outputs a printout to the Command Processor System Service console.

File

sys_command.h

C

```
void SYS_CMD_PRINT(const char * format, ...);
```

Returns

None.

Description

This function outputs a printout to the Command Processor System Service console.

Remarks

None.

Preconditions

SYS_CMD_Initialize was successfully run once.

Function

void SYS_CMD_PRINT(const char *format, ...)

SYS_CMD_READY_TO_READ Function

Allows upper layer application to confirm that the command module is ready to accept command input

File

sys_command.h

C

```
bool SYS_CMD_READY_TO_READ();
```

Returns

- true - Indicates command module is ready
- false - Indicates command module is not ready

Description

This function allows upper layer application to confirm that the command module is ready to accept command input

Remarks

None.

Preconditions

SYS_CMD_Initialize was successfully run once.

Function

bool SYS_CMD_READY_TO_READ(void)

SYS_CMD_READY_TO_WRITE Function

Allows upper layer application to confirm that the command module is ready to write output to the Console System Service.

File

sys_command.h

C

```
bool SYS_CMD_READY_TO_WRITE();
```

Returns

- true - Indicates command module is ready
- false - Indicates command module is not ready

Description

This function allows upper layer application to confirm that the command module is ready to write output to the Console System Service.

Remarks

None.

Preconditions

SYS_CMD_Initialize was successfully run once.

Function

bool SYS_CMD_READY_TO_WRITE(void)

SYS_CMD_Tasks Function

Maintains the Command Processor System Service's internal state machine.

File

sys_command.h

C

```
bool SYS_CMD_Tasks();
```

Returns

- true - Indicates success
- false - Indicates an error occurred

Description

This function is used to maintain the Command Processor System Service internal state machine.

Remarks

None.

Preconditions

SYS_CMD_Initialize was successfully run once.

Function

bool SYS_CMD_Tasks(void)

SYS_CMD_RegisterCallback Function

Registers a callback function with the command service that will be executed when the lower layer read or write queue is empty.

File

sys_command.h

C

```
void SYS_CMD_RegisterCallback(SYS_CMD_CallbackFunction cbFunc, SYS_CMD_EVENT event);
```

Returns

None.

Description

This function is used by an application to register a callback function with the command service. The callback function is called in response to an event. Separate callback functions are required for each event.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
cbFunc	The name of the callback function
event	Enumerated list of events that can trigger a callback

Function

void SYS_CMD_RegisterCallback(SYS_CMD_CallbackFunction cbFunc, SYS_CMD_EVENT event)

b) Command I/O Functions

SYS_CMDIO_GET_HANDLE Function

Gets the CMDIO Handle base via index.

File

sys_command.h

C

```
SYS_CMD_DEVICE_NODE* SYS_CMDIO_GET_HANDLE(short num);
```

Returns

- SYS_CMD_DEVICE_NODE Handle for the CMDIO - Indicates success
- NULL - Indicates not successful

Description

This function returns the handle for the CMDIO when supplied with an index.

Remarks

None.

Preconditions

SYS_CMD_Initialize was successfully run once.

Function

SYS_CMD_DEVICE_NODE* SYS_CMDIO_GET_HANDLE(short num)

SYS_CMDIO_ADD Function

Adds CMDIO parameters to the Command Processor System Service console.

File

sys_command.h

C

```
SYS_CMD_DEVICE_NODE* SYS_CMDIO_ADD(const SYS_CMD_API* opApi, const void* cmdIoParam, const
SYS_CMD_CONSOLE_IO_PARAM cmdIoType);
```

Returns

None.

Description

This function adds CMDIO Parameters to the Command Processor System Service console.

Remarks

None.

Preconditions

SYS_CMD_Initialize was successfully run once.

Function

SYS_CMD_DEVICE_NODE* SYS_CMDIO_ADD(const SYS_CMD_API* opApi, const void* cmdIoParam, const SYS_CMD_CONSOLE_IO_PARAM cmdIoType)

c) Data Types and Constants

_promptStr Macro

File

sys_command.h

C

```
#define _promptStr ">"              // prompt string
```

Description

prompt string

COMMAND_HISTORY_DEPTH Macro

Command Processor System Service Maximum Depth of Command History.

File

sys_command.h

C

```
#define COMMAND_HISTORY_DEPTH 3
```

Description

SYS CMD Processor Command History Depth

This macro defines the maximum depth of the command history.

Remarks

None.

ESC_SEQ_SIZE Macro

File

sys_command.h

C

```
#define ESC_SEQ_SIZE 2              // standard VT100 escape sequences
```

Description

standard VT100 escape sequences

LINE_TERM Macro

File

sys_command.h

C

```
#define LINE_TERM "\r\n"          // line terminator
```

Description

line terminator

MAX_CMD_ARGS Macro

Command Processor System Service Maximum Number of Argument definitions.

File

sys_command.h

C

```
#define MAX_CMD_ARGS 15
```

Description

SYS CMD Processor Maximum Number of Command Arguments

This macro defines the maximum number of arguments per command.

Remarks

None.

MAX_CMD_GROUP Macro

Command Processor System Service Maximum Number of Command Group definitions.

File

sys_command.h

C

```
#define MAX_CMD_GROUP 8
```

Description

SYS CMD Processor Maximum Number of Command Group

This macro defines the maximum number of command groups.

Remarks

None.

SYS_CMD_MAX_LENGTH Macro

Command Processor System Service Command Buffer Maximum Length definition.

File

sys_command.h

C

```
#define SYS_CMD_MAX_LENGTH 128
```

Description

SYS CMD Processor Buffer Maximum Length

This macro defines the maximum length of the command buffer.

Remarks

None.

SYS_CMD_READ_BUFFER_SIZE Macro

Command Processor System Service Read Buffer Size definition.

File

sys_command.h

C

```
#define SYS_CMD_READ_BUFFER_SIZE 128
```

Description

SYS CMD Processor Read Buffer Size

This macro defines the maximum size of the command buffer.

Remarks

None.

SYS_CMD_DEVICE_NODE Structure

Defines the data structure to store each command instance.

File

sys_command.h

C

```
struct SYS_CMD_DEVICE_NODE {
  char* cmdPnt;
  char* cmdEnd;
  char cmdBuff SYS_CMD_BUFFER_DMA_READY[SYS_CMD_MAX_LENGTH+1];
  const SYS_CMD_API* pCmdApi;
  const void* cmdIoParam;
  SYS_CMD_CONSOLE_IO_PARAM cmdIoType;
  struct SYS_CMD_DEVICE_NODE* next;
  SYS_CMD_STATE cmdState;
};
```

Members

Members	Description
const SYS_CMD_API* pCmdApi;	Cmd IO APIs
const void* cmdIoParam;	channel specific parameter

Description

SYS CMD Command Instance Node Structure

This data structure stores all the data relevant to a uniquely entered command instance. It is a node for a linked list structure to support the Command Processor System Service's command history feature

Remarks

None.

SYS_CMD_INIT Structure

Identifies the system command initialize structure.

File

sys_command.h

C

```
typedef struct {
  SYS_MODULE_INIT moduleInit;
```

```
  uint8_t consoleCmdIOParam;
  SYS_CMD_CONSOLE_IO_PARAM cmdIoType;
} SYS_CMD_INIT;
```

Members

Members	Description
SYS_MODULE_INIT moduleInit;	System module initialization

Description

SYS CMD INIT structure

This structure identifies the system command initialize structure.

Remarks

None.

SYS_CMD_API Structure

Identifies the Command API structure.

File

sys_command.h

C

```
typedef struct {
  SYS_CMD_MSG_FNC msg;
  SYS_CMD_PRINT_FNC print;
  SYS_CMD_PUTC_FNC putc;
  SYS_CMD_DATA_RDY_FNC isRdy;
  SYS_CMD_GETC_FNC getc;
  SYS_CMD_READC_FNC readc;
} SYS_CMD_API;
```

Members

Members	Description
SYS_CMD_MSG_FNC msg;	Message function API
SYS_CMD_PRINT_FNC print;	Print function API
SYS_CMD_PUTC_FNC putc;	Put single char function API
SYS_CMD_DATA_RDY_FNC isRdy;	Data available API
SYS_CMD_GETC_FNC getc;	Get single data API
SYS_CMD_READC_FNC readc;	Read single data API

Description

SYS CMD API structure

This structure identifies the Command API structure.

Remarks

None.

SYS_CMD_DATA_RDY_FNC Type

Identifies a data available function API.

File

sys_command.h

C

```
typedef bool (* SYS_CMD_DATA_RDY_FNC)(const void* cmdIoParam);
```

Description

Ready Status Check function API. This handle identifies the interface structure of the data available function API within the Command IO encapsulation.

Remarks

None.

SYS_CMD_DESCRIPTOR Structure

File

sys_command.h

C

```
typedef struct {
  const char* cmdStr;
  SYS_CMD_FNC cmdFnc;
  const char* cmdDescr;
} SYS_CMD_DESCRIPTOR;
```

Members

Members	Description
const char* cmdStr;	string identifying the command
SYS_CMD_FNC cmdFnc;	function to execute for this command
const char* cmdDescr;	simple command description

Description

a simple command descriptor

SYS_CMD_DESCRIPTOR_TABLE Structure

File

sys_command.h

C

```
typedef struct {
  int nCmds;
  const SYS_CMD_DESCRIPTOR* pCmd;
  const char* cmdGroupName;
  const char* cmdMenuStr;
} SYS_CMD_DESCRIPTOR_TABLE;
```

Members

Members	Description
int nCmds;	number of commands available in the table
const SYS_CMD_DESCRIPTOR* pCmd;	pointer to an array of command descriptors
const char* cmdGroupName;	name identifying the commands
const char* cmdMenuStr;	help string

Description

table containing the supported commands

SYS_CMD_DEVICE_LIST Structure

Defines the list structure to store a list of command instances.

File

sys_command.h

C

```
typedef struct {
  int num;
  SYS_CMD_DEVICE_NODE* head;
  SYS_CMD_DEVICE_NODE* tail;
} SYS_CMD_DEVICE_LIST;
```

Description

SYS CMD Command List Structure

This data structure defines he linked list structure to support the Command Processor System Service's command history feature

Remarks

None.

SYS_CMD_FNC Type

Identifies the command process function API.

File

sys_command.h

C

```
typedef int (* SYS_CMD_FNC)(SYS_CMD_DEVICE_NODE* pCmdIO, int argc, char **argv);
```

Description

SYS CMD Command Function

Command Process Function API. This handle identifies the interface structure of the command process function API.

Remarks

None.

SYS_CMD_GETC_FNC Type

Identifies a get single character function API.

File

sys_command.h

C

```
typedef char (* SYS_CMD_GETC_FNC)(const void* cmdIoParam);
```

Description

Get Single Character function API. This handle identifies the interface structure of the get single character function API within the Command I/O encapsulation.

Remarks

None.

SYS_CMD_HANDLE Type

Identifies a particular Command I/O instance.

File

sys_command.h

C

```
typedef const void* SYS_CMD_HANDLE;
```

Description

Command I/O Handle. This event handle identifies a registered instance of a Command IO object. Every time the application that tries to access the parameters with respect to a particular event, this event handle is used to refer to that event.

Remarks

None.

SYS_CMD_INIT_DATA Structure

Defines the data structure to store each command.

File

sys_command.h

C

```
typedef struct {
  size_t bytesRead;
  int seqBytesRead;
  char seqBuff[ESC_SEQ_SIZE + 1];
  SYS_MODULE_INDEX moduleIndices[SYS_CMD_DEVICE_MAX_INSTANCES];
  int moduleInFd;
  int moduleOutFd;
} SYS_CMD_INIT_DATA;
```

Description

SYS CMD Command App Init Structure

This data structure stores all the data relevant to a uniquely entered command. It is a node for a linked list structure to support the command history functionality

Remarks

None.

SYS_CMD_MSG_FNC Type

Identifies a message function API.

File

sys_command.h

C

```
typedef void (* SYS_CMD_MSG_FNC)(const void* cmdIoParam, const char* str);
```

Description

Message function API. This handle identifies the interface structure of the message function API within the Command I/O encapsulation.

Remarks

None.

SYS_CMD_PRINT_FNC Type

Identifies a print function API.

File

sys_command.h

C

```
typedef void (* SYS_CMD_PRINT_FNC)(const void* cmdIoParam, const char* format, ...);
```

Description

Print function API. This handle identifies the interface structure of the print function API within the Command I/O encapsulation.

Remarks

None.

SYS_CMD_PUTC_FNC Type

Identifies a single character print function API.

File

sys_command.h

C

```
typedef void (* SYS_CMD_PUTC_FNC)(const void* cmdIoParam, char c);
```

Description

Single Character Print function API. This handle identifies the interface structure of single character print function API within the Command I/O encapsulation.

Remarks

None.

SYS_CMD_READC_FNC Type

Identifies a read single character function API.

File

sys_command.h

C

```
typedef size_t (* SYS_CMD_READC_FNC)(const void* cmdIoParam);
```

Description

Read Single Character function API

This handle identifies the interface structure of read single character function API within the Command I/O encapsulation.

Remarks

None.

SYS_CMD_STATE Enumeration

Defines the various states that can be achieved by a Command instance.

File

sys_command.h

C

```
typedef enum {
  SYS_CMD_STATE_DISABLE,
  SYS_CMD_STATE_SETUP_READ,
  SYS_CMD_STATE_WAIT_FOR_READ_DONE,
  SYS_CMD_STATE_PROCESS_FULL_READ
} SYS_CMD_STATE;
```

Description

SYS CMD State Machine States

This enumeration defines the various states that can be achieved by the command operation.

Remarks

None.

SYS_CMD_CONSOLE_IO_PARAM Enumeration

Defines whether the command module is single character or full command read

File

sys_command.h

C

```
typedef enum {
  SYS_CMD_SINGLE_CHARACTER_READ_CONSOLE_IO_PARAM = 0,
  SYS_CMD_FULL_COMMAND_READ_CONSOLE_IO_PARAM = 1,
  SYS_CMD_TELNET_COMMAND_READ_CONSOLE_IO_PARAM = 2
} SYS_CMD_CONSOLE_IO_PARAM;
```

Description

SYS CMD Console I/O Parameter

This enumeration defines whether the command module is single character or full command read.

Remarks

None.

SYS_CMD_BUFFER_DMA_READY Macro

File

sys_command.h

C

```
#define SYS_CMD_BUFFER_DMA_READY
```

Description

Define this for MX #define SYS_CMD_BUFFER_DMA_READY __attribute__((coherent)) __attribute__((aligned(4))) //Define this for MZ

SYS_CONSOLE_MESSAGE Macro

File

sys_console.h

C

```
#define SYS_CONSOLE_MESSAGE(message)
```

Description

ifdef SYS_CONSOLE_REMOVE_APIS

SYS_CONSOLE_PRINT Macro

File

sys_console.h

C

```
#define SYS_CONSOLE_PRINT(fmt, ...)
```

Description

This is macro SYS_CONSOLE_PRINT.

SYS_CMD_DEVICE_MAX_INSTANCES Macro

File

sys_command.h

C

```
#define SYS_CMD_DEVICE_MAX_INSTANCES 1
```

Description

This is macro SYS_CMD_DEVICE_MAX_INSTANCES.

SYS_CMD_MESSAGE Macro

File

sys_command.h

C

```
#define SYS_CMD_MESSAGE(message)
```

Description

This is macro SYS_CMD_MESSAGE.

SYS_CMD_PRINT Macro

File

sys_command.h

C

```
#define SYS_CMD_PRINT(fmt, ...)
```

Description

This is macro SYS_CMD_PRINT.

SYS_CMD_CallbackFunction Type

Command Callback Function Handle.

File

sys_command.h

C

```
typedef void (* SYS_CMD_CallbackFunction)(void *handle);
```

Description

Command Callback Function Handle.

Remarks

None.

SYS_CMD_EVENT Enumeration

Identifies the Command Event Types

File

sys_command.h

C

```
typedef enum {
  SYS_CMD_EVENT_WRITE_COMPLETE,
  SYS_CMD_EVENT_READ_COMPLETE
} SYS_CMD_EVENT;
```

Description

SYS CMD EVENT structure

This structure identifies the Command Event Types.

Remarks

None.

Files

Files

Name	Description
sys_command.h	Command Processor System Service interface definition.

Description

This section lists the source and header files used by the library.

sys_command.h

Command Processor System Service interface definition.

Enumerations

	Name	Description
	SYS_CMD_CONSOLE_IO_PARAM	Defines whether the command module is single character or full command read
	SYS_CMD_EVENT	Identifies the Command Event Types
	SYS_CMD_STATE	Defines the various states that can be achieved by a Command instance.

Functions

	Name	Description
	SYS_CMD_ADDGRP	Allows clients to add command process to the Command Processor System Service.
	SYS_CMD_DELETE	Removes CMDIO parameters from the Command Processor System Service console.
	SYS_CMD_Initialize	Initializes data for the instance of the Command Processor module.
	SYS_CMD_MESSAGE	Outputs a message to the Command Processor System Service console.
	SYS_CMD_PRINT	Outputs a printout to the Command Processor System Service console.
	SYS_CMD_READY_TO_READ	Allows upper layer application to confirm that the command module is ready to accept command input
	SYS_CMD_READY_TO_WRITE	Allows upper layer application to confirm that the command module is ready to write output to the Console System Service.
	SYS_CMD_RegisterCallback	Registers a callback function with the command service that will be executed when the lower layer read or write queue is empty.
	SYS_CMD_Tasks	Maintains the Command Processor System Service's internal state machine.
	SYS_CMDIO_ADD	Adds CMDIO parameters to the Command Processor System Service console.
	SYS_CMDIO_GET_HANDLE	Gets the CMDIO Handle base via index.

Macros

	Name	Description
	_promptStr	prompt string
	COMMAND_HISTORY_DEPTH	Command Processor System Service Maximum Depth of Command History.
	ESC_SEQ_SIZE	standard VT100 escape sequences
	LINE_TERM	line terminator
	MAX_CMD_ARGS	Command Processor System Service Maximum Number of Argument definitions.
	MAX_CMD_GROUP	Command Processor System Service Maximum Number of Command Group definitions.
	SYS_CMD_BUFFER_DMA_READY	Define this for MX #define SYS_CMD_BUFFER_DMA_READY __attribute__((coherent)) __attribute__((aligned(4))) //Define this for MZ
	SYS_CMD_DEVICE_MAX_INSTANCES	This is macro SYS_CMD_DEVICE_MAX_INSTANCES.
	SYS_CMD_MAX_LENGTH	Command Processor System Service Command Buffer Maximum Length definition.
	SYS_CMD_MESSAGE	This is macro SYS_CMD_MESSAGE.
	SYS_CMD_PRINT	This is macro SYS_CMD_PRINT.
	SYS_CMD_READ_BUFFER_SIZE	Command Processor System Service Read Buffer Size definition.
	SYS_DEBUG	This is macro SYS_DEBUG.
	SYS_ERROR	This is macro SYS_ERROR.
	SYS_ERROR_PRINT	This is macro SYS_ERROR_PRINT.

Structures

	Name	Description
	SYS_CMD_DEVICE_NODE	Defines the data structure to store each command instance.
	SYS_CMD_API	Identifies the Command API structure.
	SYS_CMD_DESCRIPTOR	a simple command descriptor
	SYS_CMD_DESCRIPTOR_TABLE	table containing the supported commands
	SYS_CMD_DEVICE_LIST	Defines the list structure to store a list of command instances.
	SYS_CMD_INIT	Identifies the system command initialize structure.
	SYS_CMD_INIT_DATA	Defines the data structure to store each command.

Types

	Name	Description
	SYS_CMD_CallbackFunction	Command Callback Function Handle.
	SYS_CMD_DATA_RDY_FNC	Identifies a data available function API.

	SYS_CMD_FNC	Identifies the command process function API.
	SYS_CMD_GETC_FNC	Identifies a get single character function API.
	SYS_CMD_HANDLE	Identifies a particular Command I/O instance.
	SYS_CMD_MSG_FNC	Identifies a message function API.
	SYS_CMD_PRINT_FNC	Identifies a print function API.
	SYS_CMD_PUTC_FNC	Identifies a single character print function API.
	SYS_CMD_READC_FNC	Identifies a read single character function API.

Description

Command Processor System Service Interface Definition

This file contains the interface definition for the Command Processor System Service. It provides a way to interact with the Command Processor subsystem to manage the ASCII command requests from the user supported by the system.

File Name

sys_command.h

Company

Microchip Technology Inc.

Console System Service Library

This section describes the Console System Service Library.

Introduction

The Console System Service routes data or message traffic between a console device and a middleware layer or application. The most common use of the Console Service is to route debug or error messages from a PIC32-based device to a terminal program on a host development system. When fully implemented, the Console Service will be capable of routing data from any supported console device to a variety of middleware layers.

Description

The Console System Service consists of a core layer and a console device layer. The core layer handles module initialization and system functions. It provides a common API for use by applications and middleware libraries to send and receive data to and from one or more console devices. The Console System core layer maintains the status and device descriptor information for each console instance that has been initialized. The maximum number of simultaneous console instances supported by the service is defined by a configuration option. The default is four.

The console device layer contains the functional implementation of the core layer APIs. Each console device may have a different implementation, but the behavior of the API should be uniform across different devices. The console device layer interacts with the peripheral device drivers to send and receive data to and from the hardware peripheral. The details of the data transaction are abstracted by the console device layer and the peripheral device driver.

Both blocking and non-blocking implementations are provided. For a blocking implementation, the API to transfer data to or from the console device will return after the data has been successfully transferred, or an error has occurred. Non-blocking implementations return immediately and the data transfer is controlled by a state machine implemented in the console device layer. The calling program is notified of the data transfer completion by a callback mechanism, or can optionally poll the status of the console device layer to see if it is busy or ready for more data.

The console device layer provides the ability to queue data buffers written to the console. The size of the queue is defined by a configuration option. Read data is queued internally in the console device layer depending on the console device. The size of this queue is also defined by a configuration option. Each console device has configuration options specific to that device. They are explained in their respective sections in this document.

Using the Library

This topic describes the basic architecture of the Console System Service Library and provides information and examples on its use.

Description

Interface Header File: `sys_console.h`

The interface to the Console System Service library is defined in the `sys_console.h` header file. This file is included by the `sys.h` file. Any C language source (`.c`) file that uses the Console System Service library should include `sys.h`.

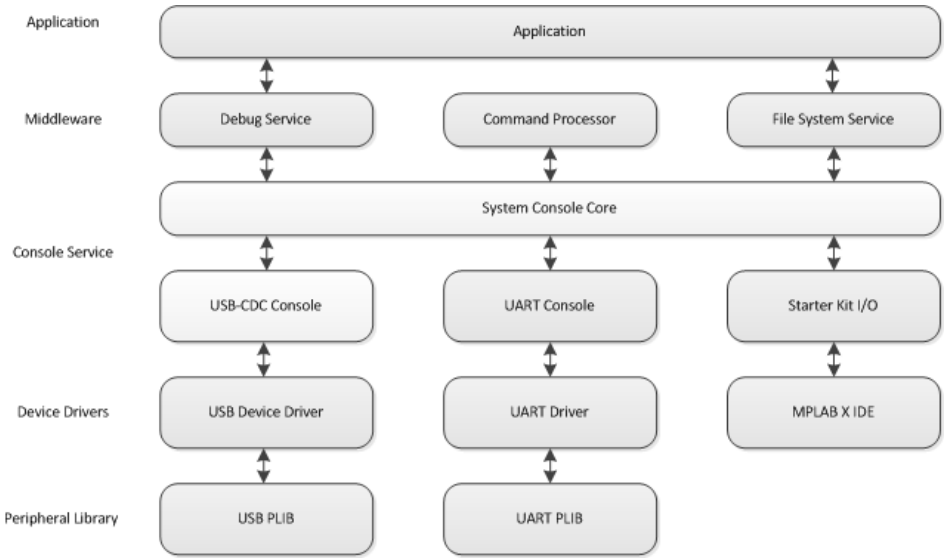
Please refer to the What is MPLAB Harmony? section for how the System Service interacts with the framework.

Abstraction Model

This library provides a set of functions that send and receive data to and from a console I/O device.

Description

Console Service Software Abstraction Block Diagram



The Console System Service is a middleware library that is part of a layered software architecture. The purpose of this software layering is to allow each module to provide a consistent interface to its client, thus making it easy for the developer to add and remove modules as needed. The console core layer provides a POSIX-like read/write API to applications and middleware libraries to send and receive data to and from the console device. Data and message buffering, along with the details of the data transfer are contained within the console device and device driver layers.

Additional APIs are provided to handle system functions, register a callback function for non-blocking implementations, and flush (reset) the internal queues in the event of an error condition.

Library Overview

Refer to the section System Services Introduction for how the system services operates in a system.

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the System Console module.

Library Interface Section	Description
System Functions	Provides system module interfaces, device initialization, tasks and status functions.
Core Functions	Reads or writes data to or from the console I/O device.

How the Library Works

The Console System Service is used to transfer data between an application or middleware layer and a console device.

Note: Not all modes are available on all devices. Please refer to the specific device data sheet to determine the supported modes.

System Functions

This topic describes Console System Service Library system functions.

Description

The Console System Service must be initialized before use. Initialization opens a specific console module instance and initializes the internal data structures for that instance. The initialization routine is provided a pointer to a SYS_CONSOLE_INIT data structure, which contains a pointer to a device descriptor for a particular console device.

USB CDC Example

```
SYS_CONSOLE_INIT consInit =
{
    .moduleInit = {0},
    .consDevDesc = &consUsbCdcDevDesc,
};
```

UART Example

```
SYS_CONSOLE_INIT consInit =
{
    .moduleInit = {0},
    .consDevDesc = &consUsartDevDesc,
};
```

The console device descriptor contains information specific to the device associated with that console instance, including pointers to device-specific implementations of the Console System service API. The device descriptor for each console device is declared in the console device implementation. A pointer to the descriptor must be provided to the initialization routine.

Status

The SYS_CONSOLE_Status function returns the status of the console device module. The internal status of the console device module is updated as the module cycles through its internal state machine. For example, the console device module may need to wait for its corresponding device driver to initialize before moving to an initialized state. Module status is converted from an internal data type to the generic Harmony SYS_STATUS data type.

Tasks

The SYS_CONSOLE_Tasks function advances the state machine of the console device module. A pointer to the console device module's Tasks() routine is provided as part of the console device descriptor during initialization.

Core Functions

This topic describes core Console System Service functions.

Description

Read

The SYS_CONSOLE_Read function reads data from a console device into a read buffer. In a blocking implementation, the API will return the number of successfully read bytes when the read operation completes. In a non-blocking implementation, the API will return immediately with number of successfully queued bytes. Completion of the read triggers a callback mechanism in which a user-defined function is executed. A pointer to the read buffer for that transaction is provided as an argument to the callback function to allow console users to distinguish between read events.

For single read events, the user may also poll the status of the console device module.

Write

The SYS_CONSOLE_Write function writes data from a write buffer or string to a console device. In a blocking implementation, the API will return the number of successfully written bytes when the write operation completes. In a non-blocking implementation, the API will return immediately with the number of successfully queued bytes. Completion of the write triggers a callback mechanism in which a user-defined function is executed. A pointer to the write buffer for that transaction is provided as an argument to the callback function to allow console users to distinguish between write events.

For single write events, the user may also poll the status of the console device module.

Register Callback

Users wishing to take advantage of the callback mechanism must register a callback function with the console service. A separate function must be registered for each event capable of triggering a callback. If no function is registered, the operation will complete normally without triggering any callback function.

Flush

Error conditions may be triggered by a queue overflow or data transfer errors. An error condition may present itself as an unexpected return value from a read or write call, or an error status returned by the SYS_CONSOLE_Status function. The SYS_CONSOLE_Flush function is provided to allow the user to terminate any pending transfers and reset the read/write queues internal to the console device.

Console Device Modules

Each supported console device has its own implementation of the Console System service APIs. Function pointers to the console device implementations are provided in the console device descriptor registered to each console instance. This allows the user to utilize the same API for all console devices, making application code more portable across different devices.

Description

Each supported console device has its own implementation of the Console System service APIs. Function pointers to the console device implementations are provided in the console device descriptor registered to each console instance. This allows the user to utilize the same API for all console devices, making application code more portable across different devices.

Application I/O (AppIO)

The AppIO provides a convenient user I/O interface to applications running on a PIC32 using MPLAB X IDE.

Description

Read

The read function accepts user input through the Input Format Field in the PIC AppIO window of MPLAX X IDE. It is the responsibility of the application programmer to properly allocate the read buffer.

Write

The write function sends output to the Output Format Window in MPLAB X IDE, a line at a time. It is the responsibility of the application programmer to properly allocate the write buffer.

USB-CDC Console Device

The USB-CDC Console Device provides a convenient user I/O interface to applications running on a PIC32 with USB support.

Description

In this implementation, the PIC32 acts as a USB device, communicating with a host PC running a terminal emulation program such as Tera Term. This provides a convenient interface for error or debug messages, or a means of communicating with a user interactively. The application does not use the USB-CDC APIs directly, instead all interaction is through the Console System service APIs.

The USB-CDC Console Device supports only non-blocking operation.

Read

While the user may request multiple bytes of data per read, a typical terminal emulator program sends only one byte per USB transaction. When multiple bytes are requested, the USB-CDC Console Device layer will queue individual byte reads until all bytes are read. The size of the read queue is a configuration option. The bytes are sent to the user-supplied read buffer as they are read, and the read callback is triggered when all bytes have been read. Only one read operation can be active at a time.

If the user requests more data bytes than the read queue will hold, the read function will queue and return the size of the read queue. In this scenario, the user can either do multiple reads until all the data is read, or configure the service to use a larger read queue.

The read function accepts a pointer to a read buffer as one of the arguments. It is the responsibility of the application programmer to properly allocate the read buffer.

Write

The USB-CDC console device is capable of writing multiple data bytes per USB transaction, and queuing multiple write transactions. The size of the write queue is a configuration option. If the user tries to queue more write transactions than the write queue can accommodate, the write function will return -1 and set the module status to SYS_STATUS_ERROR.

The write function accepts a pointer to a write buffer as one of the arguments. It is the responsibility of the application programmer to properly allocate the write buffer.

State Machine

The USB-CDC Console Device layer implements a state machine that is advanced by each call to the tasks routine. The Console System tasks routine is called periodically by the SYS_Tasks routine, which is called in a loop by main(). The state machine manages initialization of the Console Device, schedules reads and writes, and dispatches callback functions.

Register Callback

The callback registration mechanism associates a user function with a read or write completion event. The callback function includes an argument containing a pointer to the read or write buffer associated with the transfer that initiated the callback. Separate callback functions must be registered for read and write events. If there is no callback function registered, the event will complete as normal, with no callback executed.

Flush

The flush routine in the USB-CDC implementation clears any error conditions, terminates any read or write transactions, and resets the read and write queues. A flush operation is typically triggered in response to an error condition.

UART Console Device

The UART Console Device provides a convenient user I/O interface to applications running on a PIC32 with UART support.

Description

Read

While the user may request multiple bytes of data per read, a typical terminal emulator program sends only one byte per transaction. When multiple bytes are requested, the UART Console Device layer will queue individual byte reads until all bytes are read. The size of the read queue is a configuration option. The bytes are sent to the user-supplied read buffer as they are read, and the read callback is triggered when all bytes have been read. Only one read operation can be active at a time.

If the user requests more data bytes than the read queue will hold, the read function will queue and return the size of the read queue. In this scenario, the user can either do multiple reads until all the data is read, or configure the service to use a larger read queue.

The read function accepts a pointer to a read buffer as one of the arguments. It is the responsibility of the application programmer to properly allocate the read buffer.

Write

The UART console device is capable of writing multiple data bytes per transaction, and queuing multiple write transactions. The size of the write queue is a configuration option. If the user tries to queue more write transactions than the write queue can accommodate, the write function will return -1 and set the module status to SYS_STATUS_ERROR.

The write function accepts a pointer to a write buffer as one of the arguments. It is the responsibility of the application programmer to properly allocate the write buffer.

State Machine

The UART Console Device layer implements a state machine that is advanced by each call to the tasks routine. The Console System tasks routine is called periodically by the SYS_Tasks routine, which is called in a loop by main(). The state machine manages initialization of the Console Device, schedules reads and writes, and dispatches callback functions.

Register Callback

The callback registration mechanism associates a user function with a read or write completion event. The callback function includes an argument containing a pointer to the read or write buffer associated with the transfer that initiated the callback. Separate callback functions must be registered for read and write events. If there is no callback function registered, the event will complete as normal, with no callback executed.

Flush

The flush routine in the UART implementation clears any error conditions, terminates any read or write transactions, and resets the read and write queues. A flush operation is typically triggered in response to an error condition.

Configuring the Library

The configuration of the Console System Service is based on the file `system_config.h`.

This header file contains the configuration selection for the Console System Service. Based on the selections made, the Console System Service may support the selected features. These configuration settings will apply to all instances of the Console System Service.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

The Console System Service supports these configuration options:

```
/* Maximum number of simultaneous console instances */
#define CONSOLE_DEVICE_MAX_INSTANCES            1
```

Additional configuration options may be required for the selected Console Device.

Command AppIO Console Device Configuration Options

This topic provided configuration option examples for the Command AppIO Console Device.

Description

```
/* maximum number of console instances */
#define SYS_CONSOLE_DEVICE_MAX_INSTANCES        1

/* number of messages that may be queued up for read */
#define SYS_CONSOLE_APPIO_RD_QUEUE_DEPTH        8

/* number of messages that may be queued up for write */
#define SYS_CONSOLE_APPIO_WR_QUEUE_DEPTH        128
```

USB-CDC Console Device Configuration Options

This topic provided configuration option examples for the USB-CDC Console Device.

Description

USB-CDC Queues

```
/* Number of characters that may be queued for a single read */
#define CONSOLE_USB_CDC_RD_QUEUE_DEPTH          64

/* Number of messages that may be queued for write */
#define CONSOLE_USB_CDC_WR_QUEUE_DEPTH          64
```

USB Controller Driver

```
/* Enables Device Support */
#define DRV_USB_DEVICE_SUPPORT      true
```

```
/* Disables host support */
#define DRV_USB_HOST_SUPPORT        false

/* Provides 3 endpoints*/
#define DRV_USB_ENDPOINTS_NUMBER    3

/* Only one instance of the USB Peripheral*/
#define DRV_USB_INSTANCES_NUMBER    1

/* Enables interrupt mode */
#define DRV_USB_INTERRUPT_MODE      true
```

USB Device Layer

```
/* Maximum device layer instances */
#define USB_DEVICE_MAX_INSTANCES         1

/* Maximum clients for Device Layer */
#define USB_DEVICE_MAX_CLIENTS             1

/* Maximum function drivers allowed per instance of the USB device layer */
#define USB_DEVICE_FUNCTION_DRIVERS_NUMBER      1

/* EP0 size in bytes */
#define USB_DEVICE_EP0_BUFFER_SIZE          64
```

USB-CDC Function Driver

```
/* Maximum instances of CDC function driver */
#define USB_DEVICE_CDC_INSTANCES_NUMBER   1

/* CDC Transfer Queue Size for both read and
 * write. Applicable to all instances of the
 * function driver */
#define USB_DEVICE_CDC_WRITE_QUEUE_DEPTH         4
#define USB_DEVICE_CDC_READ_QUEUE_DEPTH          1
#define USB_DEVICE_CDC_SSN_QUEUE_DEPTH           1
#define USB_DEVICE_CDC_QUEUE_DEPTH_COMBINED
             (USB_DEVICE_CDC_WRITE_QUEUE_DEPTH +
              USB_DEVICE_CDC_READ_QUEUE_DEPTH +
              USB_DEVICE_CDC_SSN_QUEUE_DEPTH)
```

UART Console Device Configuration Options

This topic provided configuration option examples for the UART Console Device.

Description

```
/* Maximum number of simultaneous console instances */
#define CONSOLE_DEVICE_MAX_INSTANCES         1

/* Number of characters that may be queued for a single read */
#define CONSOLE_UART_RD_QUEUE_DEPTH          1

/* Number of messages that may be queued for write */
#define CONSOLE_UART_WR_QUEUE_DEPTH          64

// *****************************************************************************
// *****************************************************************************
// Section: UART Driver Configuration
// *****************************************************************************
// *****************************************************************************

#define DRV_USART_INTERRUPT_MODE                true

#define DRV_USART_INSTANCES_NUMBER              1

#define DRV_USART_CLIENTS_NUMBER                1
```

```
#define DRV_USART_BUFFER_QUEUE_SUPPORT          true

#define DRV_USART_BYTE_MODEL_SUPPORT            false

#define DRV_USART_READ_WRITE_MODEL_SUPPORT      false

#define DRV_USART_WRITE_QUEUE_DEPTH             CONSOLE_UART_RD_QUEUE_DEPTH

#define DRV_USART_READ_QUEUE_DEPTH              CONSOLE_UART_WR_QUEUE_DEPTH

#define DRV_USART_SSN_QUEUE_DEPTH               1

#define DRV_USART_QUEUE_DEPTH_COMBINED          (DRV_USART_WRITE_QUEUE_DEPTH +
                                                 DRV_USART_READ_QUEUE_DEPTH +
                                                 DRV_USART_SSN_QUEUE_DEPTH)
```

Building the Library

This section lists the files that are available in the Console System Service Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/system/console`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
sys_console.h	Console System Service Library API header file.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/sys_console.c	Console System Service Library implementation.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
/src/sys_console_usb_cdc.c	Required for USB-CDC console device.
/src/sys_console_uart.c	Required for UART console device.
/src/sys_console_local.h	Data structures and definitions used by the Console System Service, but not exposed to clients.
/src/sys_console_usb_cdc_local.h	Data structures and definitions used by the USB-CDC console device, but not exposed to clients.

Module Dependencies

The Console System Service is dependent upon the following modules:

- Device Control System Service Library
- USART Driver Library (if UART)
- USB Driver Library (if USB-CDC)

Library Interface

a) System Functions

	Name	Description
	SYS_CONSOLE_Initialize	Initializes data for the instance of the Console module and opens the specific module instance. **Implementation:** Static/Dynamic
	SYS_CONSOLE_Reinitialize	Reinitializes and refreshes the data structure for the instance of the Console module. **Implementation:** Static/Dynamic
	SYS_CONSOLE_Deinitialize	Deinitializes the specific module instance of the Console module. **Implementation:** Static/Dynamic
	SYS_CONSOLE_Tasks	Maintains the console's state machine. **Implementation:** Dynamic
	SYS_CONSOLE_Status	Returns status of the specific instance of the Console module. **Implementation:** Dynamic

b) Core Functions

	Name	Description
	SYS_CONSOLE_Read	Reads data from the console device. **Implementation:** Static/Dynamic
	SYS_CONSOLE_Write	Writes data to the console device. **Implementation:** Static/Dynamic
	SYS_CONSOLE_RegisterCallback	Registers a callback function with the console service that will be executed when the read or write queue is emptied. **Implementation:** Dynamic
	SYS_CONSOLE_Flush	Flushes the read and write queues and resets an overflow error for the console. **Implementation:** Static/Dynamic

c) Data Types and Constants

	Name	Description
	SYS_CONSOLE_OBJECT_INSTANCE	System Console object instance structure.
	SYS_CONSOLE_DEVICE	Lists the available console devices.
	SYS_CONSOLE_DEV_DESC	This is type SYS_CONSOLE_DEV_DESC.
	SYS_CONSOLE_INIT	Identifies the system console initialize structure.
	STDERR_FILENO	This is macro STDERR_FILENO.
	STDIN_FILENO	These are in unistd.h
	STDOUT_FILENO	This is macro STDOUT_FILENO.
	SYS_CONSOLE_INDEX_0	Console System Service index definitions.
	SYS_CONSOLE_INDEX_1	This is macro SYS_CONSOLE_INDEX_1.
	SYS_CONSOLE_INDEX_2	This is macro SYS_CONSOLE_INDEX_2.
	SYS_CONSOLE_INDEX_3	This is macro SYS_CONSOLE_INDEX_3.
	CONSOLE_DEVICE_HANDLE_INVALID	This is macro CONSOLE_DEVICE_HANDLE_INVALID.
	SYS_CONSOLE_BUFFER_DMA_READY	This is added here to prevent built errors, just in-case MHC was never run

Description

This section describes the APIs of the Console System Service Library.

Refer to each section for a detailed description.

a) System Functions

SYS_CONSOLE_Initialize Function

Initializes data for the instance of the Console module and opens the specific module instance.

Implementation: Static/Dynamic

File

sys_console.h

C

```
SYS_MODULE_OBJ SYS_CONSOLE_Initialize(const SYS_MODULE_INDEX index, const SYS_MODULE_INIT * const init);
```

Returns

If successful, returns a valid handle to an object. Otherwise, it returns SYS_MODULE_OBJ_INVALID. The returned object must be passed as argument to SYS_CONSOLE_Reinitialize, SYS_CONSOLE_Deinitialize, SYS_CONSOLE_Tasks and SYS_CONSOLE_Status routines.

Description

This function initializes the Console module, and selects the I/O device to be used. It also initializes any internal data structures.

Remarks

This routine should only be called once during system initialization unless SYS_Console_Deinitialize is first called to deinitialize the device instance before reinitializing it. If the system was already initialized it safely returns without causing any disturbance.

Preconditions

None.

Example

```
SYS_MODULE_OBJ  objectHandle;

// Populate the console initialization structure
SYS_CONSOLE_INIT consInit =
{
    .moduleInit = {0},
    .consDevDesc = &consUsbCdcDevDesc,
};

objectHandle = SYS_Console_Initialize (SYS_CONSOLE_INDEX_0, (SYS_MODULE_INIT*)&consInit);
if (SYS_MODULE_OBJ_INVALID == objectHandle)
{
    // Handle error
}
```

Parameters

Parameters	Description
index	Index for the instance to be initialized
init	Pointer to a data structure containing any data necessary to initialize the Console System service. This pointer may be null if no data is required because static overrides have been provided.

Function

SYS_MODULE_OBJ SYS_CONSOLE_Initialize(const SYS_MODULE_INDEX index,
const SYS_MODULE_INIT * const init)

SYS_CONSOLE_Reinitialize Function

Reinitializes and refreshes the data structure for the instance of the Console module.

Implementation: Static/Dynamic

File

sys_console.h

C

```
bool SYS_CONSOLE_Reinitialize(SYS_MODULE_OBJ object, const SYS_MODULE_INIT * const init);
```

Returns

- true - If successful
- false - If unsuccessful

Description

This function reinitializes and refreshes the data structure for the instance of the Console module using the supplied data.

Remarks

This operation uses the same initialization data structure as the SYS_CONSOLE_Initialize operation. This function can be called multiple times to reinitialize the module.

Preconditions

The SYS_CONSOLE_Initialize function should have been called before calling this function.

Example

```
SYS_MODULE_OBJ  objectHandle;

// Populate the console initialization structure
SYS_CONSOLE_INIT consInit =
{
    .moduleInit = {0},
    .consDevDesc = &consUsbCdcDevDesc,
};

SYS_CONSOLE_Reinitialize (objectHandle, (SYS_MODULE_INIT*)&consInit);
```

Parameters

Parameters	Description
object	Identifies the SYS CONSOLE Object returned by the Initialize interface
init	Pointer to the data structure containing any data necessary to initialize the hardware

Function

void SYS_CONSOLE_Reinitialize(SYS_MODULE_OBJ object,
const SYS_MODULE_INIT * const init)

SYS_CONSOLE_Deinitialize Function

Deinitializes the specific module instance of the Console module.

Implementation: Static/Dynamic

File

sys_console.h

C

```
bool SYS_CONSOLE_Deinitialize(SYS_MODULE_OBJ object);
```

Returns

- true - If successful
- false - If unsuccessful

Description

This function deinitializes the specific module instance disabling its operation (and any hardware for driver modules). Resets all of the internal data structures and fields for the specified instance to the default settings.

Remarks

Once the Initialize operation has been called, the Deinitialize operation must be called before the Initialize operation can be called again.

Preconditions

The SYS_CONSOLE_Initialize function should have been called before calling this function.

Example

```
SYS_MODULE_OBJ      object;     //  Returned from SYS_CONSOLE_Initialize

SYS_CONSOLE_Deinitialize (object);
```

Parameters

Parameters	Description
object	SYS CONSOLE object handle, returned from SYS_CONSOLE_Initialize

Function

void SYS_CONSOLE_Deinitialize(SYS_MODULE_OBJ object)

SYS_CONSOLE_Tasks Function

Maintains the console's state machine.

Implementation: Dynamic

File

sys_console.h

C

```
void SYS_CONSOLE_Tasks(SYS_MODULE_OBJ object);
```

Returns

None

Description

This function is used to maintain the Console System Service internal state machine and implement its ISR for interrupt-driven implementations.

Remarks

This function is normally not called directly by an application. It is called by the system's Tasks routine (SYS_Tasks) or by the appropriate raw ISR.

Preconditions

The SYS_CONSOLE_Initialize function must have been called for the specified CONSOLE driver instance.

Example

```
SYS_MODULE_OBJ      object;     // Returned from SYS_CONSOLE_Initialize

while (true)
{
    SYS_CONSOLE_Tasks (object);

    // Do other tasks
}
```

Parameters

Parameters	Description
object	SYS CONSOLE object handle, returned from SYS_CONSOLE_Initialize

Function

void SYS_CONSOLE_Tasks(SYS_MODULE_OBJ object)

SYS_CONSOLE_Status Function

Returns status of the specific instance of the Console module.

Implementation: Dynamic

File

sys_console.h

C

```
SYS_STATUS SYS_CONSOLE_Status(SYS_MODULE_OBJ object);
```

Returns

- SYS_STATUS_READY - Indicates that the driver is busy with a previous system level operation and cannot start another. Any value greater than SYS_STATUS_READY is also a normal running state in which the driver is ready to accept new operations.

- SYS_STATUS_BUSY - Indicates that the driver is busy with a previous system level operation and cannot start another.
- SYS_STATUS_ERROR - Indicates that the driver is in an error state. Any value less than SYS_STATUS_ERROR is also an error state.
- SYS_MODULE_DEINITIALIZED - Indicates that the driver has been deinitialized. This value is less than SYS_STATUS_ERROR.

Description

This function returns the status of the specific module instance disabling its operation (and any hardware for driver modules).

Remarks

None.

Preconditions

The SYS_CONSOLE_Initialize function should have been called before calling this function.

Example

```
SYS_MODULE_OBJ      object;     // Returned from SYS_CONSOLE_Initialize
SYS_STATUS          consStatus;

consStatus = SYS_CONSOLE_Status (object);
if (SYS_STATUS_ERROR >= consStatus)
{
    // Handle error
}
```

Parameters

Parameters	Description
object	SYS CONSOLE object handle, returned from SYS_CONSOLE_Initialize

Function

SYS_STATUS SYS_CONSOLE_Status(SYS_MODULE_OBJ object)

b) Core Functions

SYS_CONSOLE_Read Function

Reads data from the console device.

Implementation: Static/Dynamic

File

sys_console.h

C

```
ssize_t SYS_CONSOLE_Read(const SYS_MODULE_INDEX index, int fd, void * buf, size_t count);
```

Returns

Number of bytes actually read.

Description

This function reads the data from the console device.

Remarks

None.

Preconditions

None.

Example

```
ssize_t nr;
char myBuffer[MY_BUFFER_SIZE];
nr = SYS_CONSOLE_Read( SYS_CONSOLE_INDEX_0, STDIN_FILENO, myBuffer, MY_BUFFER_SIZE );
if (nr != MY_BUFFER_SIZE)
{
    // handle error
```

```
}
```

Parameters

Parameters	Description
index	Console instance index
fd	I/O stream handle. Maintained for backward compatibility. NULL value can be passed as a parameter.
buf	Buffer to hold the read data.
count	Number of bytes to read.

Function

int SYS_CONSOLE_Read(int handle, char *buffer, int len)

SYS_CONSOLE_Write Function

Writes data to the console device.

Implementation: Static/Dynamic

File

sys_console.h

C

```
ssize_t SYS_CONSOLE_Write(const SYS_MODULE_INDEX index, int fd, const char * buf, size_t count);
```

Returns

Number of bytes written or -1 if an error occurred.

Description

This function writes data to the console device.

Remarks

None.

Preconditions

None.

Example

```
ssize_t nr;
char myBuffer[] = "message";
nr = SYS_CONSOLE_Write( SYS_CONSOLE_INDEX_0, STDOUT_FILENO, myBuffer, strlen(myBuffer) );
if (nr != strlen(myBuffer))
{
    // Handle error
}
```

Parameters

Parameters	Description
index	Console instance index
fd	I/O stream handle. Maintained for backward compatibility. NULL value can be passed as a parameter.
buf	Buffer holding the data to be written.
count	Number of bytes to write.

Function

ssize_t SYS_CONSOLE_Write(const SYS_MODULE_INDEX index, int fd, const char *buf, size_t count)

SYS_CONSOLE_RegisterCallback Function

Registers a callback function with the console service that will be executed when the read or write queue is emptied.

Implementation: Dynamic

File

sys_console.h

C

```
void SYS_CONSOLE_RegisterCallback(const SYS_MODULE_INDEX index, consoleCallbackFunction cbFunc,
SYS_CONSOLE_EVENT event);
```

Returns

None.

Description

This function is used by an application to register a callback function with the console service. The callback function is called in response to an event. Separate callback functions are required for each event.

Remarks

None.

Preconditions

None.

Example

```
SYS_CONSOLE_RegisterCallback(SYS_CONSOLE_INDEX_0, APP_ReadComplete,
                             SYS_CONSOLE_EVENT_READ_COMPLETE);
SYS_CONSOLE_RegisterCallback(SYS_CONSOLE_INDEX_0, APP_WriteComplete,
                             SYS_CONSOLE_EVENT_WRITE_COMPLETE);
```

Parameters

Parameters	Description
index	Console instance index
consCallbackFunc	The name of the callback function
event	Enumerated list of events that can trigger a callback

Function

void SYS_CONSOLE_RegisterCallback(const SYS_MODULE_INDEX index,

consoleCallbackFunction cbFunc, SYS_CONSOLE_EVENT event)

SYS_CONSOLE_Flush Function

Flushes the read and write queues and resets an overflow error for the console.

Implementation: Static/Dynamic

File

sys_console.h

C

```
void SYS_CONSOLE_Flush(const SYS_MODULE_INDEX index);
```

Returns

None.

Description

This function flushes the read and write queues and resets an overflow error for the console.

Remarks

None.

Preconditions

None.

Example

```
SYS_CONSOLE_Flush(SYS_CONSOLE_INDEX_0);
```

Parameters

Parameters	Description
index	Console instance index

Function

void SYS_CONSOLE_Flush(const SYS_MODULE_INDEX index)

c) Data Types and Constants

SYS_CONSOLE_OBJECT_INSTANCE Structure

System Console object instance structure.

File

sys_console.h

C

```
typedef struct {
  SYS_STATUS consoleDeviceInstanceStatus;
  SYS_CONSOLE_DEV_DESC * consoleInstanceDevDesc;
  CONSOLE_DEVICE_HANDLE consoleDevHandle;
} SYS_CONSOLE_OBJECT_INSTANCE;
```

Members

Members	Description
SYS_STATUS consoleDeviceInstanceStatus;	State of this instance

Description

SYS CONSOLE OBJECT INSTANCE structure

This data type defines the System Console object instance.

Remarks

None.

SYS_CONSOLE_DEVICE Enumeration

Lists the available console devices.

File

sys_console.h

C

```
typedef enum {
  SYS_CONSOLE_DEV_USART,
  SYS_CONSOLE_DEV_USB_CDC,
  SYS_CONSOLE_DEV_APPIO,
  SYS_CONSOLE_NR_DEVS
} SYS_CONSOLE_DEVICE;
```

Description

Console device enumeration

This enumeration lists all of the available console devices. A console device is a physical peripheral used by the console service to send and receive data.

Remarks

None.

SYS_CONSOLE_DEV_DESC Structure

File

sys_console.h

C

```
typedef struct {
  SYS_CONSOLE_DEVICE consoleDevice;
  DRV_IO_INTENT intent;
  char (* sysConsoleReadC)(int fd);
  ssize_t (* sysConsoleRead)(int fd, void *buf, size_t count);
  ssize_t (* sysConsoleWrite)(int fd, const void *buf, size_t count);
  void (* sysConsoleRegisterCallback)(consoleCallbackFunction cbFunc, SYS_CONSOLE_EVENT event);
  void (* sysConsoleTasks)(SYS_MODULE_OBJ object);
  SYS_CONSOLE_STATUS (* sysConsoleStatus)(void);
  void (* sysConsoleFlush)(void);
} SYS_CONSOLE_DEV_DESC;
```

Description

This is type SYS_CONSOLE_DEV_DESC.

SYS_CONSOLE_INIT Structure

Identifies the system console initialize structure.

File

sys_console.h

C

```
typedef struct {
  SYS_MODULE_INIT moduleInit;
  SYS_CONSOLE_DEV_DESC * consDevDesc;
} SYS_CONSOLE_INIT;
```

Members

Members	Description
SYS_MODULE_INIT moduleInit;	System module initialization

Description

SYS Console Initialize structure

This structure identifies the system console initialize structure.

Remarks

None.

STDERR_FILENO Macro

File

sys_console.h

C

```
#define STDERR_FILENO 2
```

Description

This is macro STDERR_FILENO.

STDIN_FILENO Macro

File

sys_console.h

C

```
#define STDIN_FILENO 0
```

Description

These are in unistd.h

STDOUT_FILENO Macro

File

sys_console.h

C

```
#define STDOUT_FILENO 1
```

Description

This is macro STDOUT_FILENO.

SYS_CONSOLE_INDEX_0 Macro

Console System Service index definitions.

File

sys_console.h

C

```
#define SYS_CONSOLE_INDEX_0 0
```

Description

SYS Console Module Index Numbers

These constants provide Console System Service index definitions.

Remarks

These constants should be used in place of hard-coded numeric literals.

SYS_CONSOLE_INDEX_1 Macro

File

sys_console.h

C

```
#define SYS_CONSOLE_INDEX_1 1
```

Description

This is macro SYS_CONSOLE_INDEX_1.

SYS_CONSOLE_INDEX_2 Macro

File

sys_console.h

C

```
#define SYS_CONSOLE_INDEX_2 2
```

Description

This is macro SYS_CONSOLE_INDEX_2.

SYS_CONSOLE_INDEX_3 Macro

File

sys_console.h

C

```
#define SYS_CONSOLE_INDEX_3 3
```

Description

This is macro SYS_CONSOLE_INDEX_3.

CONSOLE_DEVICE_HANDLE_INVALID Macro

File

sys_console.h

C

```
#define CONSOLE_DEVICE_HANDLE_INVALID ((CONSOLE_DEVICE_HANDLE)(-1))
```

Description

This is macro CONSOLE_DEVICE_HANDLE_INVALID.

SYS_CONSOLE_BUFFER_DMA_READY Macro

File

sys_console.h

C

```
#define SYS_CONSOLE_BUFFER_DMA_READY
```

Description

This is added here to prevent built errors, just in-case MHC was never run

Files

Files

Name	Description
sys_console.h	Console System Service interface definitions.

Description

This section lists the source and header files used by the library.

sys_console.h

Console System Service interface definitions.

Enumerations

	Name	Description
	SYS_CONSOLE_DEVICE	Lists the available console devices.

Functions

	Name	Description
	SYS_CONSOLE_Deinitialize	Deinitializes the specific module instance of the Console module. **Implementation:** Static/Dynamic
	SYS_CONSOLE_Flush	Flushes the read and write queues and resets an overflow error for the console. **Implementation:** Static/Dynamic

	SYS_CONSOLE_Initialize	Initializes data for the instance of the Console module and opens the specific module instance. **Implementation:** Static/Dynamic
	SYS_CONSOLE_Read	Reads data from the console device. **Implementation:** Static/Dynamic
	SYS_CONSOLE_RegisterCallback	Registers a callback function with the console service that will be executed when the read or write queue is emptied. **Implementation:** Dynamic
	SYS_CONSOLE_Reinitialize	Reinitializes and refreshes the data structure for the instance of the Console module. **Implementation:** Static/Dynamic
	SYS_CONSOLE_Status	Returns status of the specific instance of the Console module. **Implementation:** Dynamic
	SYS_CONSOLE_Tasks	Maintains the console's state machine. **Implementation:** Dynamic
	SYS_CONSOLE_Write	Writes data to the console device. **Implementation:** Static/Dynamic

Macros

	SYS_CONSOLE_INDEX_2	This is macro SYS_CONSOLE_INDEX_2.
	SYS_CONSOLE_INDEX_3	This is macro SYS_CONSOLE_INDEX_3.
	SYS_CONSOLE_MESSAGE	ifdef SYS_CONSOLE_REMOVE_APIS
	SYS_CONSOLE_PRINT	This is macro SYS_CONSOLE_PRINT.

Structures

	Name	Description
	SYS_CONSOLE_DEV_DESC	This is type SYS_CONSOLE_DEV_DESC.
	SYS_CONSOLE_INIT	Identifies the system console initialize structure.
	SYS_CONSOLE_OBJECT_INSTANCE	System Console object instance structure.

Description

Console System Service Interface Definition

This file contains the interface definition for the Console system service. It provides a way to interact with the Console subsystem to manage the timing requests supported by the system.

File Name

sys_console.h

Company

Microchip Technology Inc.

Debug System Service Library

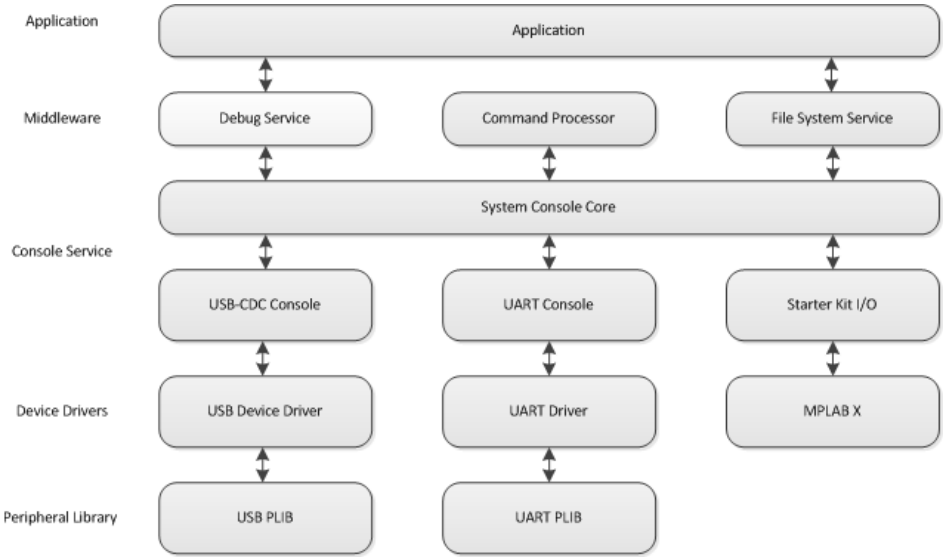
This section describes the Debug System Service Library.

Introduction

This library implements the Debug System Service. The Debug System Service provides a convenient mechanism for the application developer to send formatted or unformatted messages to a system console. The console may direct the messages to a terminal program, file, or any other supported console device. The Debug System Service maintains a global error level, which may be set during initialization and changed dynamically at run-time. Both formatted and unformatted messages can be output or not, depending on the current global error level.

Description

The Debug System Service provides a set of functions that allow the developer to output debug and/or error messages based on a global error level. The messages are sent to the System Console Service, where they are routed to a console device.



Using the Library

This topic describes the basic architecture of the Debug System Service Library and provides information and examples on its use.

Description

Interface Header File: `sys_debug.h`

The interface to the Debug System Service library is defined in the `sys_debug.h` header file. This file is included by the `sys.h` file. Any C language source (`.c`) file that uses the Debug System Service Library should include `sys.h`.

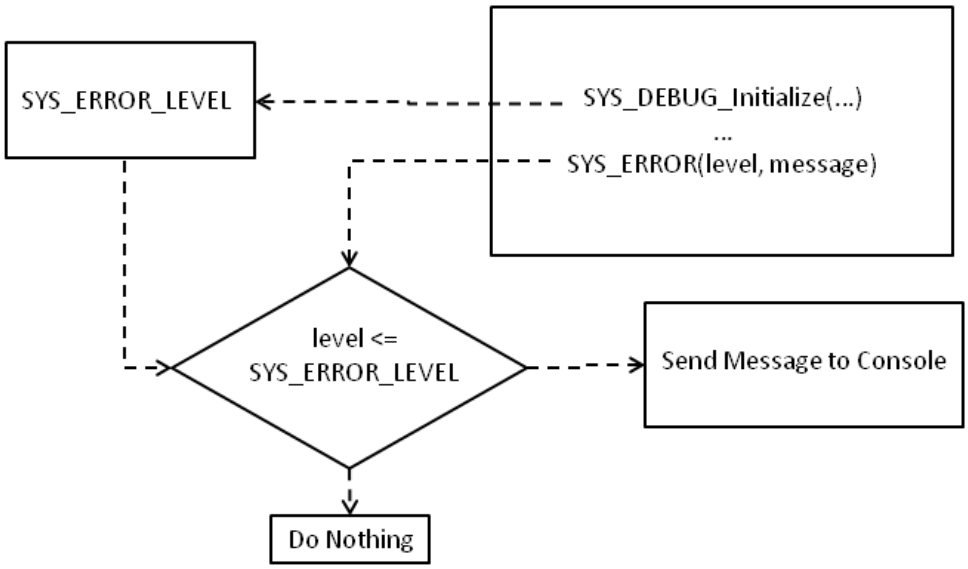
Please refer to the What is MPLAB Harmony? section for how the Debug System Service interacts with the framework.

Abstraction Model

This library provides a set of functions that allow the developer to quickly and easily provide debug and error messaging during and after program development.

Description

Debug Service Software Abstraction Block Diagram



When the Debug System Service is initialized, it sets the global system error level to the specified level. This level determines the threshold at which debug and error messages are sent to the console. This allows different debug and error reporting verbosity depending on the needs of the developer. The Debug System Service also provides APIs to dynamically set the error level during program execution. This allows the developer to increase or decrease debug verbosity to specific areas of interest within the program.

Library Overview

Refer to the section System Services Introduction for how the system services operates in a system.

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Debug System Service module.

Library Interface Section	Description
System Functions	Initializes the Debug System Service and sets the global system error level.
Changing System Error Level Functions	Reads or sets the global system debug level.

How the Library Works

The Debug System Service library can be used by a device driver, middleware layer, or application to report error conditions and output debug messages to a console device during program operation.

Debug System Initialization

The Debug System Service library must be initialized by calling the SYS_DEBUG_Initialize function. Initialization opens a specific debug module instance and initializes the internal data structures for that instance.

Example: Debug System Service Initialization

```
SYS_DEBUG_INIT debugInit =
{
    .moduleInit = {0},
    .errorLevel = SYS_ERROR_DEBUG
};
```

Debug Messages and Error Reporting

The following macros are available to output debug and error messages:

- SYS_MESSAGE(message) prints a simple message string to the output device
- SYS_DEBUG(level, message) prints a debug message to the console device if the global error level is equal to or lower than that specified by the "level" argument. The default implementation of SYS_DEBUG(level, message) resolves to nothing by the preprocessor. This is to allow the developer to leave debug messaging in released code without impacting code size or performance. Typically, the developer would define SYS_DEBUG to map to _SYS_DEBUG in a configuration file for debug builds.

  ```
  #define SYS_DEBUG(level,message) _SYS_DEBUG(level,message)
  ```
- SYS_PRINT(fmt, ...) prints formatted messages to the console. The message formatting is the same as printf.
- SYS_ERROR(level, fmt, ...) prints formatted messages to the console if the global error level is equal to or lower than that specified by the "level" argument. The message formatting is the same as printf.

Changing the System Error Level

Two functions are provided to manipulate the global system error level at runtime. This may be useful when you want to increase the debug verbosity for a particular section of code, but not for the entire program.

- SYS_ERROR_LevelGet returns the current global system error level
- SYS_ERROR_LevelSet(level) sets the current global system error level

Example: Changing the system error level

```
SYS_ERROR_LEVEL lvl;
/* Get current level */
lvl = SYS_ERROR_LevelGet();
/* Set new level */
SYS_ERROR_LevelSet(SYS_ERROR_DEBUG);
// Do something
SYS_DEBUG("Okay until here\n");
/* Restore previous level */
SYS_ERROR_LevelSet(lvl);
```

Configuring the Library

The configuration of the Debug System Service is based on the file `system_config.h`.

This header file contains the configuration selection for the Debug System Service. Based on the selections made, the Debug System Service may support the selected features. These configuration settings will apply to all instances of the Debug System Service.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

The Debug System Service supports these configuration options:

```
/* Enable debug messaging */
#define SYS_DEBUG(level,message) _SYS_DEBUG(level,message)

/* Circular buffer for formatted output */
#define DEBUG_PRINT_BUFFER_SIZE                 512
```

Building the Library

This section lists the files that are available in the Debug System Service Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/system/debug`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
sys_debug.h	Debug System Service Library API header file.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/sys_debug.c	Debug System Service Library implementation.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
/src/sys_debug_local.h	Data structures used by the Debug System Service Library, but not exposed to clients.

Module Dependencies

The Debug System Service is dependent upon the following modules:

- Device Control System Service Library
- Console System Service Library

Library Interface

a) System Functions

	Name	Description
	SYS_DEBUG_Deinitialize	Deinitializes the specific module instance of the Debug module.
	SYS_DEBUG_Initialize	Initializes the global error level and specific module instance.
	SYS_DEBUG_Reinitialize	Reinitializes and refreshes the data structure for the instance of the Debug module.
	SYS_DEBUG_Status	Returns status of the specific instance of the debug service module.

	SYS_DEBUG_Tasks	Maintains the debug module's state machine.
	SYS_DEBUG_Message	Prints a message to the console regardless of the system error level.
	SYS_DEBUG_Print	Formats and prints a message with a variable number of arguments to the console regardless of the system error level.

b) Changing System Error Level Functions

	Name	Description
	SYS_DEBUG_ErrorLevelGet	Returns the global system Error reporting level.
	SYS_DEBUG_ErrorLevelSet	Sets the global system error reporting level.

c) Data Types and Constants

	Name	Description
	SYS_DEBUG_INIT	Defines the data required to initialize the debug system service.
	SYS_ERROR_LEVEL	System error message priority levels.
	SYS_DEBUG	This is macro SYS_DEBUG.
	SYS_DEBUG_INDEX_0	Debug System Service index.
	SYS_MESSAGE	Prints a message to the console regardless of the system error level.
	SYS_ERROR	This is macro SYS_ERROR.
	SYS_PRINT	Formats and prints an error message with a variable number of arguments regardless of the system error level.
	SYS_DEBUG_MESSAGE	Prints a debug message if the system error level is defined defined at or lower than the level specified.
	SYS_DEBUG_PRINT	Formats and prints an error message if the system error level is defined at or lower than the level specified.
	SYS_DEBUG_BreakPoint	Inserts a software breakpoint instruction when building in Debug mode.
	SYS_ERROR_PRINT	This is macro SYS_ERROR_PRINT.
	_SYS_DEBUG_MESSAGE	Prints a debug message if the specified level is at or below the global system error level.
	_SYS_DEBUG_PRINT	Formats and prints a debug message if the specified level is at or below the global system error level.

Description

This section describes the APIs of the Debug System Service Library.

Refer to each section for a detailed description.

a) System Functions

SYS_DEBUG_Deinitialize Function

Deinitializes the specific module instance of the Debug module.

File

sys_debug.h

C

```
void SYS_DEBUG_Deinitialize(SYS_MODULE_OBJ object);
```

Returns

None.

Description

This function deinitializes the specific module instance disabling its operation (and any hardware for driver modules). Resets all of the internal data structures and fields for the specified instance to the default settings.

Remarks

Once the Initialize operation has been called, the Deinitialize operation must be called before the Initialize operation can be called again.

Preconditions

The SYS_DEBUG_Initialize function should have been called before calling this function.

Example

```
SYS_MODULE_OBJ      object;     //  Returned from SYS_DEBUG_Initialize
SYS_DEBUG_Deinitialize (object);
```

Parameters

Parameters	Description
object	SYS DEBUG object handle, returned from SYS_DEBUG_Initialize

Function

void SYS_DEBUG_Deinitialize(SYS_MODULE_OBJ object)

SYS_DEBUG_Initialize Function

Initializes the global error level and specific module instance.

File

sys_debug.h

C

```
SYS_MODULE_OBJ SYS_DEBUG_Initialize(const SYS_MODULE_INDEX index, const SYS_MODULE_INIT * const init);
```

Returns

If successful, returns a valid handle to an object. Otherwise, it returns SYS_MODULE_OBJ_INVALID.

Description

This function initializes the global error level. It also initializes any internal system debug module data structures.

Remarks

This routine should only be called once during system initialization. If the system was already initialized it safely returns without causing any disturbance.

Preconditions

None.

Example

```
SYS_MODULE_OBJ objectHandle;
SYS_DEBUG_INIT debugInit =
{
    .moduleInit = {0},
    .errorLevel = SYS_ERROR_DEBUG,
};

objectHandle = SYS_Debug_Initialize (SYS_DEBUG_CONSOLE, (SYS_MODULE_INIT*)&debugInit);
if (SYS_MODULE_OBJ_INVALID == objectHandle)
{
    // Handle error
}
```

Parameters

Parameters	Description
index	Index for the instance to be initialized
init	Pointer to a data structure containing any data necessary to initialize the debug service. This pointer may be null if no data is required because static overrides have been provided.

Function

SYS_MODULE_OBJ SYS_DEBUG_Initialize(const SYS_MODULE_INDEX index,
const SYS_MODULE_INIT * const init)

SYS_DEBUG_Reinitialize Function

Reinitializes and refreshes the data structure for the instance of the Debug module.

File

sys_debug.h

C

```
void SYS_DEBUG_Reinitialize(SYS_MODULE_OBJ object, const SYS_MODULE_INIT * const init);
```

Returns

None

Description

This function reinitializes and refreshes the data structure for the instance of the Debug module using the supplied data.

Remarks

This operation uses the same initialization data structure as the SYS_DEBUG_Initialize operation. This function can be called multiple times to reinitialize the module.

Preconditions

The SYS_DEBUG_Initialize function should have been called before calling this function.

Example

```
SYS_MODULE_OBJ  objectHandle;

// Populate the console initialization structure
SYS_DEBUG_INIT dbgInit =
{
    .moduleInit = {0},
    .errorLevel = SYS_ERROR_DEBUG,
};

SYS_DEBUG_Reinitialize (objectHandle, (SYS_MODULE_INIT*)&dbgInit);
```

Parameters

Parameters	Description
object	Identifies the SYS DEBUG Object returned by the Initialize interface
init	Pointer to the data structure containing any data necessary to initialize the hardware

Function

void SYS_DEBUG_Reinitialize(SYS_MODULE_OBJ object,
const SYS_MODULE_INIT * const init)

SYS_DEBUG_Status Function

Returns status of the specific instance of the debug service module.

File

sys_debug.h

C

```
SYS_STATUS SYS_DEBUG_Status(SYS_MODULE_OBJ object);
```

Returns

- SYS_STATUS_READY - Indicates that the module is running and ready to service requests. Any value greater than SYS_STATUS_READY is also a normal running state in which the module is ready to accept new operations.
- SYS_STATUS_BUSY - Indicates that the module is busy with a previous system level operation and cannot start another.
- SYS_STATUS_ERROR - Indicates that the module is in an error state. Any value less than SYS_STATUS_ERROR is also an error state.
- SYS_STATUS_UNINITIALIZED - Indicates that the module has not been initialized or has been deinitialized.

Description

This function returns the status of the specific debug service module instance.

Remarks

None.

Preconditions

The SYS_CONSOLE_Initialize function should have been called before calling this function.

Example

```
SYS_MODULE_OBJ      object;     // Returned from SYS_CONSOLE_Initialize
SYS_STATUS          debugStatus;

debugStatus = SYS_DEBUG_Status (object);
if (SYS_STATUS_ERROR >= debugStatus)
{
    // Handle error
}
```

Parameters

Parameters	Description
object	Debug module object handle, returned from SYS_DEBUG_Initialize

Function

SYS_STATUS SYS_DEBUG_Status(SYS_MODULE_OBJ object)

SYS_DEBUG_Tasks Function

Maintains the debug module's state machine.

File

sys_debug.h

C

```
void SYS_DEBUG_Tasks(SYS_MODULE_OBJ object);
```

Returns

None.

Description

This function is used to maintain the debug module's internal state machine and implement its ISR for interrupt-driven implementations.

Remarks

This function is normally not called directly by an application. It is called by the system's Tasks routine (SYS_Tasks) or by the appropriate raw ISR.

Preconditions

The SYS_DEBUG_Initialize function must have been called for the specified CONSOLE driver instance.

Example

```
SYS_MODULE_OBJ      object;     // Returned from SYS_DEBUG_Initialize

while (true)
{
    SYS_DEBUG_Tasks (object);

    // Do other tasks
}
```

Parameters

Parameters	Description
object	SYS DEBUG object handle, returned from SYS_DEBUG_Initialize

Function

void SYS_DEBUG_Tasks(SYS_MODULE_OBJ object)

SYS_DEBUG_Message Function

Prints a message to the console regardless of the system error level.

File

sys_debug.h

C

```
void SYS_DEBUG_Message(const char * message);
```

Returns

None.

Description

This function prints a message to the console regardless of the system error level. It can be used as an implementation of the SYS_MESSAGE and SYS_DEBUG_MESSAGE macros.

Remarks

Do not call this function directly. Call the SYS_MESSAGE or SYS_DEBUG_MESSAGE macros instead.

The default SYS_MESSAGE and SYS_DEBUG_MESSAGE macro definitions remove the messages and message function calls from the source code. To access and utilize the messages, define the SYS_DEBUG_USE_CONSOLE macro or override the definitions of the individual macros.

Preconditions

SYS_DEBUG_Initialize must have returned a valid object handle and the SYS_DEBUG_Tasks function must be called by the system to complete the message request.

Example

```
// In system_config.h:
#define SYS_MESSAGE(message)  SYS_DEBUG_Message(message)

// In source (.c) files:
SYS_MESSAGE("My Messagenr");
```

Parameters

Parameters	Description
message	Pointer to a message string to be displayed.

Function

SYS_DEBUG_Message(const char* message);

SYS_DEBUG_Print Function

Formats and prints a message with a variable number of arguments to the console regardless of the system error level.

File

sys_debug.h

C

```
void SYS_DEBUG_Print(const char * format, ...);
```

Returns

None.

Description

This function formats and prints a message with a variable number of arguments to the console regardless of the system error level. It can be used to implement the SYS_PRINT and SYS_DEBUG_PRINT macros.

Remarks

The format string and arguments follow the printf convention.

Do not call this function directly. Call the SYS_PRINT or SYS_DEBUG_PRINT macros instead.

The default SYS_PRINT and SYS_DEBUG_PRINT macro definitions remove the messages and message function calls. To access and utilize the messages, define the SYS_DEBUG_USE_CONSOLE macro or override the definitions of the individual macros.

Preconditions

SYS_DEBUG_Initialize must have returned a valid object handle and the SYS_DEBUG_Tasks function must be called by the system to complete the message request.

Example

```
// In system_config.h
#define SYS_PRINT(format, ...)  SYS_DEBUG_Print(format, ##__VA_ARG__)

// In source code
int result;

result = SomeOperation();
if (result > MAX_VALUE)
{
    SYS_PRINT("Result of %d exceeds max valuern", result);
}
```

Parameters

Parameters	Description
format	Pointer to a buffer containing the format string for the message to be displayed.
...	Zero or more optional parameters to be formated as defined by the format string.

Function

SYS_DEBUG_Print(const char* format, ...)

b) Changing System Error Level Functions

SYS_DEBUG_ErrorLevelGet Function

Returns the global system Error reporting level.

File

sys_debug.h

C

```
SYS_ERROR_LEVEL SYS_DEBUG_ErrorLevelGet();
```

Returns

The global System Error Level.

Description

This function returns the global System Error reporting level.

Remarks

None.

Preconditions

SYS_DEBUG_Initialize must have returned a valid object handle.

Example

```
SYS_ERROR_LEVEL level;

level = SYS_DEBUG_ErrorLevelGet();
```

Function

SYS_ERROR_LEVEL SYS_DEBUG_ErrorLevelGet(void);

SYS_DEBUG_ErrorLevelSet Function

Sets the global system error reporting level.

File

sys_debug.h

C

```
void SYS_DEBUG_ErrorLevelSet(SYS_ERROR_LEVEL level);
```

Returns

None.

Description

This function sets the global system error reporting level.

Remarks

None.

Preconditions

SYS_DEBUG_Initialize must have returned a valid object handle.

Example

```
SYS_DEBUG_ErrorLevelSet(SYS_ERROR_WARNING);
```

Parameters

Parameters	Description
level	The desired system error level.

Function

void SYS_DEBUG_ErrorLevelSet(SYS_ERROR_LEVEL level);

c) Data Types and Constants

SYS_DEBUG_INIT Structure

Defines the data required to initialize the debug system service.

File

sys_debug.h

C

```
typedef struct {
  SYS_MODULE_INIT moduleInit;
  SYS_ERROR_LEVEL errorLevel;
  SYS_MODULE_INDEX consoleIndex;
} SYS_DEBUG_INIT;
```

Members

Members	Description
SYS_MODULE_INIT moduleInit;	System module initialization
SYS_ERROR_LEVEL errorLevel;	Initial system error level setting.
SYS_MODULE_INDEX consoleIndex;	Console index to receive debug messages

Description

SYS Debug Initialize structure

This structure defines the data required to initialize the debug system service.

Remarks

None.

SYS_ERROR_LEVEL Enumeration

System error message priority levels.

File

sys_debug.h

C

```
typedef enum {
  SYS_ERROR_FATAL = 0,
  SYS_ERROR_ERROR = 1,
  SYS_ERROR_WARNING = 2,
  SYS_ERROR_INFO = 3,
  SYS_ERROR_DEBUG = 4
} SYS_ERROR_LEVEL;
```

Members

Members	Description
SYS_ERROR_FATAL = 0	Errors that have the potential to cause a system crash.
SYS_ERROR_ERROR = 1	Errors that have the potential to cause incorrect behavior.
SYS_ERROR_WARNING = 2	Warnings about potentially unexpected behavior or side effects.
SYS_ERROR_INFO = 3	Information helpful to understanding potential errors and warnings.
SYS_ERROR_DEBUG = 4	Verbose information helpful during debugging and testing.

Description

SYS_ERROR_LEVEL enumeration

This enumeration defines the supported system error message priority values.

Remarks

Used by debug message macros to compare individual message priority against a global system-wide error message priority level to determine if an individual message should be displayed.

SYS_DEBUG Macro

File

sys_command.h

C

```
#define SYS_DEBUG(level,message) SYS_DEBUG_MESSAGE(level,message)
```

Description

This is macro SYS_DEBUG.

SYS_DEBUG_INDEX_0 Macro

Debug System Service index.

File

sys_debug.h

C

```
#define SYS_DEBUG_INDEX_0 0
```

Description

SYS Debug Module Index Number

This constant defines a symbolic name for the debug system service index.

Remarks

There can only be a single debug system service instance in the system.

SYS_MESSAGE Macro

Prints a message to the console regardless of the system error level.

File

sys_debug.h

C

```
#define SYS_MESSAGE(message)
```

Returns

None.

Description

Macro: SYS_MESSAGE(const char* message)

This macro is used to print a message to the console regardless of the system error level. It can be mapped to any desired implementation.

Remarks

By default, this macro is defined as nothing, effectively removing all code generated by calls to it. To process SYS_MESSAGE calls, this macro must be defined in a way that maps calls to it to the desired implementation (see example, above).

This macro can be mapped to the system console service (along with other system debug macros) by defining SYS_DEBUG_USE_CONSOLE in the system configuration (system_config.h) instead of defining it individually.

Preconditions

If mapped to the _SYS_MESSAGE function, then the system debug service must be initialized and running.

Example

```
// In system_config.h:
#define SYS_MESSAGE(message)  _SYS_MESSAGE(message)

// In source (.c) files:
SYS_MESSAGE("My Messagenr");
```

Parameters

Parameters	Description
message	Pointer to a buffer containing the message string to be displayed.

SYS_ERROR Macro

File

sys_command.h

C

```
#define SYS_ERROR(level,fmt, ...) SYS_ERROR_PRINT(level, fmt, ##__VA_ARGS__)
```

Description

This is macro SYS_ERROR.

SYS_PRINT Macro

Formats and prints an error message with a variable number of arguments regardless of the system error level.

File

sys_debug.h

C

```
#define SYS_PRINT(fmt, ...)
```

Returns

None.

Description

This function formats and prints an error message with a variable number of if the system error level is defined at or lower than the level specified.

Remarks

The format string and arguments follow the printf convention. This function is called by the macros SYS_PRINT and SYS_ERROR_PRINT

By default, this macro is defined as nothing, effectively removing all code generated by calls to it. To process SYS_PRINT calls, this macro must be defined in a way that maps calls to it to the desired implementation (see example, above).

This macro can be mapped to the system console service (along with other system debug macros) by defining SYS_DEBUG_USE_CONSOLE in the system configuration (system_config.h) instead of defining it individually.

Preconditions

SYSTEM_CURRENT_ERROR_LEVEL must be defined.

Example

```
// In system_config.h
#define SYS_PRINT(level, format, ...)  _SYS_DEBUG_PRINT(level, format, ##__VA_ARG__)

// In source code
int result;

result = SomeOperation();
if (result > MAX_VALUE)
{
    SYS_PRINT("Result of %d exceeds max valuern", result);
    // Take appropriate action
}
```

Parameters

Parameters	Description
format	Pointer to a buffer containing the format string for the message to be displayed.
...	Zero or more optional parameters to be formated as defined by the format string.

Function

SYS_PRINT(const char* format, ...);

SYS_DEBUG_MESSAGE Macro

Prints a debug message if the system error level is defined defined at or lower than the level specified.

File

sys_debug.h

C

```
#define SYS_DEBUG_MESSAGE(level,message)
```

Returns

None.

Description

This function prints a debug message if the system error level is defined at or lower than the level specified.

Remarks

By default, this macro is defined as nothing, effectively removing all code generated by calls to it. To process SYS_DEBUG_MESSAGE calls, this macro must be defined in a way that maps calls to it to the desired implementation (see example, above).

This macro can be mapped to the system console service (along with other system debug macros) by defining SYS_DEBUG_USE_CONSOLE in the system configuration (system_config.h) instead of defining it individually.

Preconditions

SYSTEM_CURRENT_ERROR_LEVEL must be defined as SYS_ERROR_DEBUG.

Example

```
#define SYS_DEBUG_MESSAGE   _SYS_DEBUG_MESSAGE
SYS_ERROR_LevelSet(SYS_ERROR_DEBUG);
SYS_DEBUG_MESSAGE("System Debug Message nr");
```

Parameters

Parameters	Description
level	The current error level threshold for displaying the message.
message	Pointer to a buffer containing the message to be displayed.

Function

SYS_DEBUG_MESSAGE(const char* message)

SYS_DEBUG_PRINT Macro

Formats and prints an error message if the system error level is defined at or lower than the level specified.

File

sys_debug.h

C

```
#define SYS_DEBUG_PRINT(level, fmt, ...)
```

Returns

None.

Description

Macro: SYS_DEBUG_PRINT(SYS_ERROR_LEVEL level, const char* format, ...)

This macro formats and prints an error message if the system error level is defined at or lower than the level specified.o

Remarks

The format string and arguments follow the printf convention. This function is called by the macros SYS_PRINT and SYS_DEBUG_PRINT.

By default, this macro is defined as nothing, effectively removing all code generated by calls to it. To process SYS_MESSAGE calls, this macro must be defined in a way that maps calls to it to the desired implementation (see example, above).

This macro can be mapped to the system console service (along with other system debug macros) by defining SYS_DEBUG_USE_CONSOLE in the system configuration (system_config.h) instead of defining it individually.

Preconditions

SYS_DEBUG_Initialize must have returned a valid object handle.

Example

```
// In system_config.h
#define SYS_DEBUG_PRINT(level, format, ...)  _SYS_DEBUG_PRINT(level, format, ##__VA_ARG__)

// In source code
int result;

result = SomeOperation();
if (result > MAX_VALUE)
{
    SYS_DEBUG_PRINT(SYS_ERROR_WARNING, "Result of %d exceeds max valuern", result);
    // Take appropriate action
}
```

Parameters

Parameters	Description
level	The current error level threshold for displaying the message.
format	Pointer to a buffer containing the format string for the message to be displayed.
...	Zero or more optional parameters to be formated as defined by the format string.

SYS_DEBUG_BreakPoint Macro

Inserts a software breakpoint instruction when building in Debug mode.

File

sys_debug.h

C

```
#define SYS_DEBUG_BreakPoint
```

Returns

None.

Description

Macro: SYS_DEBUG_BreakPoint(void)

This macro inserts a software breakpoint instruction when building in Debug mode.

Remarks

Compiles out if not built for debugging.

Preconditions

None.

Example

```
if (myDebugTestFailed)
{
    SYS_DEBUG_BreakPoint();
}
```

SYS_ERROR_PRINT Macro

File

sys_command.h

C

```
#define SYS_ERROR_PRINT(level, fmt, ...) do { if((level) <= gblErrLvl) SYS_CMD_PRINT(fmt, ##__VA_ARGS__); }
while (0)
```

Description

This is macro SYS_ERROR_PRINT.

_SYS_DEBUG_MESSAGE Macro

Prints a debug message if the specified level is at or below the global system error level.

File

sys_debug.h

C

```
#define _SYS_DEBUG_MESSAGE(level, message) do { if((level) <= SYS_DEBUG_ErrorLevelGet())
SYS_DEBUG_Message(message); }while(0)
```

Returns

None.

Description

Macro: _SYS_DEBUG_MESSAGE(SYS_ERROR_LEVEL level, const char* message)

This macro prints a debug message if the specified level is at or below the global error level. It can be used to implement the SYS_DEBUG_MESSAGE macro.

Remarks

Do not call this macro directly. Call the SYS_DEBUG_MESSAGE macro instead.

The default SYS_DEBUG_MESSAGE macro definition removes the message and function call from the source code. To access and utilize the message, define the SYS_DEBUG_USE_CONSOLE macro or override the definition of the SYS_DEBUG_MESSAGE macro.

Preconditions

SYS_DEBUG_Initialize must have returned a valid object handle.

Example

```
// In system_config.h
#define SYS_DEBUG_MESSAGE(level,message)  _SYS_DEBUG_MESSAGE(level,message)

// In library source (.c) code.
SYS_DEBUG_MESSAGE(SYS_ERROR_WARNING, "My debug warning messagenr");
```

Parameters

Parameters	Description
level	The current error level threshold for displaying the message.
message	Pointer to a buffer containing the message to be displayed.

_SYS_DEBUG_PRINT Macro

Formats and prints a debug message if the specified level is at or below the global system error level.

File

sys_debug.h

C

```
#define _SYS_DEBUG_PRINT(level, format, ...) do { if((level) <= SYS_DEBUG_ErrorLevelGet())
SYS_DEBUG_Print(format, ##__VA_ARGS__); } while (0)
```

Returns

None.

Description

Macro: _SYS_DEBUG_PRINT(SYS_ERROR_LEVEL level, const char* format, ...)

This function formats and prints a debug message if the specified level is at or below the global system error level. It can be used to implement the SYS_DEBUG_PRINT macro.

Remarks

Do not call this macro directly. Call the SYS_DEBUG_PRINT macro instead.

The default SYS_DEBUG_PRINT macro definition removes the message and function call from the source code. To access and utilize the message, define the SYS_DEBUG_USE_CONSOLE macro or override the definition of the SYS_DEBUG_PRINT macro.

Preconditions

SYS_DEBUG_Initialize must have returned a valid object handle.

Example

```
// In system_config.h
#define SYS_DEBUG_PRINT(level, format, ...)  _SYS_DEBUG_PRINT(level, format, ##__VA_ARG__)

// In source code
int result;

result = SomeOperation();
if (result > MAX_VALUE)
{
    SYS_DEBUG_PRINT(SYS_ERROR_WARNING, "Result of %d exceeds max valuern", result);
    // Take appropriate action
}
```

Parameters

Parameters	Description
level	The current error level threshold for displaying the message.
format	Pointer to a buffer containing the format string for the message to be displayed.
...	Zero or more optional parameters to be formated as defined by the format string.

Files

Files

Name	Description
sys_debug.h	Defines the common debug definitions and interfaces used by MPLAB Harmony libraries to report errors and debug information to the user.

Description

This section lists the source and header files used by the library.

sys_debug.h

Defines the common debug definitions and interfaces used by MPLAB Harmony libraries to report errors and debug information to the user.

Enumerations

	Name	Description
	SYS_ERROR_LEVEL	System error message priority levels.

Functions

	Name	Description
	SYS_DEBUG_Deinitialize	Deinitializes the specific module instance of the Debug module.
	SYS_DEBUG_ErrorLevelGet	Returns the global system Error reporting level.
	SYS_DEBUG_ErrorLevelSet	Sets the global system error reporting level.
	SYS_DEBUG_Initialize	Initializes the global error level and specific module instance.
	SYS_DEBUG_Message	Prints a message to the console regardless of the system error level.
	SYS_DEBUG_Print	Formats and prints a message with a variable number of arguments to the console regardless of the system error level.
	SYS_DEBUG_Reinitialize	Reinitializes and refreshes the data structure for the instance of the Debug module.
	SYS_DEBUG_Status	Returns status of the specific instance of the debug service module.
	SYS_DEBUG_Tasks	Maintains the debug module's state machine.

Macros

	Name	Description
	_SYS_DEBUG_MESSAGE	Prints a debug message if the specified level is at or below the global system error level.
	_SYS_DEBUG_PRINT	Formats and prints a debug message if the specified level is at or below the global system error level.
	SYS_DEBUG_BreakPoint	Inserts a software breakpoint instruction when building in Debug mode.
	SYS_DEBUG_BUFFER_DMA_READY	This should be defined in system_config.h. It is added here as a build safe-guard.
	SYS_DEBUG_INDEX_0	Debug System Service index.
	SYS_DEBUG_MESSAGE	Prints a debug message if the system error level is defined defined at or lower than the level specified.
	SYS_DEBUG_PRINT	Formats and prints an error message if the system error level is defined at or lower than the level specified.
	SYS_MESSAGE	Prints a message to the console regardless of the system error level.
	SYS_PRINT	Formats and prints an error message with a variable number of arguments regardless of the system error level.

Structures

	Name	Description
	SYS_DEBUG_INIT	Defines the data required to initialize the debug system service.

Description

Debug System Services Library Header

This header file defines the common debug definitions and interface macros (summary below) and prototypes used by MPLAB Harmony libraries to report errors and debug information to the user.

File Name

sys_debug.h

Company

Microchip Technology Inc.

Device Control System Service Library

This section describes the Device Control System Service Library.

Introduction

This library provides a low-level abstraction of the Device Control System Service Library that is available on the Microchip family of PIC32 microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, there by hiding differences from one microcontroller variant to another.

Description

The Device Control System Service provides the developer with simple APIs to configure and control device-specific functions. These functions may involve one or more peripherals, or no peripherals at all.

Using the Library

This topic describes the basic architecture of the Device Control System Service Library and provides information and examples on its use.

Description

Interface Header File: `sys_devcon.h`

The interface to the Device Control System Service library is defined in the `sys_devcon.h` header file.

Please refer to the What is MPLAB Harmony? section for how the Device Control System Service interacts with the framework.

Abstraction Model

This topic provides a description of the software abstraction for the Device Control System Service.

Description

The Device Control System Service is a collection of device-specific operations that may not be tied to any specific peripheral, multiple peripherals, or may not involve any peripherals at all. This service provides functions to optimize system performance, perform cache management, and do other system-level tasks that may be needed by multiple modules.

Library Overview

Refer to the section System Services Introduction for how the system services operates in a system.

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Device Control module.

Library Interface Section	Description
System Interaction Functions	Provides system module APIs. Device initialization, deinitialization, reinitialization and status functions.
Core Functionality Functions	Device-specific configuration and control functions.
Cache Functions	Configuration and control functions specific to L1 Cache.
Data Types and Constants	Device-specific enumerations, structures, and constants.

How the Library Works

System Interaction

Initialization and Reinitialization

Initialization of the Device Control System Service initializes the status of the module and sets the state of the internal state machine.

The Device Control Status and Tasks routines are provided as stubs for future enhancement. They are not currently required for this system service.

Core Functionality

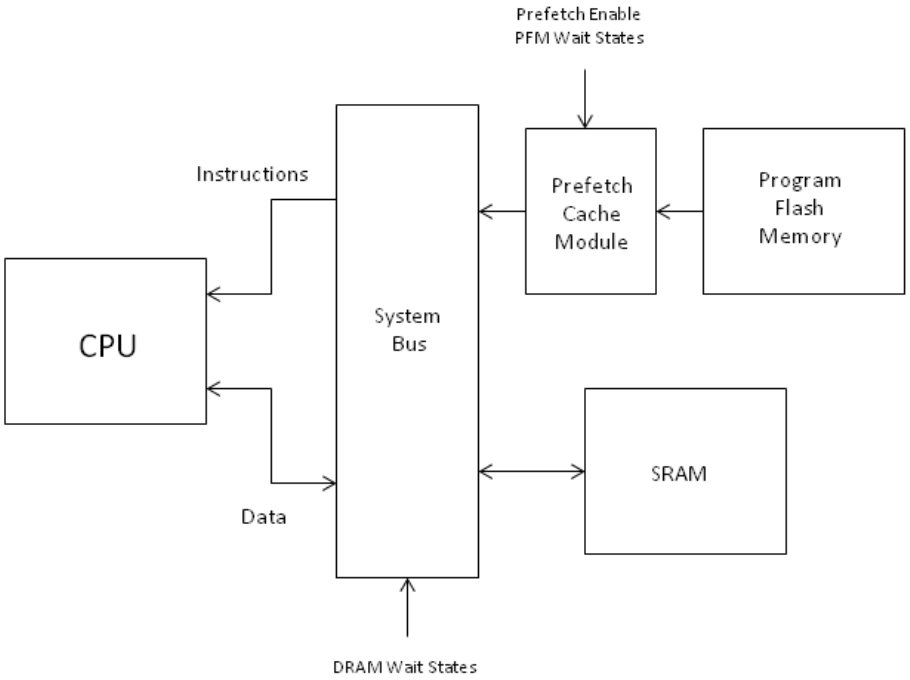
System Performance Tuning

When any PIC32 device is powered up, the Program Flash Memory and Data RAM memory wait states are not set to optimum values. By setting these wait states to the minimum required for the programmed clock speed, enabling the prefetch cache (if available), performance can be optimized. This service provides a single API that performs this optimization across all PIC32 devices.

The SYS_DEVCON_PerformanceConfig function takes the current system clock frequency as an argument and uses this value to set the program Flash wait states to the optimum value. It enables the Prefetch Cache module on both PIC32MX and PIC32MZ devices, and sets the SRAM Wait state for PIC32MX devices.

```
SYS_DEVCON_PerformanceConfig( unsigned int sysclk )
```

Performance Tuning Block Diagram



System Locking and Unlocking

Many operations within the PIC32 device require the system to be unlocked before the operation is performed. This is a safety feature which prevents errant code from altering critical settings by mistake. The unlock sequence consists of writing a series of "magic numbers" to a specific register in sequence. The critical operation is then performed, and the system is relocked by writing to the same register. This service provides convenient APIs that work across all PIC32 devices to perform this lock/unlock sequence.

```
SYS_DEVCON_SystemUnlock();
// critical operation
SYS_DEVCON_SystemLock();
```

Note: For the operations that require a lock/unlock sequence, refer to the specific device data sheet to determine the requirement for your device.

L1 Cache

This topic provides a description of the management functions for the Level 1 (L1) Cache that is available in PIC32MZ family devices.

Description

The Device Control System Service contains an interface for controlling the L1 Cache in the PIC32MZ family of devices.

The L1 cache is divided into two parts, a Data Cache (D-cache) and an Instruction Cache (I-cache). These blocks of high-speed memory both serve to compensate for the lengthy access time of main memory, by fetching instructions and data for the CPU ahead of time. The CPU can then access the information directly through the cache in a single clock cycle, rather than having to wait multiple clock cycles for accesses to main memory. The L1 cache provides a drastic increase in performance, but the user must be aware of hazards that exist when using the cache.

Cache Coherency

Cache coherency is the discipline of ensuring that the data stored in main memory matches the corresponding data in the cache. The majority of the cache-related APIs deal with cache coherency. These functions allow the user to flush, clean and invalidate entire cache(s), or just a range of addresses within the cache.

Caches most often lose coherency when a bus master other than the CPU modifies memory. This happens frequently with DMA. Two examples are provided in the following section.

Examples

Example 1:

Imagine a situation where you would like to transfer data from a source buffer to a destination buffer using DMA. You would write data to the source buffer, start the DMA transfer, and then expect that the same data now appears in the destination buffer. With the cache in write-back mode (the default mode for the PIC32MZ family), this will not be the case. When transferring data out of memory using DMA, it is possible that the desired data is held in the D-cache, but has never been written back to main memory. Therefore, in this case, you write data to the source buffer and it gets stored in cache. When the DMA transfer executes, it will pull the data from the source buffer out of RAM and then transfer it to the destination buffer in RAM. The problem is that the fresh data was stored in the cache but never written back to RAM, so what has happened is that stale data was copied over rather than the intended data. What is needed is a way to force the cache to write its data back to main memory before the DMA transfer. This is known as a *write-back operation* and would be performed with the use of the function:
SYS_DEVCON_DataCacheClean(uint32_t addr, size_t len)

The example application, devcon_cache_clean, in the Device Control System Service Examples demonstrates this situation and shows how to resolve the issue.

Example 2:

The second situation involves writing data into memory using DMA. Imagine that the cache is holding a chunk of data known as destination_buffer. You then execute a DMA transfer to copy some new data from a source buffer into destination_buffer. The issue here is that main memory now contains the correct data, but the cache holds a copy of stale data for destination_buffer. The CPU cannot see this problem and it will keep pulling the data out of the cache, not even realizing that it's stale. What is needed is a way to tell the cache to pull the fresh data out of main memory, to replace the stale data that the cache contains. This is known as an *invalidate operation*. It is performed with the use of the function:
SYS_DEVCON_DataCacheInvalidate(uint32_t addr, size_t len)

The example application, devcon_cache_invalidate, in the Device Control System Service Examples demonstrates this situation and shows how to resolve the issue.

Configuring the Library

No configuration is required for the Device Control System Service.

Building the Library

This section lists the files that are available in the Device Control System Service Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/system/devcon`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`sys_devcon.h`	Device Control System Service Library API header file.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/sys_devcon.c	Device Control System Service Library implementation.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
src/sys_devcon_pic32mx.c	PIC32MX-specific implementation of SYS_DEVCON_PerformanceConfig.
/src/sys_devcon_pic32mz.c	PIC32MZ-specific implementation of SYS_DEVCON_PerformanceConfig.
/src/sys_devcon_local.h	Data structures and definitions used by the Device Control System Service, but not exposed to clients.
/src/sys_devcon_cache_pic3mz.S	PIC32MZ-specific implementation to support L1 Cache.

Module Dependencies

The Device Control System Service is not dependent upon any other modules.

Library Interface

a) System Interaction Functions

	Name	Description
	SYS_DEVCON_Deinitialize	Deinitializes the specific module instance of the DEVCON module
	SYS_DEVCON_Initialize	Initializes data for the instance of the Device Control module and opens the specific module instance.
	SYS_DEVCON_Reinitialize	Reinitializes and refreshes the hardware for the instance of the Device Control module.
	SYS_DEVCON_Status	Returns status of the specific instance of the Device Control module.
	SYS_DEVCON_Tasks	Maintains the system Device Control state machine.

b) Core Functionality Functions

	Name	Description
	SYS_DEVCON_SystemLock	Performs a system lock sequence by writing to the SYSKEY register.
	SYS_DEVCON_SystemUnlock	Performs a system unlock sequence by writing to the SYSKEY register.
	SYS_DEVCON_JTAGDisable	Disables the JTAG port on the device.
	SYS_DEVCON_JTAGEnable	Enables the JTAG port on the device.
	SYS_DEVCON_TraceDisable	Disables the trace output port on the device.
	SYS_DEVCON_TraceEnable	Enables the trace output port on the device.
	SYS_DEVCON_PerformanceConfig	Configures the PFM wait states and Prefetch Cache module for maximum performance.
	SYS_DEVCON_PowerModeEnter	Puts the device in a low-power state.

c) Cache Functions

	Name	Description
	SYS_DEVCON_CacheClean	Writes back and invalidates an address range in either cache.
	SYS_DEVCON_CacheCoherencyGet	Returns the current cache coherency attribute for kseg0.
	SYS_DEVCON_CacheCoherencySet	Sets the cache coherency attribute for kseg0.
	SYS_DEVCON_CacheFlush	Flushes the L1 cache.
	SYS_DEVCON_CacheInit	Initializes the L1 cache.
	SYS_DEVCON_CacheSync	Synchronizes the instruction and data caches.
	SYS_DEVCON_DataCacheClean	Writes back and invalidates an address range in the data cache.
	SYS_DEVCON_DataCacheFlush	Flushes the L1 data cache.

	SYS_DEVCON_DataCacheInvalidate	Invalidates an address range in the data cache.
	SYS_DEVCON_DataCacheLock	Fetches and locks a block of data in the data cache.
	SYS_DEVCON_DataCacheAssociativityGet	Returns the number of ways in the data cache.
	SYS_DEVCON_DataCacheLineSizeGet	Returns the data cache line size.
	SYS_DEVCON_DataCacheLinesPerWayGet	Returns the number of lines per way in the data cache.
	SYS_DEVCON_DataCacheSizeGet	Returns the total number of bytes in the data cache.
	SYS_DEVCON_InstructionCacheFlush	Flushes (invalidates) the L1 instruction cache.
	SYS_DEVCON_InstructionCacheInvalidate	Invalidates an address range in the instruction cache.
	SYS_DEVCON_InstructionCacheLock	Fetches and locks a block of instructions in the instruction cache.
	SYS_DEVCON_InstructionCacheAssociativityGet	Returns the number of ways in the instruction cache.
	SYS_DEVCON_InstructionCacheLineSizeGet	Returns the instruction cache line size.
	SYS_DEVCON_InstructionCacheLinesPerWayGet	Returns the number of lines per way in the instruction cache.
	SYS_DEVCON_InstructionCacheSizeGet	Returns the total number of bytes in the instruction cache.

d) Data Types and Constants

	Name	Description
	SYS_DEVCON_HANDLE	Identifies a particular registered event instance.
	SYS_DEVCON_INIT	Identifies the system device control initialize structure.
	SYS_DEVCON_INDEX_0	Device Control System Service index definitions.
	SYS_CACHE_COHERENCY	System L1 cache coherency settings.
	SYS_POWER_MODE	System power mode settings.

Description

This section describes the APIs of the Device Control System Service Library.

Refer to each section for a detailed description.

a) System Interaction Functions

SYS_DEVCON_Deinitialize Function

Deinitializes the specific module instance of the DEVCON module

File

sys_devcon.h

C

```
void SYS_DEVCON_Deinitialize(SYS_MODULE_OBJ object);
```

Returns

None.

Description

This function deinitializes the specific module instance disabling its operation (and any hardware for driver modules). Resets all of the internal data structures and fields for the specified instance to the default settings.

Remarks

Once the Initialize operation has been called, the Deinitialize operation must be called before the Initialize operation can be called again.

Preconditions

The SYS_DEVCON_Initialize function should have been called before calling this function.

Example

```
SYS_MODULE_OBJ      object;     //  Returned from SYS_DEVCON_Initialize
SYS_STATUS          status;

SYS_DEVCON_Deinitialize (object);

status = SYS_DEVCON_Status (object);
if (SYS_MODULE_DEINITIALIZED == status)
```

```
{
    // Check again later if you need to know
    // when the SYS DEVCON is deinitialized.
}
```

Parameters

Parameters	Description
object	SYS DEVCON object handle, returned from SYS_DEVCON_Initialize

Function

void SYS_DEVCON_Deinitialize(SYS_MODULE_OBJ object)

SYS_DEVCON_Initialize Function

Initializes data for the instance of the Device Control module and opens the specific module instance.

File

sys_devcon.h

C

```
SYS_MODULE_OBJ SYS_DEVCON_Initialize(const SYS_MODULE_INDEX index, const SYS_MODULE_INIT * const init);
```

Returns

If successful, returns a valid handle to an object. Otherwise, it returns SYS_MODULE_OBJ_INVALID. The returned object must be passed as argument to SYS_DEVCON_Reinitialize, SYS_DEVCON_Deinitialize, SYS_DEVCON_Tasks and SYS_DEVCON_Status routines.

Description

This function initializes the instance of the Device Control module, using the specified initialization data. It also initializes any internal data structures.

Remarks

This routine should only be called once during system initialization unless SYS_DEVCON_Deinitialize is first called to deinitialize the device instance before reinitializing it. If the system was already initialized it safely returns without causing any disturbance.

Preconditions

None.

Example

```
SYS_MODULE_OBJ  objectHandle;
SYS_DEVCON_INIT    initConfig;

// Populate the DEVCON initialization structure
initConfig.moduleInit.value     = SYS_MODULE_POWER_RUN_FULL;

objectHandle = SYS_DEVCON_Initialize (SYS_DEVCON_INDEX_0, (SYS_MODULE_INIT*)&initConfig);
if (SYS_MODULE_OBJ_INVALID == objectHandle)
{
    // Handle error
}
```

Parameters

Parameters	Description
index	Index for the instance to be initialized
init	Pointer to a data structure containing any data necessary to initialize the Device Control module. This pointer may be null if no data is required because static overrides have been provided.

Function

SYS_MODULE_OBJ SYS_DEVCON_Initialize(const SYS_MODULE_INDEX index,
const SYS_MODULE_INIT * const init)

SYS_DEVCON_Reinitialize Function

Reinitializes and refreshes the hardware for the instance of the Device Control module.

File

sys_devcon.h

C

```
void SYS_DEVCON_Reinitialize(SYS_MODULE_OBJ object, const SYS_MODULE_INIT * const init);
```

Returns

None

Description

This function reinitializes the instance of the Device Control module using the supplied data. It modifies the internal data structure.

Remarks

This operation uses the same initialization data structure as the SYS_DEVCON_Initialize operation. This operation can be used to change the power state of a DEVCON module. This function can be called multiple times to reinitialize the module. This operation uses the same initialization data structure as the Initialize operation. This operation can also be used to refresh the hardware registers as defined by the initialization data.

Preconditions

The SYS_DEVCON_Initialize function should have been called before calling this function.

Example

```
SYS_MODULE_OBJ  objectHandle;
SYS_DEVCON_INIT    initConfig;
SYS_STATUS      devconStatus;

// Populate the device control initialization structure
initConfig.moduleInit.value     = SYS_MODULE_POWER_RUN_FULL;

SYS_DEVCON_Reinitialize (objectHandle, (SYS_MODULE_INIT*)&initConfig);

devconStatus = SYS_DEVCON_Status (object);
if (SYS_STATUS_ERROR >= devconStatus)
{
    // Handle error
}
```

Parameters

Parameters	Description
object	Identifies the SYS DEVCON Object returned by the Initialize interface
init	Pointer to the data structure containing any data necessary to initialize the hardware

Function

void SYS_DEVCON_Reinitialize(SYS_MODULE_OBJ object,
const SYS_MODULE_INIT * const init)

SYS_DEVCON_Status Function

Returns status of the specific instance of the Device Control module.

File

sys_devcon.h

C

```
SYS_STATUS SYS_DEVCON_Status(SYS_MODULE_OBJ object);
```

Returns

- SYS_STATUS_READY - Indicates that any previous operations have succeeded and the module is ready for additional operations. Any value greater than SYS_STATUS_READY is also a normal running state in which the driver is ready to accept new operations.

- SYS_STATUS_BUSY - Indicates that the driver is busy with a previous system level operation and cannot start another.
- SYS_STATUS_ERROR - Indicates that the driver is in an error state. Any value less than SYS_STATUS_ERROR is also an error state.
- SYS_MODULE_DEINITIALIZED - Indicates that the driver has been deinitialized. This value is less than SYS_STATUS_ERROR. Once the Initialize operation has been called, the Deinitialize operation must be called before the Initialize operation can be called again.

Description

This function returns the status of the specific module instance disabling its operation (and any hardware for driver modules).

Remarks

None.

Preconditions

The SYS_DEVCON_Initialize function should have been called before calling this function.

Example

```
SYS_MODULE_OBJ      object;     // Returned from SYS_DEVCON_Initialize
SYS_STATUS          tmrStatus;

devconStatus = SYS_DEVCON_Status (object);
else if (SYS_STATUS_ERROR >= devconStatus)
{
    // Handle error
}
```

Parameters

Parameters	Description
object	SYS DEVCON object handle, returned from SYS_DEVCON_Initialize

Function

SYS_STATUS SYS_DEVCON_Status(SYS_MODULE_OBJ object)

SYS_DEVCON_Tasks Function

Maintains the system Device Control state machine.

File

sys_devcon.h

C

```
void SYS_DEVCON_Tasks(SYS_MODULE_OBJ object);
```

Returns

None.

Description

This function is used to maintain the system Device Control internal state machine.

Remarks

This function is normally not called directly by an application. It is called by the system's Tasks routine (SYS_Tasks) or by the appropriate raw ISR.

Preconditions

The SYS_DEVCON_Initialize function must have been called for the specified DEVCON driver instance.

Example

```
SYS_MODULE_OBJ      object;     // Returned from SYS_DEVCON_Initialize

while (true)
{
    SYS_DEVCON_Tasks (object);

    // Do other tasks
}
```

Parameters

Parameters	Description
object	SYS DEVCON object handle, returned from SYS_DEVCON_Initialize

Function

void SYS_DEVCON_Tasks(SYS_MODULE_OBJ object)

b) Core Functionality Functions

SYS_DEVCON_SystemLock Function

Performs a system lock sequence by writing to the SYSKEY register.

File

sys_devcon.h

C

```
void SYS_DEVCON_SystemLock();
```

Returns

None.

Description

Performs a system lock sequence by writing to the SYSKEY register. A system lock sequence is required after performing the action that required a system lock sequence.

Remarks

None.

Preconditions

None.

Example

```
SYS_DEVCON_SystemUnlock();
// Perform some action
SYS_DEVCON_SystemLock();
```

Function

void SYS_DEVCON_SystemLock(void)

SYS_DEVCON_SystemUnlock Function

Performs a system unlock sequence by writing to the SYSKEY register.

File

sys_devcon.h

C

```
void SYS_DEVCON_SystemUnlock();
```

Returns

None.

Description

Performs a system unlock sequence by writing to the SYSKEY register. A system unlock sequence is required before performing certain actions such as changing a clock frequency or I/O unlocking.

Remarks

None.

Preconditions

None.

Example

```
SYS_DEVCON_SystemUnlock();
// Perform some action
SYS_DEVCON_SystemLock();
```

Function

void SYS_DEVCON_SystemUnlock(void)

SYS_DEVCON_JTAGDisable Function

Disables the JTAG port on the device.

File

sys_devcon.h

C

```
void SYS_DEVCON_JTAGDisable();
```

Returns

None.

Description

This function disables the JTAG port on the device.

Remarks

None.

Preconditions

None.

Example

```
SYS_DEVCON_JTAGDisable();
```

Function

void SYS_DEVCON_JTAGDisable(void)

SYS_DEVCON_JTAGEnable Function

Enables the JTAG port on the device.

File

sys_devcon.h

C

```
void SYS_DEVCON_JTAGEnable();
```

Returns

None.

Description

This function enables the JTAG port on the device.

Remarks

None.

Preconditions

None.

Example

```
SYS_DEVCON_JTAGEnable();
```

Function

void SYS_DEVCON_JTAGEnable(void)

SYS_DEVCON_TraceDisable Function

Disables the trace output port on the device.

File

sys_devcon.h

C

```
void SYS_DEVCON_TraceDisable();
```

Returns

None.

Description

This function disables the trace output port on the device.

Remarks

None.

Preconditions

None.

Example

```
SYS_DEVCON_TraceDisable();
```

Function

void SYS_DEVCON_TraceDisable(void)

SYS_DEVCON_TraceEnable Function

Enables the trace output port on the device.

File

sys_devcon.h

C

```
void SYS_DEVCON_TraceEnable();
```

Returns

None.

Description

This function enables the trace output port on the device.

Remarks

None.

Preconditions

None.

Example

```
SYS_DEVCON_TraceEnable();
```

Function

void SYS_DEVCON_TraceEnable(void)

SYS_DEVCON_PerformanceConfig Function

Configures the PFM wait states and Prefetch Cache module for maximum performance.

File

sys_devcon.h

C

```
void SYS_DEVCON_PerformanceConfig(unsigned int sysclk);
```

Returns

None.

Description

This function configures the PFM wait states and Prefetch Cache module for maximum performance.

Remarks

None.

Preconditions

The SYS_DEVCON_Initialize function should have been called before calling this function.

Example

```
SYS_DEVCON_PerformanceConfig(SYS_FREQUENCY);
```

Function

void SYS_DEVCON_PerformanceConfig(unsigned int sysclk)

SYS_DEVCON_PowerModeEnter Function

Puts the device in a low-power state.

File

sys_devcon.h

C

```
void SYS_DEVCON_PowerModeEnter(SYS_POWER_MODE pwrMode);
```

Returns

None.

Description

This function places the device in a low-power state.

Remarks

None.

Preconditions

None.

Example

```
SYS_DEVCON_PowerModeEnter(SYS_POWER_MODE_SLEEP);
```

Parameters

Parameters	Description
pwrMode	The low power state to enter.

Function

void SYS_DEVCON_PowerModeEnter(SYS_POWER_MODE pwrMode)

c) Cache Functions

SYS_DEVCON_CacheClean Function

Writes back and invalidates an address range in either cache.

File

sys_devcon.h

C

```
void SYS_DEVCON_CacheClean(uint32_t addr, size_t len);
```

Returns

None.

Description

This function writes back (data) and invalidates (data and address) an address range in either cache.

Remarks

None.

Preconditions

None.

Example

```
SYS_DEVCON_CacheClean(&myData, sizeof(myData));
```

Parameters

Parameters	Description
addr	Starting address of data block.
len	Size of data block.

Function

void SYS_DEVCON_CacheClean(uint32_t addr, size_t len)

SYS_DEVCON_CacheCoherencyGet Function

Returns the current cache coherency attribute for kseg0.

File

sys_devcon.h

C

```
SYS_CACHE_COHERENCY SYS_DEVCON_CacheCoherencyGet();
```

Returns

The current cache coherency attribute for kseg0.

Description

This function returns the current cache coherency attribute for kseg0.

Remarks

None.

Preconditions

None.

Example

```
SYS_CACHE_COHERENCY cacheCoherency;
cacheCoherency = SYS_DEVCON_CacheCoherencyGet();
```

Function

SYS_CACHE_COHERENCY SYS_DEVCON_CacheCoherencyGet(void)

SYS_DEVCON_CacheCoherencySet Function

Sets the cache coherency attribute for kseg0.

File

sys_devcon.h

C

```
void SYS_DEVCON_CacheCoherencySet(SYS_CACHE_COHERENCY cacheCoherency);
```

Returns

None.

Description

This function sets the cache coherency attribute for kseg0.

Remarks

Use with caution. May cause unpredictable behavior in a running system.

Preconditions

None.

Example

```
SYS_DEVCON_CacheCoherencySet(SYS_CACHE_WRITEBACK_WRITEALLOCATE);
```

Parameters

Parameters	Description
cacheCoherency	The desired coherency attribute.

Function

void SYS_DEVCON_CacheCoherencySet(SYS_CACHE_COHERENCY cacheCoherency)

SYS_DEVCON_CacheFlush Function

Flushes the L1 cache.

File

sys_devcon.h

C

```
void SYS_DEVCON_CacheFlush();
```

Returns

None.

Description

This function flushes both instruction and data caches. Invalidate entire instruction cache; writes back and invalidates the entire data cache.

Remarks

Simplest way to synchronize caches with memory, but not necessarily the most efficient.

Preconditions

None.

Example

```
SYS_DEVCON_CacheFlush();
```

Function

void SYS_DEVCON_CacheFlush(void)

SYS_DEVCON_CacheInit Function

Initializes the L1 cache.

File

sys_devcon.h

C

```
void SYS_DEVCON_CacheInit(SYS_CACHE_COHERENCY cacheCoherency);
```

Returns

None.

Description

This function initializes both instruction and data caches. Invalidates all entries and zeros all tags. Sets coherency attribute for kseg0.

Remarks

Use with caution. Invalidates all cache lines without writing data back to memory. Any dirty data in the cache will be lost.

Preconditions

None.

Example

```
SYS_DEVCON_CacheInit(SYS_CACHE_WRITEBACK_WRITEALLOCATE);
```

Parameters

Parameters	Description
cacheCoherency	The desired kseg0 coherency attribute.

Function

void SYS_DEVCON_CacheInit(SYS_CACHE_COHERENCY cacheCoherency)

SYS_DEVCON_CacheSync Function

Synchronizes the instruction and data caches.

File

sys_devcon.h

C

```
void SYS_DEVCON_CacheSync(uint32_t addr, size_t len);
```

Returns

None.

Description

This function synchronizes the instruction and data caches. Used when modifying the instruction stream (breakpoints, self-modifying code, relocating executable code to RAM). Flushes an address range from the data cache and invalidates that same range from the instruction cache.

Remarks

None.

Preconditions

None.

Example

```
SYS_DEVCON_CacheSync(&myCode, myCodeSize);
```

Parameters

Parameters	Description
addr	Starting address of code block.
len	Size of code block.

Function

void SYS_DEVCON_CacheSync(uint32_t addr, size_t len)

SYS_DEVCON_DataCacheClean Function

Writes back and invalidates an address range in the data cache.

File

sys_devcon.h

C

```
void SYS_DEVCON_DataCacheClean(uint32_t addr, size_t len);
```

Returns

None.

Description

This function writes back and invalidates an address range in the data cache.

Remarks

None.

Preconditions

None.

Example

```
SYS_DEVCON_DataCacheClean(&myData, sizeof(myData));
```

Parameters

Parameters	Description
addr	Starting address of data block.
len	Size of data block.

Function

void SYS_DEVCON_DataCacheClean(uint32_t addr, size_t len)

SYS_DEVCON_DataCacheFlush Function

Flushes the L1 data cache.

File

sys_devcon.h

C

```
void SYS_DEVCON_DataCacheFlush();
```

Returns

None.

Description

This function writes back and invalidates the entire data cache.

Remarks

None.

Preconditions

None.

Example

```
SYS_DEVCON_DataCacheFlush();
```

Function

void SYS_DEVCON_DataCacheFlush(void)

SYS_DEVCON_DataCacheInvalidate Function

Invalidates an address range in the data cache.

File

sys_devcon.h

C

```
void SYS_DEVCON_DataCacheInvalidate(uint32_t addr, size_t len);
```

Returns

None.

Description

This function invalidates an address range in the data cache.

Remarks

Use caution. Any dirty data in the cache will be lost.

Preconditions

None.

Example

```
SYS_DEVCON_DataCacheInvalidate(&myData, sizeof(myData));
```

Parameters

Parameters	Description
addr	Starting address of data block.
len	Size of data block.

Function

void SYS_DEVCON_DataCacheInvalidate(uint32_t addr, size_t len)

SYS_DEVCON_DataCacheLock Function

Fetches and locks a block of data in the data cache.

File

sys_devcon.h

C

```
void SYS_DEVCON_DataCacheLock(uint32_t addr, size_t len);
```

Returns

None.

Description

This function fetches and locks a block of data in the data cache.

Remarks

Global flush functions will invalidate and unlock any cache lines locked with this function.

Preconditions

None.

Example

```
SYS_DEVCON_DataCacheLock(&myData, sizeof(myData));
```

Parameters

Parameters	Description
addr	Starting address of data block.
len	Size of data block.

Function

void SYS_DEVCON_DataCacheLock(uint32_t addr, size_t len)

SYS_DEVCON_DataCacheAssociativityGet Function

Returns the number of ways in the data cache.

File

sys_devcon.h

C

```
size_t SYS_DEVCON_DataCacheAssociativityGet();
```

Returns

The number of ways in the data cache.

Description

This function returns the number of ways in the data cache.

Remarks

None.

Preconditions

None.

Example

```
unsigned int size;
size = SYS_DEVCON_DataCacheAssociativityGet();
```

Function

size_t SYS_DEVCON_DataCacheAssociativityGet(void)

SYS_DEVCON_DataCacheLineSizeGet Function

Returns the data cache line size.

File

sys_devcon.h

C

```
size_t SYS_DEVCON_DataCacheLineSizeGet();
```

Returns

The number of bytes per line in the data cache.

Description

This function returns the data cache line size.

Remarks

None.

Preconditions

None.

Example

```
unsigned int size;
size = SYS_DEVCON_DataCacheLineSizeGet();
```

Function

size_t SYS_DEVCON_DataCacheLineSizeGet(void)

SYS_DEVCON_DataCacheLinesPerWayGet Function

Returns the number of lines per way in the data cache.

File

sys_devcon.h

C

```
size_t SYS_DEVCON_DataCacheLinesPerWayGet();
```

Returns

The number of lines per way in the data cache.

Description

This function returns the number of lines per way in the data cache.

Remarks

None.

Preconditions

None.

Example

```
unsigned int size;
size = SYS_DEVCON_DataCacheLinesPerWayGet();
```

Function

size_t SYS_DEVCON_DataCacheLinesPerWayGet(void)

SYS_DEVCON_DataCacheSizeGet Function

Returns the total number of bytes in the data cache.

File

sys_devcon.h

C

```
size_t SYS_DEVCON_DataCacheSizeGet();
```

Returns

The total number of bytes in the data cache.

Description

This function returns the total number of bytes in the data cache.

Remarks

None.

Preconditions

None.

Example

```
unsigned int size;
size = SYS_DEVCON_DataCacheSizeGet();
```

Function

size_t SYS_DEVCON_DataCacheSizeGet(void)

SYS_DEVCON_InstructionCacheFlush Function

Flushes (invalidates) the L1 instruction cache.

File

sys_devcon.h

C

```
void SYS_DEVCON_InstructionCacheFlush();
```

Returns

None.

Description

This function invalidates the entire instruction cache.

Remarks

None.

Preconditions

None.

Example

```
SYS_DEVCON_InstructionCacheFlush();
```

Function

void SYS_DEVCON_InstructionCacheFlush(void)

SYS_DEVCON_InstructionCacheInvalidate Function

Invalidates an address range in the instruction cache.

File

sys_devcon.h

C

```
void SYS_DEVCON_InstructionCacheInvalidate(uint32_t addr, size_t len);
```

Returns

None.

Description

This function invalidates an address range in the instruction cache.

Remarks

None.

Preconditions

None.

Example

```
SYS_DEVCON_InstructionCacheInvalidate(&myCode, myCodeSize);
```

Parameters

Parameters	Description
addr	Starting address of code block.
len	Size of code block.

Function

void SYS_DEVCON_InstructionCacheInvalidate(uint32_t addr, size_t len)

SYS_DEVCON_InstructionCacheLock Function

Fetches and locks a block of instructions in the instruction cache.

File

sys_devcon.h

C

```
void SYS_DEVCON_InstructionCacheLock(uint32_t addr, size_t len);
```

Returns

None.

Description

This function fetches and locks a block of instructions in the instruction cache.

Remarks

Global flush functions will invalidate and unlock any cache lines locked with this function.

Preconditions

None.

Example

```
SYS_DEVCON_InstructionCacheLock(&myCode, myCodeSize);
```

Parameters

Parameters	Description
addr	Starting address of code block.
len	Size of code block.

Function

void SYS_DEVCON_InstructionCacheLock(uint32_t addr, size_t len)

SYS_DEVCON_InstructionCacheAssociativityGet Function

Returns the number of ways in the instruction cache.

File

sys_devcon.h

C

```
size_t SYS_DEVCON_InstructionCacheAssociativityGet();
```

Returns

The number of ways in the instruction cache.

Description

This function returns the number of ways in the instruction cache.

Remarks

None.

Preconditions

None.

Example

```
unsigned int size;
size = SYS_DEVCON_InstructionCacheAssociativityGet();
```

Function

size_t SYS_DEVCON_InstructionCacheAssociativityGet(void)

SYS_DEVCON_InstructionCacheLineSizeGet Function

Returns the instruction cache line size.

File

sys_devcon.h

C

```
size_t SYS_DEVCON_InstructionCacheLineSizeGet();
```

Returns

The number of bytes per line in the instruction cache.

Description

This function returns the instruction cache line size.

Remarks

None.

Preconditions

None.

Example

```
unsigned int size;
size = SYS_DEVCON_InstructionCacheLineSizeGet();
```

Function

size_t SYS_DEVCON_InstructionCacheLineSizeGet(void)

SYS_DEVCON_InstructionCacheLinesPerWayGet Function

Returns the number of lines per way in the instruction cache.

File

sys_devcon.h

C

```
size_t SYS_DEVCON_InstructionCacheLinesPerWayGet();
```

Returns

The number of lines per way in the instruction cache.

Description

This function returns the number of lines per way in the instruction cache.

Remarks

None.

Preconditions

None.

Example

```
unsigned int size;
size = SYS_DEVCON_InstructionCacheLinesPerWayGet();
```

Function

size_t SYS_DEVCON_InstructionCacheLinesPerWayGet(void)

SYS_DEVCON_InstructionCacheSizeGet Function

Returns the total number of bytes in the instruction cache.

File

sys_devcon.h

C

```
size_t SYS_DEVCON_InstructionCacheSizeGet();
```

Returns

The total number of bytes in the instruction cache.

Description

This function returns the total number of bytes in the instruction cache.

Remarks

None.

Preconditions

None.

Example

```
unsigned int size;
size = SYS_DEVCON_InstructionCacheSizeGet();
```

Function

size_t SYS_DEVCON_InstructionCacheSizeGet(void)

d) Data Types and Constants

SYS_DEVCON_HANDLE Type

Identifies a particular registered event instance.

File

sys_devcon.h

C

```
typedef int8_t SYS_DEVCON_HANDLE;
```

Description

SYS DEVCON Handle. This event handle identifies a registered instance of an event. Every time the application that tries to access the parameters with respect to a particular event, shall used this event handle to refer to that event.

Remarks

None.

SYS_DEVCON_INIT Structure

Identifies the system device control initialize structure.

File

sys_devcon.h

C

```
typedef struct {
  SYS_MODULE_INIT moduleInit;
} SYS_DEVCON_INIT;
```

Members

Members	Description
SYS_MODULE_INIT moduleInit;	System module initialization

Description

SYS DEVCON Initialize structure

This structure identifies the system device control initialize structure.

Remarks

None.

SYS_DEVCON_INDEX_0 Macro

Device Control System Service index definitions.

File

sys_devcon.h

C

```
#define SYS_DEVCON_INDEX_0 0
```

Description

SYS Device Control Module Index Numbers

These constants provide Device Control System Service index definitions.

Remarks

These constants should be used in place of hard-coded numeric literals.

SYS_CACHE_COHERENCY Enumeration

System L1 cache coherency settings.

File

sys_devcon.h

C

```
typedef enum {
  SYS_CACHE_WRITETHROUGH_NO_WRITEALLOCATE = 0,
  SYS_CACHE_WRITETHROUGH_WRITEALLOCATE = 1,
  SYS_CACHE_DISABLE = 2,
  SYS_CACHE_WRITEBACK_WRITEALLOCATE = 3
} SYS_CACHE_COHERENCY;
```

Description

SYS_CACHE_COHERENCY enumeration

This enumeration defines the supported system L1 cache coherency settings.

Remarks

Used to read or write cache coherency policy for kseg0.

SYS_POWER_MODE Enumeration

System power mode settings.

File

sys_devcon.h

C

```
typedef enum {
  SYS_POWER_MODE_IDLE,
  SYS_POWER_MODE_SLEEP
} SYS_POWER_MODE;
```

Description

SYS_POWER_MODE enumeration

This enumeration defines the supported system power mode settings.

Remarks

None.

Files

Files

Name	Description
sys_devcon.h	Device Control (DEVCON) System Service interface definition.

Description

This section lists the source and header files used by the library.

sys_devcon.h

Device Control (DEVCON) System Service interface definition.

Enumerations

	Name	Description
	SYS_CACHE_COHERENCY	System L1 cache coherency settings.
	SYS_POWER_MODE	System power mode settings.

Functions

	Name	Description
	SYS_DEVCON_CacheClean	Writes back and invalidates an address range in either cache.
	SYS_DEVCON_CacheCoherencyGet	Returns the current cache coherency attribute for kseg0.
	SYS_DEVCON_CacheCoherencySet	Sets the cache coherency attribute for kseg0.
	SYS_DEVCON_CacheFlush	Flushes the L1 cache.
	SYS_DEVCON_CacheInit	Initializes the L1 cache.
	SYS_DEVCON_CacheSync	Synchronizes the instruction and data caches.
	SYS_DEVCON_DataCacheAssociativityGet	Returns the number of ways in the data cache.
	SYS_DEVCON_DataCacheClean	Writes back and invalidates an address range in the data cache.
	SYS_DEVCON_DataCacheFlush	Flushes the L1 data cache.
	SYS_DEVCON_DataCacheInvalidate	Invalidates an address range in the data cache.
	SYS_DEVCON_DataCacheLineSizeGet	Returns the data cache line size.
	SYS_DEVCON_DataCacheLinesPerWayGet	Returns the number of lines per way in the data cache.
	SYS_DEVCON_DataCacheLock	Fetches and locks a block of data in the data cache.
	SYS_DEVCON_DataCacheSizeGet	Returns the total number of bytes in the data cache.
	SYS_DEVCON_Deinitialize	Deinitializes the specific module instance of the DEVCON module
	SYS_DEVCON_Initialize	Initializes data for the instance of the Device Control module and opens the specific module instance.
	SYS_DEVCON_InstructionCacheAssociativityGet	Returns the number of ways in the instruction cache.
	SYS_DEVCON_InstructionCacheFlush	Flushes (invalidates) the L1 instruction cache.
	SYS_DEVCON_InstructionCacheInvalidate	Invalidates an address range in the instruction cache.
	SYS_DEVCON_InstructionCacheLineSizeGet	Returns the instruction cache line size.

	SYS_DEVCON_InstructionCacheLinesPerWayGet	Returns the number of lines per way in the instruction cache.
	SYS_DEVCON_InstructionCacheLock	Fetches and locks a block of instructions in the instruction cache.
	SYS_DEVCON_InstructionCacheSizeGet	Returns the total number of bytes in the instruction cache.
	SYS_DEVCON_JTAGDisable	Disables the JTAG port on the device.
	SYS_DEVCON_JTAGEnable	Enables the JTAG port on the device.
	SYS_DEVCON_PerformanceConfig	Configures the PFM wait states and Prefetch Cache module for maximum performance.
	SYS_DEVCON_PowerModeEnter	Puts the device in a low-power state.
	SYS_DEVCON_Reinitialize	Reinitializes and refreshes the hardware for the instance of the Device Control module.
	SYS_DEVCON_Status	Returns status of the specific instance of the Device Control module.
	SYS_DEVCON_SystemLock	Performs a system lock sequence by writing to the SYSKEY register.
	SYS_DEVCON_SystemUnlock	Performs a system unlock sequence by writing to the SYSKEY register.
	SYS_DEVCON_Tasks	Maintains the system Device Control state machine.
	SYS_DEVCON_TraceDisable	Disables the trace output port on the device.
	SYS_DEVCON_TraceEnable	Enables the trace output port on the device.

Macros

	Name	Description
	SYS_DEVCON_INDEX_0	Device Control System Service index definitions.

Structures

	Name	Description
	SYS_DEVCON_INIT	Identifies the system device control initialize structure.

Types

	Name	Description
	SYS_DEVCON_HANDLE	Identifies a particular registered event instance.

Description

Device Control System Service Interface Definition

This file contains the interface definition for the Device Control System Service. It provides a way to interact with the Device Control subsystem to manage the device control requests supported by the system.

File Name

sys_devcon.h

Company

Microchip Technology Inc.

Direct Memory Access (DMA) System Service Library

This section describes the Direct Memory Access (DMA) System Service Library.

Introduction

This library provides an interface to interact with the DMA subsystem to control and manage the data transfer between different peripherals and/or memory without intervention from the CPU.

Description

The Direct Memory Access (DMA) controller is a bus master module that is useful for data transfers between different peripherals without intervention from the CPU. The source and destination of a DMA transfer can be any of the memory-mapped modules. For example, memory, or one of the Peripheral Bus (PBUS) devices such as the SPI, UART, and so on.

Using the Library

This topic describes the basic architecture of the DMA System Service Library and provides information and examples on its use.

Description

Interface Header File: `sys_dma.h`

The interface to the DMA System Service library is defined in the `sys_dma.h` header file. This file is included by the `system.h` file. Any C language source (`.c`) file that uses the DMA System Service Library should include `system.h`.

Please refer to the What is MPLAB Harmony? section for how the DMA System Service interacts with the framework.

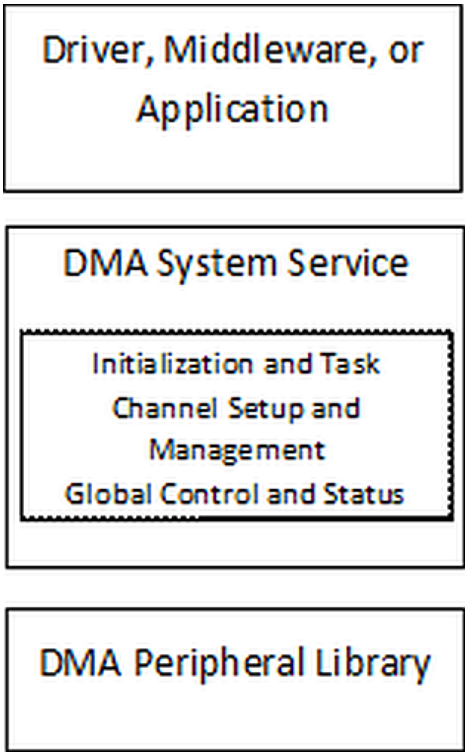
Abstraction Model

This model explains how the system interfaces with the DMA System Service and the application.

Description

This library provides an abstraction of the DMA subsystem that is used by device drivers, middleware libraries and applications to transmit and receive data.

DMA Software Abstraction Block Diagram



DMA System Service

The DMA system services provide support for initializing the DMA controller, managing the transfer state machine, setup/management of channels, and global module control and status management.

Initialization and Tasks

Each software module (device driver, middleware, or application) that needs to use the DMA for data transfer must enable the DMA controller. This is normally done by calling the initialization routine of the DMA subsystem in the module's initialization routine, which is called by the SYS_Initialize service. The initialization routine returns a DMA module object, which should be used as a parameter in the call to Task routines.

The Task routines implement the data transfer state machine for synchronous and asynchronous data transfer operations. If Asynchronous (interrupt) mode of operation is desired, the Task routine(SYS_DMA_TasksISR) should be called from the respective channel ISR. If Synchronous mode of operation if desired, the Task routine(SYS_DMA_Tasks) should be called from the SYS_Tasks function.

Channel Setup and Management

Any module that needs to use the DMA system service must request for channel allocation. An allocated channel is used to setup the channel parameters like the mode of operation(Basic, CRC, chaining etc). Setup the transfer trigger types(Synchronous/Asynchronous). Add a transfer by Setting up the source, destination address and transfer sizes. The DMA transfer starts either forcefully or based on events according to the setting. The channel status events are used to manage the data transfer.

Global Control and Status Management

Provides for control and status of the DMA module. The user can suspend a DMA operation or alternatively resume an already suspended operation. The status of last DMA operation can also be retrieved.

Library Overview

Please refer to the System Service Introduction for a detailed description of MPLAB Harmony system services.

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the DMA module.

Library Interface Section	Description
Initialization and Task Functions	These functions initialize and enable the DMA subsystem and manage the task State machine.
Channel Setup and Management Functions	These DMA Channel and Setup Management functions enable: • Channel Allocation and Release • Setting up of a channel for basic and advanced modes of operations • Channel Enable/Disable • Adding a data transfer • Synchronous data transfer start/abort • Asynchronous data transfer start/abort • Channel Busy status • Channel Computed CRC • Setting the transfer event trigger callback
Global Control and Status Functions	These DMA functions enable global control and status.

How the Library Works

Initialization and Tasks

Describes the functions that can be used for DMA initialization, and provides examples of their usage.

Description

Initialization Function Usage

The DMA subsystem is initialized by calling the initialization routine. The routine also enables the DMA module.

Function Name: SYS_DMA_Initialize

Example

```
//To Enable the Stop in Idle mode feature

SYS_MODULE_OBJ objectHandle;
SYS_DMA_INIT initParam;

initParam.sidl = SYS_DMA_SIDL_ENABLE;

objectHandle = SYS_DMA_Initialize((SYS_MODULE_INIT*)&initParam;);
if(SYS_MODULE_OBJ_INVALID == objectHandle)
{
// Handle error
}
```

Task Function Usage

The task routine implements the data transfer state machine and returns a callback on the completion, abortion or error in a data transfer.

Function Name: SYS_DMA_Tasks

Example

```
// 'object' Returned from SYS_DMA_Initialize
    while (true)
    {
        SYS_DMA_Tasks (object);
        // Do other tasks
    }
```

Note: The SYS_DMA_Tasks function should be used in Synchronous (polling) mode only. This function should not be called from an ISR.

Function Name: SYS_DMA_TasksError

Example

```
// 'object' Returned from SYS_DMA_Initialize
    while (true)
    {
        SYS_DMA_TasksError (object);
        // Do other tasks
    }
```

Note: The SYS_DMA_TasksError function should be used in Synchronous (polling) mode only. This function should not be called from an ISR.

Function Name: SYS_DMA_TasksISR

Example

```
// 'object' Returned from SYS_DMA_Initialize
// Channel 3 is setup for receiving data by USART peripheral in interrupt mode

// Following is the DMA Channel 3 ISR

void __ISR(_DMA3_VECTOR,ipl5) _InterruptHandler_BT_USART_RX_DMA_CHANNEL(void)
{
 SYS_DMA_TasksISR(object, DMA_CHANNEL_3);
}
```

Note: The SYS_DMA_TasksISR function should be used in Asynchronous (interrupt) mode only. This function should not be called from the SYS_Tasks function.

Function Name: SYS_DMA_TasksErrorISR

Example

```
// 'object' Returned from SYS_DMA_Initialize
// Channel 3 is setup for receiving data by USART peripheral in interrupt mode

// Following is the DMA Channel 3 ISR

void __ISR(_DMA3_VECTOR,ipl5) _InterruptHandler_BT_USART_RX_DMA_CHANNEL(void)
{
 SYS_DMA_TasksErrorISR(object, DMA_CHANNEL_3);
}
```

Note: The SYS_DMA_TasksErrorISR function should be used in Asynchronous (interrupt) mode only. This function should not be called from the SYS_Tasks function.

Channel Setup and Management

Describes the functions that can be used for DMA channel setup and management, and provides examples of their usage.

Description

Channel Allocation and Release Functions

Channel Allocate and Release functions allocate/release a particular channel from the available channels on the particular device.

Channel Allocation Function

Channel Allocate function takes a parameter specifying the requested channel number. If the requested channel is available the function allocates the channel and returns a channel handle. If the user is not particular about any specific channel, the user can specify DMA_CHANNEL_ANY enumerator values. When DMA_CHANNEL_ANY values are specified an available channel is allocated and a channel handle is returned. The function returns an invalid channel handle SYS_DMA_CHANNEL_HANDLE_INVALID when the requested channel is not available for allocation.

The valid channel handle returned by this function must be used in all subsequent DMA channel function calls.

Function Name: SYS_DMA_ChannelAllocate

Example 1

```
/* The following examples requests for allocation of a channel handle with Channel number 2 */
SYS_DMA_CHANNEL_HANDLE  handle
```

```
DMA_CHANNEL             channel;
channel = DMA_CHANNEL_2;
handle  = SYS_DMA_ChannelAllocate(channel);
```

Example 2

```
/* The following example requests for allocation of a channel handle with no choice of channel number */
SYS_DMA_CHANNEL_HANDLE  handle
DMA_CHANNEL             channel;
channel = DMA_CHANNEL_ANY;
handle  = SYS_DMA_ChannelAllocate(channel);
```

Precondition: DMA should be initialized by calling SYS_DMA_Initialize.

Channel Release Function

Channel Release function Deallocates and frees the DMA channel specified by the channel handle.

Function Name: SYS_DMA_ChannelRelease

Example

```
/* The following example requests for release of a channel handle with Channel number 2 */
DMA_CHANNEL             channel;
SYS_DMA_CHANNEL_HANDLE  handle;
channel = DMA_CHANNEL_2;
handle  = SYS_DMA_ChannelAllocate(channel);
SYS_DMA_ChannelRelease(handle);
```

Precondition: DMA should be initialized by calling SYS_DMA_Initialize.

Channel Setup Functions

The DMA subsystem supports the following modes of operations. The setting up of these modes of operation can be done by the following functions.

- Basic Transfer Mode
- Pattern Match Abort Mode
- Channel Chaining Mode
- Channel Auto Enable Mode
- CRC Mode

Note: The operation modes are not mutually exclusive.

General Channel Setup Function

This function sets up the channel for the supported operating modes. The function does the following:

- Sets up the channel priority
- Enables the specified mode
- Sets up the DMA asynchronous transfer mode

If the DMA channel transfer is intended to be synchronous, the parameter 'eventSrc' (asynchronous trigger source) can be specified as ‘DMA_TRIGGER_SOURCE_NONE’. When the channel trigger source is specified as ‘DMA_TRIGGER_SOURCE_NONE’, The DMA channel transfer needs to be forcefully started by calling the respective function.

Notes:

1. Enabling of the available operation mode is not mutually exclusive. More than one operation mode can be enabled by bitwise ORing the operating mode enable parameter.
2. To setup the specific features of the supported operation modes the corresponding function needs to be called after calling this function.

Function Name: SYS_DMA_ChannelSetup

Example

```
/* Configure channel number, priority and enables basic and CRC mode */
SYS_DMA_CHANNEL_HANDLE  handle;
DMA_CHANNEL             channel;
SYS_DMA_CHANNEL_OP_MODE modeEnable;
DMA_TRIGGER_SOURCE      eventSrc;
channel     = DMA_CHANNEL_2;
modeEnable  = (SYS_DMA_CHANNEL_OP_MODE_BASIC | SYS_DMA_CHANNEL_OP_MODE_CRC);
eventSrc    = DMA_TRIGGER_USART_1_TRANSMIT;
handle      = SYS_DMA_ChannelAllocate(channel);
SYS_DMA_ChannelSetup(handle, modeEnable,eventSrc);
```

Precondition: DMA should be initialized by calling SYS_DMA_Initialize.

Pattern Match Abort Mode Function

This function sets up the termination of DMA operation when the specified pattern is matched. Additionally on supported devices, the function also sets up the ignoring of part of a pattern (8-bit) from match abort pattern (16-bit).

Before calling this function the pattern match termination mode must have been enabled by calling the general channel setup function

Function Name: SYS_DMA_ChannelSetupMatchAbortMode

Example 1

```
/* The following code is for a device with 8-bit pattern value and no support for pattern match ignore
feature */
SYS_DMA_CHANNEL_HANDLE       handle;
DMA_CHANNEL                  channel;
uint16_t                     pattern;
DMA_PATTERN_LENGTH           length
SYS_DMA_CHANNEL_IGNORE_MATCH ignore;
uint8_t                      ignorePattern;
channel            = DMA_CHANNEL_2;
priority           = DMA_CHANNEL_PRIORITY_1;
pattern            = 0x00; //Stop transfer on detection of a NULL character
length             = DMA_PATTERN_LENGTH_NONE;
ignore             = SYS_DMA_CHANNEL_IGNORE_MATCH_DISABLE;
ignorePattern      = 0;
handle             = SYS_DMA_ChannelAllocate(channel);
SYS_DMA_ChannelSetupMatchAbortMode(handle, pattern, length, ignoreEnable, ignorePattern);
```

Example 2

```
/* The following code is for a device with 16-bit pattern value and support for pattern match ignore
feature */
SYS_DMA_CHANNEL_HANDLE       handle;
DMA_CHANNEL                  channel;
uint16_t                     pattern;
DMA_PATTERN_LENGTH           length
SYS_DMA_CHANNEL_IGNORE_MATCH ignore;
uint8_t                      ignorePattern;
priority           = DMA_CHANNEL_PRIORITY_1;
channel            = DMA_CHANNEL_2;
pattern            = 0x0D0A; //Stop transfer on detection of '\r\n'
length             = DMA_PATTERN_MATCH_LENGTH_2BYTES;
ignore             = SYS_DMA_CHANNEL_IGNORE_MATCH_ENABLE;
ignorePattern      = 0x00; \\ Any null character between the termination pattern '\r' and '\n' is ignored.
handle             = SYS_DMA_ChannelAllocate(channel);
SYS_DMA_ChannelSetupMatchAbortMode(handle, pattern, length, ignore, ignorePattern);
```

Preconditions:

1. DMA should be initialized by calling SYS_DMA_Initialize.

2. Channel should be setup and pattern match mode enabled by calling SYS_DMA_ChannelSetup.

CRC Operation Mode Setup Function

This function sets up the CRC computation features of the channel. Before calling this function the CRC mode must have been enabled by calling the general channel setup function

Function Name: SYS_DMA_ChannelSetupCRCMode

Example

```
/* DMA calculation using the CRC background mode */
SYS_DMA_CHANNEL_HANDLE             handle;
DMA_CHANNEL                        channel;
SYS_DMA_CHANNEL_OPERATION_MODE_CRC crc;
channel        = DMA_CHANNEL_2;
crc.type       = DMA_CRC_LFSR;
crc.mode       = SYS_DMA_CHANNEL_CRC_MODE_BACKGROUND;
crc.polyLength = 16;
crc.bitOrder   = DMA_CRC_BIT_ORDER_LSB;
crc.byteOrder  = DMA_CRC_BYTEORDER_NO_SWAPPING;
crc.writeOrder = SYS_DMA_CRC_WRITE_ORDER_MAINTAIN;
crc.data       = 0xFFFF;
crc.xorBitMask = 0x1021;
handle         = SYS_DMA_ChannelAllocate(channel);
SYS_DMA_ChannelCRCSet(handle, crc);
```

Preconditions:

1. DMA should be initialized by calling SYS_DMA_Initialize.
2. Channel should be setup and CRC mode enabled by calling SYS_DMA_ChannelSetup.

Channel Enable/Disable Functions

The Enable/Disable functions allow to enable/disable a channel on the run.

Note: When a data transfer is added by calling SYS_DMA_ChannelTransferAdd, the channel is automatically enabled.

Function Name: SYS_DMA_ChannelEnable

Example

```
SYS_DMA_CHANNEL_HANDLE handle;
DMA_CHANNEL            channel;
channel  = DMA_CHANNEL_2;
handle   = SYS_DMA_ChannelAllocate(channel);
SYS_DMA_ChannelEnable(handle);
```

Precondition: DMA should be initialized by calling SYS_DMA_Initialize.

Function Name: SYS_DMA_ChannelDisable

Example

```
SYS_DMA_CHANNEL_HANDLE  handle;
DMA_CHANNEL             channel;
channel = DMA_CHANNEL_2;
handle  = SYS_DMA_ChannelAllocate(channel);
SYS_DMA_ChannelDisable(handle);
```

Precondition: DMA should be initialized by calling SYS_DMA_Initialize.

Channel Data Transfer Function

This function adds a data transfer to a DMA channel and Enables the channel to start data transfer. The source and the destination addresses, source and destination lengths, The number of bytes transferred per cell event are set and the channel is enabled to start the data transfer.

Function Name: SYS_DMA_ChannelTransferAdd

Example

```
/* Add 10 bytes of data transfer to UART */
SYS_DMA_CHANNEL_HANDLE  handle;
uint8_t                 buf[10];
void                    *srcAddr;
void                    *destAddr;
size_t                  srcSize;
size_t                  destSize;
size_t                  cellSize;
DMA_CHANNEL             channel;
channel  = DMA_CHANNEL_2;
srcAddr  = (uint8_t *) buf;
srcSize  = 10;
destAddr = (uin8_t*) &U2TXREG; //Uart 2 TX register is the DMA destination
destSize = 1;
cellSize = 1;
handle   = SYS_DMA_ChannelAllocate(channel);
SYS_DMA_ChannelTransferAdd(handle,srcAddr,srcSize,destAddr,destSize,cellSize);
```

Preconditions:

1. DMA should be initialized by calling SYS_DMA_Initialize.
2. Channel should be setup and enabled by calling SYS_DMA_ChannelSetup.

Synchronous Data Transfer Start/Abort Functions

These functions allows to force start/abort data transfer on the selected channel.

Note: The DMA should have been set up, transfer added before calling these functions.

Function Name: SYS_DMA_ChannelForceStart

Example

```
SYS_DMA_CHANNEL_HANDLE  handle;
DMA_CHANNEL             channel;
channel = DMA_CHANNEL_2;
handle  = SYS_DMA_ChannelAllocate(channel);
SYS_DMA_ChannelForceStart(handle);
```

Function Name: SYS_DMA_ChannelForceAbort

Example

```
SYS_DMA_CHANNEL_HANDLE  handle;
DMA_CHANNEL             channel;
channel   = DMA_CHANNEL_2;
handle    = SYS_DMA_ChannelAllocate(channel);
SYS_DMA_ChannelForceAbort(handle);
```

Asynchronous Data Transfer Abort Function

This function sets an event source and enables cell transfer abort event for the same for the selected channel.

Note: Asynchronous data transfer is started in general channel setup function. A channel is setup for asynchronous data transfer by default when the appropriate trigger source is specified in general channel setup function call.

Function Name: SYS_DMA_ChannelAbortEventSet

Example

```
SYS_DMA_CHANNEL_HANDLE  handle;
DMA_CHANNEL             channel;
DMA_TRIGGER_SOURCE      eventSrc;
channel  = DMA_CHANNEL_2;
eventSrc = DMA_TRIGGER_CTMU;
handle   = SYS_DMA_ChannelAllocate(channel);
SYS_DMA_ChannelAbortEventSet(handle, eventSrc);
```

Preconditions:

1. DMA should be initialized by calling SYS_DMA_Initialize.

2. Channel should be setup and enabled by calling SYS_DMA_ChannelSetup.

Channel Busy Status Function

This function gets the busy status of the selected channel.

Function Name: SYS_DMA_ChannelIsBusy

Example

```
SYS_DMA_CHANNEL_HANDLE  handle;
DMA_CHANNEL             channel;
bool                    busyStat;
channel  = DMA_CHANNEL_2;
handle   = SYS_DMA_ChannelAllocate(channel);
busyStat = SYS_DMA_ChannelIsBusy(handle);
```

Precondition: DMA should be initialized by calling SYS_DMA_Initialize.

Channel Computed CRC Function

This function gets the computed CRC.

Note: The CRC generator must have been previously set up by calling the CRC mode setup function.

To get the computed CRC value this function must be called after the block transfer completion event.

Function Name: SYS_DMA_ChannelGetCRC

Example

```
SYS_DMA_CHANNEL_HANDLE handle;
DMA_CHANNEL            channel;
uint32_t               computedCRC;
channel     = DMA_CHANNEL_2;
handle      = SYS_DMA_ChannelAllocate(channel);
computedCRC = SYS_DMA_ChannelCRCSet();
```

Precondition: DMA should be initialized by calling SYS_DMA_Initialize.

Channel Transfer Event Handler Set Function

This function allows to set an event handler for the transfer complete, abort or error events

Function Name: SYS_DMA_ChannelTransferEventHandlerSet

Example

```
SYS_DMA_CHANNEL_HANDLE handle;
DMA_CHANNEL channel;
MY_APP_OBJ myAppObj;   //Application specific object
channel = DMA_CHANNEL_2;
```

```
handle = SYS_DMA_ChannelAllocate(channel);
SYS_DMA_ChannelTransferEventHandlerSet(handle, APP_DMASYSTransferEventHandler, (uintptr_t)&myAppObj);

// Event Processing Technique. Event is received when the transfer is processed.

    void APP_DMASYSTransferEventHandler(SYS_DMA_TRANSFER_EVENT event, SYS_DMA_CHANNEL_HANDLE handle,
uintptr_t contextHandle)
    {
        switch(event)
        {
            case SYS_DMA_TRANSFER_EVENT_COMPLETE:
                // This means the data was transferred.
                break;
            case SYS_DMA_TRANSFER_EVENT_ERROR:
                // Error handling here.
                break;
            default:
                break;
        }
    }
```

Precondition: DMA should be initialized by calling SYS_DMA_Initialize.

Channel Error Get Function

This function returns the error associated with the channel access.

Function Name: SYS_DMA_ChannelErrorGet

Example

```
SYS_DMA_CHANNEL_HANDLE handle;
DMA_CHANNEL channel;
channel = DMA_CHANNEL_2;
handle = SYS_DMA_ChannelAllocate(channel);
// Do Channel setup and Transfer Add.
// In the Even Handler Check if there was an Error
if(SYS_DMA_ERROR_ADDRESS_ERROR == SYS_DMA_ChannelErrorGet(handle))
 {
        // There was an address error.
    // Do error handling here.
}
```

Precondition: DMA should be initialized by calling SYS_DMA_Initialize.

Global Control and Status

Global Control and Status Function Usage:

Suspend/Resume Functions

These functions allows an enabled DMA module to suspend DMA operations. Operation of the suspended module can also be resumed using these functions.

Function Name: SYS_DMA_Suspend

Example 1

```
SYS_DMA_Suspend();
```

Precondition: DMA should be initialized by calling SYS_DMA_Initialize.

Function Name: SYS_DMA_Resume

Example 2

```
SYS_DMA_Resume();
```

Precondition: DMA should be initialized by calling SYS_DMA_Initialize.

Busy Status Function

This function gets the busy status of DMA module.

Function Name: SYS_DMA_IsBusy

Example

```
bool busyStat;
busyStat = SYS_DMA_IsBusy();
```

Precondition: DMA should be initialized by calling SYS_DMA_Initialize.

Memory to Memory Transfer

Provides a code example for a memory to memory data transfer.

Description

The following code is a typical usage example of using the DMA System Service for a memory to memory data transfer.

```
/* Destination Memory Address pointer */
uint8_t                     *pDmaSrc;
/* Source Memory Address pointer */
uint8_t                     *pDmaDst;
/* Transfer Size */
size_t                      txferSize;

/* Maximum Transfer Size */
#define     MAX_TRANSFER_SIZE           100
/* The data pattern to be transferred*/
#define     SOURCE_TRANSFER_PATTERN     'W'

 /*****************************************************************
  The below routine sets up a memory to memory data transfer. It also
  registers an event handler which is called when the data transfer
  completes */
void SYS_DMA_TEST_Memory2Memory(void)
{
    uint8_t                     *pSrcTemp;
    uint32_t                    index;
    SYS_DMA_INIT                dmaInit;
    SYS_DMA_CHANNEL_HANDLE      channelHandle;

    /* Initializing source and destination variables */
    pDmaSrc             =   (uint8_t *) NULL;
    pDmaDst             =   (uint8_t *) NULL;
    pSrcTemp            =   (uint8_t *) NULL;
    txferSize           =   MAX_TRANSFER_SIZE;
    pDmaSrc             =   (uint8_t*) malloc(txferSize);
    pDmaDst             =   (uint8_t*) malloc(txferSize);
    pSrcTemp            =   pDmaSrc;

    if(((uint8_t*) NULL != pDmaSrc) && ((uint8_t*) NULL != pDmaDst))
    {
        /* Initialize the source memory block with the pattern */
        for(index=0; index < txferSize; index++)
        {
            *pSrcTemp++= SOURCE_TRANSFER_PATTERN;
        }

        /* Initialize the DMA system service */
        dmaInit.sidl = SYS_DMA_SIDL_DISABLE;
        sysObj = SYS_DMA_Initialize((SYS_MODULE_INIT*)&dmaInit);

        /* Allocate a DMA channel */
        channelHandle = SYS_DMA_ChannelAllocate(DMA_CHANNEL_1);
        if(SYS_DMA_CHANNEL_HANDLE_INVALID != channelHandle)
        {
            /* Register an event handler for the channel */
            SYS_DMA_ChannelTransferEventHandlerSet(channelHandle,
                    Sys_DMA_Mem2Mem_Event_Handler, (uintptr_t)&sysContext);

            /* Setup the channel */
            SYS_DMA_ChannelSetup(channelHandle,
                                 SYS_DMA_CHANNEL_OP_MODE_BASIC,
                                 DMA_TRIGGER_SOURCE_NONE);

            /* Add the memory block transfer request */
            SYS_DMA_ChannelTransferAdd(channelHandle,pDmaSrc,txferSize,
                                       pDmaDst,txferSize,txferSize);
```

```
            /* Start the DMA transfer */
            SYS_DMA_ChannelForceStart(channelHandle);
        }
        else
        {
            /* Channel Handle not available */
            ;
        }

    }
}

/* Below is an Event handler for the registered memory to memory DMA channel */
static void Sys_DMA_Mem2Mem_Event_Handler(SYS_DMA_TRANSFER_EVENT event,
        SYS_DMA_CHANNEL_HANDLE handle, uintptr_t contextHandle)
{
    int32_t fail=0;
    uint32_t index;

    /* Success event */
    if(SYS_DMA_TRANSFER_EVENT_COMPLETE == event)
    {
        /* Verify the contents of destination block matches the
         * memory contents of the source block */
        for(index=0; index < txferSize; index++)
        {
            if(*pDmaSrc++!=*pDmaDst++) // compare the buffers
            {
                fail = -1;
            }
        }
        if(0==fail)
        {
            /* Transfer Success */
        }
        else
        {
            /* Transfer Failed */
        }
    }
    /* Failure Event */
    else if(SYS_DMA_TRANSFER_EVENT_ABORT == event)
    {
    }
}
```

Configuring the Library

The configuration of the DMA System Service is based on the file `system_config.h`

This header file contains the configuration selection for the DMA system service. Based on the selections made, the DMA System Service may support the selected features. These configuration settings will apply to all instances of the DMA System Service.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

Building the Library

This section lists the files that are available in the Direct Memory Access (DMA) System Service Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/system/dma`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
sys_dma.h	DMA System Service Library API header file.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/sys_dma.c	DMA System Service Library implementation.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for the DMA System Service Library.

Module Dependencies

The DMA System Service Library does not depend on any other modules.

Library Interface

a) Initialization and Task Functions

	Name	Description
	SYS_DMA_Tasks	Maintains the system service's state machine.
	SYS_DMA_TasksError	Maintains the system service's error state machine.
	SYS_DMA_Initialize	Initializes and Enables the DMA Controller.
	SYS_DMA_TasksErrorISR	Maintains the system service's state machine and implements its ISR.
	SYS_DMA_TasksISR	Maintains the system service's state machine and implements its ISR.

b) Channel Setup and Management Functions

	Name	Description
	SYS_DMA_ChannelAbortEventSet	Sets an event source and enables cell transfer abort event for the same for the selected channel.
	SYS_DMA_ChannelAllocate	Allocates the specified DMA channel and returns a handle to it.
	SYS_DMA_ChannelDisable	Disables a channel.
	SYS_DMA_ChannelEnable	Enables a channel.
	SYS_DMA_ChannelForceAbort	Force abort of transfer on the selected channel.
	SYS_DMA_ChannelForceStart	Force start of transfer on the selected channel.
	SYS_DMA_ChannelIsBusy	Returns the busy status of the specified DMA channel.
	SYS_DMA_ChannelRelease	Deallocates and frees the channel specified by the handle.
	SYS_DMA_ChannelSetupMatchAbortMode	Setup the pattern match abort mode.
	SYS_DMA_ChannelTransferAdd	Adds a data transfer to a DMA channel and Enables the channel to start data transfer.
	SYS_DMA_ChannelErrorGet	This function returns the error(if any) associated with the last client request.
	SYS_DMA_ChannelTransferEventHandlerSet	This function allows a DMA system service client to set an event handler.
	SYS_DMA_ChannelCRCGet	Returns the computed CRC.
	SYS_DMA_ChannelCRCSet	Sets up the CRC operation mode.
	SYS_DMA_ChannelSetup	Setup the DMA channel parameters.
	SYS_DMA_ChannelDestinationTransferredSizeGet	Returns the number of bytes transferred to destination.
	SYS_DMA_ChannelSourceTransferredSizeGet	Returns the number of bytes transferred from source.
	SYS_DMA_ChannelTransferSet	Sets up a data transfer to a DMA channel.

c) Global Control and Status Functions

	Name	Description
	SYS_DMA_IsBusy	Returns the busy status of the DMA module.
	SYS_DMA_Resume	Resume DMA operations.
	SYS_DMA_Suspend	Suspend DMA transfers.

d) Data Types and Constants

	Name	Description
	SYS_DMA_CHANNEL_CHAIN_PRIO	Identifies the priority of chaining channel.
	SYS_DMA_CHANNEL_CRC_MODE	Identifies the operation mode of the CRC module.
	SYS_DMA_CHANNEL_OP_MODE	Identifies the available DMA operating modes.
	SYS_DMA_CHANNEL_OPERATION_MODE_CRC	Defines the attributes for CRC operation mode.
	SYS_DMA_CRC_WRITE_ORDER	Identifies altering/maintaining write order post CRC computation.
	SYS_DMA_TRANSFER_EVENT	Enumeration of possible DMA System service events.
	SYS_DMA_CHANNEL_HANDLE	Assigns the handle for requested channel.
	SYS_DMA_CHANNEL_IGNORE_MATCH	Enables/Disables the feature to ignore a byte between a 2-byte match abort pattern.
	SYS_DMA_INIT	Indicates the error information for the DMA System service.
	SYS_DMA_SIDL	Enable/Disable DMA operations in Idle mode.
	SYS_DMA_CHANNEL_COUNT	Identifies the maximum number of DMA channel handles to be defined.
	SYS_DMA_CHANNEL_HANDLE_INVALID	Defines an invalid channel handle.

Description

This section describes the APIs of the DMA System Service Library.

Refer to each section for a detailed description.

a) Initialization and Task Functions

SYS_DMA_Tasks Function

Maintains the system service's state machine.

File

sys_dma.h

C

```
void SYS_DMA_Tasks(SYS_MODULE_OBJ object);
```

Returns

None.

Description

This function is used to maintain the DMA system service's internal state machine. This function is specifically designed for non DMA interrupt trigger implementations(polling mode), and should be used only in polling mode. this function should be called from the SYS_Tasks() function.

Remarks

This function is normally not called directly by an application. It is called by the system's Tasks routine (SYS_Tasks).

This function is deprecated. Any calls made to this functions will have no effect.

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize.

Example

```
// 'object' Returned from SYS_DMA_Initialize

while (true)
{
    SYS_DMA_Tasks ((object) );
```

```
    // Do other tasks
}
```

Parameters

Parameters	Description
object	Object handle for the DMA module (returned from SYS_DMA_Initialize)

Function

void SYS_DMA_Tasks(SYS_MODULE_OBJ object)

SYS_DMA_TasksError Function

Maintains the system service's error state machine.

File

sys_dma.h

C

```
void SYS_DMA_TasksError(SYS_MODULE_OBJ object);
```

Returns

None.

Description

This function is used to maintain the DMA system service's error state machine. This function is specifically designed for non DMA interrupt trigger implementations(polling mode), and should be used only in polling mode. this function should be called from the SYS_Tasks() function.

Remarks

This function is normally not called directly by an application. It is called by the system's Tasks routine (SYS_Tasks).

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize.

Example

```
// 'object' Returned from SYS_DMA_Initialize

while (true)
{
    SYS_DMA_TasksError (object);
    // Do other tasks
}
```

Parameters

Parameters	Description
object	Object handle for the DMA module (returned from SYS_DMA_Initialize)

Function

void SYS_DMA_TasksError(SYS_MODULE_OBJ object)

SYS_DMA_Initialize Function

Initializes and Enables the DMA Controller.

File

sys_dma.h

C

```
SYS_MODULE_OBJ SYS_DMA_Initialize(const SYS_MODULE_INIT * const init);
```

Returns

If successful, returns a valid handle to the DMA module object. Otherwise, it returns SYS_MODULE_OBJ_INVALID.

Description

This function Enables the DMA module. Enable/Disable stop in idle mode feature based on the passed parameter value.

This function initializes the DMA module making it ready for clients to open and use it. The initialization data is specified by the init parameter.

Remarks

This function must be called before any other DMA systems service routines are called.

Not all features are available on all micro-controllers.

Preconditions

None.

Example

```
SYS_MODULE_OBJ objectHandle;
SYS_DMA_INIT initParam;

initParam.sidl = SYS_DMA_SIDL_ENABLE;
objectHandle = SYS_DMA_Initialize(DRV_I2S_INDEX_1,
                                  (SYS_MODULE_INIT*)initParam);
if (SYS_MODULE_OBJ_INVALID == objectHandle)
{
    // Handle error
}
```

Parameters

Parameters	Description
init	Pointer to the data structure containing any data necessary to initialize the hardware. This pointer may be null if no data is required and default initialization is to be used.

Function

SYS_MODULE_OBJ SYS_DMA_Initialize(const SYS_MODULE_INIT * const init)

SYS_DMA_TasksErrorISR Function

Maintains the system service's state machine and implements its ISR.

File

sys_dma.h

C

```
void SYS_DMA_TasksErrorISR(SYS_MODULE_OBJ object, DMA_CHANNEL activeChannel);
```

Returns

None.

Description

This function is used to maintain the DMA system service's internal error state machine and implement its ISR for DMA interrupt trigger implementations(interrupt mode). This function is specifically designed for DMA interrupt trigger implementations (interrupt mode). In interrupt mode, this function should be called in the interrupt service routine of the DMA channel that is associated with this transfer.

Remarks

It is called by appropriate raw ISR.

This function may execute in an ISR context and will never block or access any resources that may cause it to block.

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize.

Example

```
// 'object' Returned from SYS_DMA_Initialize

void __ISR(_DMA3_VECTOR,ipl5) _InterruptHandler_BT_USART_RX_DMA_CHANNEL(void)
{
    // ....
```

```
    SYS_DMA_TasksErrorISR(object, DMA_CHANNEL_3);
}
```

Parameters

Parameters	Description
object	Object handle for the DMA module (returned from SYS_DMA_Initialize)
activeChannel	DMA channel number of the ISR being serviced.

Function

void SYS_DMA_TasksErrorISR(SYS_MODULE_OBJ object, DMA_CHANNEL activeChannel)

SYS_DMA_TasksISR Function

Maintains the system service's state machine and implements its ISR.

File

sys_dma.h

C

```
void SYS_DMA_TasksISR(SYS_MODULE_OBJ object, DMA_CHANNEL activeChannel);
```

Returns

None.

Description

This function is used to maintain the DMA system service's internal state machine and implement its ISR for DMA interrupt trigger implementations(interrupt mode). This function is specifically designed for DMA interrupt trigger implementations (interrupt mode). In interrupt mode, this function should be called in the interrupt service routine of the DMA channel that is associated with this transfer.

Remarks

It is called by appropriate raw ISR.

This function may execute in an ISR context and will never block or access any resources that may cause it to block.

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize.

Example

```
// 'object' Returned from SYS_DMA_Initialize

void __ISR(_DMA3_VECTOR,ipl5) _InterruptHandler_BT_USART_RX_DMA_CHANNEL(void)
{
    SYS_DMA_TasksISR(object, DMA_CHANNEL_3);
}
```

Parameters

Parameters	Description
object	Object handle for the DMA module (returned from SYS_DMA_Initialize)
activeChannel	DMA channel number of the ISR being serviced.

Function

void SYS_DMA_TasksISR(SYS_MODULE_OBJ object, DMA_CHANNEL activeChannel)

b) Channel Setup and Management Functions

SYS_DMA_ChannelAbortEventSet Function

Sets an event source and enables cell transfer abort event for the same for the selected channel.

File

sys_dma.h

C

```
void SYS_DMA_ChannelAbortEventSet(SYS_DMA_CHANNEL_HANDLE handle, DMA_TRIGGER_SOURCE eventSrc);
```

Returns

None.

Description

This functions enables a cell transfer abort event for the selected source event.

Remarks

If the parameter 'eventSrc' is specified as DMA_TRIGGER_SOURCE_NONE the current DMA transfer will be aborted. The behavior is a same as calling SYS_DMA_ChannelForceAbort.

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize. DMA channel should have been allocated by calling SYS_DMA_ChannelAllocate. The function SYS_DMA_ChannelSetup must have been called to setup and enable the required features. The function 'SYS_DMA_ChannelTransferAdd' to add a transfer.

Example

```
// 'handle' is a valid handle returned
// by the SYS_DMA_ChannelAllocate function.

// pDmaSrc, pDmaDst is the  source,destination address
// txferSrcSize, txferDesSize is the source,destination transfer size
// cellSize is the cell size
MY_APP_OBJ          myAppObj;
// Client registers an event handler with service. This is done once

SYS_DMA_ChannelTransferEventHandlerSet( handle, APP_DMATransferEventHandle,
                                (uintptr_t)&myAppObj );

SYS_DMA_ChannelSetup(handle, SYS_DMA_CHANNEL_OP_MODE_BASIC,
                             DMA_TRIGGER_SOURCE_NONE);

SYS_DMA_ChannelTransferAdd(handle,pDmaSrc,txferSrcSize,
                           pDmaDst,txferDesSize,cellSize);

SYS_DMA_ChannelAbortEventSet(handle, DMA_TRIGGER_CTMU);

SYS_DMA_ChannelForceStart(handle);

if(SYS_DMA_CHANNEL_HANDLE_INVALID == handle)
{
    // Error handling here
}

// Event Processing Technique. Event is received when
// the transfer is processed.

void APP_DMATransferEventHandle( SYS_DMA_TRANSFER_EVENT event,
        SYS_DMA_CHANNEL_HANDLE handle, uintptr_t contextHandle )
{

    switch(event)
    {
        case SYS_DMA_TRANSFER_EVENT_ABORT:

            // This means the data was transferred.
            break;

        case SYS_DMA_TRANSFER_EVENT_ERROR:

            // Error handling here.
```

```
            if(SYS_DMA_ERROR_ADDRESS_ERROR == DRV_I2S_ErrorGet(myI2SHandle))
            {
                // There was an address error.
                // Do error handling here.
            }

            break;

        default:
            break;
    }
}
```

Parameters

Parameters	Description
handle	Handle of the DMA channel as returned by the SYS_DMA_ChannelAllocate function.
eventSrc	The event causing the cell transfer abort

Function

void SYS_DMA_ChannelAbortEventSet
(
SYS_DMA_CHANNEL_HANDLE handle,
DMA_TRIGGER_SOURCE eventSrc
)

SYS_DMA_ChannelAllocate Function

Allocates the specified DMA channel and returns a handle to it.

File

sys_dma.h

C

```
SYS_DMA_CHANNEL_HANDLE SYS_DMA_ChannelAllocate(DMA_CHANNEL channel);
```

Returns

The channel handle for the requested channel number.

If an error occurs, the return value is SYS_DMA_CHANNEL_HANDLE_INVALID. Error can occur.

- if the requested channel number is invalid.
- if the requested channel number is not free.

Description

This function opens the specified DMA channel and provides a handle that must be provided to all other client-level operations to identify the caller and the DMA channel.

Remarks

The handle returned is valid until the SYS_DMA_ChannelRelease routine is called. This function must be called before any other DMA channel Setup and management routines are called

Preconditions

Function SYS_DMA_Initialize must have been called before calling this function.

Example

```
DMA_CHANNEL channel;
SYS_DMA_CHANNEL_HANDLE handle

channel = DMA_CHANNEL_2;
handle = SYS_DMA_ChannelAllocate(channel);
if (SYS_DMA_CHANNEL_HANDLE_INVALID == handle)
{
    // Failed to allocate the channel
}
```

```
else
{
    // Proceed with setting up the channel and adding the transfer
}
```

Parameters

Parameters	Description
channel	Channel number requested for allocation. When channel number specified is DMA_CHANNEL_ANY a random channel is allocated for DMA transfers.

Function

SYS_DMA_CHANNEL_HANDLE SYS_DMA_ChannelAllocate (DMA_CHANNEL channel)

SYS_DMA_ChannelDisable Function

Disables a channel.

File

sys_dma.h

C

```
void SYS_DMA_ChannelDisable(SYS_DMA_CHANNEL_HANDLE handle);
```

Returns

None.

Description

This function disables a channel.

Remarks

None.

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize. DMA channel should have been allocated by calling SYS_DMA_ChannelAllocate. The function SYS_DMA_ChannelSetup must have been called to setup and enable the required features. A DMA channel should have been enabled either by calling 'SYS_DMA_ChannelTransferAdd' or 'SYS_DMA_ChannelEnable'

Example

```
// 'handle' is a valid handle returned
// by the SYS_DMA_ChannelAllocate function.

SYS_DMA_ChannelDisable(handle);
```

Parameters

Parameters	Description
handle	Handle of the DMA channel as returned by the SYS_DMA_ChannelAllocate function.

Function

void SYS_DMA_ChannelDisable(SYS_DMA_CHANNEL_HANDLE handle)

SYS_DMA_ChannelEnable Function

Enables a channel.

File

sys_dma.h

C

```
void SYS_DMA_ChannelEnable(SYS_DMA_CHANNEL_HANDLE handle);
```

Returns

None.

Description

This function enables a channel.

Remarks

This function may not required to be called when starting DMA setup (by SYS_DMA_ChannelSetup) and transfer Add (by SYS_DMA_ChannelTransferAdd). But may be needed to be called in the registered callback to enable the channel and continue the data transfer with the existing transfer parameters previously set with 'SYS_DMA_ChannelTransferAdd'. The DMA channel is by default disabled on the completion of block transfer(callback generated)

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize. DMA channel should have been allocated by calling SYS_DMA_ChannelAllocate. The function SYS_DMA_ChannelSetup must have been called to setup and enable the required features.

Example

```
// 'handle' is a valid handle returned
// by the SYS_DMA_ChannelAllocate function.

SYS_DMA_ChannelEnable(handle);
```

Parameters

Parameters	Description
handle	Handle of the DMA channel as returned by the SYS_DMA_ChannelAllocate function.

Function

void SYS_DMA_ChannelEnable(SYS_DMA_CHANNEL_HANDLE handle)

SYS_DMA_ChannelForceAbort Function

Force abort of transfer on the selected channel.

File

sys_dma.h

C

```
void SYS_DMA_ChannelForceAbort(SYS_DMA_CHANNEL_HANDLE handle);
```

Returns

None.

Description

The function aborts a DMA transfer to occur for the selected channel.

Remarks

This function must be used to abort the DMA transfer when the channel has been setup(by calling SYS_DMA_ChannelSetup) with the eventSrc as DMA_TRIGGER_SOURCE_NONE. and SYS_DMA_ChannelAbortEventSet has not been called.

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize. DMA channel should have been allocated by calling SYS_DMA_ChannelAllocate. The function SYS_DMA_ChannelSetup must have been called to setup and enable the required features. The function 'SYS_DMA_ChannelTransferAdd' to add a transfer.

Example

```
// 'handle' is a valid handle returned
// by the SYS_DMA_ChannelAllocate function.

// pDmaSrc, pDmaDst is the  source,destination address
// txferSrcSize, txferDesSize is the source,destination transfer size
// cellSize is the cell size

MY_APP_OBJ          myAppObj;
// Client registers an event handler with service. This is done once

SYS_DMA_ChannelTransferEventHandlerSet( handle, APP_DMATransferEventHandle,
```

```
                                    (uintptr_t)&myAppObj );

    SYS_DMA_ChannelSetup(handle, SYS_DMA_CHANNEL_OP_MODE_BASIC,
                                 DMA_TRIGGER_SOURCE_NONE);

    SYS_DMA_ChannelTransferAdd(handle,pDmaSrc,txferSrcSize,
                               pDmaDst,txferDesSize,cellSize);

    SYS_DMA_ChannelForceStart(handle);

    if(SYS_DMA_CHANNEL_HANDLE_INVALID == handle)
    {
        // Error handling here
    }

    ....
    ....
    // Client may need to abort a transfer
    SYS_DMA_ChannelForceAbort(handle);

    // Event Processing Technique. Event is received when
    // the transfer is processed.

    void APP_DMATransferEventHandle( SYS_DMA_TRANSFER_EVENT event,
            SYS_DMA_CHANNEL_HANDLE handle, uintptr_t contextHandle )
    {

        switch(event)
        {
            case SYS_DMA_TRANSFER_EVENT_ABORT:

                // This means the data was transferred.
                break;

            case SYS_DMA_TRANSFER_EVENT_ERROR:

                // Error handling here.

                if(SYS_DMA_ERROR_ADDRESS_ERROR == DRV_I2S_ErrorGet(myI2SHandle))
                {
                    // There was an address error.
                    // Do error handling here.
                }

                break;

            default:
                break;
        }
    }
```

Parameters

Parameters	Description
handle	Handle of the DMA channel as returned by the SYS_DMA_ChannelAllocate function.

Function

void SYS_DMA_ChannelForceAbort(SYS_DMA_CHANNEL_HANDLE handle)

SYS_DMA_ChannelForceStart Function

Force start of transfer on the selected channel.

File

sys_dma.h

C

```
void SYS_DMA_ChannelForceStart(SYS_DMA_CHANNEL_HANDLE handle);
```

Returns

None.

Description

The function force start a DMA transfer to occur for the selected channel.

Remarks

This function must be used to start the DMA transfer when the channel has been setup(by calling SYS_DMA_ChannelSetup) with the eventSrc as DMA_TRIGGER_SOURCE_NONE.

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize. DMA channel should have been allocated by calling SYS_DMA_ChannelAllocate. The function SYS_DMA_ChannelSetup must have been called to setup and enable the required features. The function 'SYS_DMA_ChannelTransferAdd' to add a transfer.

Example

```
// 'handle' is a valid handle returned
// by the SYS_DMA_ChannelAllocate function.

// pDmaSrc, pDmaDst is the  source,destination address
// txferSrcSize, txferDesSize is the source,destination transfer size
// cellSize is the cell size
MY_APP_OBJ          myAppObj;
// Client registers an event handler with service. This is done once

SYS_DMA_ChannelTransferEventHandlerSet( handle, APP_DMATransferEventHandle,
                                (uintptr_t)&myAppObj );

SYS_DMA_ChannelSetup(handle, SYS_DMA_CHANNEL_OP_MODE_BASIC,
                             DMA_TRIGGER_SOURCE_NONE);

SYS_DMA_ChannelTransferAdd(handle,pDmaSrc,txferSrcSize,
                           pDmaDst,txferDesSize,cellSize);

SYS_DMA_ChannelForceStart(handle);

if(SYS_DMA_CHANNEL_HANDLE_INVALID == handle)
{
    // Error handling here
}

// Event Processing Technique. Event is received when
// the transfer is processed.

void APP_DMATransferEventHandle( SYS_DMA_TRANSFER_EVENT event,
        SYS_DMA_CHANNEL_HANDLE handle, uintptr_t contextHandle )
{

    switch(event)
    {
        case SYS_DMA_TRANSFER_EVENT_COMPLETE:

            // This means the data was transferred.
            break;

        case SYS_DMA_TRANSFER_EVENT_ERROR:

            // Error handling here.

            if(SYS_DMA_ERROR_ADDRESS_ERROR == DRV_I2S_ErrorGet(myI2SHandle))
            {
                // There was an address error.
                // Do error handling here.
            }

            break;
```

```
            default:
                break;
        }
    }
```

Parameters

Parameters	Description
handle	Handle of the DMA channel as returned by the SYS_DMA_ChannelAllocate function.

Function

void SYS_DMA_ChannelForceStart(SYS_DMA_CHANNEL_HANDLE handle)

SYS_DMA_ChannelIsBusy Function

Returns the busy status of the specified DMA channel.

File

sys_dma.h

C

```
bool SYS_DMA_ChannelIsBusy(SYS_DMA_CHANNEL_HANDLE handle);
```

Returns

bool - true, if the selected DMA channel is active or enabled

- false, if the selected DMA channel is inactive or disabled

Description

This function returns the busy status of the selected DMA channel

Remarks

This feature may not be available on all devices. Refer to the specific device data sheet to determine availability.

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize. DMA channel should have been allocated by calling SYS_DMA_ChannelAllocate.

Example

```
bool                        busyStat;

busyStat    = SYS_DMA_ChannelGetBusy(handle);
```

Parameters

Parameters	Description
handle	Handle of the DMA channel as returned by the SYS_DMA_ChannelAllocate function.

Function

bool SYS_DMA_ChannelIsBusy(SYS_DMA_CHANNEL_HANDLE handle)

SYS_DMA_ChannelRelease Function

Deallocates and frees the channel specified by the handle.

File

sys_dma.h

C

```
void SYS_DMA_ChannelRelease(SYS_DMA_CHANNEL_HANDLE handle);
```

Returns

None.

Description

This function deallocates an allocated-channel of the DMA module, invalidating the handle.

Remarks

After calling this routine, the handle passed in "handle" must not be used with any of the remaining service's routines. A new handle must be obtained by calling SYS_DMA_ChannelAllocate before the caller may use the service again

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize. DMA channel should have been allocated by calling SYS_DMA_ChannelAllocate

Example

```
DMA_CHANNEL channel;
SYS_DMA_CHANNEL_HANDLE handle;

channel = DMA_CHANNEL_2;
handle = SYS_DMA_ChannelAllocate(channel);
SYS_DMA_ChannelRelease(handle);
```

Parameters

Parameters	Description
handle	A valid allocated-channel handle, returned from the service's Allocate routine

Function

void SYS_DMA_ChannelRelease(SYS_DMA_CHANNEL_HANDLE handle)

SYS_DMA_ChannelSetupMatchAbortMode Function

Setup the pattern match abort mode.

File

sys_dma.h

C

```
void SYS_DMA_ChannelSetupMatchAbortMode(SYS_DMA_CHANNEL_HANDLE handle, uint16_t pattern, DMA_PATTERN_LENGTH
length, SYS_DMA_CHANNEL_IGNORE_MATCH ignore, uint8_t ignorePattern);
```

Returns

None.

Description

This function sets up the termination of DMA operation when the specified pattern is matched. Additionally on supported parts the function also sets up the ignoring of part of a pattern(8-bit) from match abort pattern(16-bit).

Remarks

The parameter 'pattern' (8-bit or 16-bit) is device-specific. Not all features are available on all devices. Refer to the specific device data sheet for details.

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize. DMA channel should have been allocated by calling SYS_DMA_ChannelAllocate. The function SYS_DMA_ChannelSetup must be called to enable SYS_DMA_CHANNEL_OP_MODE_MATCH_ABORT before setting up pattern match mode features.

Example

```
// Example 1
// The following code is for a device with an 8-bit pattern value and no
// support for pattern match ignore feature

// 'handle' is a valid handle returned
// by the SYS_DMA_ChannelAllocate function.
uint16_t                        pattern;
DMA_PATTERN_LENGTH              length;
SYS_DMA_CHANNEL_IGNORE_MATCH    ignore;
uint8_t                         ignorePattern;
```

```
pattern         = 0x00; //Stop transfer on detection of a NULL character
length          = DMA_PATTERN_LENGTH_NONE;
ignore          = SYS_DMA_CHANNEL_IGNORE_MATCH_DISABLE;
ignorePattern   = 0;
SYS_DMA_ChannelSetupMatchAbortMode(handle, pattern, length,
                                   ignoreEnable, ignorePattern);

// Example 2
// The following code is for a device with a 16-bit pattern value and
// support for pattern match ignore feature

// 'handle' is a valid handle returned
// by the SYS_DMA_ChannelAllocate function.
uint16_t                        pattern;
DMA_PATTERN_LENGTH              length;
SYS_DMA_CHANNEL_IGNORE_MATCH    ignore;
uint8_t                         ignorePattern;

pattern         = 0x0D0A; //Stop transfer on detection of 'rn'
length          = DMA_PATTERN_MATCH_LENGTH_2BYTES;
ignore          = SYS_DMA_CHANNEL_IGNORE_MATCH_ENABLE;
ignorePattern   = 0x00; \ Any null character between the termination pattern
                        \ 'r' and 'n' is ignored.
SYS_DMA_ChannelSetupMatchAbortMode(handle, pattern, length,
                                       ignore, ignorePattern);
```

Parameters

Parameters	Description
handle	Handle of the DMA channel as returned by the SYS_DMA_ChannelAllocate function.
pattern	The pattern that needs to be matched to abort a DMA transfer.
length	Match pattern length can be 1-byte or 2-byte.
ignore	Enable/Disable a byte between a 2-byte pattern match.
ignorePattern	The part of the pattern(8-bit) that needs to be ignored from the match abort pattern(16-bit)

Function

void SYS_DMA_ChannelSetupMatchAbortMode

(

SYS_DMA_CHANNEL_HANDLE handle,

uint16_t pattern,

DMA_PATTERN_LENGTH length,

SYS_DMA_CHANNEL_IGNORE_MATCH ignore,

uint8_t ignorePattern

)

SYS_DMA_ChannelTransferAdd Function

Adds a data transfer to a DMA channel and Enables the channel to start data transfer.

File

sys_dma.h

C

```
void SYS_DMA_ChannelTransferAdd(SYS_DMA_CHANNEL_HANDLE handle, const void * srcAddr, size_t srcSize, const
void * destAddr, size_t destSize, size_t cellSize);
```

Returns

None.

Description

This function adds a data transfer characteristics for a DMA channel. The The source and the destination addresses, source and destination lengths, The number of bytes transferred per cell event are set. It also enables the channel to start data transfer.

If the requesting client registered an event callback with the service, the service will issue a SYS_DMA_TRANSFER_EVENT_COMPLETE or

SYS_DMA_TRANSFER_EVENT_ABORT event if the transfered was processed successfully of SYS_DMA_TRANSFER_EVENT_ERROR event if the transfer was not processed successfully.

Remarks

For PIC32MZ series of devices, if the source/destination addresses are RAM memory addresses, the the source/destination buffers should be made coherent to avoid the cache coherency issues. For example:

```
uint8_t buffer[1024];
// The buffer can be made coherent by adding the 'coherent' attribute, as follows:
uint8_t __attribute__((coherent)) __attribute__((aligned(16))) buffer[1024];
```

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize. DMA channel should have been allocated by calling SYS_DMA_ChannelAllocate. The function SYS_DMA_ChannelSetup must have been called to setup and enable the required features.

Example

```
// Add 10 bytes of data transfer to UART TX

// 'handle' is a valid handle returned
// by the SYS_DMA_ChannelAllocate function.
MY_APP_OBJ          myAppObj;
uint8_t             buf[10];
void                *srcAddr;
void                *destAddr;
size_t              srcSize;
size_t              destSize;
size_t              cellSize;

srcAddr     = (uint8_t *) buf;
srcSize     = 10;
destAddr    = (uin8_t*) &U2TXREG;
destSize    = 1;
cellSize    = 1;

// User registers an event handler with system service. This is done once

SYS_DMA_ChannelTransferEventHandlerSet(handle, APP_DMASYSTransferEventHandler,
                                                    (uintptr_t)&myAppObj);

SYS_DMA_ChannelTransferAdd(handle,srcAddr,srcSize,destAddr,destSize,cellSize);

if(SYS_DMA_CHANNEL_HANDLE_INVALID == handle)
{
    // Error handling here
}

// Event Processing Technique. Event is received when
// the transfer is processed.

void APP_DMASYSTransferEventHandler(SYS_DMA_TRANSFER_EVENT event,
        SYS_DMA_CHANNEL_HANDLE handle, uintptr_t contextHandle)
{
    switch(event)
    {
        case SYS_DMA_TRANSFER_EVENT_COMPLETE:

            // This means the data was transferred.
            break;

        case SYS_DMA_TRANSFER_EVENT_ERROR:

            // Error handling here.
            break;

        default:
            break;
    }
}
```

Parameters

Parameters	Description
handle	Handle of the DMA channel as returned by the SYS_DMA_ChannelAllocate function.
srcAddr	Source of the DMA transfer
srcSize	Size of the source
destAddr	Destination of the DMA transfer
destSize	Size of the destination
cellSize	Size of the cell

Function

void SYS_DMA_ChannelTransferAdd
(
SYS_DMA_CHANNEL_HANDLE handle,
const void *srcAddr, size_t srcSize
const void *destAddr, size_t destSize,
size_t cellSize
)

SYS_DMA_ChannelErrorGet Function

This function returns the error(if any) associated with the last client request.

File

sys_dma.h

C

```
SYS_DMA_ERROR SYS_DMA_ChannelErrorGet(SYS_DMA_CHANNEL_HANDLE handle);
```

Returns

A SYS_DMA_ERROR type indicating last known error status.

Description

This function returns the error(if any) associated with the last client request. If the service send a SYS_DMA_TRANSFER_EVENT_ERROR to the client, the client can call this function to know the error cause. The error status will be updated on every operation and should be read frequently (ideally immediately after the service operation has completed) to know the relevant error status.

Remarks

It is the client's responsibility to make sure that the error status is obtained frequently. The service will update the error status regardless of whether this has been examined by the client.

Preconditions

The SYS_DMA_Initialize routine must have been called for the DMA sub system. SYS_DMA_ChannelAllocate must have been called to obtain a valid opened channel handle.

Example

```
// 'handle' is a valid handle returned
// by the SYS_DMA_ChannelAllocate function.

// pDmaSrc, pDmaDst is the  source,destination address
// txferSrcSize, txferDesSize is the source,destination transfer size
// cellSize is the cell size
MY_APP_OBJ          myAppObj;
// Client registers an event handler with service. This is done once

SYS_DMA_ChannelTransferEventHandlerSet( handle, APP_DMATransferEventHandle,
                                (uintptr_t)&myAppObj );

SYS_DMA_ChannelSetup(handle, SYS_DMA_CHANNEL_OP_MODE_BASIC,
                             DMA_TRIGGER_SOURCE_NONE);

SYS_DMA_ChannelTransferAdd(handle,pDmaSrc,txferSrcSize,
```

```
                                pDmaDst,txferDesSize,cellSize);

    SYS_DMA_ChannelForceStart(handle);

    if(SYS_DMA_CHANNEL_HANDLE_INVALID == handle)
    {
        // Error handling here
    }

    // Event Processing Technique. Event is received when
    // the transfer is processed.

    void APP_DMATransferEventHandle( SYS_DMA_TRANSFER_EVENT event,
            SYS_DMA_CHANNEL_HANDLE handle, uintptr_t contextHandle )
    {

        switch(event)
        {
            case SYS_DMA_TRANSFER_EVENT_COMPLETE:

                // This means the data was transferred.
                break;

            case SYS_DMA_TRANSFER_EVENT_ERROR:

                // Error handling here.

                if(SYS_DMA_ERROR_ADDRESS_ERROR == SYS_DMA_ChannelErrorGet(handle))
                {
                    // There was an address error.
                    // Do error handling here.
                }

                break;

            default:
                break;
        }
    }
```

Parameters

Parameters	Description
handle	Handle of the DMA channel as returned by the SYS_DMA_ChannelAllocate function.

Function

SYS_DMA_ERROR SYS_DMA_ChannelErrorGet(SYS_DMA_CHANNEL_HANDLE handle)

SYS_DMA_ChannelTransferEventHandlerSet Function

This function allows a DMA system service client to set an event handler.

File

sys_dma.h

C

```
void SYS_DMA_ChannelTransferEventHandlerSet(SYS_DMA_CHANNEL_HANDLE handle, const
SYS_DMA_CHANNEL_TRANSFER_EVENT_HANDLER eventHandler, const uintptr_t contextHandle);
```

Returns

None.

Description

This function allows a client to set an event handler. The client may want to receive transfer related events in cases when it uses non-blocking read and write functions. The event handler should be set before the client intends to perform operations that could generate events.

This function accepts a contextHandle parameter. This parameter could be set by the client to contain (or point to) any client specific data object that should be associated with this DMA channel.

Remarks

None.

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize. DMA channel should have been allocated by calling SYS_DMA_ChannelAllocate.

Example

```
// 'handle' is a valid handle returned
// by the SYS_DMA_ChannelAllocate function.
MY_APP_OBJ          myAppObj;
uint8_t             buf[10];
void                *srcAddr;
void                *destAddr;
size_t              srcSize;
size_t              destSize;
size_t              cellSize;

srcAddr     = (uint8_t *) buf;
srcSize     = 10;
destAddr    = (uin8_t*) &U2TXREG;
destSize    = 1;
cellSize    = 1;
channelHandle = SYS_DMA_ChannelAllocate(channel);
// User registers an event handler with system service. This is done once

SYS_DMA_ChannelTransferEventHandlerSet(handle, APP_DMASYSTransferEventHandler,
                                                        (uintptr_t)&myAppObj);

SYS_DMA_ChannelTransferAdd(handle,srcAddr,srcSize,destAddr,destSize,cellSize);

if(SYS_DMA_CHANNEL_HANDLE_INVALID == handle)
{
    // Error handling here
}

// Event Processing Technique. Event is received when
// the transfer is processed.

void APP_DMASYSTransferEventHandler(SYS_DMA_TRANSFER_EVENT event,
        SYS_DMA_CHANNEL_HANDLE handle, uintptr_t contextHandle)
{
    switch(event)
    {
        case SYS_DMA_TRANSFER_EVENT_COMPLETE:

            // This means the data was transferred.
            break;

        case SYS_DMA_TRANSFER_EVENT_ERROR:

            // Error handling here.
            break;

        default:
            break;
    }
}
```

Parameters

Parameters	Description
handle	A valid channel handle, returned from the system service's Allocate routine
eventHandler	Pointer to the event handler function.
contextHandle	Value identifying the context of the application/driver/middleware that registered the event handling function.

Function

void SYS_DMA_ChannelTransferEventHandlerSet
(
SYS_DMA_CHANNEL_HANDLE handle,
const SYS_DMA_CHANNEL_TRANSFER_EVENT_HANDLER eventHandler,
const uintptr_t contextHandle
)

SYS_DMA_ChannelCRCGet Function

Returns the computed CRC.

File

sys_dma.h

C

```
uint32_t SYS_DMA_ChannelCRCGet();
```

Returns

uint32_t - The Computed CRC.

Description

This function returns the computed CRC

Remarks

To get the computed CRC value this function must be called after the block transfer completion event (i.e., after getting and processing the callback registered with SYS_DMA_ChannelTransferEventHandlerSet).

This feature may not be available on all devices. Refer to the specific device data sheet to determine availability.

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize. DMA channel should have been allocated by calling SYS_DMA_ChannelAllocate. The function SYS_DMA_ChannelSetup must be called to enable SYS_DMA_CHANNEL_OP_MODE_CRC before setting up the CRC mode. The CRC generator must have been previously setup using SYS_DMA_ChannelCRCSet.

Example

```
uint32_t                    computedCRC;

computedCRC     = SYS_DMA_ChannelCRCGet();
```

Function

uint32_t SYS_DMA_ChannelCRCGet(void)

SYS_DMA_ChannelCRCSet Function

Sets up the CRC operation mode.

File

sys_dma.h

C

```
void SYS_DMA_ChannelCRCSet(SYS_DMA_CHANNEL_HANDLE handle, SYS_DMA_CHANNEL_OPERATION_MODE_CRC crc);
```

Returns

None.

Description

This function sets up the CRC computation features.

Remarks

This feature may not be available on all devices. Refer to the specific device data sheet to determine availability.

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize. DMA channel should have been allocated by calling SYS_DMA_ChannelAllocate. The function SYS_DMA_ChannelSetup must be called to enable SYS_DMA_CHANNEL_OP_MODE_CRC before setting up the CRC mode.

Example

```
//Example 1
// DMA calculation using the CRC background mode

// 'handle' is a valid handle returned
// by the SYS_DMA_ChannelAllocate function.
SYS_DMA_CHANNEL_OPERATION_MODE_CRC  crc;

crc.type            = DMA_CRC_LFSR;
crc.mode            = SYS_DMA_CHANNEL_CRC_MODE_BACKGROUND;
crc.polyLength      = 16;
crc.bitOrder        = DMA_CRC_BIT_ORDER_LSB;
crc.byteOrder       = DMA_CRC_BYTEORDER_NO_SWAPPING;
crc.writeOrder      = SYS_DMA_CRC_WRITE_ORDER_MAINTAIN;
crc.data            = 0xFFFF;
crc.xorBitMask      = 0x1021;
SYS_DMA_ChannelCRCSet(handle, crc);
```

Parameters

Parameters	Description
handle	Handle of the DMA channel as returned by the SYS_DMA_ChannelAllocate function.
crc.type	CRC will calculate an IP header checksum or an LFSR CRC.
crc.mode	Compute the CRC in Background/Append mode.
crc.polyLength	Denotes the length of the polynomial.
crc.bitOrder	CRC is calculated LSb/MSb first.
crc.byteOrder	Byte selection order input pre-CRC Generator
crc.writeOrder	Write byte order selection post-CRC computation
crc.data	Computed/Seed CRC
crc.xorBitMask	Enable/Disable XOR bit mask on the corresponding bits when mode is LFSR

Function

void SYS_DMA_ChannelCRCSet

(

SYS_DMA_CHANNEL_HANDLE handle,

SYS_DMA_CHANNEL_OPERATION_MODE_CRC crc

)

SYS_DMA_ChannelSetup Function

Setup the DMA channel parameters.

File

sys_dma.h

C

```
void SYS_DMA_ChannelSetup(SYS_DMA_CHANNEL_HANDLE handle, SYS_DMA_CHANNEL_OP_MODE modeEnable,
DMA_TRIGGER_SOURCE eventSrc);
```

Returns

None.

Description

This function sets up the DMA channel parameters. It sets the channel priority and enables the mode of operations for the current system design.

Remarks

If SYS_DMA_CHANNEL_OP_MODE_MATCH_ABORT, SYS_DMA_CHANNEL_OP_MODE_CHAIN or SYS_DMA_CHANNEL_OP_MODE_CRC

mode of operation is enabled, then corresponding mode setup API's needs to be called to set the related parameters.

If the parameter 'eventSrc' is specified as DMA_TRIGGER_SOURCE_NONE then SYS_DMA_ChannelForceStart must be called to start the DMA channel transfer.

Not all features are available on all microcontrollers.

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize. DMA channel should have been allocated by calling SYS_DMA_ChannelAllocate.

Example

```
    // 'handle' is a valid handle returned
    // by the SYS_DMA_ChannelAllocate function.

SYS_DMA_CHANNEL_OP_MODE     modeEnable;
DMA_TRIGGER_SOURCE          eventSrc;

channel         =   DMA_CHANNEL_2;
modeEnable      =   (SYS_DMA_CHANNEL_OP_MODE_BASIC | SYS_DMA_CHANNEL_OP_MODE_CRC);
eventSrc        =   DMA_TRIGGER_USART_1_TRANSMIT;
 // Setup channel number, and enables basic and CRC mode
SYS_DMA_ChannelSetup(handle, modeEnable,eventSrc);
```

Parameters

Parameters	Description
handle	Handle of the DMA channel as returned by the SYS_DMA_ChannelAllocate function.
priority	The priority to be associated to the channel.
modeEnable	The supported operating modes to be enabled. This parameter can be logically ORed to specify multiple options.
eventSrc	The event causing the cell transfer start.

Function

void SYS_DMA_ChannelSetup

(

SYS_DMA_CHANNEL_HANDLE handle,

SYS_DMA_CHANNEL_OP_MODE modeEnable

DMA_TRIGGER_SOURCE eventSrc

)

SYS_DMA_ChannelDestinationTransferredSizeGet Function

Returns the number of bytes transferred to destination.

File

sys_dma.h

C

```
size_t SYS_DMA_ChannelDestinationTransferredSizeGet(SYS_DMA_CHANNEL_HANDLE handle);
```

Returns

size_t - Returns the number of bytes received from the submitted size.

Description

When a data transfer request is submitted. At any time while the transmission is in progress the size of the amount of data transferred to destination can be known by calling this function.

Remarks

None.

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize. DMA channel should have been allocated by calling SYS_DMA_ChannelAllocate. Data transfer should have been initiated by calling SYS_DMA_ChannelTransferAdd or SYS_DMA_ChannelTransferSet.

Example

```
// 'handle' is a valid handle returned
// by the SYS_DMA_ChannelAllocate function.
MY_APP_OBJ          myAppObj;
uint8_t             buf[10];
void                *srcAddr;
void                *destAddr;
size_t              srcSize;
size_t              destSize;
size_t              cellSize;
size_t              transferredSize;

srcAddr     = (uin8_t*) &U2RXREG;
srcSize     = 1;
destAddr    = (uint8_t *) buf ;
destSize    = 10;
cellSize    = 1;
channelHandle = SYS_DMA_ChannelAllocate(channel);
// User registers an event handler with system service. This is done once

SYS_DMA_ChannelTransferEventHandlerSet(handle, APP_DMASYSTransferEventHandler,
                                                    (uintptr_t)&myAppObj);

SYS_DMA_ChannelTransferAdd(handle,srcAddr,srcSize,destAddr,destSize,cellSize);

if(SYS_DMA_CHANNEL_HANDLE_INVALID == handle)
{
    // Error handling here
}

// The data is being transferred after adding the transfer to the DMA channel.
// The user can get to know dynamically the amount of data
// transmitted to destination by calling SYS_DMA_ChannelDestinationTransferredSizeGet
transferredSize = SYS_DMA_ChannelDestinationTransferredSizeGet(channelHandle);
```

Parameters

Parameters	Description
handle	A valid channel handle, returned from the system service's Allocate routine

Function

size_t SYS_DMA_ChannelDestinationTransferredSizeGet(SYS_DMA_CHANNEL_HANDLE handle)

SYS_DMA_ChannelSourceTransferredSizeGet Function

Returns the number of bytes transferred from source.

File

sys_dma.h

C

```
size_t SYS_DMA_ChannelSourceTransferredSizeGet(SYS_DMA_CHANNEL_HANDLE handle);
```

Returns

size_t - Returns the number of bytes transferred from the submitted size.

Description

When a data transfer request is submitted. At any time while the transmission is in progress the size of the amount of data transferred from source can be known by calling this function.

Remarks

None.

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize. DMA channel should have been allocated by calling

SYS_DMA_ChannelAllocate. Data transfer should have been initiated by calling SYS_DMA_ChannelTransferAdd or SYS_DMA_ChannelTransferSet.

Example

```
// 'handle' is a valid handle returned
// by the SYS_DMA_ChannelAllocate function.
MY_APP_OBJ          myAppObj;
uint8_t             buf[10];
void                *srcAddr;
void                *destAddr;
size_t              srcSize;
size_t              destSize;
size_t              cellSize;
size_t              transferredSize;

srcAddr     = (uint8_t *) buf;
srcSize     = 10;
destAddr    = (uin8_t*) &U2TXREG;
destSize    = 1;
cellSize    = 1;
channelHandle = SYS_DMA_ChannelAllocate(channel);
// User registers an event handler with system service. This is done once

SYS_DMA_ChannelTransferEventHandlerSet(handle, APP_DMASYSTransferEventHandler,
                                                    (uintptr_t)&myAppObj);

SYS_DMA_ChannelTransferAdd(handle,srcAddr,srcSize,destAddr,destSize,cellSize);

if(SYS_DMA_CHANNEL_HANDLE_INVALID == handle)
{
    // Error handling here
}

// The data is being transferred after adding the transfer to the DMA channel.
// The user can get to know dynamically the amount of data
// transmitted from source by calling SYS_DMA_ChannelSourceTransferredSizeGet
transferredSize = SYS_DMA_ChannelSourceTransferredSizeGet(channelHandle);
```

Parameters

Parameters	Description
handle	A valid channel handle, returned from the system service's Allocate routine

Function

size_t SYS_DMA_ChannelSourceTransferredSizeGet(SYS_DMA_CHANNEL_HANDLE handle)

SYS_DMA_ChannelTransferSet Function

Sets up a data transfer to a DMA channel.

File

sys_dma.h

C

```
void SYS_DMA_ChannelTransferSet(SYS_DMA_CHANNEL_HANDLE handle, const void * srcAddr, size_t srcSize, const
void * destAddr, size_t destSize, size_t cellSize);
```

Returns

None.

Description

This function sets up data transfer characteristics for a DMA channel. The The source and the destination addresses, source and destination lengths, The number of bytes transferred per cell event are set. This function does not enables the DMA channel. The channel has to be explicitly enabled to start the data transfer. The above functions could be used in situations where in the user intends to setup transfer parameters but do not intend to enable the channel immediately. For example to chain to DMA channels in a cyclic order where the channels remains disabled. The channel is enabled automatically by the DMA when the transfer trigger condition occurs.

Remarks

For PIC32MZ series of devices, if the source/destination addresses are RAM memory addresses, the the source/destination buffers should be made coherent to avoid the cache coherency issues. For example:

```
uint8_t buffer[1024];
// The buffer can be made coherent by adding the 'coherent' attribute, as follows:
uint8_t __attribute__((coherent)) __attribute__((aligned(16))) buffer[1024];
```

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize. DMA channel should have been allocated by calling SYS_DMA_ChannelAllocate. The function SYS_DMA_ChannelSetup must have been called to setup and enable the required features.

Example

```
// Set up 10 bytes of data transfer to UART TX

// 'handle' is a valid handle returned
// by the SYS_DMA_ChannelAllocate function.
MY_APP_OBJ          myAppObj;
uint8_t             buf[10];
void                *srcAddr;
void                *destAddr;
size_t              srcSize;
size_t              destSize;
size_t              cellSize;

srcAddr     = (uint8_t *) buf;
srcSize     = 10;
destAddr    = (uin8_t*) &U2TXREG;
destSize    = 1;
cellSize    = 1;

// User registers an event handler with system service. This is done once

SYS_DMA_ChannelTransferEventHandlerSet(handle, APP_DMASYSTransferEventHandler,
                                                        (uintptr_t)&myAppObj);

SYS_DMA_ChannelTransferSet(handle,srcAddr,srcSize,destAddr,destSize,cellSize);
SYS_DMA_ChannelEnable(handle);

if(SYS_DMA_CHANNEL_HANDLE_INVALID == handle)
{
    // Error handling here
}

// Event Processing Technique. Event is received when
// the transfer is processed.

void APP_DMASYSTransferEventHandler(SYS_DMA_TRANSFER_EVENT event,
        SYS_DMA_CHANNEL_HANDLE handle, uintptr_t contextHandle)
{
    switch(event)
    {
        case SYS_DMA_TRANSFER_EVENT_COMPLETE:

            // This means the data was transferred.
            break;

        case SYS_DMA_TRANSFER_EVENT_ERROR:

            // Error handling here.
            break;

        default:
            break;
    }
}
```

Parameters

Parameters	Description
handle	Handle of the DMA channel as returned by the SYS_DMA_ChannelAllocate function.
srcAddr	Source of the DMA transfer
srcSize	Size of the source
destAddr	Destination of the DMA transfer
destSize	Size of the destination
cellSize	Size of the cell

Function

void SYS_DMA_ChannelTransferSet
(
SYS_DMA_CHANNEL_HANDLE handle,
const void *srcAddr, size_t srcSize
const void *destAddr, size_t destSize,
size_t cellSize
)

c) Global Control and Status Functions

SYS_DMA_IsBusy Function

Returns the busy status of the DMA module.

File

sys_dma.h

C

```
bool SYS_DMA_IsBusy();
```

Returns

Boolean

- true - The DMA module is active
- false - The DMA module is inactive and disabled

```
bool busyStat;
busyStat = SYS_DMA_IsBusy();
```

Description

This function returns the busy status of the DMA module

Remarks

This feature may not be available on all devices. Refer to the specific device data sheet to determine availability.

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize.

Function

bool SYS_DMA_IsBusy(void)

SYS_DMA_Resume Function

Resume DMA operations.

File

sys_dma.h

C

```
void SYS_DMA_Resume();
```

Returns

None.

Description

This function disables DMA suspend. It resumes the DMA operation suspended by calling SYS_DMA_Suspend. The DMA operates normally.

Remarks

None

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize.

Example

```
SYS_DMA_Resume();
```

Function

void SYS_DMA_Resume(void)

SYS_DMA_Suspend Function

Suspend DMA transfers.

File

sys_dma.h

C

```
void SYS_DMA_Suspend();
```

Returns

None.

Description

This function suspends DMA transfers to allow CPU uninterrupted access to data bus

Remarks

None

Preconditions

DMA should have been initialized by calling SYS_DMA_Initialize.

Example

```
SYS_DMA_Suspend();
```

Function

void SYS_DMA_Suspend(void)

d) Data Types and Constants

SYS_DMA_CHANNEL_CHAIN_PRIO Enumeration

Identifies the priority of chaining channel.

File

sys_dma.h

C

```
typedef enum {
  SYS_DMA_CHANNEL_CHAIN_PRIO_HIGH,
  SYS_DMA_CHANNEL_CHAIN_PRIO_LOW
} SYS_DMA_CHANNEL_CHAIN_PRIO;
```

Members

Members	Description
SYS_DMA_CHANNEL_CHAIN_PRIO_HIGH	Chain to channel higher in natural priority
SYS_DMA_CHANNEL_CHAIN_PRIO_LOW	Chain to channel lower in natural priority

Description

DMA Channel chaining priority

This data type identifies the priority of chaining channel.

Channel chaining priority identifies the channel that will be enabled on completion of block data transfer on the master channel.

Remarks

None.

SYS_DMA_CHANNEL_CRC_MODE Enumeration

Identifies the operation mode of the CRC module.

File

sys_dma.h

C

```
typedef enum {
  SYS_DMA_CHANNEL_CRC_MODE_BACKGROUND,
  SYS_DMA_CHANNEL_CRC_MODE_APPEND
} SYS_DMA_CHANNEL_CRC_MODE;
```

Members

Members	Description
SYS_DMA_CHANNEL_CRC_MODE_BACKGROUND	DMA reads the data from the source, passes it through the CRC module and writes it to the destination. the calculated CRC is left in the DCRCDATA register at the end of the block transfer.
SYS_DMA_CHANNEL_CRC_MODE_APPEND	DMA only feeds source data to the CRC module. it does not write source data to the destination address. When a block transfer complete or pattern abort event occur, The DMA writes the CRC value to the destination address

Description

DMA channel CRC mode

This data type identifies CRC operating mode. The CRC computation can be in background mode or append mode.

Remarks

None.

SYS_DMA_CHANNEL_OP_MODE Enumeration

Identifies the available DMA operating modes.

File

sys_dma.h

C

```
typedef enum {
  SYS_DMA_CHANNEL_OP_MODE_BASIC,
  SYS_DMA_CHANNEL_OP_MODE_MATCH_ABORT,
  SYS_DMA_CHANNEL_OP_MODE_CHAIN_HIGH,
  SYS_DMA_CHANNEL_OP_MODE_CHAIN_LOW,
  SYS_DMA_CHANNEL_OP_MODE_AUTO,
  SYS_DMA_CHANNEL_OP_MODE_CRC
} SYS_DMA_CHANNEL_OP_MODE;
```

Members

Members	Description
SYS_DMA_CHANNEL_OP_MODE_BASIC	The normal DMA operation mode. The DMA channel will transfer data from a source to a destination without CPU intervention
SYS_DMA_CHANNEL_OP_MODE_MATCH_ABORT	Pattern Match abort mode allows the user to end a transfer if data written during a transaction matches a specific pattern, as defined by the DCHxDAT register
SYS_DMA_CHANNEL_OP_MODE_CHAIN_HIGH	Channel chaining operating mode enhances the normal DMA channel operations. A channel(slave) can be chained to an adjacent channel(master). The slave channel will be enabled when a block transfer of the master channel completes. only one of the below two chaining priorities must be provided. Chaining priority High.
SYS_DMA_CHANNEL_OP_MODE_CHAIN_LOW	Chaining priority Low
SYS_DMA_CHANNEL_OP_MODE_AUTO	Auto enable operating mode allows a channel to be kept active, even if a block transfer completes or pattern match occurs. This prevents the user from having to re-enable the channel each time a block transfer completes.
SYS_DMA_CHANNEL_OP_MODE_CRC	CRC operating mode allows computation of 16, 32-bit CRC.

Description

DMA channel operation modes

This data type Identifies the available DMA operating modes.

The supported DMA modes are not mutually exclusive, but can be simultaneously operational.

Remarks

These supported DMA modes can be logically OR'd together. They are passed into the SYS_DMA_ChannelSetup function through the modeEnable parameter.

SYS_DMA_CHANNEL_OPERATION_MODE_CRC Structure

Defines the attributes for CRC operation mode.

File

sys_dma.h

C

```
typedef struct {
  DMA_CRC_TYPE type;
  SYS_DMA_CHANNEL_CRC_MODE mode;
  uint8_t polyLength;
  DMA_CRC_BIT_ORDER bitOrder;
  DMA_CRC_BYTE_ORDER byteOrder;
  SYS_DMA_CRC_WRITE_ORDER writeOrder;
  uint32_t data;
  uint32_t xorBitMask;
} SYS_DMA_CHANNEL_OPERATION_MODE_CRC;
```

Members

Members	Description
DMA_CRC_TYPE type;	CRC type (PLIB-level). Type Selection identifies whether the CRC module will calculate an IP header checksum or an LFSR CRC
SYS_DMA_CHANNEL_CRC_MODE mode;	CRC mode, Background or Append
uint8_t polyLength;	Polynomial length, This value is redundant when the selected CRC type is IP header checksum. When the CRC type is LFSR, Identifies the length of the polynomial.
DMA_CRC_BIT_ORDER bitOrder;	Bit order (PLIB-level). Identifies whether the CRC is computed LSb or MSb first
DMA_CRC_BYTE_ORDER byteOrder;	Byte order (PLIB-level). Identifies the byte selection order input pre-CRC Generator.
SYS_DMA_CRC_WRITE_ORDER writeOrder;	Post CRC Write order
uint32_t data;	CRC data feed: While enabling the CRC mode, this field gives the seed for the CRC computation. On block transfer complete or pattern match abort the field have the computed CRC.
uint32_t xorBitMask;	XOR bit mask, This value is redundant when the selected CRC type is IP header checksum. When the CRC type is LFSR, Identifies the XOR bit mask input to the shift register during CRC computation.

Description

DMA channel CRC mode

This data type defines the attributes for CRC operation mode.

Remarks

This feature may not be available on all devices. Refer to the specific device data sheet to determine availability.

SYS_DMA_CRC_WRITE_ORDER Enumeration

Identifies altering/maintaining write order post CRC computation.

File

sys_dma.h

C

```
typedef enum {
  SYS_DMA_CRC_WRITE_ORDER_MAINTAIN,
  SYS_DMA_CRC_WRITE_ORDER_CHANGE
} SYS_DMA_CRC_WRITE_ORDER;
```

Members

Members	Description
SYS_DMA_CRC_WRITE_ORDER_MAINTAIN	Source data is written to the destination unchanged regardless of the selected pre-CRC byte order.
SYS_DMA_CRC_WRITE_ORDER_CHANGE	Source data is written to the destination reordered according to the selected pre-CRC byte order.

Description

DMA channel CRC write order

This data type identifies write byte order selection post CRC computation.

Remarks

None.

SYS_DMA_TRANSFER_EVENT Enumeration

Enumeration of possible DMA System service events.

File

sys_dma.h

C

```
typedef enum {
  SYS_DMA_TRANSFER_EVENT_COMPLETE,
  SYS_DMA_TRANSFER_EVENT_ERROR,
  SYS_DMA_TRANSFER_EVENT_ABORT
} SYS_DMA_TRANSFER_EVENT;
```

Members

Members	Description
SYS_DMA_TRANSFER_EVENT_COMPLETE	Data was transferred successfully.
SYS_DMA_TRANSFER_EVENT_ERROR	Error while processing the request
SYS_DMA_TRANSFER_EVENT_ABORT	Data transfer was aborted.

Description

DMA System service Events

This data type provides an enumeration of all possible DMA System service events.

Remarks

None.

SYS_DMA_CHANNEL_HANDLE Type

Assigns the handle for requested channel.

File

sys_dma.h

C

```
typedef uintptr_t SYS_DMA_CHANNEL_HANDLE;
```

Description

DMA System Service Channel Handle

A channel handle value is returned by a call to the SYS_DMA_ChannelAllocate function. This handle is associated with the channel number that is used for data transfer and it allows the application to track the data transfer.

The channel handle once assigned to a client expires when the client calls SYS_DMA_ChannelRelease. exits.

Remarks

None.

SYS_DMA_CHANNEL_IGNORE_MATCH Enumeration

Enables/Disables the feature to ignore a byte between a 2-byte match abort pattern.

File

sys_dma.h

C

```
typedef enum {
  SYS_DMA_CHANNEL_IGNORE_MATCH_DISABLE,
  SYS_DMA_CHANNEL_IGNORE_MATCH_ENABLE
} SYS_DMA_CHANNEL_IGNORE_MATCH;
```

Members

Members	Description
SYS_DMA_CHANNEL_IGNORE_MATCH_DISABLE	Disabling the feature to ignore a byte between a 2-byte match abort pattern.
SYS_DMA_CHANNEL_IGNORE_MATCH_ENABLE	Enable the feature to ignore a byte between a 2-byte match abort pattern.

Description

DMA Channel ignore pattern match

This data type allows enabling/disabling the feature to ignore a byte between a 2-byte match abort pattern.

Remarks

This feature may not be available on all devices. Refer to the specific device data sheet to determine availability.

SYS_DMA_INIT Enumeration

Indicates the error information for the DMA System service.

File

sys_dma.h

C

```
typedef enum {
} SYS_DMA_INIT;
```

Description

DMA System service Error

This enumeration indicates the error information for the DMA System service.

Remarks

None.

SYS_DMA_SIDL Enumeration

Enable/Disable DMA operations in Idle mode.

File

sys_dma.h

C

```
typedef enum {
  SYS_DMA_SIDL_DISABLE,
  SYS_DMA_SIDL_ENABLE
} SYS_DMA_SIDL;
```

Members

Members	Description
SYS_DMA_SIDL_DISABLE	When the CPU enters idle mode, the DMA module continue operations
SYS_DMA_SIDL_ENABLE	When the CPU enters idle mode, the DMA module will discontinue operations

Description

DMA stop in idle mode

This data type allows enabling/disabling of DMA operations in idle mode.

Remarks

The field 'sidl' (in init data structure 'SYS_DMA_INIT') is enable/disable while initializing the DMA module by calling SYS_DMA_Initialize.

This feature may not be available on all devices. Refer to the specific device data sheet to determine availability.

SYS_DMA_CHANNEL_COUNT Macro

Identifies the maximum number of DMA channel handles to be defined.

File

sys_dma.h

C

```
#define SYS_DMA_CHANNEL_COUNT DMA_NUMBER_OF_CHANNELS
```

Description

DMA System Service Channel Count

This constant identifies the maximum number of DMA channel handles that should be defined.

Remarks

This value is derived from device-specific header files defined as part of the peripheral libraries.

SYS_DMA_CHANNEL_HANDLE_INVALID Macro

Defines an invalid channel handle.

File

sys_dma.h

C

```
#define SYS_DMA_CHANNEL_HANDLE_INVALID ((SYS_DMA_CHANNEL_HANDLE)(-1))
```

Description

DMA System Service Invalid Channel Handle

This is the definition of an invalid channel handle. An invalid buffer handle is returned by SYS_DMA_ChannelAllocate function if the channel number request was not successful.

Remarks

None.

Files

Files

Name	Description
sys_dma.h	DMA System Service.

Description

This section lists the source and header files used by the library.

sys_dma.h

DMA System Service.

Enumerations

	Name	Description
	SYS_DMA_CHANNEL_CHAIN_PRIO	Identifies the priority of chaining channel.
	SYS_DMA_CHANNEL_CRC_MODE	Identifies the operation mode of the CRC module.
	SYS_DMA_CHANNEL_IGNORE_MATCH	Enables/Disables the feature to ignore a byte between a 2-byte match abort pattern.
	SYS_DMA_CHANNEL_OP_MODE	Identifies the available DMA operating modes.
	SYS_DMA_CRC_WRITE_ORDER	Identifies altering/maintaining write order post CRC computation.
	SYS_DMA_INIT	Indicates the error information for the DMA System service.
	SYS_DMA_SIDL	Enable/Disable DMA operations in Idle mode.
	SYS_DMA_TRANSFER_EVENT	Enumeration of possible DMA System service events.

Functions

	Name	Description
	SYS_DMA_ChannelAbortEventSet	Sets an event source and enables cell transfer abort event for the same for the selected channel.
	SYS_DMA_ChannelAllocate	Allocates the specified DMA channel and returns a handle to it.
	SYS_DMA_ChannelCRCGet	Returns the computed CRC.
	SYS_DMA_ChannelCRCSet	Sets up the CRC operation mode.
	SYS_DMA_ChannelDestinationTransferredSizeGet	Returns the number of bytes transferred to destination.
	SYS_DMA_ChannelDisable	Disables a channel.
	SYS_DMA_ChannelEnable	Enables a channel.
	SYS_DMA_ChannelErrorGet	This function returns the error(if any) associated with the last client request.
	SYS_DMA_ChannelForceAbort	Force abort of transfer on the selected channel.
	SYS_DMA_ChannelForceStart	Force start of transfer on the selected channel.
	SYS_DMA_ChannelIsBusy	Returns the busy status of the specified DMA channel.
	SYS_DMA_ChannelRelease	Deallocates and frees the channel specified by the handle.
	SYS_DMA_ChannelSetup	Setup the DMA channel parameters.
	SYS_DMA_ChannelSetupMatchAbortMode	Setup the pattern match abort mode.
	SYS_DMA_ChannelSourceTransferredSizeGet	Returns the number of bytes transferred from source.
	SYS_DMA_ChannelTransferAdd	Adds a data transfer to a DMA channel and Enables the channel to start data transfer.
	SYS_DMA_ChannelTransferEventHandlerSet	This function allows a DMA system service client to set an event handler.
	SYS_DMA_ChannelTransferSet	Sets up a data transfer to a DMA channel.
	SYS_DMA_Initialize	Initializes and Enables the DMA Controller.
	SYS_DMA_IsBusy	Returns the busy status of the DMA module.
	SYS_DMA_Resume	Resume DMA operations.
	SYS_DMA_Suspend	Suspend DMA transfers.
	SYS_DMA_Tasks	Maintains the system service's state machine.
	SYS_DMA_TasksError	Maintains the system service's error state machine.
	SYS_DMA_TasksErrorISR	Maintains the system service's state machine and implements its ISR.
	SYS_DMA_TasksISR	Maintains the system service's state machine and implements its ISR.

Macros

	Name	Description
	SYS_DMA_CHANNEL_COUNT	Identifies the maximum number of DMA channel handles to be defined.
	SYS_DMA_CHANNEL_HANDLE_INVALID	Defines an invalid channel handle.

Structures

	Name	Description
	SYS_DMA_CHANNEL_OPERATION_MODE_CRC	Defines the attributes for CRC operation mode.

Types

	Name	Description
	SYS_DMA_CHANNEL_HANDLE	Assigns the handle for requested channel.

Description

DMA System Service Library Interface Definition

This file contains the interface definition for the DMA System Service. It provides a way to interact with the DMA subsystem to manage the data transfer between different peripherals and/or memory without intervention from the CPU.

File Name

sys_dma.h

Microchip Technology Inc.

File System Service Library

This section describes the File System Service Library.

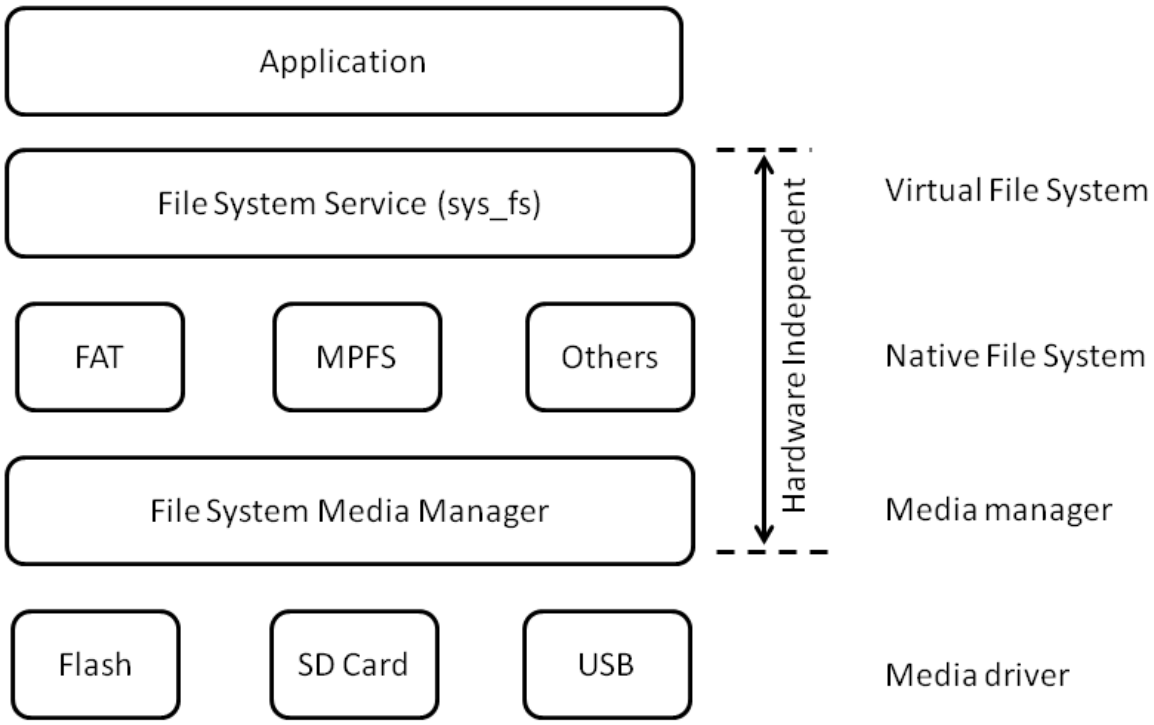
Introduction

Introduction to the MPLAB Harmony File System (FS).

Description

The MPLAB Harmony File System (FS) provides file system services to MPLAB Harmony based applications. The architecture of the File System Service is shown in the following figure.

File System Architecture



The File System Service provides an application programming interface (API) through which a utility or user program requests services of a file system. Some file system APIs may also include interfaces for maintenance operations, such as creating or initializing a file system and verifying the file system for integrity.

The File System service is really a framework designed to support multiple file systems (native file system) and multiple media in the same application. Examples of native file systems are FAT12,FAT16, FAT32, and the Microchip File System (MPFS) among others. MPFS is a read-only file system, which is used to store the files that do not change for example Web pages, images, etc. Each of these native file systems have a common set of APIs that can be used to access the files of that particular native file system.

The File System Service abstracts the native file system calls and provides a common interface to the user/application layer. For example, while the application layer requests for a file read or write from a disk, due to the presence of the this abstraction, the application need not be bothered about the native file system implemented on that disk. Instead, the application can call the read/write API of the File System, which in turn translates to the read/write command of the native file system used on the required disk.

This simplifies the implementation of the higher application layer and also provides a mechanism to add more native file system to the File System framework in the future.

Note: "File System Service" and "sys_fs" are synonymous.

File System Service Library Porting Guide

This section provides information for porting an existing File System (FS) application that uses legacy MLA code to MPLAB Harmony.

Description

Differences between the legacy MLA code and MPLAB Harmony are described and examples are provided in the following topics:

- Initialization
- System Configuration
- Mounting a Volume
- Opening a File
- Reading a File
- Writing a File
- Closing a File
- File EOF
- File Tell
- File Seek
- SYS_FS_Tasks

Comparison of API Names

This topic lists the API names for MLA versus the API name in MPLAB Harmony.

Description

API Name in MLA	API Name in MPLAB Harmony
N/A	SYS_FS_Mount
N/A	SYS_FS_Unmount
N/A	SYS_FS_FileError
FSInit	SYS_FS_Initialize
N/A	SYS_FS_Tasks
Fsfclose	SYS_FS_FileClose
Fsfeof	SYS_FS_FileEOF
FSfread	SYS_FS_FileRead
FSftell	SYS_FS_FileTell
FSfwrite	SYS_FS_FileWrite
N/A	SYS_FS_FileSize
wFSfopen	SYS_FS_FileOpen
N/A	SYS_FS_FileStat
FSfseek	SYS_FS_FileSeek

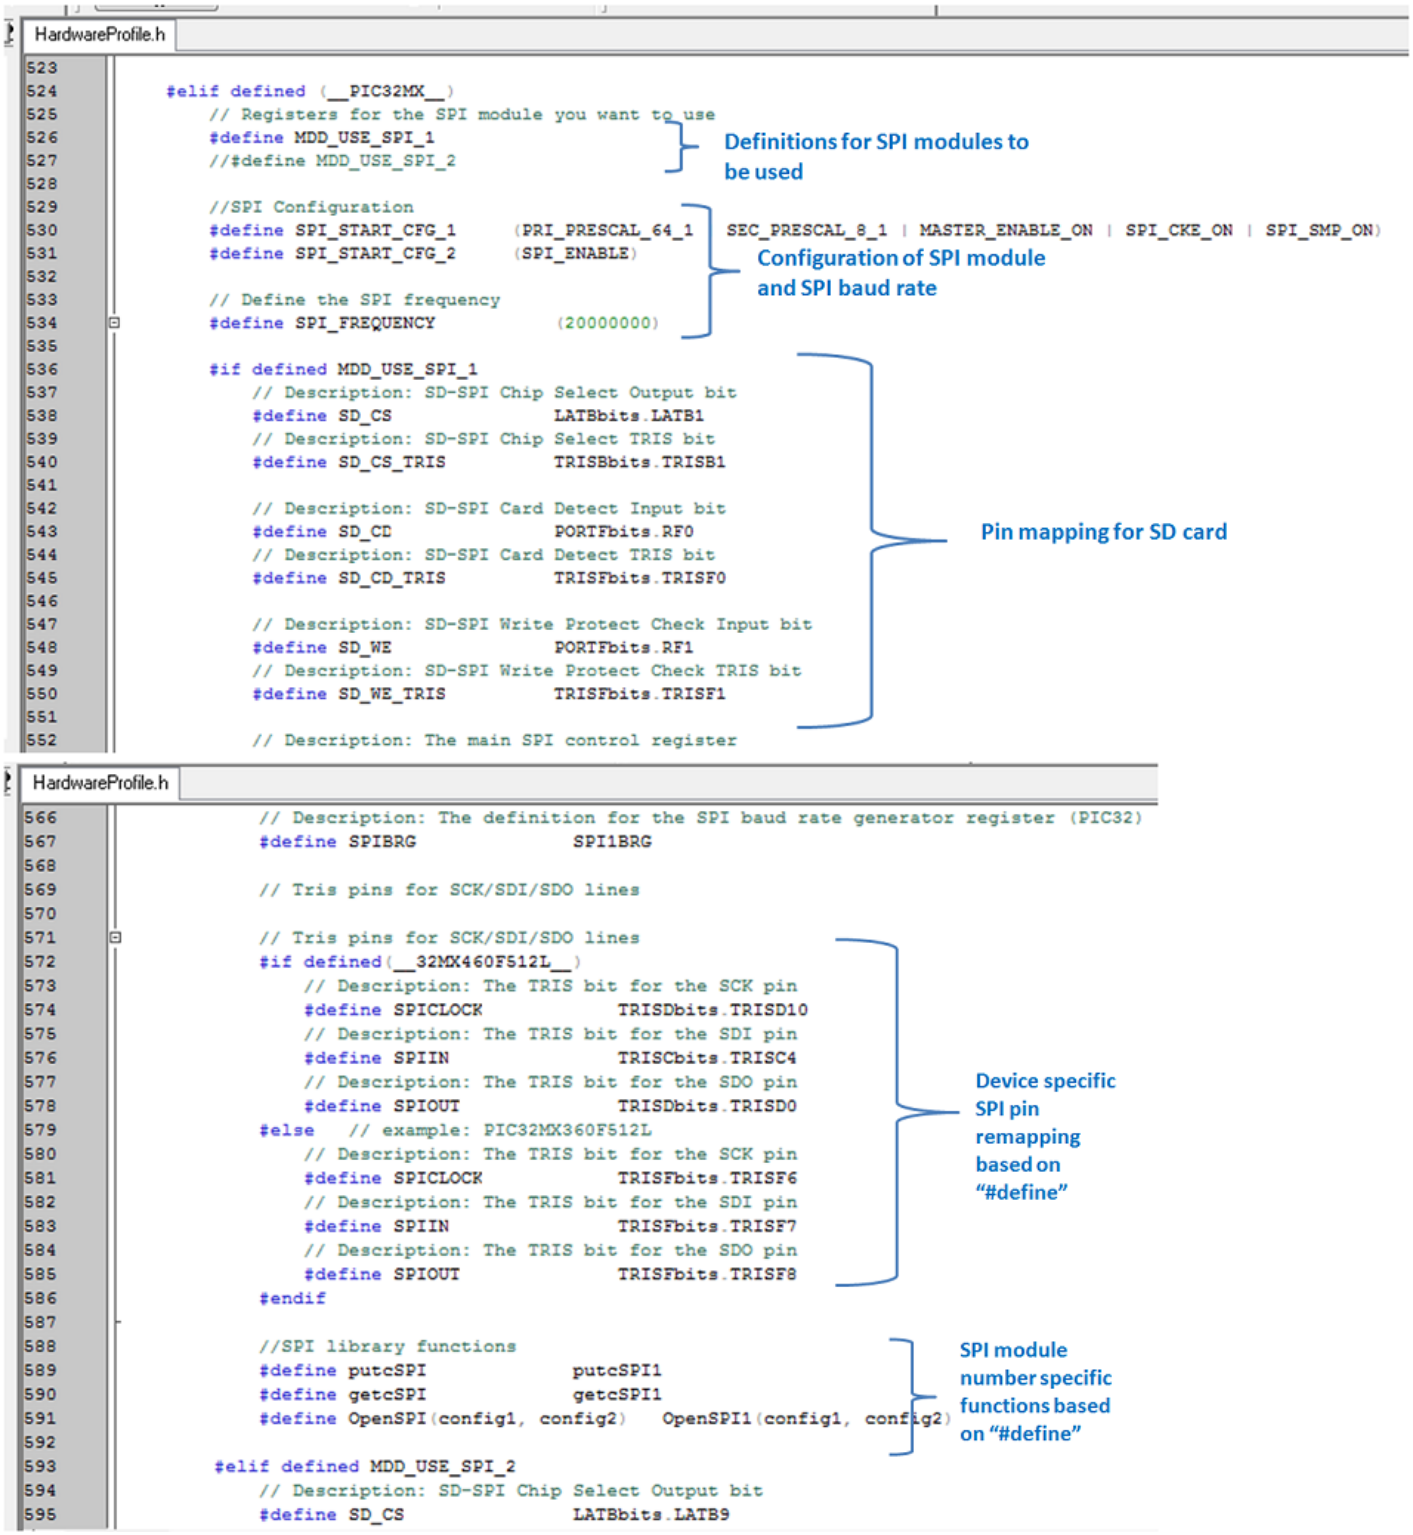
Initialization

This topic describes the differences in initialization.

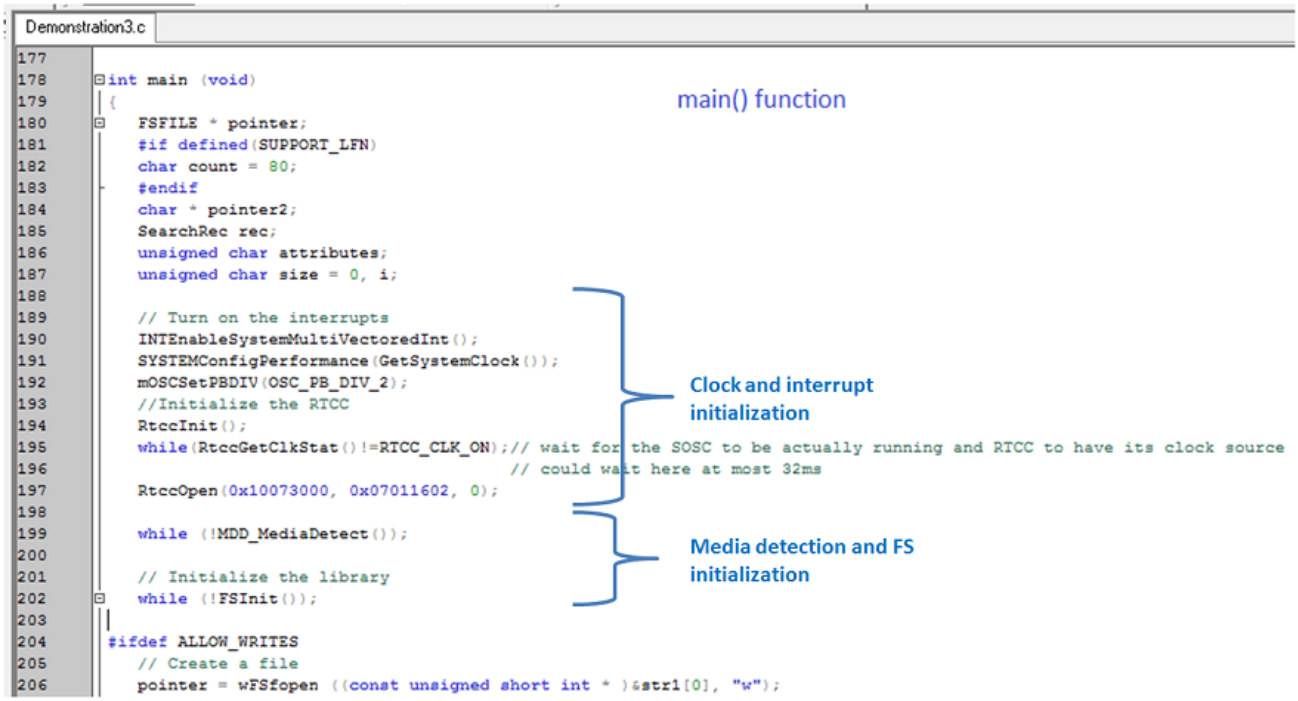
Description

MLA Initialization (Legacy code):

In legacy MLA code, the initialization involves modification of the header file `HardwareProfile.h`. The header file has definitions for the SPI modules used (SPI1 or SPI2), configuration for SPI module, clock frequency, pin mapping for SD card, and pin remapping for SPI (SDI, SDO and SCLK pins). The following two images illustrate these modifications.



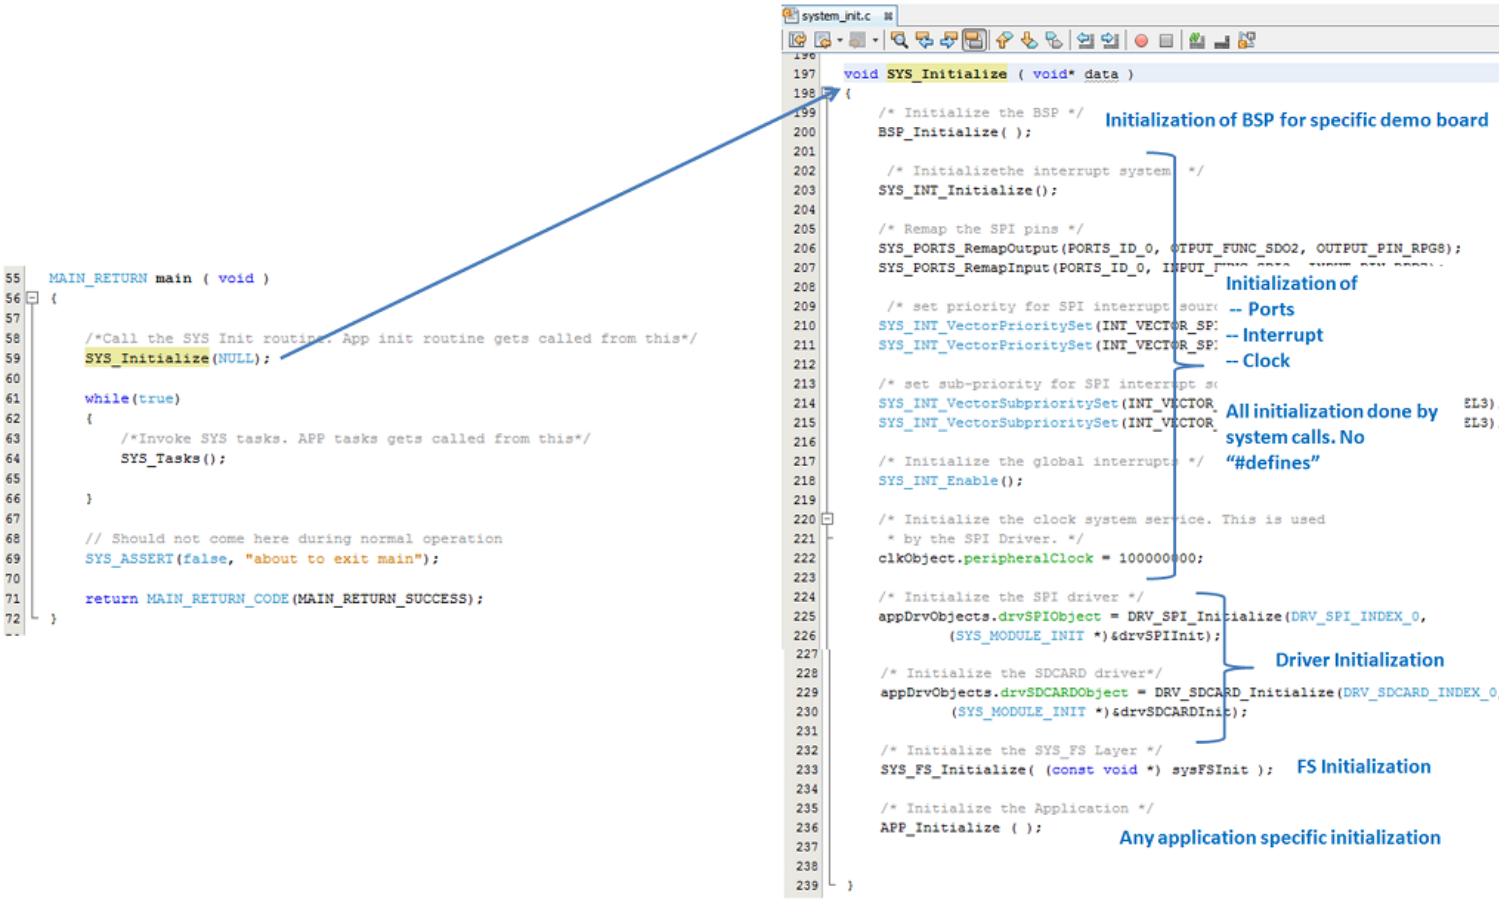
Inside the main function, the initialization of interrupts and the clock occurs in a series of function calls. Then, the media detect function is called for the media used. Later, the FS init function is called, which internally performs the disk mount, and if the mount process and FS initialization is successful, the functions returns as '1'.



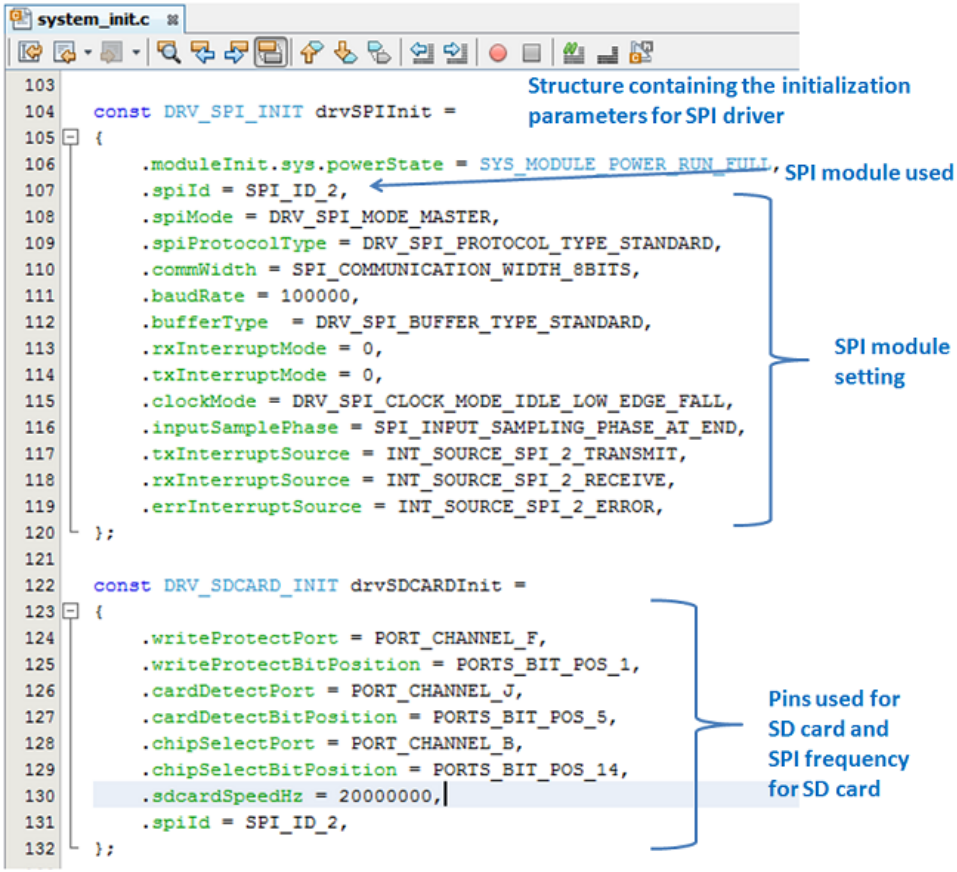
MPLAB Harmony Initialization:

In the case of MPLAB Harmony, the initialization is done by the SYS_Initialize function, which is called from the main function.

Inside the SYS_Initialize function, the BSP, interrupt, clock, port remapping, driver initialization, FS initialization and application-specific initialization is done. All initialization is done by calling specific system function calls, as shown in the following image. For more information, refer to the demonstration code provided as a part of the MPLAB Harmony release package.



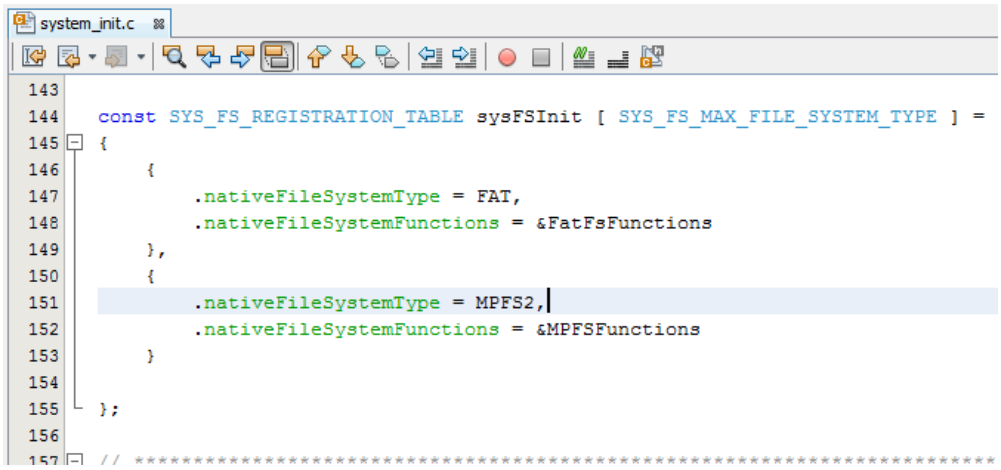
The SPI module selection and configuration of the SPI module is done through the SPI driver initialization structure. Similarly, the selection of pins related to SD card functionality and the selection of the SPI clock frequency is done through the SD card driver initialization structure. The initialization structures are passed as input parameters during driver initialization function calls. There are no `#define` used, as was done in the case of legacy MLA code.



```
const DRV_SPI_INIT drvSPIInit =
{
    .moduleInit.sys.powerState = SYS_MODULE_POWER_RUN_FULL,
    .spiId = SPI_ID_2,
    .spiMode = DRV_SPI_MODE_MASTER,
    .spiProtocolType = DRV_SPI_PROTOCOL_TYPE_STANDARD,
    .commWidth = SPI_COMMUNICATION_WIDTH_8BITS,
    .baudRate = 100000,
    .bufferType  = DRV_SPI_BUFFER_TYPE_STANDARD,
    .rxInterruptMode = 0,
    .txInterruptMode = 0,
    .clockMode = DRV_SPI_CLOCK_MODE_IDLE_LOW_EDGE_FALL,
    .inputSamplePhase = SPI_INPUT_SAMPLING_PHASE_AT_END,
    .txInterruptSource = INT_SOURCE_SPI_2_TRANSMIT,
    .rxInterruptSource = INT_SOURCE_SPI_2_RECEIVE,
    .errInterruptSource = INT_SOURCE_SPI_2_ERROR,
};

const DRV_SDCARD_INIT drvSDCARDInit =
{
    .writeProtectPort = PORT_CHANNEL_F,
    .writeProtectBitPosition = PORTS_BIT_POS_1,
    .cardDetectPort = PORT_CHANNEL_J,
    .cardDetectBitPosition = PORTS_BIT_POS_5,
    .chipSelectPort = PORT_CHANNEL_B,
    .chipSelectBitPosition = PORTS_BIT_POS_14,
    .sdcardSpeedHz = 20000000,
    .spiId = SPI_ID_2,
};
```

Since MPLAB Harmony supports multiple file systems, there is a structure which needs to be defined and then passed as an input parameter to the SYS_FS_Init function.



```
const SYS_FS_REGISTRATION_TABLE sysFSInit [ SYS_FS_MAX_FILE_SYSTEM_TYPE ] =
{
    {
        .nativeFileSystemType = FAT,
        .nativeFileSystemFunctions = &FatFsFunctions
    },
    {
        .nativeFileSystemType = MPFS2,
        .nativeFileSystemFunctions = &MPFSFunctions
    }

};

// ******************************************************************************
```

System Configuration

This topic describes differences in system configuration.

Description

system_config.h file in MPLAB Harmony:

The file `system_config.h` contains the various system configurations required to run an application. Examples of system configurations related to, but not limited to drivers are:

- SPI driver configuration: such as DRV_SPI_INSTANCES_NUMBER, DRV_SPI_CLIENTS_NUMBER, DRV_SPI_INTERRUPT_MODE, DRV_SPI_BUFFER_SIZE, etc.
- SD Card driver configuration: such as DRV_SDCARD_INSTANCES_NUMBER, DRV_SDCARD_CLIENTS_NUMBER, DRV_SDCARD_QUEUE_POOL_SIZE, etc.

These configurations are required to configure the drivers used for the FS. Since the driver concept was not present in the legacy MLA code, this is a new addition to MPLAB Harmony. To get detailed information about each of the configuration parameter, please refer to the specific driver

documentation.

Media manager configuration:

- SYS_FS_MEDIA_NUMBER - Number of media that will be used in the application. For example, if the application uses SD card and Mass storage device the SYS_FS_MEDIA_NUMBER should be defined as 2.
- SYS_FS_VOLUME_NUMBER - Number of volumes that will be used in the application. MPLAB Harmony supports multi-partitioned media. If the application uses a SD card that has three partitions and a Mass storage device, which has one partition, the SYS_FS_VOLUME_NUMBER should be defined as 4.
- Clock related configurations are present in the file, which are used to set the clock for the device

File system related configuration:

- SYS_FS_MAX_FILE_SYSTEM_TYPE - Number of native file system that will be used in the application. MPLAB Harmony supports multiple native file systems. If the application uses two file systems, FAT FS and MPFS2, SYS_FS_MAX_FILE_SYSTEM_TYPE should be defined as 2.
- SYS_FS_MAX_FILES - Maximum number of files that will be opened by the application at a time
- Other application-specific configuration settings

SYS_Tasks in MPLAB Harmony:

In the case of MPLAB Harmony, certain tasks need to be executed periodically. These tasks are executed from a common function called SYS_Tasks, which is in turn called from the main loop (while(1)) loop. While the concept of running certain functions from the main loop is not new, the legacy MLA demonstration code did not have any functions that had to run from the main loop. However, in case of MPLAB Harmony, it is mandatory that certain tasks should be running periodically from the main loop.

In the case of the FS application, tasks that have to run from SYS_Tasks function are:

- SYS_FS_Tasks - This task maintains the working of the SYS_FS layer and other file system related layers. It is extremely essential that this function runs periodically from the SYS_Tasks function.
- Driver task - Consider a case where the FS application uses a SD card; there is no hardware module that controls the SD card. In such a case, the task routine for the SD card must run from SYS_Tasks. This is required so that the internal driver mechanism for the SD card continues working.
- Any other application related task

system_tasks.c

```
88      Remarks:
89        When not using the dynamic system "Tasks" service, this routine must be
90        implemented by the application's system configuration (in the application's
91        configuration-specific "sys_tasks.c" file).
92    */
93
94  void SYS_Tasks ( void )
95  {
96      /* Task routine for sys_fs */
97      SYS_FS_Tasks();
98
99      /* Call the SDCARD Task */
100     DRV_SDCARD_Tasks(appDrvObjects.drvSDCARDObject);
101
102     /* Call the application's tasks routine */
103     APP_Tasks ( );
104
105 }
```

Mounting a Volume

This topic describes differences when mounting a volume.

Description

Mounting a Volume in MLA versus MPLAB Harmony:

In MLA, the complete mounting of a volume was achieved by calling the two functions, MDD_MediaDetect and FSInit, until the function returns success. The features of mounting a volume in MLA were:

- There are two functions that completely achieve the mounting process
- Both functions were of input type as "void" (no input argument)
- Both functions were called in blocking mode

```
193     //Initialize the RTCC
194     RtccInit();
195     while(RtccGetClkStat()!=RTCC_CLK_ON);// wait for the SOSC to be actually runni
196                                          // could wait here at most 32ms
197     RtccOpen(0x10073000, 0x07011602, 0);
198
199     while (!MDD_MediaDetect());
200
201     // Initialize the library
202     while (!FSInit());
203
204 #ifdef ALLOW_WRITES
205     // Create a file
206     pointer = wFSfopen ((const unsigned short int * )&str1[0], "w");
207     if (pointer == NULL)
208         while(1);
```

In MPLAB Harmony, the mounting of a volume is achieved by calling the SYS_FS_Mount function until the function returns success. The features of mounting a volume in MPLAB Harmony are:

- SYS_FS_Mount function includes both media detection and mounting the volume. Please note that, MPLAB Harmony FS still needs the function SYS_FS_Initialize to be called during system initialization. Though the name SYS_FS_Initialize seems similar to the MLA function FSInit, the task achieved by calling these functions are very different.
- SYS_FS_Initialize (MPLAB Harmony function) - Just does the initialization of SYS_FS layer. It does not do any mounting of volumes.
- FSInit (MLA function) - Did the initialization of FS and also did mount the disk.
- SYS_FS_Mount function accepts input parameter such as devName, mntName, fileSystemType, etc. To know each of the parameter in detail, pleas refer to the documentation of the SYS_FS_Mount function.
- SYS_FS_Mount has to be running in a non-blocking mode. The following image shows an application where SYS_FS_Mount is called from the state machine implementation. This is required as the implementation of the state machine allows the SYS_Tasks function to be run periodically. This is quite different from the earlier implementations of MLA.

```
140
141     switch(appData.state)
142     {
143         case APP_MOUNT_DISK:
144             if(SYS_FS_Mount("/dev/mmcblka1", "/mnt/myDrive", FAT, 0, NULL) != 0)
145             {
146                 /* The disk could not be mounted. Try
147                  * mounting again untill success. */
148
149                 appData.state = APP_MOUNT_DISK;
150             }
151             else
152             {
153                 /* Mount was successful. Unmount the disk, for testing. */
154
155                 appData.state = APP_UNMOUNT_DISK;
156             }
157             break;
```

Opening a File

This topic describes differences when opening a file.

Description

Opening a file in MLA versus MPLAB Harmony:

Opening a file remains similar for both MLA and MPLAB Harmony. However, a critical difference in MPLAB Harmony is that, while opening the file, the complete path of the file must be specified. In addition, the path must be preceded by the string `/mnt/`. The complete path is required because the MPLAB Harmony FS implements a multi-partition media support. Therefore, the file path should include the name of volume (assigned media partition), and from where the file is to be opened. For more details, please refer to the documentation of the SYS_FS_FileOpen function. The following two figures illustrate opening a file in MLA as opposed to MPLAB Harmony.

In MLA, the error in opening a file was indicated by the file open function returning a NULL, while, in MPLAB harmony, the file open returns SYS_FS_HANDLE_INVALID.

```
244 #endif
245
246     // Open file 1 in read mode
247     pointer = wFSfopen ((const unsigned short int * )&str1[0], "r");
248     if (pointer == NULL)
249         while(1);
250
251     if (wFSrename ((const unsigned short int * )&str3[0], pointer))
252         while(1);
253
254     // Read one four-byte object
255     if (FSfread (receiveBuffer, 4, 1, pointer) != 1)
256         while(1);
```

Figure 1: Opening a File in MLA

```
173
174         case APP_OPEN_FILE:
175
176             appData.fileHandle = SYS_FS_FileOpen("/mnt/myDrive/FILE_TOO_LONG_NAME_EXAMPLE_123.JPG",
177                     (SYS_FS_FILE_OPEN_READ));
178             if(appData.fileHandle == SYS_FS_HANDLE_INVALID)
179             {
180                 /* Could not open the file. Error out*/
181                 appData.state = APP_ERROR;
182             }
183             else
184             {
```

Figure 2: Opening a File in MPLAB Harmony

Reading a File

This topic describes the differences between legacy MLA code for FS and MPLAB Harmony FS, while reading a file.

Description

Reading a file in MLA versus MPLAB Harmony:

Reading a file remains similar for both MLA and MPLAB Harmony, as depicted in the following figures. The smaller differences are that, the name of the function to read the file is different, the order of parameters passed are different, and MPLAB Harmony only takes three parameters. The MPLAB Harmony function only enables byte based access.

Although both the MLA and MPLAB Harmony file read functions return the number of bytes read, the MPLAB Harmony functions also return '-1' if there were any errors while reading the file.

Demonstration3.c

```
253
254     // Read one four-byte object
255     if (FSfread (receiveBuffer, 4, 1, pointer) != 1)
256        while(1);
257
258     // Check if this is the end of the file- it shouldn't be
259     if (FSfeof (pointer))
```

Figure 1: Reading a File in MLA

Start Page | app.c | main.c

```
201
202             if(SYS_FS_FileRead((void *)appData.data, 512, appData.fileHandle) == -1)
203             {
204                 /* There was an error while reading the file.
205                  * Close the file and error out. */
206
207                 SYS_FS_FileClose(appData.fileHandle);
208                 appData.state = APP_ERROR;
209             }
```

Figure 2: Reading a File in MPLAB Harmony

Writing a File

This topic describes the differences between legacy MLA code for FS and MPLAB Harmony FS, while writing to a file.

Description

Writing to a file in MLA versus MPLAB Harmony:

Writing to a file remains similar for both MLA and MPLAB Harmony, as depicted in the following figures. The smaller differences are that the name of the function to write to the file is different, the order of parameters passed are different, and MPLAB Harmony only takes three parameters. The MPLAB Harmony function only enables byte based access.

Although both the MLA and MPLAB Harmony file read functions return the number of bytes written, the MPLAB Harmony functions also return '-1' if there were any errors while writing to the file.

```
Demonstration3.c  FSIO.h
208         while(1);
209
210     // Write 21 1-byte objects from sendBuffer into the file
211     if (FSfwrite (sendBuffer, 1, 21, pointer) != 21)
212         while(1);
213
```

Figure 1: Writing to a File in MLA

```
Start Page  app.c  main.c
212             /* If read was success, try writing to the new file */
213             if(SYS_FS_FileWrite((const void *)appData.data, 512, appData.fileHandle1) == -1)
214             {
215                 /* Write was not successful. Close the file
```

Figure 2: Writing to a File in MPLAB Harmony

Closing a File

This topic describes the differences between legacy MLA code for FS and MPLAB Harmony FS, while closing a file.

Description

Closing a file in MLA versus MPLAB Harmony:

Closing a file remains similar for both MLA and MPLAB Harmony, as depicted in the following figures. The smaller difference is that the name of the function is different.

```
Demonstration3.c  FSIO.h
227
228     // Close the file
229     if (FSfclose (pointer))
230         while(1);
231
```

Figure 1: Closing a File in MLA

```
Start Page  app.c  main.c
229             /* Close both files */
230             SYS_FS_FileClose(appData.fileHandle);
231             SYS_FS_FileClose(appData.fileHandle1);
232              /* The test was successful. Lets idle. */
```

Figure 2: Closing a File in MPLAB Harmony

File EOF

This topic describes the differences between legacy MLA code for FS and MPLAB Harmony FS, while checking for end of file.

Description

Checking for EOF in MLA versus MPLAB Harmony:

The EOF function remains similar for both MLA and MPLAB Harmony, as depicted in the following figures. The smaller difference is that the name of the function is different.

```
Demonstration3.c  FSIO.h
257
258     // Check if this is the end of the file- it shouldn't be
259     if (FSfeof (pointer))
260         while(1);
```

Figure 1: EOF in MLA

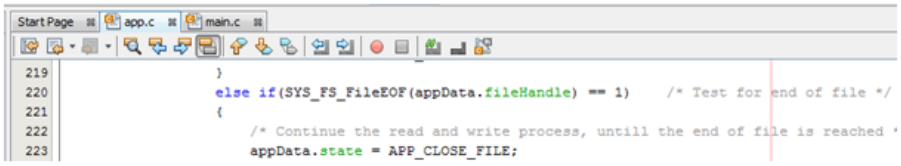


Figure 2: EOF in MPLAB Harmony

File Tell

This topic describes the differences between legacy MLA code for FS and MPLAB Harmony FS, while checking for file pointer (tell).

Description

Checking for file pointer (tell) in MLA versus MPLAB Harmony:

The function to check for file pointer (tell) remains similar for both MLA and MPLAB Harmony, as depicted in the following figures. The smaller difference is that the name of the function is different.

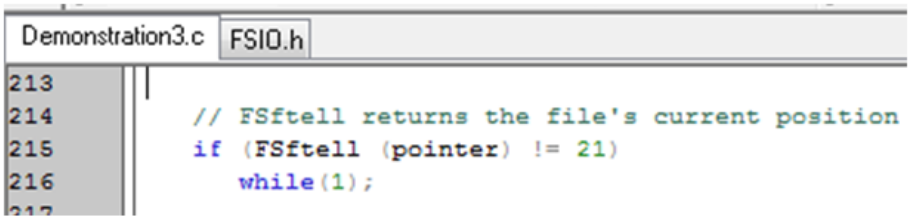

Figure 1: Tell Function in MLA

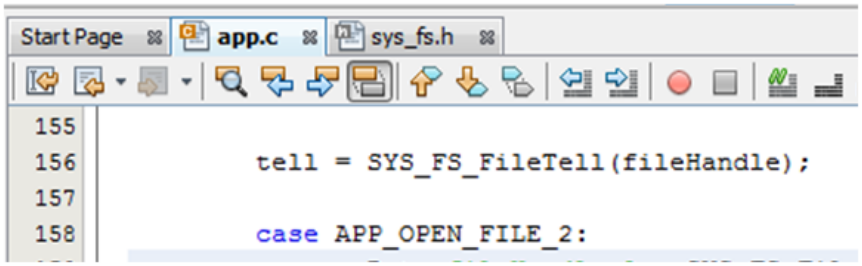

Figure 2: Tell Function in MLA Harmony

File Seek

This topic describes the differences between legacy MLA code for FS and MPLAB Harmony FS, while performing a file seek.

Description

File seek in MLA versus MPLAB Harmony:

The function to perform file seek remains similar for both MLA and MPLAB Harmony, as depicted in the following figures. The smaller difference is that the name of the function is different.

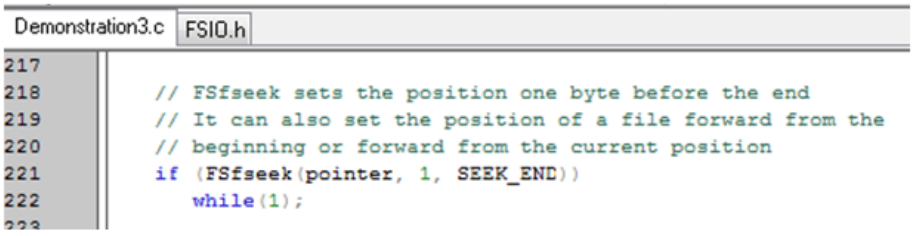

Figure 1: File Seek in MLA

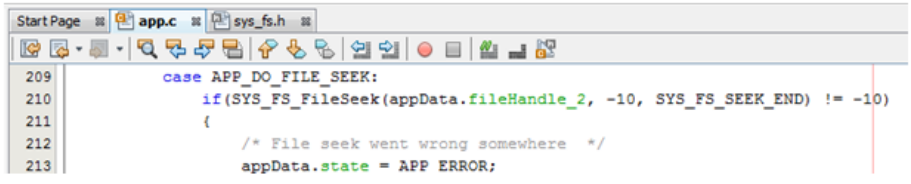

Figure 2: File Seek in MPLAB Harmony

SYS_FS_Tasks

This topic describes the differences between legacy MLA code for FS and MPLAB Harmony FS with respect to the SYS_FS_Tasks function.

Description

SYS_FS_Tasks in MLA Versus MPLAB Harmony:

MPLAB Harmony needs the SYS_FS_Tasks function to be running periodically from the SYS_Tasks function. The MLA code did not have any such function that had to be running periodically.

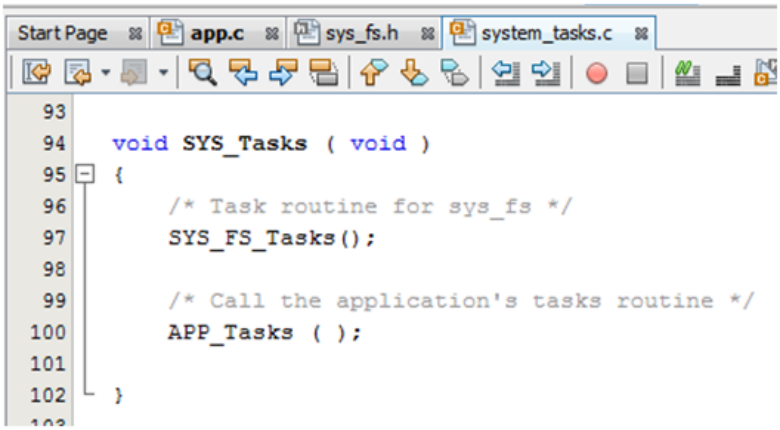

Figure 1: Running SYS_FS_Tasks Function from SYS_Tasks

Using the Library

This topic describes the basic architecture of the File System Service Library and provides information and examples on its use.

Description

Interface Header File: `sys_fs.h`

The interface to the File System Service library is defined in the `sys_fs.h` header file. This file is included by the system.h file. Any C language source (`.c`) file that uses the File System Service Library should include `system.h`.

Please refer to the What is MPLAB Harmony? section for how the File System Service interacts with the framework.

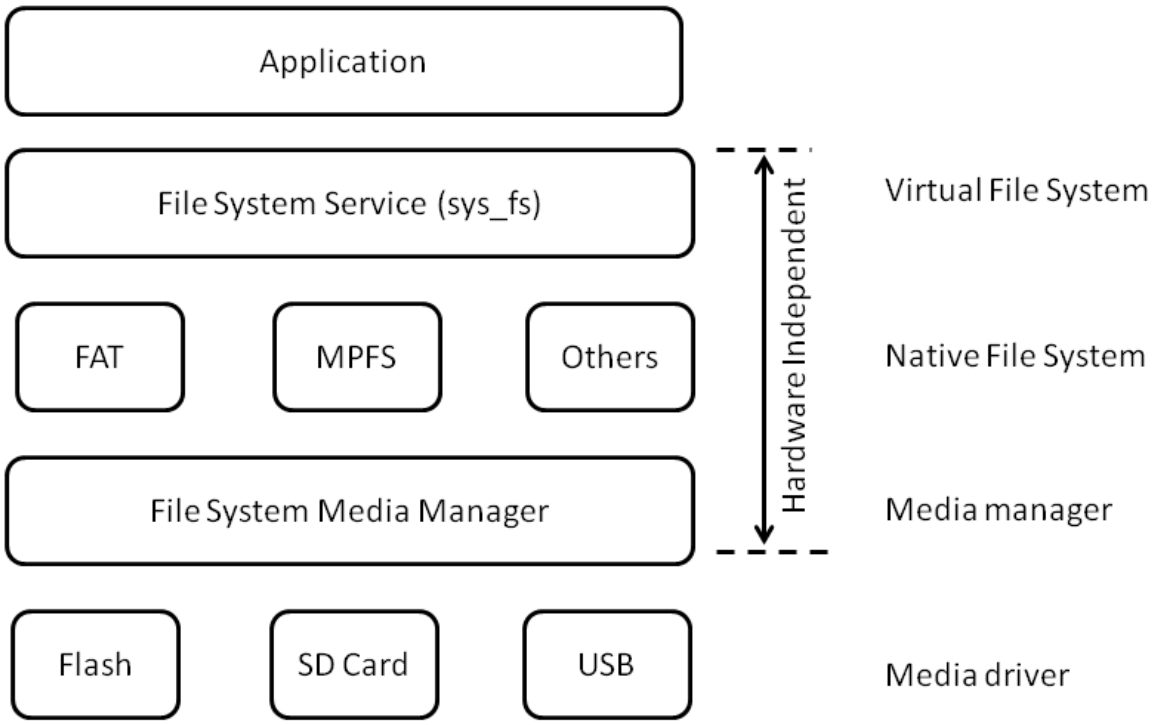
Abstraction Model

This topic describes the abstraction model of the MPLAB Harmony File System.

Description

The FS framework features a modular and layered architecture, as shown in the following figure.

FS Framework Architecture



As seen in the figure, the FS Framework consists of the following major blocks:

- The **Driver** for the physical media has to be included as a part of the FS Framework. This layer provides a low-level interface to access the physical media. This layer also enables multiple instances of media. Examples of drivers are:
- NVM driver – To access files using NVM (Flash memory)
- SPI driver – To access files from SD card, which interfaces using the SPI peripheral
- The **Media driver** provides a mechanism to access the media as "sectors". Sectors are the smallest storage element accessed by a file system and are contiguous memory locations. Typically, each sector has 512 bytes. Depending on the requirement, in some cases, the driver and media driver could be combined as one layer.
- The **Media manager** implements a disk and sector based media access mechanism. It also performs disk allocated/deallocated on media attach/detach. Due to the implementation of this layer, the FS Framework can support multiple disks. The media manager detects and analyzes a media based on its Master Boot Record (MBR). Therefore, it is mandatory for the media to have a MBR for it to work with the FS.
- The **Native file system** implements support for the media file system format. Examples of native file systems are: FAT12, FAT32, and MPFS, among other. At present, only the FAT and MPFS files systems are supported by the FS framework; however, more native file systems can be included.
- The **Virtual file system (or SYS_FS)** layer provides a file system independent file system operation interface. This layer translates virtual file systems calls to native file system calls. Due to this layer, applications can now support multiple file systems. Interfaces provided by this layer, but not limited to, include:
- SYS_FS_mount
- SYS_FS_open
- SYS_FS_read
- SYS_FS_write
- SYS_FS_close

Library Overview

Please refer to the System Service Introduction for a detailed description of MPLAB Harmony system services.

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the File System module.

Library Interface Section	Description
File and Directory Operation Functions	Provides file and directory operation interface routines.
General Operation Functions	Provides general operation interface routines.

How the Library Works

This topic provides information on how the MPLAB Harmony File System works.

Description

The MPLAB Harmony File System (FS) provides embedded application developers with a file system framework for retrieving and storing data from various media.

The MPLAB Harmony file system is designed to support multiple file systems (native file systems) and multiple media at the same time. Examples of native file systems are FAT12, FAT32, MPFS, and JFS, among others. Each of these native file systems has a common set of APIs that can be used to access the files of that particular native file system. The FS is a part of the MPLAB Harmony installation and is accompanied by demonstration applications that highlight usage. These demonstrations can also be modified or updated to build custom applications.

FS features include the following:

- Support for multiple file system (FAT, MPFS)
- Supports multiple physical media (NVM, SD card)
- More physical media can be interfaced with the FS, once the driver is available for the media
- Modular and Layered architecture

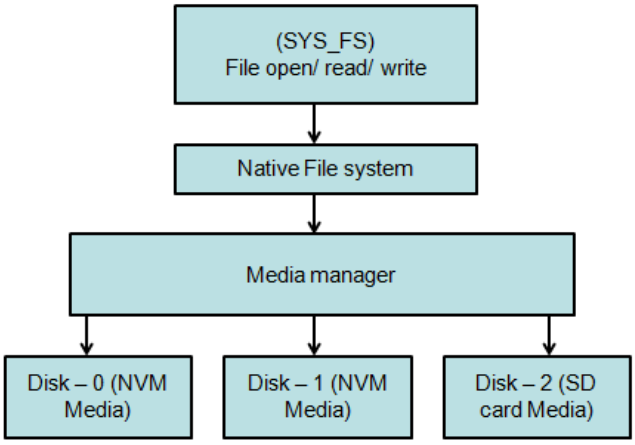
Application Interaction

This topic describes how an application must interact with the File System.

Description

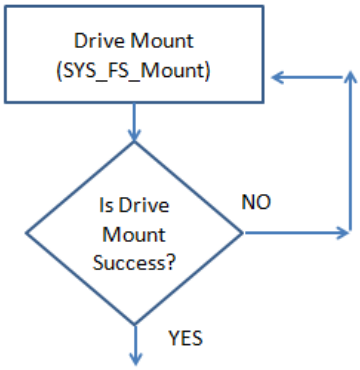
The interaction of various layers is shown in the following figure.

Application Interaction with FS Framework



In the process of using the FS Framework, the application must first **mount** the media drive for the FS Framework to access the media. Unless the mounting process returns successfully, the application should continue trying to mount the drive. If the drive is not attached, the mounting process will fail. In such a situation, the application should not proceed further unless the mounting is success.

Application Mounts a Drive

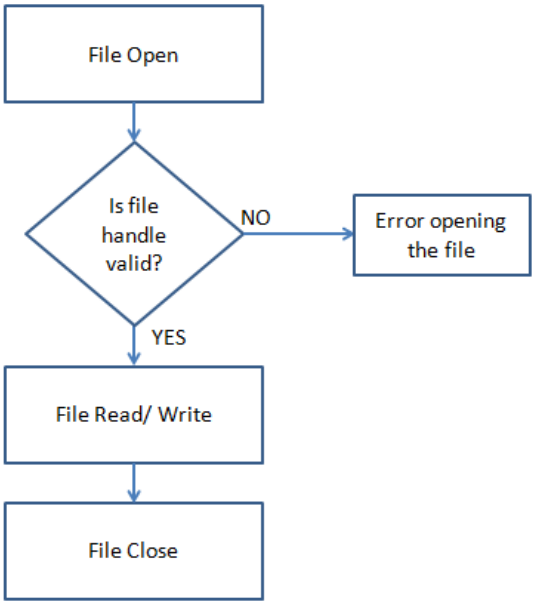


Once the drive is mounted, the application code can then **open the file** from the drive with different attributes (such as read-only or write). If the file open returns a valid handle, the application can proceed further. Otherwise, the application will enter an error state. The reason for an invalid

handle could be that the application was trying to read a file from the drive that does not exist. Another reason for an invalid handle is when the application tries to write to a drive that is write-protected.

Once the file is opened, the valid file handle is further used to **read/write** data to the file. Once the required operation is performed on the file, the file can then be **closed** by the application by passing the file handle. The following figure illustrates the process.

Further File System Operations



Using the File System

This topic describes how to use the File System.

Description

Use the Available Library Demonstration Applications

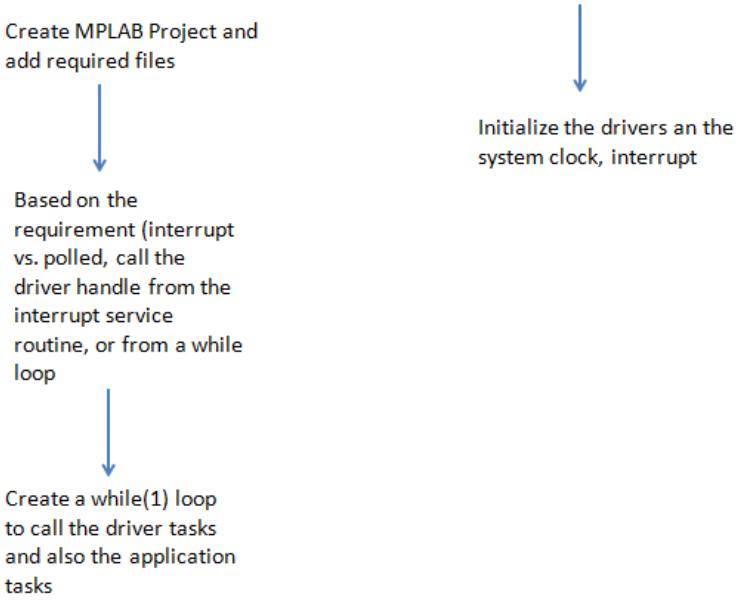
The FS framework release package contains a set of demonstration applications that are representative of common scenario (single/multi-media and single/multi-native file systems). These demonstrations can be easily modified to include application-specific initialization and application logic. The application logic must be non-blocking and could be implemented as a state machine.

- The application specific initialization can be called in the SYS_Initialize function (in the `system_init.c` file). The SYS_Initialize function is called when the device comes out of Power-on Reset (POR).
- The application logic can be called in the SYS_Tasks function (in the `system_tasks.c` file). The application logic can interact with the FS layer by using relevant API calls, as provided in the APP_Tasks (in the `app.c` file)

Building a FS Application from Scratch

In a case where the available demonstration applications do not meet the end application requirements, an application to use the FS framework can be created from scratch. The following figure shows a flowchart for the steps that need to be performed.

Steps to Create a FS Application



Step 1:

Create a MPLAB Project and add the required FS framework files to the project. The following files are needed to build the a FS project

- `system_config.h` - This file should contain the compile time configuration macros for the Driver, Media Layer, and FS layer. The file also contains the clock speed setting, which is set for the microcontroller.
- `system_init.c` – This file should contain the initial settings for each driver. It should also call the functions required to initialize different drivers to be used by the FS.
- `ff.c`, `diskio.c`, `mpfs.c`, `sys_fs.c`, `sys_fs_media_manager.c` – These files are part of the FS, which must be included in the project
- `sys_int_pic32.c` and `plib_int_pic32.c` - These files implement the system interrupt service that is required by the FS
- `sys_ports.c` – If the FS is using a SD card as media, this file needs to be included (for Chip Select)
- Driver – The driver for media to be used by FS should also be included
- Application specific files - These file will implement the application logic

Step 2:

Since the MPLAB Harmony drivers included with the File System operate in interrupt mode, a driver Handler should be defined as follows:

```
/* Use this for PIC32MX */
void __ISR ( _SPI1_VECTOR,ipl4 ) _InterruptHandler_SPI_stub ( void )
{
    DRV_SPI_Tasks((SYS_MODULE_OBJ)appDrvObjects.drvSPIObject);
}

/* Use this for PIC32MZ */
void __ISR ( _SPI2_RX_VECTOR,ipl4 ) _InterruptHandler_SPI_RX_stub ( void )
{
    DRV_SPI_Tasks((SYS_MODULE_OBJ)appDrvObjects.drvSPIObject);
}

void __ISR ( _SPI2_TX_VECTOR,ipl4 ) _InterruptHandler_SPI_TX_stub ( void )
{
    DRV_SPI_Tasks((SYS_MODULE_OBJ)appDrvObjects.drvSPIObject);
}
```

Step 3:

The application should create a `while(1)` loop that continuously updates the driver layer State Machine and the application state machine. This requires the application state machine to be non-blocking.

```
/* This while(1) loop will continuously update the driver layer state machine and the application state
machine */

while(1)
{
    /* Task routine for sys_fs */
    SYS_FS_Tasks();

    /* Call the SDCARD Task */
    DRV_SDCARD_Tasks(appDrvObjects.drvSDCARDObject);
```

```
    /* Call the application's tasks routine */
    APP_Tasks ( );

}
```

Step 4:

If interrupt-based operation is needed, the interrupts need to be enabled first. The application should then initialize the driver layer. Refer to the driver specific documentation regarding usage.

```
/* Initialize the interrupt system  */

SYS_INT_Initialize();

/* Initialize the global interrupts */
SYS_INT_Enable();

/* set priority for SPI interrupt source */
SYS_INT_VectorPrioritySet(INT_VECTOR_SPI1, INT_PRIORITY_LEVEL3);

/* set sub-priority for SPI interrupt source */
SYS_INT_VectorSubprioritySet(INT_VECTOR_SPI1, INT_SUBPRIORITY_LEVEL3);

/* Initialize the global interrupts */
SYS_INT_Enable();

/* Initialize the SPI driver */
appDrvObjects.drvSPIObject = DRV_SPI_Initialize(DRV_SPI_INDEX_0,
        (SYS_MODULE_INIT *)&drvSPIInit);

/* Initialize the SDCARD driver*/
appDrvObjects.drvSDCARDObject = DRV_SDCARD_Initialize(DRV_SDCARD_INDEX_0,
        (SYS_MODULE_INIT *)&drvSDCARDInit);
```

Step 5:

The application code can be implemented as a non-blocking state machine inside the APP_TASKS function, as shown in the following example for an application to read a file and write the content into another newly created file.

The input file `TEST.JPG` is not provided with the release package. It could be any arbitrary JPEG file chosen by the user, and then suitably renamed to `TEST.JPG`. The reason for choosing a JPEG file for test purposes is that the duplicate file `TEST1.JPG` created by the FS demonstration could be easily verified for correctness by inserting the SD card in the computer and opening the `TEST1.JPG` file.

```
void APP_Tasks ( void )
{
    /* The application task state machine */

    switch(appData.state)
    {
        case APP_MOUNT_DISK:
            if(SYS_FS_Mount("/dev/mmcblka1", "/mnt/myDrive", FAT, 0, NULL) != 0)
            {
                /* The disk could not be mounted. Try
                 * mounting again until success. */

                appData.state = APP_MOUNT_DISK;
            }
            else
            {
                /* Mount was successful. Open a file.
                 * Let the switch case fall through. */
                appData.state = APP_OPEN_FILE;
            }
            break;

        case APP_OPEN_FILE:

            appData.fileHandle = SYS_FS_FileOpen("/mnt/myDrive/TEST.JPG",
                    (FA_READ));
            if(appData.fileHandle == SYS_FS_HANDLE_INVALID)
            {
                /* Could not open the file. Error out*/
                appData.state = APP_ERROR;
            }
```

```
            else
            {
                appData.fileHandle1 = SYS_FS_FileOpen("/mnt/myDrive/TEST1.JPG",
                        (FA_WRITE|FA_CREATE_ALWAYS));
                if(appData.fileHandle == SYS_FS_HANDLE_INVALID)
                {
                    /* Could not open the file. Error out*/
                    appData.state = APP_ERROR;
                }
                else
                {
                    /* Check the file to be read */
                    appData.state = APP_CHECK_FILE;
                }
            }
            break;

        case APP_CHECK_FILE:
            /* check the size of file */
            fileSize = SYS_FS_FileSize(appData.fileHandle);
            /* since, we will read 512 bytes at a time, find the number of times, the read has to be
             performed */
            sectorCounter = integralSector = (fileSize/512);
            /* find the remaining bytes */
            balanceSector = (fileSize%512);

            appData.state = APP_READ_WRITE_TO_FILE;

            break;

        case APP_READ_WRITE_TO_FILE:

            if(SYS_FS_FileRead((void *)appData.data, 512, appData.fileHandle) == -1)
            {
                /* There was an error while reading the file.
                 * Close the file and error out. */

                SYS_FS_FileClose(appData.fileHandle);
                appData.state = APP_ERROR;
            }
            else if(SYS_FS_FileWrite((const void *)appData.data, 512, appData.fileHandle1) == -1)
            {
                /* Write was not successful. Close the file
                 * and error out.*/
                SYS_FS_FileClose(appData.fileHandle1);
                appData.state = APP_ERROR;
            }
            else
            {
                sectorCounter--;
                /* if entire integral sectors are written, write the balance sector*/
                if(sectorCounter == 0)
                {
                    if(SYS_FS_FileRead((void *)appData.data, balanceSector, appData.fileHandle) == -1)
                    {
                        /* There was an error while reading the file.
                         * Close the file and error out. */

                        SYS_FS_FileClose(appData.fileHandle);
                        appData.state = APP_ERROR;
                    }
                    else if(SYS_FS_FileWrite((const void *)appData.data, balanceSector,
appData.fileHandle1) == -1)
                    {
                        /* Write was not successful. Close the file
                         * and error out.*/
                        SYS_FS_FileClose(appData.fileHandle1);
                        appData.state = APP_ERROR;
                    }
```

```
                    else
                    {
                        appData.state = APP_CLOSE_FILE;
                    }
                }
            }
            break;

        case APP_CLOSE_FILE:
            /* Close both files */
            SYS_FS_FileClose(appData.fileHandle);
            SYS_FS_FileClose(appData.fileHandle1);
             /* The test was successful. Lets idle. */
            appData.state = APP_IDLE;
            break;

        case APP_IDLE:
            /* The application comes here when the demonstration
               has completed successfully. Switch on green LED. */
            BSP_SwitchONLED(LED_2);
            break;
        case APP_ERROR:
            /* The application comes here when the demonstration
               has failed. Switch on the red LED.*/
            BSP_SwitchONLED(LED_1);
            break;
        default:
            break;

    }

} //End of APP_Tasks
```

Configuring the Library

Lists and describes the library configuration macros.

Macros

	Name	Description
	SYS_FS_AUTOMOUNT_ENABLE	Enable/Disable Auto Mount Feature of File system
	SYS_FS_MAX_FILE_SYSTEM_TYPE	Number of file systems used in the application
	SYS_FS_MAX_FILES	Number of simultaneous files access
	SYS_FS_MEDIA_MAX_BLOCK_SIZE	Media Sector Size information
	SYS_FS_MEDIA_NUMBER	Number of media used in the application
	SYS_FS_VOLUME_NUMBER	This macro defines number of volumes used in the application

Description

The configuration of the File System Service is based on the file `system_config.h`.

This header file contains the configuration selection for the File System service. Based on the selections made, the File System Service may support the selected features. These configuration settings will apply to all instances of the File System Service.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

SYS_FS_AUTOMOUNT_ENABLE Macro

Enable/Disable Auto Mount Feature of File system

File

sys_fs_config_template.h

C

```
#define SYS_FS_AUTOMOUNT_ENABLE 1
```

Description

Enable/Disable Auto Mount Feature of File system

Enable/Disable Auto Mount Feature of File system

Remarks

None.

SYS_FS_MAX_FILE_SYSTEM_TYPE Macro

Number of file systems used in the application

File

sys_fs_config_template.h

C

```
#define SYS_FS_MAX_FILE_SYSTEM_TYPE 1
```

Description

Number of File system types

Number of fil systems used in the application

Remarks

None.

SYS_FS_MAX_FILES Macro

Number of simultaneous files access

File

sys_fs_config_template.h

C

```
#define SYS_FS_MAX_FILES 1
```

Description

Number of simultaneous files access

Number of simultaneous files access

Remarks

None.

SYS_FS_MEDIA_MAX_BLOCK_SIZE Macro

Media Sector Size information

File

sys_fs_config_template.h

C

```
#define SYS_FS_MEDIA_MAX_BLOCK_SIZE 512
```

Description

Media Sector Size information

Media Sector Size information

Remarks

None.

SYS_FS_MEDIA_NUMBER Macro

Number of media used in the application

File

sys_fs_config_template.h

C

```
#define SYS_FS_MEDIA_NUMBER 1
```

Description

Number of media used in the application

Number of media used in the application

Remarks

None.

SYS_FS_VOLUME_NUMBER Macro

This macro defines number of volumes used in the application

File

sys_fs_config_template.h

C

```
#define SYS_FS_VOLUME_NUMBER 1
```

Description

Number of Volumes

This macro defines the number of volumes used in the application

Remarks

None.

Building the Library

This section lists the files that are available in the File System Service Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/system/fs`.

Interface File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
/sys_fs.h	This file contains function and type declarations required to Interact with the MPLAB Harmony File System Framework.
/fat_fs/src/file_system/ff.h	FAT File System module include file. This file should be included when using the FAT File System.
/mpfs/mpfs.h	This file contains the interface definition for handling the Microchip File System (MPFS). This file should be included when using MPFS.

Required File(s)

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/dynamic/sys_fs.c	This file contains implementation of File System interfaces.
/src/dynamic/sys_fs_media_manager.c	This file contains implementation File System Media Manager functions.
/fat_fs/src/file_system/ff.c	This file implements the FAT File system functions. This file should be included when using FAT File System.
/fat_fs/src/hardware_access/diskio.c	Low-level disk I/O module for FAT File System. This file should be included when using FAT File System.
/mpfs/src/mpfs.c	This file implements the MPFS functions. This file should be included when using MPFS.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The File System Service Library depends on the following modules:

- NVM Driver Library (if media is NVM)
- Secure Digital (SD) Card Driver Library (if media is a SD Card)
- SPI Driver Library (if media is a SD Card)
- Device Control System Service Library
- Interrupt System Service Library
- Ports System Service Library
- Clock System Service Library

Library Interface

a) File and Directory Operation Functions

	Name	Description
	SYS_FS_FileClose	Closes a file.
	SYS_FS_FileEOF	Checks for end of file.
	SYS_FS_FileOpen	Opens a file.
	SYS_FS_FileSeek	Moves the file pointer by the requested offset.
	SYS_FS_FileSize	Returns the size of the file in bytes.
	SYS_FS_FileTell	Obtains the file pointer position.
	SYS_FS_FileNameGet	Reads the file name.
	SYS_FS_FilePrintf	Writes a formatted string into a file.
	SYS_FS_FileTestError	Checks for errors in the file.
	SYS_FS_FileDirectoryModeSet	Sets the mode for the file or directory.
	SYS_FS_FileDirectoryRemove	Removes a file or directory.
	SYS_FS_FileDirectoryRenameMove	Renames or moves a file or directory.
	SYS_FS_FileDirectoryTimeSet	Sets or changes the time for a file or directory.
	SYS_FS_FileTruncate	Truncates a file
	SYS_FS_FileCharacterPut	Writes a character to a file.
	SYS_FS_FileStringGet	Reads a string from the file into a buffer.
	SYS_FS_FileStringPut	Writes a string to a file.
	SYS_FS_Error	Returns the last error.
	SYS_FS_FileError	Returns the file specific error.
	SYS_FS_FileRead	Read data from the file.
	SYS_FS_FileWrite	Writes data to the file.
	SYS_FS_CurrentWorkingDirectoryGet	Gets the current working directory
	SYS_FS_DirectoryChange	Changes to a the directory specified.
	SYS_FS_DirectoryMake	Makes a directory.
	SYS_FS_DirClose	Closes an opened directory.

	SYS_FS_DirOpen	Open a directory
	SYS_FS_DirRead	Reads the specified directory.
	SYS_FS_DirSearch	Searches for a file or directory.
	SYS_FS_FileSync	Flushes the cached information when writing to a file.
	SYS_FS_DirRewind	Rewinds to the beginning of the directory.
	SYS_FS_FileStat	Gets file status.

b) General Operation Functions

	Name	Description
	SYS_FS_Initialize	Initializes the file system abstraction layer (sys_fs layer).
	SYS_FS_Mount	Mounts the file system.
	SYS_FS_Tasks	Maintains the File System tasks and functionalities.
	SYS_FS_Unmount	Unmounts the file system.
	SYS_FS_CurrentDriveGet	Gets the current drive
	SYS_FS_CurrentDriveSet	Sets the drive.
	SYS_FS_DriveLabelGet	Gets the drive label.
	SYS_FS_DriveLabelSet	Sets the drive label
	SYS_FS_DriveFormat	Formats a drive.
	SYS_FS_DrivePartition	Partitions a physical drive (media).
	SYS_FS_DriveSectorGet	Obtains total number of sectors and number of free sectors for the specified drive.
	SYS_FS_EventHandlerSet	Allows a client to identify an event handling function for the file system to call back when mount/unmount operation has completed.

c) Data Types and Constants

	Name	Description
	SYS_FS_ERROR	Lists the various error cases.
	SYS_FS_FILE_OPEN_ATTRIBUTES	Lists the various attributes (modes) in which a file can be opened.
	SYS_FS_FILE_SEEK_CONTROL	Lists the various modes of file seek.
	SYS_FS_FILE_SYSTEM_TYPE	Enumerated data type identifying native file systems supported.
	SYS_FS_FSTAT	File System status
	SYS_FS_FUNCTIONS	SYS FS Function signature structure for native file systems.
	SYS_FS_HANDLE	This type defines the file handle.
	SYS_FS_REGISTRATION_TABLE	The sys_fs layer has to be initialized by passing this structure with suitably initialized members.
	SYS_FS_RESULT	Lists the various results of a file operation.
	FAT_FS_MAX_LFN	Maximum length of the Long File Name.
	FAT_FS_MAX_SS	Lists the definitions for FAT file system sector size.
	FAT_FS_USE_LFN	Lists the definitions for FAT file system LFN selection.
	SYS_FS_HANDLE_INVALID	Invalid file handle
	SYS_FS_FILE_DIR_ATTR	Enumerated data type identifying the various attributes for file/directory.
	SYS_FS_TIME	The structure to specify the time for a file or directory.
	SYS_FS_FORMAT	Specifes the partitioning rule.
	SYS_FS_EVENT	Identifies the possible file system events.
	SYS_FS_EVENT_HANDLER	Pointer to the File system Handler function.

Description

This section describes the APIs of the File System Service Library.

Refer to each section for a detailed description.

a) File and Directory Operation Functions

SYS_FS_FileClose Function

Closes a file.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_FileClose(SYS_FS_HANDLE handle);
```

Returns

SYS_FS_RES_SUCCESS - File close operation was successful. SYS_FS_RES_FAILURE - File close operation failed. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

This function closes an opened file.

Remarks

None.

Preconditions

A valid file handle must be obtained before closing a file.

Example

```
SYS_FS_HANDLE fileHandle;
fileHandle = SYS_FS_FileOpen("/mnt/myDrive/FILE.JPG",
        (SYS_FS_FILE_OPEN_READ));

if(fileHandle != SYS_FS_HANDLE_INVALID)
{
    // File open is successful
}

SYS_FS_FileClose(fileHandle);
```

Parameters

Parameters	Description
handle	A valid handle, which was obtained while opening the file.

Function

```
SYS_FS_RESULT SYS_FS_FileClose
(
    SYS_FS_HANDLE handle
);
```

SYS_FS_FileEOF Function

Checks for end of file.

File

sys_fs.h

C

```
bool SYS_FS_FileEOF(SYS_FS_HANDLE handle);
```

Returns

On success returns true indicating that the file pointer has reached the end of the file. On failure returns false. This could be due to file pointer having not reached the end of the file. Or due to an invalid file handle. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

Checks whether or not the file position indicator is at the end of the file.

Remarks

None.

Preconditions

A valid file handle must be obtained before knowing a EOF.

Example

```
SYS_FS_HANDLE fileHandle;
bool eof;

fileHandle = SYS_FS_FileOpen("/mnt/myDrive/FILE.JPG",
        (SYS_FS_FILE_OPEN_READ));

if(fileHandle != SYS_FS_HANDLE_INVALID)
{
    // File open is successful
}
...
...

eof = SYS_FS_FileEOF(fileHandle);

if(eof == false)
{
    // Check the error state using SYS_FS_FileError
}
```

Parameters

Parameters	Description
handle	file handle obtained during file Open.

Function

bool SYS_FS_FileEOF

(

SYS_FS_HANDLE handle

);

SYS_FS_FileOpen Function

Opens a file.

File

sys_fs.h

C

```
SYS_FS_HANDLE SYS_FS_FileOpen(const char* fname, SYS_FS_FILE_OPEN_ATTRIBUTES attributes);
```

Returns

On success - A valid file handle will be returned On failure - SYS_FS_HANDLE_INVALID. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function opens a file with the requested attributes.

Remarks

None.

Preconditions

Prior to opening a file, the name of the volume on which the file resides should be known and the volume should be mounted.

Example

```
SYS_FS_HANDLE fileHandle;

fileHandle = SYS_FS_FileOpen("/mnt/myDrive/FILE.JPG",
        (SYS_FS_FILE_OPEN_READ));
```

```
if(fileHandle != SYS_FS_HANDLE_INVALID)
{
    // File open succeeded.
}
else
{
    // File open failed.
}

// Using SYS_FS_CurrentDriveSet () function.

SYS_FS_HANDLE fileHandle;

SYS_FS_CurrentDriveSet("/mnt/myDrive");

fileHandle = SYS_FS_FileOpen("FILE.JPG", (SYS_FS_FILE_OPEN_READ));
if(fileHandle != SYS_FS_HANDLE_INVALID)
{
    // File open succeeded.
}
else
{
    // File open failed.
}
```

Parameters

Parameters	Description
fname	The name of the file to be opened along with the path. The fname
format is as follows	"/mnt/volumeName/dirName/fileName". volumeName is the name of the volume/drive. dirName is the name of the directory under which the file is located. fileName is the name of the file to be opened. The "/mnt/volumeName" portion from the fName can be omitted if the SYS_FS_CurrentDriveSet () has been invoked to set the current drive/volume.
attributes	Access mode of the file, of type SYS_FS_FILE_OPEN_ATTRIBUTES

Function

SYS_FS_HANDLE SYS_FS_FileOpen
(
const char* fname,
SYS_FS_FILE_OPEN_ATTRIBUTES attributes
);

SYS_FS_FileSeek Function

Moves the file pointer by the requested offset.

File

sys_fs.h

C

```
int32_t SYS_FS_FileSeek(SYS_FS_HANDLE fildes, int32_t offset, SYS_FS_FILE_SEEK_CONTROL whence);
```

Returns

On success - The number of bytes by which file pointer is moved (0 or positive number) On Failure - (-1) If the chosen offset value was (-1), the success or failure can be determined with SYS_FS_Error.

Description

This function sets the file pointer for a open file associated with the file handle, as follows: whence = SYS_FS_SEEK_SET - File offset is set to offset bytes from the beginning. whence = SYS_FS_SEEK_CUR - File offset is set to its current location plus offset. whence = SYS_FS_SEEK_END - File offset is set to the size of the file plus offset. The offset specified for this option should be negative for the file pointer to be valid.

Trying to move the file pointer using SYS_FS_FileSeek, beyond the range of file will only cause the pointer to be moved to the last location of the file.

Remarks

None.

Preconditions

A valid file handle must be obtained before seeking a file.

Example

```
SYS_FS_HANDLE fileHandle;
int status;

fileHandle = SYS_FS_FileOpen("/mnt/myDrive/FILE.JPG",
        (SYS_FS_FILE_OPEN_READ));

if(fileHandle != SYS_FS_HANDLE_INVALID)
{
    // File open is successful
}
...
...

status = SYS_FS_FileSeek(fileHandle, 5, SYS_FS_SEEK_CUR);

if((status != -1) && (status == 5))
{
    // Success
}
```

Parameters

Parameters	Description
handle	A valid file handle obtained during file open.
offset	The number of bytes which act as file offset. This value could be a positive or negative value.
whence	Type of File Seek operation as specified in SYS_FS_FILE_SEEK_CONTROL.

Function

int32_t SYS_FS_FileSeek
(
    SYS_FS_HANDLE handle,
int32_t offset,
    SYS_FS_FILE_SEEK_CONTROL whence
);

SYS_FS_FileSize Function

Returns the size of the file in bytes.

File

sys_fs.h

C

```
int32_t SYS_FS_FileSize(SYS_FS_HANDLE handle);
```

Returns

On success returns the size of the file in bytes. On failure returns -1. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

This function returns the size of the file as pointed by the handle.

Remarks

None.

Preconditions

A valid file handle must be obtained before knowing a file size.

Example

```
SYS_FS_HANDLE fileHandle;
long fileSize;

fileHandle = SYS_FS_FileOpen("/mnt/myDrive/FILE.JPG",
        (SYS_FS_FILE_OPEN_READ));

if(fileHandle != SYS_FS_HANDLE_INVALID)
{
    // File open is successful
}
...
...

fileSize = SYS_FS_FileSize(fileHandle);

if(fileSize != -1)
{
    // Success
}
```

Parameters

Parameters	Description
handle	File handle obtained during file Open.

Function

int32_t SYS_FS_FileSize
(
    SYS_FS_HANDLE handle
);

SYS_FS_FileTell Function

Obtains the file pointer position.

File

sys_fs.h

C

```
int32_t SYS_FS_FileTell(SYS_FS_HANDLE handle);
```

Returns

On success returns the current file position. On failure returns -1. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

Obtains the current value of the file position indicator for the file pointed to by handle.

Remarks

None.

Preconditions

A valid file handle must be obtained before performing a file tell.

Example

```
SYS_FS_HANDLE fileHandle;
int32_t tell;

fileHandle = SYS_FS_FileOpen("/mnt/myDrive/FILE.JPG",
        (SYS_FS_FILE_OPEN_READ));
```

```
if(fileHandle != SYS_FS_HANDLE_INVALID)
{
    // File open is successful
}
...
...

tell = SYS_FS_FileTell(fileHandle);

if(tell != -1)
{
    // Success
}
```

Parameters

Parameters	Description
handle	File handle obtained during file Open.

Function

int32_t SYS_FS_FileTell
(
    SYS_FS_HANDLE handle
);

SYS_FS_FileNameGet Function

Reads the file name.

File

sys_fs.h

C

```
bool SYS_FS_FileNameGet(SYS_FS_HANDLE handle, uint8_t* cName, uint16_t wLen);
```

Returns

Returns true if the file name was read successfully. Returns false if the file name was not read successfully. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function reads the file name of a file that is already open.

Remarks

None.

Preconditions

The file handle referenced by handle is already open.

Example

```
SYS_FS_HANDLE fileHandle;
bool stat;
uint8_t fileName[255];

fileHandle = SYS_FS_FileOpen("/mnt/myDrive/FILE.JPG",
        (SYS_FS_FILE_OPEN_READ));

if(fileHandle != SYS_FS_HANDLE_INVALID)
{
    // File open is successful
}
...
...

stat = SYS_FS_FileNameGet(fileHandle, fileName, 8 );
```

```
if(stat == false)
{
    // file not located based on handle passed
    // Check the error state using SYS_FS_FileError
}
```

Parameters

Parameters	Description
handle	File handle obtained during file Open.
cName	Where to store the name of the file.
wLen	The maximum length of data to store in cName.

Function

```
bool SYS_FS_FileNameGet
(
    SYS_FS_HANDLE handle,
uint8_t* cName,
uint16_t wLen
);
```

SYS_FS_FilePrintf Function

Writes a formatted string into a file.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_FilePrintf(SYS_FS_HANDLE handle, const char * string, ...);
```

Returns

SYS_FS_RES_SUCCESS - Formatted string write operation was successful. SYS_FS_RES_FAILURE - Formatted string write operation was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

This function writes a formatted string into a file.

Remarks

None.

Preconditions

The file into which a string has to be written, must exist and should be open.

Example

```
SYS_FS_RESULT res;
SYS_FS_HANDLE fileHandle;

fileHandle = SYS_FS_FileOpen("/mnt/myDrive/FILE.txt", (SYS_FS_FILE_OPEN_WRITE_PLUS));

if(fileHandle != SYS_FS_HANDLE_INVALID)
{
    // File open is successful
}

// Write a string
res = SYS_FS_FilePrintf(fileHandle, "%d", 1234);
if( res != SYS_FS_RES_SUCCESS)
{
    // write operation failed.
}
```

Parameters

Parameters	Description
handle	File handle to which formatted string is to be written.
string	Pointer to formatted string which has to be written into file.

Function

```
SYS_FS_RESULT SYS_FS_FilePrintf
(
    SYS_FS_HANDLE handle,
const char *string,
...
);
```

SYS_FS_FileTestError Function

Checks for errors in the file.

File

sys_fs.h

C

```
bool SYS_FS_FileTestError(SYS_FS_HANDLE handle);
```

Returns

On success returns false indicating that the file has no errors. On failure returns true. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

This function checks whether or not file has any errors.

Remarks

None.

Preconditions

A valid file handle must be obtained before passing to the function

Example

```
SYS_FS_HANDLE fileHandle;
bool err;

fileHandle = SYS_FS_FileOpen("/mnt/myDrive/FILE.JPG", (SYS_FS_FILE_OPEN_READ));

if(fileHandle != SYS_FS_HANDLE_INVALID)
{
    // File open is successful
}
...
...

err = SYS_FS_FileTestError(fileHandle);
if(err == true)
{
    // either file has error, or there
    // was an error in working with the "SYS_FS_FileTestError" function
}
```

Parameters

Parameters	Description
handle	file handle obtained during file Open.

Function

bool SYS_FS_FileTestError
(
SYS_FS_HANDLE handle
);

SYS_FS_FileDirectoryModeSet Function

Sets the mode for the file or directory.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_FileDirectoryModeSet(const char* path, SYS_FS_FILE_DIR_ATTR attr, SYS_FS_FILE_DIR_ATTR
mask);
```

Returns

SYS_FS_RES_SUCCESS - Mode set operation was successful. SYS_FS_RES_FAILURE - Mode set operation was unsucessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function sets the mode for a file or directory from the specified list of attributes.

Remarks

None.

Preconditions

The file or directory for which the mode is to be set must exist.

Example

```
// Set read-only flag, clear archive flag and others are retained.
SYS_FS_FileDirectoryModeSet("file.txt", SYS_FS_ATTR_RDO, SYS_FS_ATTR_RDO | SYS_FS_ATTR_ARC);
```

Parameters

Parameters	Description
path	Path for the file/directory, for which the mode is to be set.
attr	Attribute flags to be set in one or more combination of the type SYS_FS_FILE_DIR_ATTR. The specified flags are set and others are cleared.
mask	Attribute mask of type SYS_FS_FILE_DIR_ATTR that specifies which attribute is changed. The specified attributes are set or cleared.

Function

SYS_FS_RESULT SYS_FS_FileDirectoryModeSet
(
const char* path,
SYS_FS_FILE_DIR_ATTR attr,
SYS_FS_FILE_DIR_ATTR mask
);

SYS_FS_FileDirectoryRemove Function

Removes a file or directory.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_FileDirectoryRemove(const char* path);
```

Returns

SYS_FS_RES_SUCCESS - Indicates that the file or directory remove operation was successful. SYS_FS_RES_FAILURE - Indicates that the file or directory remove operation was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function removes a file or directory as specified by the path.

Remarks

None.

Preconditions

- The disk has to be mounted before a directory could be removed.
- The file or directory to be removed has to present.
- The file/sub-directory must not have read-only attribute (AM_RDO), or the function will be rejected with FR_DENIED.
- The sub-directory must be empty and must not be current directory, or the function will be rejected with FR_DENIED.
- The file/sub-directory must not be opened.

Example

```
SYS_FS_RESULT res;

res = SYS_FS_FileDirectoryRemove("Dir1");

if(res == SYS_FS_RES_FAILURE)
{
    // Directory remove operation failed
}
//...
//...
```

Parameters

Parameters	Description
path	Path of the File or directory to be removed.

Function

SYS_FS_RESULT SYS_FS_FileDirectoryRemove
(
const char* path
);

SYS_FS_FileDirectoryRenameMove Function

Renames or moves a file or directory.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_FileDirectoryRenameMove(const char * oldPath, const char * newPath);
```

Returns

SYS_FS_RES_SUCCESS - Rename/move operation was successful. SYS_FS_RES_FAILURE - Rename/move operation was unsucessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function renames or moves a file or directory.

Remarks

This function cannot move files/ directory from one drive to another. Do not rename/ move files which are open.

Preconditions

The file or directory to be renamed or moved must exist. This function cannot move files or directories from one drive to another. Do not rename or

move files that are open.

Example

```
SYS_FS_RESULT res;

// rename "file.txt" to "renamed_file.txt"
res = SYS_FS_FileDirectoryRenameMove("file.txt", "renamed_file.txt");
if( res != SYS_FS_RES_SUCCESS)
{
    // Rename operation failed.
}

// Now, move "renamed_file.txt" inside directory "Dir1"
res = SYS_FS_FileDirectoryRenameMove("renamed_file.txt", "Dir1/renamed_file.txt");
if( res != SYS_FS_RES_SUCCESS)
{
    // File move operation failed.
}
```

Parameters

Parameters	Description
oldPath	Path for the file/directory, which has to be renamed/moved.
newPath	New Path for the file/directory.

Function

SYS_FS_RESULT SYS_FS_FileDirectoryRenameMove
(
const char *oldPath,
const char *newPath
);

SYS_FS_FileDirectoryTimeSet Function

Sets or changes the time for a file or directory.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_FileDirectoryTimeSet(const char* path, SYS_FS_TIME * time);
```

Returns

SYS_FS_RES_SUCCESS - Set time operation was successful. SYS_FS_RES_FAILURE - Set time operation was unsucessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function sets or change the time for a file or directory.

Remarks

None.

Preconditions

The file/directory for which time is to be set must exist.

Example

```
void setTime(void)
{
    SYS_FS_RESULT res;
    SYS_FS_TIME time;

    time.packedTime = 0;

    // All FAT FS times are calculated based on 0 = 1980
```

```
        time.discreteTime.year = (2013 - 1980);  // Year is 2013
        time.discreteTime.month = 8;             // Month (August)
        time.discreteTime.day = 9;               // Day (9)
        time.discreteTime.hour = 15;             // 3 PM
        time.discreteTime.minute = 06;           // 06 minutes
        time.discreteTime.second = 00;           // 00 seconds

        res = SYS_FS_FileDirectoryTimeSet("file.txt", &time);
        if( res != SYS_FS_RES_SUCCESS)
        {
            // time change has gone wrong
        }
    }
```

Parameters

Parameters	Description
path	A path for the file/directory, for which the time is to be set.
ptr	Pointer to the structure of type SYS_FS_TIME, which contains the time data to be set.

Function

```
  SYS_FS_RESULT SYS_FS_FileDirectoryTimeSet
(
const char* path,
    SYS_FS_TIME *time
);
```

SYS_FS_FileTruncate Function

Truncates a file

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_FileTruncate(SYS_FS_HANDLE handle);
```

Returns

SYS_FS_RES_SUCCESS - File truncate operation was successful. SYS_FS_RES_FAILURE - File truncate operation was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

This function truncates the file size to the current file read/write pointer. This function has no effect if the file read/write pointer is already pointing to end of the file.

Remarks

None.

Preconditions

A valid file handle has to be passed as input to the function. The file has to be opened in a mode where writes to file is possible (such as read plus or write mode).

Example

```
SYS_FS_HANDLE fileHandle;
size_t nbytes;
size_t bytes_read;
SYS_FS_RESULT res;

fileHandle = SYS_FS_FileOpen("/mnt/myDrive/FILE.JPG",
        (SYS_FS_FILE_OPEN_READ));

if(fileHandle != SYS_FS_HANDLE_INVALID)
{
    // File open is successful
}
```

```
// Read the file content
nbytes = sizeof(buf);
bytes_read = SYS_FS_FileRead(buf, nbytes, fileHandle);
// Truncate the file
res = SYS_FS_FileTruncate(fileHandle);
if(res != SYS_FS_RES_SUCCESS)
{
    // Truncation failed.
}

SYS_FS_FileClose(fileHandle);
```

Parameters

Parameters	Description
handle	A valid handle which was obtained while opening the file.

Function

```
SYS_FS_RESULT SYS_FS_FileTruncate
(
    SYS_FS_HANDLE handle
);
```

SYS_FS_FileCharacterPut Function

Writes a character to a file.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_FileCharacterPut(SYS_FS_HANDLE handle, char data);
```

Returns

SYS_FS_RES_SUCCESS - Write operation was successful. SYS_FS_RES_FAILURE - Write operation was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

This function writes a character to a file.

Remarks

None.

Preconditions

The file into which a character has to be written, has to be present and should have been opened.

Example

```
SYS_FS_RESULT res;
SYS_FS_HANDLE fileHandle;

fileHandle = SYS_FS_FileOpen("/mnt/myDrive/FILE.JPG", (SYS_FS_FILE_OPEN_WRITE_PLUS));
if(fileHandle != SYS_FS_HANDLE_INVALID)
{
    // File open is successful
}

// Write a character to the file.
res = SYS_FS_FileCharacterPut(fileHandle, 'c');
if(res != SYS_FS_RES_SUCCESS)
{
    // Character write operation failed.
}
```

Parameters

Parameters	Description
handle	file handle to which the character is to be written.
data	character to be written to the file.

Function

```
    SYS_FS_RESULT SYS_FS_FileCharacterPut
(
      SYS_FS_HANDLE handle,
char data
);
```

SYS_FS_FileStringGet Function

Reads a string from the file into a buffer.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_FileStringGet(SYS_FS_HANDLE handle, char* buff, uint32_t len);
```

Returns

SYS_FS_RES_SUCCESS - String read operation was successful. SYS_FS_RES_FAILURE - String read operation was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

This function reads a string of specified length from the file into a buffer. The read operation continues until

1. 'n' is stored
2. reached end of the file or
3. the buffer is filled with len - 1 characters.

The read string is terminated with a '0'.

Remarks

None.

Preconditions

The file from which a string has to be read, has to be present and should have been opened.

Example

```
SYS_FS_RESULT res;
SYS_FS_HANDLE fileHandle;
char buffer[100];

fileHandle = SYS_FS_FileOpen("/mnt/myDrive/FILE.JPG", (SYS_FS_FILE_OPEN_WRITE_PLUS));
if(fileHandle != SYS_FS_HANDLE_INVALID)
{
    // File open is successful
}

// Read a string from the file.
res = SYS_FS_FileStringGet(fileHandle, buffer, 50);
if( res != SYS_FS_RES_SUCCESS)
{
    //String read operation failed.
}
```

Parameters

Parameters	Description
handle	Handle of the file from which string is to be read.
buff	Buffer in which the string is to be stored.

len	length of string to be read.

Function

SYS_FS_RESULT SYS_FS_FileStringGet
(
SYS_FS_HANDLE handle,
char* buff,
uint32_t len
);

SYS_FS_FileStringPut Function

Writes a string to a file.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_FileStringPut(SYS_FS_HANDLE handle, const char * string);
```

Returns

SYS_FS_RES_SUCCESS - String write operation was successful. SYS_FS_RES_FAILURE - String write operation was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

This function writes a string into a file. The string to be written should be NULL terminated. The terminator character will not be written.

Remarks

None.

Preconditions

The file into which a string has to be written, has to be present and should have been opened.

Example

```
SYS_FS_RESULT res;
SYS_FS_HANDLE fileHandle;

fileHandle = SYS_FS_FileOpen("/mnt/myDrive/FILE.JPG", SYS_FS_FILE_OPEN_WRITE_PLUS));
if(fileHandle != SYS_FS_HANDLE_INVALID)
{
    // File open is successful
}

// Write a string
res = SYS_FS_FileStringPut(fileHandle, "Hello World");
if(res != SYS_FS_RES_SUCCESS)
{
    // String write operation failed.
}
```

Parameters

Parameters	Description
handle	File handle to which string is to be written.
string	Pointer to the null terminated string which has to be written into file.

Function

SYS_FS_RESULT SYS_FS_FileStringPut
(
SYS_FS_HANDLE handle,
const char *string
);

SYS_FS_Error Function

Returns the last error.

File

sys_fs.h

C

```
SYS_FS_ERROR SYS_FS_Error();
```

Returns

Error code of type SYS_FS_ERROR.

Description

When a file system operation fails, the application can know the reason of failure by calling the SYS_FS_Error. This function only reports the errors which are not file (or file handle) specific. For example, for functions such as SYS_FS_Mount and SYS_FS_FileOpen, which do not take handle, any errors happening inside such function calls could be reported using SYS_FS_Error function. Even for functions, which take handle as its input parameters, the SYS_FS_Error function can be used to report the type of error for cases where the passed handle itself is invalid.

Remarks

None.

Preconditions

This function has to be called immediately after a failure is observed while doing a file operation. Any subsequent failure will overwrite the cause of previous failure.

Example

```
SYS_FS_HANDLE fileHandle;
SYS_FS_ERROR err;

fileHandle = SYS_FS_FileOpen("/mnt/myDrive/FILE.JPG",
        (SYS_FS_FILE_OPEN_READ));

if(fileHandle == SYS_FS_HANDLE_INVALID)
{
    // If failure, now know the specific reason for failure
    err = SYS_FS_Error();
}
```

Function

SYS_FS_ERROR SYS_FS_Error
(
void
)

SYS_FS_FileError Function

Returns the file specific error.

File

sys_fs.h

C

```
SYS_FS_ERROR SYS_FS_FileError(SYS_FS_HANDLE handle);
```

Returns

Error code of type SYS_FS_ERROR.

Description

For file system functions which accepts valid handle, any error happening in those functions could be retrieved with SYS_FS_FileError. This function returns errors which are file specific.

Please note that if an invalid handle is passed to a file system function, in such a case, SYS_FS_FileError will not return the correct type of error,

as the handle was invalid. Therefore, it would be prudent to check the errors using the SYS_FS_Error function.

Remarks

None.

Preconditions

This function has to be called immediately after a failure is observed while doing a file operation. Any subsequent failure will overwrite the cause of previous failure.

Example

```
 ...
const char *buf = "Hello World";
size_t nbytes;
size_t bytes_written;
SYS_FS_HANDLE fd;
SYS_FS_ERROR err;
...

bytes_written = SYS_FS_FileWrite((const void *)buf, nbytes, fd);

if(bytes_written == -1)
{
    // error while writing file
    // find the type (reason) of error
    err = SYS_FS_FileError(fd);
}
```

Parameters

Parameters	Description
handle	A valid file handle

Function

SYS_FS_ERROR SYS_FS_FileError
(
SYS_FS_HANDLE handle
);

SYS_FS_FileRead Function

Read data from the file.

File

sys_fs.h

C

```
size_t SYS_FS_FileRead(SYS_FS_HANDLE handle, void * buf, size_t nbyte);
```

Returns

On success returns the number of bytes read successfully(0 or positive number). On failure returns -1. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

This function attempts to read nbyte bytes of data from the file associated with the file handle into the buffer pointed to by buf.

Remarks

None.

Preconditions

A valid file handle must be obtained before reading a file.

Example

```
...
char buf[20];
```

```
size_t nbytes;
size_t bytes_read;
SYS_FS_HANDLE fd;
...
nbytes = sizeof(buf);
bytes_read = SYS_FS_FileRead(fd, buf, nbytes);
...
```

Parameters

Parameters	Description
handle	File handle obtained during file open.
buf	Pointer to buffer into which data is read.
nbyte	Number of bytes to be read

Function

size_t SYS_FS_FileRead
(
SYS_FS_HANDLE handle,
void *buf,
size_t nbyte
);

SYS_FS_FileWrite Function

Writes data to the file.

File

sys_fs.h

C

```
size_t SYS_FS_FileWrite(SYS_FS_HANDLE handle, const void * buf, size_t nbyte);
```

Returns

On success returns the number of bytes written successfully(0 or positive number). On failure returns -1. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

This function attempts to write nbyte bytes from the buffer pointed to by buf to the file associated with the file handle.

Remarks

None.

Preconditions

A valid file handle must be obtained before writing a file.

Example

```
...
const char *buf = "Hello World";
size_t nbytes;
size_t bytes_written;
SYS_FS_HANDLE fd;
...

bytes_written = SYS_FS_FileWrite(fd, (const void *)buf, nbytes);
...
```

Parameters

Parameters	Description
handle	File handle obtained during file open.
buf	Pointer to buffer from which data is to be written
nbyte	Number of bytes to be written

Function

size_t SYS_FS_FileWrite
(
SYS_FS_HANDLE handle,
const void *buf,
size_t nbyte
);

SYS_FS_CurrentWorkingDirectoryGet Function

Gets the current working directory

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_CurrentWorkingDirectoryGet(char * buff, uint32_t len);
```

Returns

SYS_FS_RES_SUCCESS - Get current working directory operation was successful. SYS_FS_RES_FAILURE - Get current working directory operation was unsucessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function gets the current working directory path along with the working drive.

Remarks

None.

Preconditions

At least one disk must be mounted.

Example

```
SYS_FS_RESULT res;
char buffer[16];

switch(appState)
{
    case TRY_MOUNT:
        if(SYS_FS_Mount("/dev/mmcblka1", "/mnt/myDrive", FAT, 0, NULL) != SYS_FS_RES_SUCCESS)
        {
            // Failure, try mounting again
        }
        else
        {
            // Mount was successful. Create a directory.
            appState = CREATE_DIR;
        }
        break;

    case CREATE_DIR:
        res = SYS_FS_DirectoryMake("Dir1");
        if(res == SYS_FS_RES_FAILURE)
        {
            // Directory creation failed
            appState = ERROR;
        }
        else
        {
            // Directory creation was successful. Change to the new
            // directory.
            appState = CHANGE_DIR;
        }
        break;
```

```
        case CHANGE_DIR:
            res = SYS_FS_DirectoryChange("Dir1");
            if(res == SYS_FS_RES_FAILURE)
            {
                // Directory change failed
                appState = ERROR;
            }
            else
            {
                // Directory change was successful. Get current working
                // directory
                appState = GET_CWD;
            }
            break;

        case GET_CWD:
            res = SYS_FS_CurrentWorkingDirectoryGet(buffer, 15);
            if(res == SYS_FS_RES_FAILURE)
            {
                // Get current directory operation failed
                appState = ERROR;
            }
            break;
    }
```

Parameters

Parameters	Description
buff	Pointer to a buffer which will contain the name of the current working directory and drive, once the function completes.
len	Size of the buffer.

Function

SYS_FS_RESULT SYS_FS_CurrentWorkingDirectoryGet

(

char *buff,

uint32_t len

);

SYS_FS_DirectoryChange Function

Changes to a the directory specified.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_DirectoryChange(const char* path);
```

Returns

SYS_FS_RES_SUCCESS - Indicates that the directory change operation was successful. SYS_FS_RES_FAILURE - Indicates that the directory change operation was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function changes the present directory to a new directory.

Remarks

None.

Preconditions

The disk has to be mounted and the directory to be changed must exist.

Example

```
SYS_FS_RESULT res;
```

```
res = SYS_FS_DirectoryChange("Dir1");

if(res == SYS_FS_RES_FAILURE)
{
    // Directory change failed
}
```

Parameters

Parameters	Description
path	Path of the directory to be changed to.

Function

SYS_FS_RESULT SYS_FS_DirectoryChange
(
const char* path
);

SYS_FS_DirectoryMake Function

Makes a directory.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_DirectoryMake(const char* path);
```

Returns

SYS_FS_RES_SUCCESS - Indicates that the creation of the directory was successful. SYS_FS_RES_FAILURE - Indicates that the creation of the directory was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function makes a new directory as per the specified path.

Remarks

None.

Preconditions

The disk has to be mounted before a directory could be made.

Example

```
SYS_FS_RESULT res;

res = SYS_FS_DirectoryMake("Dir1");

if(res == SYS_FS_RES_FAILURE)
{
    // Directory make failed
}
```

Parameters

Parameters	Description
path	Path of the new directory

Function

SYS_FS_RESULT SYS_FS_DirectoryMake
(
const char* path
);

SYS_FS_DirClose Function

Closes an opened directory.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_DirClose(SYS_FS_HANDLE handle);
```

Returns

SYS_FS_RES_SUCCESS - Directory close operation was successful. SYS_FS_RES_FAILURE - Directory close operation was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

This function closes a directory that was opened earlier opened with the SYS_FS_DirOpen function.

Remarks

None.

Preconditions

A valid directory handle must be obtained before closing the directory.

Example

```
SYS_FS_HANDLE dirHandle;

dirHandle = SYS_FS_DirOpen("/mnt/myDrive/Dir1");

if(dirHandle != SYS_FS_HANDLE_INVALID)
{
    // Directory open is successful
}

// Perform required operation on the directory

// Close the directory
if(SYS_FS_DirClose(dirHandle) == SYS_FS_RES_FAILURE)
{
    // Close operation failed.
}
```

Parameters

Parameters	Description
handle	directory handle obtained during directory open.

Function

```
SYS_FS_RESULT SYS_FS_DirClose
(
    SYS_FS_HANDLE handle
);
```

SYS_FS_DirOpen Function

Open a directory

File

sys_fs.h

C

```
SYS_FS_HANDLE SYS_FS_DirOpen(const char* path);
```

Returns

On success a valid handle to the directory will be returned. On failure SYS_FS_HANDLE_INVALID will be returned. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function opens the requested directory.

Remarks

None

Preconditions

The volume on which the directory is present should be mounted.

Example

```
SYS_FS_HANDLE dirHandle;

dirHandle = SYS_FS_DirOpen("/mnt/myDrive/Dir1");
// For root directory, end with a "/"
// dirHandle = SYS_FS_DirOpen("/mnt/myDrive/");

if(dirHandle != SYS_FS_HANDLE_INVALID)
{
    // Directory open is successful
}
```

Parameters

Parameters	Description
path	Path to the directory along with the volume name. The string of volume and directory name has to be preceded by "/mnt/". Also, the volume name and directory name has to be separated by a slash "/". If the directory specified is only the root directory, the path has to be ended with "/".

Function

SYS_FS_HANDLE SYS_FS_DirOpen

(

const char* path

);

SYS_FS_DirRead Function

Reads the specified directory.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_DirRead(SYS_FS_HANDLE handle, SYS_FS_FSTAT * stat);
```

Returns

SYS_FS_RES_SUCCESS - Indicates that the directory read operation was successful. SYS_FS_RES_FAILURE - Indicates that the directory read operation was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

This function reads the files and directories specified in the open directory.

Remarks

None.

Preconditions

A valid directory handle must be obtained before reading a directory.

Example

```
SYS_FS_HANDLE dirHandle;
SYS_FS_FSTAT stat;
char longFileName[300];
uintptr_t  longFileSize;

dirHandle = SYS_FS_DirOpen("/mnt/myDrive/Dir1");

if(dirHandle != SYS_FS_HANDLE_INVALID)
{
    // Directory open is successful
}

// If long file name is used, the following elements of the "stat"
// structure needs to be initialized with address of proper buffer.
stat.lfname = longFileName;
stat.lfsize = 300;

if(SYS_FS_DirRead(dirHandle, &stat) == SYS_FS_RES_FAILURE)
{
    // Directory read failed.
}
```

Parameters

Parameters	Description
handle	Directory handle obtained during directory open.
stat	Empty structure of type SYS_FS_FSTAT, where the properties of the open directory will be populated after the SYS_FS_DirRead function returns successfully. If LFN is used, then the "lfname" member of the SYS_FS_FSTAT structure should be initialized with the address of suitable buffer. Also, the "lfsize" should be initialized with the size of the buffer. Once the function returns, the buffer whose address is held in "lfname" will have the file name(long file name)

Function

```
  SYS_FS_RESULT SYS_FS_DirRead
(
    SYS_FS_HANDLE handle,
    SYS_FS_FSTAT *stat
);
```

SYS_FS_DirSearch Function

Searches for a file or directory.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_DirSearch(SYS_FS_HANDLE handle, const char * name, SYS_FS_FILE_DIR_ATTR attr,
SYS_FS_FSTAT * stat);
```

Returns

SYS_FS_RES_SUCCESS - Indicates that the file or directory was found. The stat parameter will contain information about the file or directory.
SYS_FS_RES_FAILURE - Indicates that the file or directory was not found. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

This function searches for the requested file or directory. The file or directory is specified in the attr parameter, which is of type SYS_FS_FILE_DIR_ATTR.

Remarks

None.

Preconditions

A valid directory handle must be obtained before searching the directory.

Example

```
SYS_FS_HANDLE dirHandle;
SYS_FS_FSTAT stat;
char longFileName[300];
uintptr_t  longFileSize;

dirHandle = SYS_FS_DirOpen("/mnt/myDrive/Dir1");

if(dirHandle != SYS_FS_HANDLE_INVALID)
{
   // Directory open is successful
}

// If long file name is used, the following elements of the "stat"
// structure needs to be initialized with address of proper buffer.
stat.lfname = longFileName;
stat.lfsize = 300;

if(SYS_FS_DirSearch(dirHandle, "FIL*.*", SYS_FS_ATTR_ARC, &stat) == SYS_FS_RES_FAILURE)
{
   // Specified file not found
}
else
{
   // File found. Read the complete file name from "stat.lfname" and
   // other file parameters from the "stat" structure
}
```

Parameters

Parameters	Description
handle	directory handle obtained during directory open.
name	name of file or directory needed to be searched. The file
name can have wild card entries as follows	• - Indicates the rest of the filename or extension can vary (e.g. FILE.*)
?	Indicates that one character in a filename can vary (e.g. F?LE.T?T)
attr	Attribute of the name of type SYS_FS_FILE_DIR_ATTR. This attribute specifies whether to search a file or a directory. Other attribute types could also be specified.
stat	Empty structure of type SYS_FS_FSTAT, where the properties of the file/directory will be populated. If LFN is used, then the "lfname" member of the SYS_FS_FSTAT structure should be initialized with address of suitable buffer. Also, the "lfsize" should be initialized with the size of buffer. Once the function returns, the buffer whose address is held in "lfname" will have the file name (long file name).

Function

```
  SYS_FS_RESULT SYS_FS_DirSearch
(
    SYS_FS_HANDLE handle,
const char * name,
    SYS_FS_FILE_DIR_ATTR attr,
    SYS_FS_FSTAT *stat
);
```

SYS_FS_FileSync Function

Flushes the cached information when writing to a file.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_FileSync(SYS_FS_HANDLE handle);
```

Returns

SYS_FS_RES_SUCCESS - File sync operation was successful. SYS_FS_RES_FAILURE - File sync operation was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

This function flushes the cached information when writing to a file. The SYS_FS_FileSync function performs the same process as SYS_FS_FileClose function; however, the file is left open and can continue read/write/seek operations to the file.

Remarks

None.

Preconditions

A valid file handle has to be passed as input to the function. The file which has to be flushed, has to be present and should have been opened in write mode.

Example

```
SYS_FS_RESULT res;
SYS_FS_HANDLE fileHandle;
const char *buf = "Hello World";
size_t nbytes;
size_t bytes_written;

fileHandle = SYS_FS_FileOpen("/mnt/myDrive/FILE.JPG", (SYS_FS_FILE_OPEN_WRITE_PLUS));

if(fileHandle != SYS_FS_HANDLE_INVALID)
{
    // File open is successful
}

// Write data to the file
bytes_written = SYS_FS_FileWrite((const void *)buf, nbytes, fileHandle);

// Flush the file
res = SYS_FS_FileSync(fileHandle);
if( res != SYS_FS_RES_SUCCESS)
{
    // renaming has gone wrong
}
```

Parameters

Parameters	Description
handle	valid file handle

Function

```
SYS_FS_RESULT SYS_FS_FileSync
(
    SYS_FS_HANDLE handle
);
```

SYS_FS_DirRewind Function

Rewinds to the beginning of the directory.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_DirRewind(SYS_FS_HANDLE handle);
```

Returns

SYS_FS_RES_SUCCESS - Directory rewind operation was successful. SYS_FS_RES_FAILURE - Directory rewind operation was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error or SYS_FS_FileError.

Description

This function rewinds the directory to the start. Once a search of directory or directory read is completed, the rewind function is used to begin searching the directory from the start.

Remarks

None.

Preconditions

A valid directory handle must be obtained before reading a directory.

Example

```
SYS_FS_HANDLE dirHandle;
SYS_FS_FSTAT stat;
char longFileName[300];
uintptr_t  longFileSize;

dirHandle = SYS_FS_DirOpen("/mnt/myDrive/Dir1");

if(dirHandle != SYS_FS_HANDLE_INVALID)
{
    // Directory open is successful
}

// If long file name is used, the following elements of the "stat"
// structure needs to be initialized with address of proper buffer.
stat.lfname = longFileName;
stat.lfsize = 300;

if(SYS_FS_DirRead(dirHandle, &stat) == SYS_FS_RES_FAILURE)
{
   // Directory read operation failed.
}

// Do more search
// Do some more search

// Now, rewind the directory to begin search from start

if(SYS_FS_DirRewind(dirHandle) == SYS_FS_RES_FAILURE)
{
   // Directory rewind failed.
}
```

Parameters

Parameters	Description
handle	directory handle obtained during directory open.

Function

```
SYS_FS_RESULT SYS_FS_DirRewind
(
    SYS_FS_HANDLE handle
);
```

SYS_FS_FileStat Function

Gets file status.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_FileStat(const char * fname, SYS_FS_FSTAT * buf);
```

Returns

SYS_FS_RES_SUCCESS - File stat operation was successful. SYS_FS_RES_FAILURE - File stat operation was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function obtains information about a file associated with the file name, and populates the information in the structure pointed to by buf. This function can read the status of file regardless of whether a file is opened or not.

Remarks

None.

Preconditions

Prior to opening a file, the name of the volume on which the file resides should be known and the volume should be mounted.

Example

```
SYS_FS_fStat fileStat;

if(SYS_FS_FileStat("/mnt/myDrive/FILE.TXT", &fileStat) == SYS_FS_RES_SUCCESS)
{
    // Successfully read the status of file "FILE.TXT"
}
```

Parameters

Parameters	Description
fname	Name of the file with the path and the volume name. The string of volume and file name has to be preceded by "/mnt/". Also, the volume name and file name has to be separated by a slash "/".
buf	pointer to SYS_FS_FSTAT structure.

Function

```
SYS_FS_RESULT SYS_FS_FileStat
(
const char   *fname,
    SYS_FS_FSTAT *buf
)
```

b) General Operation Functions

SYS_FS_Initialize Function

Initializes the file system abstraction layer (sys_fs layer).

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_Initialize(const void* initData);
```

Returns

SYS_FS_RES_SUCCESS - SYS FS Layer was initialized successfully. SYS_FS_RES_FAILURE - SYS FS Layer initialization failed. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function initializes the abstraction layer (sys_fs layer) and sets up the necessary parameters.

Preconditions

This is the first function to be called during usage of sys_fs. Calling other functions of sys_fs without initializing the sys_fs will cause unpredictable

behavior.

Example

```
// This code shows an example of how the SYS FS is initialized
// Only one file system is used

#define SYS_FS_MAX_FILE_SYSTEM_TYPE            1

// Function pointer table for FAT FS
const SYS_FS_FUNCTIONS FatFsFunctions =
{
    .mount   = f_mount,
    .unmount = f_unmount,
    .open    = f_open,
    .read    = f_read,
    .write   = f_write,
    .close   = f_close,
    .seek    = f_lseek,
    .tell    = f_tell,
    .eof     = f_eof,
    .size    = f_size,
    .fstat   = f_stat,
};

const SYS_FS_REGISTRATION_TABLE sysFSInit [ SYS_FS_MAX_FILE_SYSTEM_TYPE ] =
{
    {
    .nativeFileSystemType = FAT,
    .nativeFileSystemFunctions = &FatFsFunctions
    }
};

SYS_FS_Initialize((const void *)sysFSInit);
```

Parameters

Parameters	Description
initData	Pointer to an array of type SYS_FS_REGISTRATION_TABLE. The number of elements of array is decided by the definition SYS_FS_MAX_FILE_SYSTEM_TYPE. If the application uses one file system (say only FAT FS), SYS_FS_MAX_FILE_SYSTEM_TYPE is defined to be 1. Otherwise, if the application uses 2 file systems (say FAT FS and MPFS2), SYS_FS_MAX_FILE_SYSTEM_TYPE is defined to be 2.

Function

SYS_FS_RESULT SYS_FS_Initialize
(
const void* initData
);

SYS_FS_Mount Function

Mounts the file system.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_Mount(const char * devName, const char * mountName, SYS_FS_FILE_SYSTEM_TYPE
filesystemtype, unsigned long mountflags, const void * data);
```

Returns

SYS_FS_RES_SUCCESS - Mount was successful. SYS_FS_RES_FAILURE - Mount was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

The mount command attaches the file system specified to a volume. The call to the mount should be non blocking in nature. The application code

has to allow the SYS_FS_Tasks to run periodically while calling the SYS_FS_Mount function. If the SYS_FS_Mount is called in a blocking mode, then the SYS_Tasks() never gets a chance to run and therefore, the media will not be analyzed and finally, the SYS_FS_Mount will never succeed. This will result in a deadlock.

There is no mechanism available for the application to know if the specified volume (devName) is really attached or not. The only available possibility is to keep trying to mount the volume (with the devname), until success is achieved.

It is prudent that the application code implements a time-out mechanism while trying to mount a volume (by calling SYS_FS_Mount). The trial for mount should continue at least 10 times before before assuming that the mount will never succeed. This has to be done for every new volume to be mounted.

The standard names for volumes (devName) used in the MPLAB Harmony file system is as follows: NVM - "nvm" "media number" "volume number" SD card - "mmcblk" "media number" "volume number" MSD - "sd" "media number" "volume number"

Where, "media number" a, b, c... depends on the number of the type of connected media, and where, "volume number" 1, 2, 3... depends on the number of partitions in that media.

The convention for assigning names to volumes is further described below with examples:

If a SD card (with four partitions) is attached to the system, and assuming all four partitions are recognized, there will be four devNames:

1. mmcblka1
2. mmcblka2
3. mmcblka3 and
4. mmcblka4

Subsequently, if NVM media is attached that has only one partition, the devname will be: nvma1.

Later, if another SD card is attached to the system that has one partition, the devname will be mmcblkb1.

Finally, there will be six volume names (or devNames), which are available for the application to be mounted and used for the file system.

Remarks

None

Preconditions

The "devName" name for the volume has to be known. The file system type with which each of the volumes are formatted has to be known. Trying to mount a volume with a file system which is different from what the volume is actually formatted, will cause mount failure.

Example

```
switch(appState)
{
    case TRY_MOUNT:
        if(SYS_FS_Mount("/dev/mmcblka1", "/mnt/myDrive", FAT, 0, NULL) != SYS_FS_RES_SUCCESS)
        {
            // Failure, try mounting again
        }
        else
        {
            // Mount was successful. Do further file operations
            appState = DO_FURTHER_STUFFS;
        }
    break;
}
```

Parameters

Parameters	Description
devName	The device name (name of volume) which needs to be mounted. The devName has to be preceded by the string "/dev/".
mountName	Mount name for the device to be mounted. This is a name provided by the user. In future, while accessing the mounted volume (say, during SYS_FS_FileOpen operation), the mountName is used to refer the path for file. The mount name has to be preceded by the string "/mnt/"
filesystemtype	Native file system of SYS_FS_FILE_SYSTEM_TYPE type.
mountflags	Mounting control flags. This parameter is reserved for future enhancements. Therefore, always pass zero.
data	The data argument is interpreted by the different file systems. This parameter is reserved for future enhancements. Therefore, always pass NULL.

Function

SYS_FS_RESULT SYS_FS_Mount

(

const char *devName,

const char *mountName,
SYS_FS_FILE_SYSTEM_TYPE filesystemtype,
unsigned long mountflags,
const void *data
);

SYS_FS_Tasks Function

Maintains the File System tasks and functionalities.

File

sys_fs.h

C

```
void SYS_FS_Tasks();
```

Returns

None.

Description

This function is used to run the various tasks and functionalities of sys_fs layer.

Remarks

This function is not called directly by an application. It is called by the system's Tasks routine (SYS_Tasks).

Preconditions

The SYS_FS_Initialize routine must have been called before running the tasks.

Example

```
void SYS_Tasks ( void )
{
    SYS_FS_Tasks ();
    // Do other tasks
}
```

Function

void SYS_FS_Tasks
(
void
);

SYS_FS_Unmount Function

Unmounts the file system.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_Unmount(const char * mountName);
```

Returns

SYS_FS_RES_SUCCESS - Unmount was successful. SYS_FS_RES_FAILURE - Unmount was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function removes (unmounts) the attachment of the volume from the file system.

Preconditions

The volume name has to be know in order to pass as input to Unmount. The specified volume name to be unmounted should have been already mounted.

Example

```
if(SYS_FS_Unmount("/mnt/myDrive") != SYS_FS_RES_SUCCESS)
{
    // Failure, try unmounting again
}
else
{
    // Unmount was successful.
}
```

Parameters

Parameters	Description
mountName	Mount name for the volume to be unmounted. The mount name has to be preceded by the string "/mnt/".

Function

SYS_FS_RESULT SYS_FS_Unmount

(

const char *mountName

);

SYS_FS_CurrentDriveGet Function

Gets the current drive

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_CurrentDriveGet(char* buffer);
```

Returns

SYS_FS_RES_SUCCESS - Current drive get operation was successful. SYS_FS_RES_FAILURE - Current drive get operation was unsucessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function gets the present drive being used. The drive information is populated in the buffer.

Remarks

None.

Preconditions

The disk has to be mounted.

Example

```
SYS_FS_RESULT res;
char buffer[255];

res = SYS_FS_CurrentDriveGet(buffer);
if(res == SYS_FS_RES_FAILURE)
{
    // Operation failed.
}
```

Parameters

Parameters	Description
buffer	Pointer to buffer which will hold the name of present drive being used.

Function

SYS_FS_RESULT SYS_FS_CurrentDriveGet

(

char* buffer
);

SYS_FS_CurrentDriveSet Function

Sets the drive.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_CurrentDriveSet(const char* path);
```

Returns

SYS_FS_RES_SUCCESS - Current drive set operation was successful. SYS_FS_RES_FAILURE - Current drive set operation was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function sets the present drive to the one as specified by the path. By default, the drive mounted last becomes the current drive for the system. This is useful for applications where only one drive (volume) is used. In such an application, there is no need to call the SYS_FS_CurrentDriveSet function. However, in the case of an application where there are multiple volumes, the user can select the current drive for the application by calling this function.

Remarks

None.

Preconditions

The disk has to be mounted.

Example

```
SYS_FS_RESULT res;

res = SYS_FS_CurrentDriveSet("/mnt/myDrive");
if(res == SYS_FS_RES_FAILURE)
{
    // Drive change failed
}
```

Parameters

Parameters	Description
path	Path for the drive to be set.

Function

SYS_FS_RESULT SYS_FS_CurrentDriveSet
(
const char* path
);

SYS_FS_DriveLabelGet Function

Gets the drive label.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_DriveLabelGet(const char* drive, char * buff, uint32_t * sn);
```

Returns

SYS_FS_RES_SUCCESS - Drive label information retrieval was successful. SYS_FS_RES_FAILURE - Drive label information retrieval was unsucessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function gets the label for the drive specified. If no drive is specified, the label for the current drive is obtained.

Remarks

None.

Preconditions

At least one disk must be mounted.

Example

```
SYS_FS_RESULT res;
char buffer[255];
uint32_t serialNo;

switch(appState)
{
    case TRY_MOUNT:
        if(SYS_FS_Mount("/dev/mmcblka1", "/mnt/myDrive", FAT, 0, NULL) != SYS_FS_RES_SUCCESS)
        {
            // Failure, try mounting again
        }
        else
        {
            // Mount was successful. Get label now
            appState = GET_LABEL;
        }
        break;

    case GET_LABEL:
        res = SYS_FS_DriveLabelGet("/mnt/myDrive", buffer, &serialNo);

        if(res == SYS_FS_RES_FAILURE)
        {
            // Fetching drive label information failed
        }
        //...
        //...
        break;
}
```

Parameters

Parameters	Description
drive	Pointer to buffer which will hold the name of drive being for which the label is requested. If this string is NULL, then then label of the current drive is obtained by using this function.
buff	Buffer which will hold the string of label.
sn	Serial number of the drive. If this information is not needed, it can be set as NULL.

Function

SYS_FS_RESULT SYS_FS_DriveLabelGet

(

const char* drive,

char *buff,

uint32_t *sn

);

SYS_FS_DriveLabelSet Function

Sets the drive label

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_DriveLabelSet(const char * drive, const char * label);
```

Returns

SYS_FS_RES_SUCCESS - Drive label set operation was successful. SYS_FS_RES_FAILURE - Drive label set operation was unsucessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function sets the label for the drive specified. If no drive is specified, the label for the current drive is set.

Remarks

None.

Preconditions

At least one disk must be mounted.

Example

```
SYS_FS_RESULT res;

switch(appState)
{
    case TRY_MOUNT:
        if(SYS_FS_Mount("/dev/mmcblka1", "/mnt/myDrive", FAT, 0, NULL) != SYS_FS_RES_SUCCESS)
        {
            // Failure, try mounting again
        }
        else
        {
            // Mount was successful. Get label now
            appState = GET_LABEL;
        }
        break;

    case GET_LABEL:
        res = SYS_FS_DriveLabelSet("/mnt/myDrive", "MY_LABEL");
        if(res == SYS_FS_RES_FAILURE)
        {
            // Drive label get failed
        }
        //...
        //...
        break;
}
```

Parameters

Parameters	Description
drive	Pointer to string that holds the name of drive being for which the label is to be set. If this string is NULL, the label of the current drive is set by using this function.
label	Pointer to string which contains the label to be set.

Function

SYS_FS_RESULT SYS_FS_DriveLabelSet

(

const char* drive,

const char *label

);

SYS_FS_DriveFormat Function

Formats a drive.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_DriveFormat(const char* drive, SYS_FS_FORMAT fmt, uint32_t clusterSize);
```

Returns

SYS_FS_RES_SUCCESS - Drive format was successful. SYS_FS_RES_FAILURE - Drive format was unsucessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function formats a logic drive (create a FAT file system on the logical drive), as per the format specified.

If the logical drive that has to be formatted has been bound to any partition (1-4) by multiple partition feature, the FAT volume is created into the specified partition. In this case, the second argument fmt is ignored. The physical drive must have been partitioned prior to using this function.

Remarks

None.

Preconditions

At least one disk must be mounted. The physical drive must have already been partitioned.

Example

```
SYS_FS_RESULT res;

switch(appState)
{
    case TRY_MOUNT:
        if(SYS_FS_Mount("/dev/mmcblka1", "/mnt/myDrive", FAT, 0, NULL) != SYS_FS_RES_SUCCESS)
        {
            // Failure, try mounting again
        }
        else
        {
            // Mount was successful. Format now.
            appState = FORMAT_DRIVE;
        }
        break;

    case FORMAT_DRIVE:
        res = SYS_FS_DriveFormat("/mnt/myDrive", SYS_FS_FORMAT_SFD, 0);
        if(res == SYS_FS_RES_FAILURE)
        {
            // Format of the drive failed.
        }
        //...
        break;
}
```

Parameters

Parameters	Description
drive	Pointer to buffer which will hold the name of drive being for which the format is to be done. If this string is NULL, then then current drive will be formatted. It is important to end the drive name with a "/".
fmt	Format type.
clusterSize	Cluster size. The value must be sector (size * n), where n is 1 to 128 and power of 2. When a zero is given, the cluster size depends on the volume size.

Function

```
SYS_FS_RESULT SYS_FS_DriveFormat
(
const char* drive,
    SYS_FS_FORMAT fmt,
uint32_t clusterSize
);
```

SYS_FS_DrivePartition Function

Partitions a physical drive (media).

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_DrivePartition(const char * path, const uint32_t partition[], void * work);
```

Returns

SYS_FS_RES_SUCCESS - Partition was successful. SYS_FS_RES_FAILURE - Partition was unsuccessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

This function partitions a physical drive (media) into requested partition sizes. This function will alter the MBR of the physical drive and make it into multi partitions. Windows operating systems do not support multi partitioned removable media. Maximum 4 partitions can be created on a media.

Remarks

None

Preconditions

Prior to partitioning the media, the media should have a valid MBR and it should be mounted as a volume with the file system.

Example

```
//==============================================================================
// Initially, consider the case of a SD card that has only one partition.
//==============================================================================
SYS_FS_RESULT res;

// Following 4 element array specifies the size of 2 partitions as
// 256MB (=524288 sectors). The 3rd and 4th partition are not created
// since, the sizes of those are zero.
uint32_t plist[] = {524288, 524288, 0, 0};

// Work area for function SYS_FS_DrivePartition
char work[FAT_FS_MAX_SS];

switch(appState)
{
    case TRY_MOUNT:
        if(SYS_FS_Mount("/dev/mmcblka1", "/mnt/myDrive", FAT, 0, NULL) != SYS_FS_RES_SUCCESS)
        {
            // Failure, try mounting again
        }
        else
        {
            // Mount was successful. Partition now.
            appState = PARTITION_DRIVE;
        }
        break;

    case PARTITION_DRIVE:
        res = SYS_FS_DrivePartition("/mnt/myDrive", plist, work);
        if(res == SYS_FS_RES_FAILURE)
        {
            // Drive partition went wrong
        }
        else
        {
            // Partition was successful. Power cycle the board so that
            // all partitions are recognized. Then try mounting both
            // partitions.
        }
        break;
```

```
        default:
            break;
    }

    //=======================================================================
    //The following code is after the SD card is partitioned and then
    //powered ON.
    //=======================================================================
    SYS_FS_RESULT res;

    switch(appState)
    {
        case TRY_MOUNT_1ST_PARTITION:
            if(SYS_FS_Mount("/dev/mmcblka1", "/mnt/myDrive1", FAT, 0, NULL) != SYS_FS_RES_SUCCESS)
            {
                // Failure, try mounting again
                appState = TRY_MOUNT_1ST_PARTITION;
            }
            else

                // Mount was successful. Mount second partition.
                appState = TRY_MOUNT_2ND_PARTITION;
            }
            break;

        case TRY_MOUNT_2ND_PARTITION:
            if(SYS_FS_Mount("/dev/mmcblka2", "/mnt/myDrive2", FAT, 0, NULL) != SYS_FS_RES_SUCCESS)
            {
                // Failure, try mounting again
                appState = TRY_MOUNT_2ND_PARTITION;
            }
            else
            {
                // Mount was successful. Try formating first partition.
                appState = TRY_FORMATING_1ST_PARTITION;
            }
            break;

        case TRY_FORMATING_1ST_PARTITION:
            if(SYS_FS_DriveFormat("/mnt/myDrive1/", SYS_FS_FORMAT_FDISK, 0) == SYS_FS_RES_FAILURE)
            {
                // Failure
            }
            else
            {
                // Try formating second partitions.
                appState = TRY_FORMATING_2ND_PARTITION;
            }

        case TRY_FORMATING_2ND_PARTITION:
            if(SYS_FS_DriveFormat("/mnt/myDrive2/", SYS_FS_FORMAT_FDISK, 0) == SYS_FS_RES_FAILURE)
            {
                // Failure
            }
            else
            {
                // Use both partitions as 2 separate volumes.
            }

        default:
            break;
    }
```

Parameters

Parameters	Description
path	Path to the volume with the volume name. The string of volume name has to be preceded by "/mnt/". Also, the volume name and directory name has to be separated by a slash "/".

partition	Array with 4 items, where each items mentions the sizes of each partition in terms of number of sector. 0th element of array specifies the number of sectors for first partition and 3rd element of array specifies the number of sectors for fourth partition.
work	Pointer to the buffer for function work area. The size must be at least FAT_FS_MAX_SS bytes.

Function

SYS_FS_RESULT SYS_FS_DrivePartition
(
const char *path,
const uint32_t partition[],
void * work
);

SYS_FS_DriveSectorGet Function

Obtains total number of sectors and number of free sectors for the specified drive.

File

sys_fs.h

C

```
SYS_FS_RESULT SYS_FS_DriveSectorGet(const char * path, uint32_t * totalSectors, uint32_t * freeSectors);
```

Returns

SYS_FS_RES_SUCCESS - Sector information get operation was successful. SYS_FS_RES_FAILURE - Sector information get operation was unsucessful. The reason for the failure can be retrieved with SYS_FS_Error.

Description

Function to obtain the total number of sectors and number of free sectors in a drive (media).

Remarks

None.

Preconditions

The drive for which the information is to be retrieved should be mounted.

Example

```
uint32_t totalSectors, freeSectors;
SYS_FS_RESULT res;

if(SYS_FS_Mount("/dev/mmcblka1", "/mnt/myDrive", FAT, 0, NULL) != SYS_FS_RES_SUCCESS)
{
    // Failure, try mounting again
}
else
{
    // Mount was successful.
    // Do other FS stuffs.
}
// Perform usual FS tasks.
//....
//....

// Now, determine the total sectors and free sectors
res = SYS_FS_DriveSectorGet("/mnt/myDrive", &totalSectors, &freeSectors);
if(res == SYS_FS_RES_FAILURE)
{
    //Sector information get operation failed.
}
```

Parameters

Parameters	Description
path	Path to the volume with the volume name. The string of volume name must be preceded by "/mnt/". Also, the volume name and directory name must be separated by a slash "/".
totalSectors	Pointer to a variable passed to the function, which will contain the total number of sectors available in the drive (media).
freeSectors	Pointer to a variable passed to the function, which will contain the free number of sectors available in the drive (media).

Function

SYS_FS_RESULT SYS_FS_DriveSectorGet
(
const char* path,
uint32_t *totalSectors,
uint32_t *freeSectors
);

SYS_FS_EventHandlerSet Function

Allows a client to identify an event handling function for the file system to call back when mount/unmount operation has completed.

File

sys_fs.h

C

```
void SYS_FS_EventHandlerSet(const void * eventHandler, const uintptr_t context);
```

Returns

None.

Description

This function allows a client to identify an event handling function for the File System to call back when mount/unmount operation has completed. The file system will pass mount name back to the client by calling "eventHandler".

Remarks

If the client does not want to be notified when the mount/unmount operation has completed, it does not need to register a callback.

Preconditions

The SYS_FS_Initialize() routine must have been called.

Example

```
// Client registers an event handler with file system. This is done once.
SYS_FS_EventHandlerSet(APP_SysFSEventHandler, (uintptr_t)NULL);

// Event Processing Technique. Event is received when operation is done.
void APP_SysFSEventHandler
(
    SYS_FS_EVENT event,
    void* eventData,
    uintptr_t context
)
{
    switch(event)
    {
        case SYS_FS_EVENT_MOUNT:
            if(0 == strcmp((const char *)mountName,"/mnt/myDrive1"))
            {
                gSDCardMountFlag = true;
            }
            else if(0 == strcmp((const char *)mountName,"/mnt/myDrive2"))
            {
                gNVMMountFlag = true;
```

```
                }
                break;

            case SYS_FS_EVENT_UNMOUNT:
                if(0 == strcmp((const char *)mountName,"/mnt/myDrive1"))
                {
                    gSDCardMountFlag = false;
                }
                else if(0 == strcmp((const char *)mountName,"/mnt/myDrive2"))
                {
                    gNVMMountFlag = false;
                }
                appData.state = APP_ERROR;
                break;

            case SYS_FS_EVENT_ERROR:
                break;
        }
    }
```

Parameters

Parameters	Description
eventHandler	Pointer to the event handler function implemented by the user
context	The value of parameter will be passed back to the client unchanged, when the eventHandler function is called. It can be used to identify any client specific data object that identifies the instance of the client module (for example, it may be a pointer to the client module's state structure).

Function

void SYS_FS_EventHandlerSet

(

const void * eventHandler,

const uintptr_t context

);

c) Data Types and Constants

SYS_FS_ERROR Enumeration

Lists the various error cases.

File

sys_fs.h

C

```
typedef enum {
  SYS_FS_ERROR_OK = 0,
  SYS_FS_ERROR_DISK_ERR,
  SYS_FS_ERROR_INT_ERR,
  SYS_FS_ERROR_NOT_READY,
  SYS_FS_ERROR_NO_FILE,
  SYS_FS_ERROR_NO_PATH,
  SYS_FS_ERROR_INVALID_NAME,
  SYS_FS_ERROR_DENIED,
  SYS_FS_ERROR_EXIST,
  SYS_FS_ERROR_INVALID_OBJECT,
  SYS_FS_ERROR_WRITE_PROTECTED,
  SYS_FS_ERROR_INVALID_DRIVE,
  SYS_FS_ERROR_NOT_ENABLED,
  SYS_FS_ERROR_NO_FILESYSTEM,
  SYS_FS_ERROR_FORMAT_ABORTED,
  SYS_FS_ERROR_TIMEOUT,
  SYS_FS_ERROR_LOCKED,
  SYS_FS_ERROR_NOT_ENOUGH_CORE,
  SYS_FS_ERROR_TOO_MANY_OPEN_FILES,
```

```
  SYS_FS_ERROR_INVALID_PARAMETER,
  SYS_FS_ERROR_NOT_ENOUGH_FREE_VOLUME,
  SYS_FS_ERROR_FS_NOT_SUPPORTED,
  SYS_FS_ERROR_FS_NOT_MATCH_WITH_VOLUME,
  SYS_FS_ERROR_NOT_SUPPORTED_IN_NATIVE_FS
} SYS_FS_ERROR;
```

Members

Members	Description
SYS_FS_ERROR_OK = 0	Success
SYS_FS_ERROR_DISK_ERR	(1) A hard error occurred in the low level disk I/O layer
SYS_FS_ERROR_INT_ERR	(2) Assertion failed
SYS_FS_ERROR_NOT_READY	(3) The physical drive cannot work
SYS_FS_ERROR_NO_FILE	(4) Could not find the file
SYS_FS_ERROR_NO_PATH	(5) Could not find the path
SYS_FS_ERROR_INVALID_NAME	(6) The path name format is invalid
SYS_FS_ERROR_DENIED	(7) Access denied due to prohibited access or directory full
SYS_FS_ERROR_EXIST	(8) Access denied due to prohibited access
SYS_FS_ERROR_INVALID_OBJECT	(9) The file/directory object is invalid
SYS_FS_ERROR_WRITE_PROTECTED	(10) The physical drive is write protected
SYS_FS_ERROR_INVALID_DRIVE	(11) The logical drive number is invalid
SYS_FS_ERROR_NOT_ENABLED	(12) The volume has no work area
SYS_FS_ERROR_NO_FILESYSTEM	(13) There is no valid volume
SYS_FS_ERROR_FORMAT_ABORTED	(14) The Format() aborted due to any parameter error
SYS_FS_ERROR_TIMEOUT	(15) Could not get a grant to access the volume within defined period
SYS_FS_ERROR_LOCKED	(16) The operation is rejected according to the file sharing policy
SYS_FS_ERROR_NOT_ENOUGH_CORE	(17) LFN working buffer could not be allocated
SYS_FS_ERROR_TOO_MANY_OPEN_FILES	(18) Number of open files
SYS_FS_ERROR_INVALID_PARAMETER	(19) Given parameter is invalid
SYS_FS_ERROR_NOT_ENOUGH_FREE_VOLUME	(20) Too many mounts requested. Not enough free volume available
SYS_FS_ERROR_FS_NOT_SUPPORTED	(21) Requested native file system is not supported
SYS_FS_ERROR_FS_NOT_MATCH_WITH_VOLUME	(22) Requested native file system does not match the format of volume
SYS_FS_ERROR_NOT_SUPPORTED_IN_NATIVE_FS	(23) Function not supported in native file system layer

Description

File Error enumeration

This enumeration lists the various error cases. When the application calls for a file system function which has a return type of SYS_FS_RESULT and if the return value is SYS_FS_RES_FAILURE, the application can know the specific reason for failure by calling the SYS_FS_FileError function. The return value of SYS_FS_FileError function will be one of the enumeration of type SYS_FS_ERROR.

Remarks

None.

SYS_FS_FILE_OPEN_ATTRIBUTES Enumeration

Lists the various attributes (modes) in which a file can be opened.

File

sys_fs.h

C

```
typedef enum {
  SYS_FS_FILE_OPEN_READ = 0,
  SYS_FS_FILE_OPEN_WRITE,
  SYS_FS_FILE_OPEN_APPEND,
  SYS_FS_FILE_OPEN_READ_PLUS,
  SYS_FS_FILE_OPEN_WRITE_PLUS,
  SYS_FS_FILE_OPEN_APPEND_PLUS
} SYS_FS_FILE_OPEN_ATTRIBUTES;
```

Members

Members	Description
SYS_FS_FILE_OPEN_READ = 0	reading the file = possible, if file exists. reading the file = file open returns error, if file does not exist. writing to the file = not possible. Write operation returns error
SYS_FS_FILE_OPEN_WRITE	reading the file = not possible. Read operation returns error. writing to the file = possible. If file exists, write happens from the beginning of the file, overwriting the existing content of the file. writing to the file = If file does not exist, a new file will be created and data will be written into the newly created file.
SYS_FS_FILE_OPEN_APPEND	reading the file = not possible. Read operation returns error writing to the file = possible. If file exists, write happens from the end of the file, preserving the existing content of the file. writing to the file = If file does not exist, a new file will be created and data will be written into the newly created file.
SYS_FS_FILE_OPEN_READ_PLUS	reading the file = possible, if file exists. reading the file = file open returns error, if file does not exist. writing to the file = possible, if file exists, staring from the beginning of the file (overwriting). writing to the file = file open returns error, if file does not exist.
SYS_FS_FILE_OPEN_WRITE_PLUS	reading the file = possible, if file exists. reading the file = If file does not exist, a new file will be created. writing to the file = possible. If file exists, write happens from the beginning of the file, overwriting the existing content of the file. writing to the file = If file does not exist, a new file will be created and data will be written into the newly created file.
SYS_FS_FILE_OPEN_APPEND_PLUS	reading the file = possible, if file exists. File read pointer will be moved to end of the file in this mode. reading the file = If file does not exist, a new file will be created. writing to the file = possible. If file exists, write happens from the end of the file, preserving the existing content of the file. writing to the file = If file does not exist, a new file will be created and data will be written into the newly created file.

Description

File open attributes

This enumeration lists the various attributes (modes) in which a file can be opened.

Remarks

None.

SYS_FS_FILE_SEEK_CONTROL Enumeration

Lists the various modes of file seek.

File

sys_fs.h

C

```
typedef enum {
  SYS_FS_SEEK_SET,
  SYS_FS_SEEK_CUR,
  SYS_FS_SEEK_END
} SYS_FS_FILE_SEEK_CONTROL;
```

Members

Members	Description
SYS_FS_SEEK_SET	Set file offset to input number of bytes from the start of file
SYS_FS_SEEK_CUR	Set file offset to its current location plus input number of bytes
SYS_FS_SEEK_END	Set file offset to size of the file plus input number of bytes

Description

File Seek control

This enumeration lists the various modes of file seek. When the application calls the SYS_FS_FileSeek function, it specifies the kind of seek that needs to be performed.

Remarks

None.

SYS_FS_FILE_SYSTEM_TYPE Enumeration

Enumerated data type identifying native file systems supported.

File

sys_fs.h

C

```
typedef enum {
  UNSUPPORTED_FS = 0,
  FAT,
  MPFS2
} SYS_FS_FILE_SYSTEM_TYPE;
```

Members

Members	Description
UNSUPPORTED_FS = 0	Unsupported File System
FAT	FAT FS native File system
MPFS2	MPFS2 native File system

Description

File System type

These enumerated values identify the native file system supported by the SYS FS.

Remarks

None.

SYS_FS_FSTAT Structure

File System status

File

sys_fs.h

C

```
typedef struct {
  uint32_t fsize;
  uint16_t fdate;
  uint16_t ftime;
  uint8_t fattrib;
  char fname[13];
  char * lfname;
  uint32_t lfsize;
} SYS_FS_FSTAT;
```

Members

Members	Description
uint32_t fsize;	File size
uint16_t fdate;	Last modified date
uint16_t ftime;	Last modified time
uint8_t fattrib;	Attribute
char fname[13];	Short file name (8.3 format)
char * lfname;	Pointer to the LFN buffer
uint32_t lfsize;	Size of LFN buffer in TCHAR

Description

SYS FS File status structure

This structure holds the various status of a file. The SYS_FS_FileStat () populates the contents of this structure.

Remarks

None.

SYS_FS_FUNCTIONS Structure

SYS FS Function signature structure for native file systems.

File

sys_fs.h

C

```

int (* open)(uintptr_t handle, const char* path, uint8_t mode);	Function pointer of native file system for opening a file
int (* read)(uintptr_t fp, void* buff, uint32_t btr, uint32_t *br);	Function pointer of native file system for reading a file
int (* write)(uintptr_t fp, const void* buff, uint32_t btw, uint32_t* bw);	Function pointer of native file system for writing to a file
int (* close)(uintptr_t fp);	Function pointer of native file system for closing a file
int (* seek)(uintptr_t handle, uint32_t offset);	Function pointer of native file system for moving the file pointer by a • desired offset
uint32_t (* tell)(uintptr_t handle);	Function pointer of native file system for finding the position of the • file pointer
bool (* eof)(uintptr_t handle);	Function pointer of native file system to check if the end of file is • reached
uint32_t (* size)(uintptr_t handle);	Function pointer of native file system to know the size of file
int (* fstat)(const char* path, uintptr_t fno);	Function pointer of native file system to know the status of file
int (* mkdir)(const char *path);	Function pointer of native file system to create a directory
int (* chdir)(const char *path);	Function pointer of native file system to change a directory
int (* remove)(const char *path);	Function pointer of native file system to remove a file or directory
int (* getlabel)(const char *path, char *buff, uint32_t *sn);	Function pointer of native file system to get the volume label

int (* setlabel)(const char *label);	Function pointer of native file system to set the volume label
int (* truncate)(uintptr_t handle);	Function pointer of native file system to truncate the file
int (* currWD)(char* buff, uint32_t len);	Function pointer of native file system to obtain the current working • directory
int (* chdrive)(uint8_t drive);	Function pointer of native file system to set the current drive
int (* chmode)(const char* path, uint8_t attr, uint8_t mask);	Function pointer of native file system to change the attribute for file • or directory
int (* chtime)(const char* path, uintptr_t ptr);	Function pointer of native file system to change the time for a file or • directory
int (* rename)(const char *oldPath, const char *newPath);	Function pointer of native file system to rename a file or directory
int (* sync)(uintptr_t fp);	Function pointer of native file system to flush file
char * (* getstrn)(char* buff, int len, uintptr_t handle);	Function pointer of native file system to read a string from a file
int (* putchr)(char c, uintptr_t handle);	Function pointer of native file system to write a character into a file
int (* putstrn)(const char* str, uintptr_t handle);	Function pointer of native file system to write a string into a file
int (* formattedprint)(uintptr_t handle, const char *str, ...);	Function pointer of native file system to print a formatted string to • file
bool (* testerror)(uintptr_t handle);	Function pointer of native file system to test an error in a file
int (* formatDisk)(uint8_t vol, uint8_t sfd, uint32_t au);	Function pointer of native file system to format a disk
int (* openDir)(uintptr_t handle, const char *path);	Function pointer of native file system to open a directory
int (* readDir)(uintptr_t handle, uintptr_t stat);	Function pointer of native file system to read a directory
int (* closeDir)(uintptr_t handle);	Function pointer of native file system to close an opened directory
int (* partitionDisk)(uint8_t pdrv, const uint32_t szt[], void* work);	Function pointer of native file system to partition a physical drive
int (* getCluster)(const char *path, uint32_t *tot_sec, uint32_t *free_sec);	Function pointer of native file system to get total sectors and free • sectors

Description

SYS FS Function signature structure for native file systems

The SYS FS layer supports functions from each native file system layer. This structure specifies the signature for each function from native file system (parameter that needs to be passed to each function and return type for each function). If a new native file system is to be integrated with the SYS FS layer, the functions should follow the signature.

The structure of function pointer for the two native file systems: FAT FS and MPFS2 is already provided in the respective source files for the native file system. Hence the following structure is not immediately useful for the user. But the explanation for the structure is still provided for advanced users who would wish to integrate a new native file system to the MPLAB Harmony File System framework.

Remarks

None.

SYS_FS_HANDLE Type

This type defines the file handle.

File

sys_fs.h

C

```
typedef uintptr_t SYS_FS_HANDLE;
```

Description

SYS FS File Handle

This type defines the file handle. File handle is returned by the File Open function on successful operation.

Remarks

None.

SYS_FS_REGISTRATION_TABLE Structure

The sys_fs layer has to be initialized by passing this structure with suitably initialized members.

File

sys_fs.h

C

```
typedef struct {
  SYS_FS_FILE_SYSTEM_TYPE nativeFileSystemType;
  const SYS_FS_FUNCTIONS * nativeFileSystemFunctions;
} SYS_FS_REGISTRATION_TABLE;
```

Members

Members	Description
SYS_FS_FILE_SYSTEM_TYPE nativeFileSystemType;	Native file system of type SYS_FS_FILE_SYSTEM_TYPE
const SYS_FS_FUNCTIONS * nativeFileSystemFunctions;	Pointer to the structure of type SYS_FS_FUNCTIONS which has the list of

Description

SYS_FS_REGISTRATION_TABLE structure

When the SYS FS layer is initialized, it has to know the type of native file system it has to support and the list of functions for native file system. The members of this structure can be initialized with suitable values and then passed on to SYS_FS_Initialize initialization function. Please refer to the example code provided for SYS_FS_Initialize.

Remarks

None.

SYS_FS_RESULT Enumeration

Lists the various results of a file operation.

File

sys_fs.h

C

```
typedef enum {
  SYS_FS_RES_SUCCESS = 0,
  SYS_FS_RES_FAILURE = -1
} SYS_FS_RESULT;
```

Members

Members	Description
SYS_FS_RES_SUCCESS = 0	Operation succeeded
SYS_FS_RES_FAILURE = -1	Operation failed

Description

File operation result enum

This enumeration lists the various results of a file operation. When a file operation function is called from the application, and if the return type of the function is SYS_FS_RESULT, then the enumeration below specifies the possible values returned by the function.

Remarks

None.

FAT_FS_MAX_LFN Macro

Maximum length of the Long File Name.

File

sys_fs.h

C

```
#define FAT_FS_MAX_LFN 255
```

Description

FAT File System LFN (Long File Name) max length

Defines the maximum length of file name during LFN selection. Set the value to 255.

Remarks

None.

FAT_FS_MAX_SS Macro

Lists the definitions for FAT file system sector size.

File

sys_fs.h

C

```
#define FAT_FS_MAX_SS 512
```

Description

FAT File System Sector size

Maximum sector size to be handled. Always set the value of sector size to 512

Remarks

None.

FAT_FS_USE_LFN Macro

Lists the definitions for FAT file system LFN selection.

File

sys_fs.h

C

```
#define FAT_FS_USE_LFN 1
```

Description

FAT File System LFN (long file name) selection

The FAT_FS_USE_LFN option switches the LFN support. Set the value to 1.

Remarks

None.

SYS_FS_HANDLE_INVALID Macro

Invalid file handle

File

sys_fs.h

C

```
#define SYS_FS_HANDLE_INVALID ((SYS_FS_HANDLE)(-1))
```

Description

SYS FS File Invalid Handle

This value defines the invalid file handle. Invalid file handle is returned on an unsucessful File Open operation.

Remarks

None.

SYS_FS_FILE_DIR_ATTR Enumeration

Enumerated data type identifying the various attributes for file/directory.

File

sys_fs.h

C

```
typedef enum {
  SYS_FS_ATTR_RDO = 0x01,
  SYS_FS_ATTR_HID = 0x02,
  SYS_FS_ATTR_SYS = 0x04,
  SYS_FS_ATTR_VOL = 0x08,
  SYS_FS_ATTR_LFN = 0x0F,
  SYS_FS_ATTR_DIR = 0x10,
  SYS_FS_ATTR_ARC = 0x20,
  SYS_FS_ATTR_MASK = 0x3F
} SYS_FS_FILE_DIR_ATTR;
```

Members

Members	Description
SYS_FS_ATTR_RDO = 0x01	Read only
SYS_FS_ATTR_HID = 0x02	Hidden
SYS_FS_ATTR_SYS = 0x04	System
SYS_FS_ATTR_VOL = 0x08	Volume label
SYS_FS_ATTR_LFN = 0x0F	LFN entry
SYS_FS_ATTR_DIR = 0x10	Directory
SYS_FS_ATTR_ARC = 0x20	Archive
SYS_FS_ATTR_MASK = 0x3F	Mask of defined bits

Description

File or directory attribute

These enumerated values are the possible attributes for a file or directory.

Remarks

None.

SYS_FS_TIME Union

The structure to specify the time for a file or directory.

File

sys_fs.h

C

```
typedef union {
  struct discreteTime {
    unsigned second : 5;
    unsigned minute : 6;
    unsigned hour : 5;
    unsigned day : 5;
    unsigned month : 4;
    unsigned year : 7;
  }
  struct timeDate {
    uint16_t time;
    uint16_t date;
  }
  uint32_t packedTime;
} SYS_FS_TIME;
```

Members

Members	Description
unsigned second : 5;	Second / 2 (0..29)
unsigned minute : 6;	Minute (0..59)
unsigned hour : 5;	Hour (0..23)
unsigned day : 5;	Day in month(1..31)
unsigned month : 4;	Month (1..12)
unsigned year : 7;	Year from 1980 (0..127)
uint16_t time;	Time (hour, min, seconds)
uint16_t date;	Date (year, month, day)
uint32_t packedTime;	Combined time information in a 32-bit value

Description

SYS FS File time structure

This structure holds the date and time to be used to set for a file or directory.

bits 31-25: Year from 1980 (0..127) bits 24-21: Month (1..12) bits 20-16: Day in month(1..31) bits 15-11: Hour (0..23) bits 10-5 : Minute (0..59) bits 4-0 : Seconds / 2 (0..29)

Remarks

None.

SYS_FS_FORMAT Enumeration

Specifes the partitioning rule.

File

sys_fs.h

C

```
typedef enum {
  SYS_FS_FORMAT_FDISK = 0,
  SYS_FS_FORMAT_SFD = 1
} SYS_FS_FORMAT;
```

Members

Members	Description
SYS_FS_FORMAT_FDISK = 0	Format disk with multiple partition
SYS_FS_FORMAT_SFD = 1	Format disk with single partition

Description

File formating partition rule

This type specifies the partitioning rule. When SYS_FS_FORMAT_FDISK format is specified, a primary partition occupying the entire disk space is created and then an FAT volume is created on the partition. When SYS_FS_FORMAT_SFD format is specified, the FAT volume starts from the first sector of the physical drive.

The SYS_FS_FORMAT_FDISK partitioning is usually used for hard disk, MMC, SDC, CFC and U Disk. It can divide a physical drive into one or more partitions with a partition table on the MBR. However Windows does not support multiple partition on the removable media. The SYS_FS_FORMAT_SFD is non-partitioned method. The FAT volume starts from the first sector on the physical drive without partition table. It is usually used for floppy disk, micro drive, optical disk, and super-floppy media.

SYS_FS_EVENT Enumeration

Identifies the possible file system events.

File

sys_fs.h

C

```
typedef enum {
  SYS_FS_EVENT_MOUNT,
  SYS_FS_EVENT_UNMOUNT,
```

```
    SYS_FS_EVENT_ERROR
} SYS_FS_EVENT;
```

Members

Members	Description
SYS_FS_EVENT_MOUNT	Media has been mounted successfully.
SYS_FS_EVENT_UNMOUNT	Media has been unmounted successfully.
SYS_FS_EVENT_ERROR	There was an error during the operation

Description

SYS FS Media Events

This enumeration identifies the possible events that can result from a file system.

Remarks

One of these values is passed in the "event" parameter of the event handling callback function that client registered with the file system by setting the event handler when media mount or unmount is completed.

SYS_FS_EVENT_HANDLER Type

Pointer to the File system Handler function.

File

sys_fs.h

C

```
typedef void (* SYS_FS_EVENT_HANDLER)(SYS_FS_EVENT event, void* eventData, uintptr_t context);
```

Returns

None.

Description

File System Event Handler function pointer

This data type defines the required function signature for the file system event handling callback function. A client must register a pointer to an event handling function whose function signature (parameter and return value types) match the types specified by this function pointer in order to receive event call backs from the file system.

Remarks

None.

Parameters

Parameters	Description
event	Identifies the type of event
eventData	Handle returned from the media operation requests
context	Value identifying the context of the application that registered the event handling function

Files

Files

Name	Description
sys_fs.h	Functions and type declarations required to interact with the MPLAB Harmony File System Service.
sys_fs_config_template.h	File System Service configuration templates.

Description

This section lists the source and header files used by the library.

sys_fs.h

Functions and type declarations required to interact with the MPLAB Harmony File System Service.

Enumerations

	Name	Description
	SYS_FS_ERROR	Lists the various error cases.
	SYS_FS_EVENT	Identifies the possible file system events.
	SYS_FS_FILE_DIR_ATTR	Enumerated data type identifying the various attributes for file/directory.
	SYS_FS_FILE_OPEN_ATTRIBUTES	Lists the various attributes (modes) in which a file can be opened.
	SYS_FS_FILE_SEEK_CONTROL	Lists the various modes of file seek.
	SYS_FS_FILE_SYSTEM_TYPE	Enumerated data type identifying native file systems supported.
	SYS_FS_FORMAT	Specifes the partitioning rule.
	SYS_FS_RESULT	Lists the various results of a file operation.

Functions

	Name	Description
	SYS_FS_CurrentDriveGet	Gets the current drive
	SYS_FS_CurrentDriveSet	Sets the drive.
	SYS_FS_CurrentWorkingDirectoryGet	Gets the current working directory
	SYS_FS_DirClose	Closes an opened directory.
	SYS_FS_DirectoryChange	Changes to a the directory specified.
	SYS_FS_DirectoryMake	Makes a directory.
	SYS_FS_DirOpen	Open a directory
	SYS_FS_DirRead	Reads the specified directory.
	SYS_FS_DirRewind	Rewinds to the beginning of the directory.
	SYS_FS_DirSearch	Searches for a file or directory.
	SYS_FS_DriveFormat	Formats a drive.
	SYS_FS_DriveLabelGet	Gets the drive label.
	SYS_FS_DriveLabelSet	Sets the drive label
	SYS_FS_DrivePartition	Partitions a physical drive (media).
	SYS_FS_DriveSectorGet	Obtains total number of sectors and number of free sectors for the specified drive.
	SYS_FS_Error	Returns the last error.
	SYS_FS_EventHandlerSet	Allows a client to identify an event handling function for the file system to call back when mount/unmount operation has completed.
	SYS_FS_FileCharacterPut	Writes a character to a file.
	SYS_FS_FileClose	Closes a file.
	SYS_FS_FileDirectoryModeSet	Sets the mode for the file or directory.
	SYS_FS_FileDirectoryRemove	Removes a file or directory.
	SYS_FS_FileDirectoryRenameMove	Renames or moves a file or directory.
	SYS_FS_FileDirectoryTimeSet	Sets or changes the time for a file or directory.
	SYS_FS_FileEOF	Checks for end of file.
	SYS_FS_FileError	Returns the file specific error.
	SYS_FS_FileNameGet	Reads the file name.
	SYS_FS_FileOpen	Opens a file.
	SYS_FS_FilePrintf	Writes a formatted string into a file.
	SYS_FS_FileRead	Read data from the file.
	SYS_FS_FileSeek	Moves the file pointer by the requested offset.
	SYS_FS_FileSize	Returns the size of the file in bytes.
	SYS_FS_FileStat	Gets file status.
	SYS_FS_FileStringGet	Reads a string from the file into a buffer.
	SYS_FS_FileStringPut	Writes a string to a file.
	SYS_FS_FileSync	Flushes the cached information when writing to a file.
	SYS_FS_FileTell	Obtains the file pointer position.
	SYS_FS_FileTestError	Checks for errors in the file.
	SYS_FS_FileTruncate	Truncates a file
	SYS_FS_FileWrite	Writes data to the file.
	SYS_FS_Initialize	Initializes the file system abstraction layer (sys_fs layer).
	SYS_FS_Mount	Mounts the file system.

	SYS_FS_Tasks	Maintains the File System tasks and functionalities.
	SYS_FS_Unmount	Unmounts the file system.

Macros

	Name	Description
	FAT_FS_MAX_LFN	Maximum length of the Long File Name.
	FAT_FS_MAX_SS	Lists the definitions for FAT file system sector size.
	FAT_FS_USE_LFN	Lists the definitions for FAT file system LFN selection.
	SYS_FS_HANDLE_INVALID	Invalid file handle

Structures

	Name	Description
	SYS_FS_FSTAT	File System status
	SYS_FS_FUNCTIONS	SYS FS Function signature structure for native file systems.
	SYS_FS_REGISTRATION_TABLE	The sys_fs layer has to be initialized by passing this structure with suitably initialized members.

Types

	Name	Description
	SYS_FS_EVENT_HANDLER	Pointer to the File system Handler function.
	SYS_FS_HANDLE	This type defines the file handle.

Unions

	Name	Description
	SYS_FS_TIME	The structure to specify the time for a file or directory.

Interrupt System Service Library

This section describes the Interrupt System Service Library.

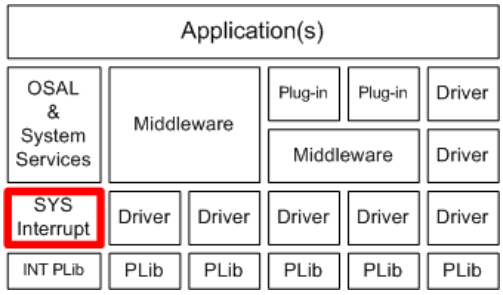
Introduction

Interrupt System Service for Microchip Microcontrollers

This library provides a low-level abstraction of the Interrupt System Service Library that is available on the Microchip family of PIC32 microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thereby hiding differences from one microcontroller variant to another.

Description

This library implements the Interrupt System Service. It is part of the system services that provides support for processing interrupts. The Interrupt System provides support for initializing the processor's interrupt controller, registering Interrupt Service Routines (ISRs) and managing interrupts. These features enable making efficient and dynamic applications, drivers, and middleware that respond to external events as they occur in real time.



Using the Library

This topic describes the basic architecture of the Interrupt System Service Library and provides information and examples on its use.

Description

Interface Header File: `sys_int.h`

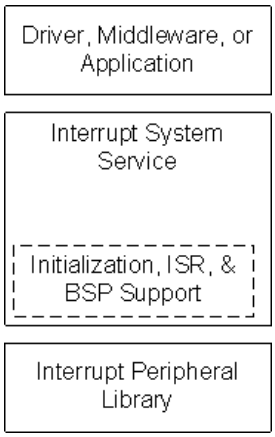
The interface to the Interrupt System Service library is defined in the `sys_int.h` header file, which is included by the `sys.h` system service header file. Any C language source (`.c`) file that uses the Interrupt System Service library should include `sys.h`.

Please refer to the What is MPLAB Harmony? section for how the library interacts with the framework.

Abstraction Model

This library provides an abstraction of the interrupt subsystem that is used by device drivers, middleware libraries and applications to receive and control interrupts in real time.

Description



Interrupt System Service

The interrupt system services provide support for initializing the processor's interrupt controller, managing Interrupt Service Routines (ISRs) and

managing interrupts.

Initialization

Each software module (device driver, library, or application) that needs to receive an interrupt must enable that interrupt itself. This is normally done in the module's initialization routine which is called by the SYS_Initialize service.

A module that intends to use an interrupt must first register the Tasks function that is to be called when the desired source causes an interrupt. Then, it must enable that source, once it is ready to start receiving interrupts.

If the interrupt system service is configured for static usage, the routine that dynamically registers the Tasks function will be nulled out by a macro (generating no run-time code) and, instead, the Tasks routine must be called statically from the function that implements the raw ISR vector. How this is done is different for each processor family, as explained in the following section.

Interrupt Service Routine (ISR)

Each software module (device driver, library, or application) that needs to receive an interrupt must implement a Tasks routine to handle that interrupt. In order for the module to operate in an interrupt-driven mode, the Tasks routine must be called from within the appropriate "raw" Interrupt Service Routine (ISR).

How the raw ISR is implemented is highly dependent upon the specific processor being used. Libraries are available that implement raw ISRs for each processor family in a way that allows dynamic registration and deregistration of Tasks routines. These libraries maintain tables that associate the Tasks routine registered by the SYS INIT service with each interrupt source in the system.

Alternately, in a statically-linked system implementation, the ISR may be implemented by the system designer or integrator (in the configuration-specific `system_interrupt.c` file). Such "static" ISR implementations must identify the source of the interrupt then directly call the appropriate module's Tasks routine. This requires knowledge of the modules that have been included in the system and cannot be implemented in advance as a library.

Note: It is also possible, in a highly optimized system (or to support highly resource-restricted parts), to implement the logic of the module's Tasks routine directly in the raw ISR. However, this method is not recommended unless absolutely necessary to meet system timing requirements.

Board Support Packages (BSPs)

If the processor is affixed directly to the board, the BSP may also implement any required "raw" ISRs, eliminating the need for the system designer or integrator to implement the ISR(s) himself. Refer to the documentation for the BSP in use for details on what initialization and ISR support it provides. This support is not implemented by the Interrupt System Services library.

Library Overview

Refer to the System Service Introduction section for how the system services operates in a system.

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Interrupt System Service.

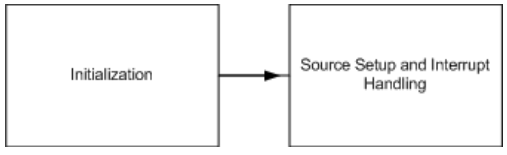
Library Interface Section	Description
Interrupt System Setup Functions	Provides processor specific initialization of the interrupt system
Global Interrupt Management Functions	Provide interface routines to enable/disable all interrupts on the system
Interrupt Source Management Functions	Provides setup and status routines for: • Setting up the source enable configuration • Querying the source interrupt status

How the Library Works

The Interrupt System Service Library can be used by a device driver, middleware layer, or application to provide access to, and control over, interrupts to the processor.

Description

The following diagram describes the major components of the usage model.



Note: Not all modes are available on all devices. Please refer to the specific device data sheet to determine the modes supported for your device.

Interrupt System Setup

The Interrupt System Service library must be initialized by calling the SYS_INT_Initialize function. If the MPLAB Harmony dynamic initialization service is used, the SYS_INT_Initialize function will be called automatically when the SYS_Initialize function is called. In a statically initialized system, the system designer or integrator must implement the SYS_Initialize function and that function must call SYS_INT_Initialize before initializing any modules that might require use if the interrupt system service. Once the library has been initialized, call the function SYS_INT_Enable to enable interrupts to the processor. However, before enabling the generation of interrupts to the processor, each individual module (driver, library, or application) must have a "Tasks" routine to in place (either registered with SYS_INT_DynamicRegister or statically linked to the raw ISR) to handle the interrupt before it enables its own interrupt.

Example: Initializing the System Interrupt Library

```
SYS_INT_Initialize();
// Initialize all interrupt-aware software modules
SYS_INT_Enable();
```

Critical Sections

Critical Sections

Critical sections of code are small sections of code that must execute atomically, with no possibility of being interrupted. To support this, the following technique can be used.

Global Interrupt Management provides routines to create a global critical section of code.

Global Critical Section

If no interrupts of any kind can be allowed within a critical section of code, the following routines can be used to ensure this.

- SYS_INT_Disable: To start a critical section, all interrupts are disabled with the call of this function
- SYS_INT_Enable : To end a critical section, interrupts are enabled from the interrupt controller to the core
- SYS_INT_IsEnabled: Status to indicate if whether or interrupts are currently enabled

Example: Global Critical Section

```
bool flag;
flag = SYS_INT_Disable();

// Do something critical

if (flag)
{
    SYS_INT_Enable();
}
```

Source Interrupt Management provides interface routines to create local critical sections.

Local Critical Sections

Normally, it is not necessary to globally disable all possible interrupts. For example, in a driver for a specific device, it is not normally important if an unrelated interrupt occurs in the middle of a critical section of code. However, if the interrupt for the source that the driver manages must not occur within a critical section of code, it can be protected using the following technique.

Example: Local Critical Section

```
bool flag;
// interrupt source enable status before disable is called
flag = SYS_INT_SourceDisable(MY_DRIVER_INTERRUPT_SOURCE);

// Do something critical

if (flag)
{
    SYS_INT_SourceEnable(MY_DRIVER_INTERRUPT_SOURCE);
}
```

Note: These methods of protecting critical sections is usually implemented as part of an Operating System Abstraction Layer (OSAL), so it is not normally necessary to use these examples explicitly. Normally, the OSAL will provide single functions or macros that implement this functionality. So, if available, an OSAL method is preferred over implementing the critical section code as shown in the previous examples.

Source Interrupt Management

The driver, middleware, or application's interrupt-handling Tasks routine must do two things at a minimum, in the following order.

1. Remove the cause of the interrupt.
2. Clear the interrupt source by calling the function SYS_INT_SourceStatusClear.

Exactly what actions are necessary to remove the cause of an interrupt is completely dependent on the source of the interrupt. This is normally the main purpose of the driver itself and is beyond the scope of this section. Refer to the documentation for the peripheral being managed.

Warning The cause of the interrupt must be removed before clearing the interrupt source or the interrupt may reoccur immediately after the source is cleared potentially causing an infinite loop. An infinite loop may also occur if the source is not cleared before the interrupt-handler returns.

Example: Handling Interrupts

```
void DRV_MYDEV_Tasks( SYS_MODULE_OBJ object )
{
    // Remove the cause of the interrupt
    //...

    // Clear Interrupt source
    SYS_INT_SourceStatusClear(myIntSourceID);
}
```

Note: The value of `myIntSourceID` is usually either a static or dynamic configuration option. Refer to the documentation for the specific device driver to identify how to define the interrupt source ID.

Testing Interrupt

Sometimes it is necessary to cause an interrupt in software, possibly for testing purposes. To support this, the function SYS_INT_SourceStatusSet is provided.

Example: Causing an Interrupt in Software

```
SYS_INT_SourceStatusSet(MY_DRIVER_INTERRUPT_SOURCE);
```

Note: This feature is not available for all interrupt sources on all Microchip microcontrollers. Refer to the specific device data sheet to determine whether it is possible for software to set a specific interrupt source.

Configuring the Library

This section provides information on configuring the Interrupt System Service Library.

Description

To use the Interrupt System Service Library, the following must be correctly configured:

- Select the Appropriate Processor
- Initialize the Interrupt System Service
- Configure the Raw ISR Support

Select the Appropriate Processor

The following data types are dependent on the processor selection and are actually defined in the Interrupt Peripheral Library for the specific microcontroller being used.

- INT_SOURCE
- INT_PRIORITY
- INT_SUBPRIORITY

These data types are configured by selecting the appropriate processor in MPLAB X IDE, which adds the "mprocessor" option to the compiler command line to identify the correct processor and processor-specific implementation of the peripheral library to use. Since the Interrupt System Service Library is part of the Microchip Firmware Framework, it will be built with the correct definition of these data types.

Initialize the Interrupt System Service

There are two ways to initialize the interrupt system service, depending on whether you are using a static configuration or a dynamic configuration.

For a Dynamic configuration the constant SYS_INT_DYNAMIC needs to be defined. This makes the SYS_INT_DynamicRegister and SYS_INT_DynamicDeregister functions available. The required driver tasks routines need to be registered using SYS_INT_DynamicRegister function.

For a Static configuration, the system designer or integrator must implement the SYS_INT_Initialize function. This function's purpose is to perform any actions necessary to initialize the interrupt subsystem and interrupt controller on the specific processor and system, usually interacting directly

with the Interrupt Peripheral Library to accomplish these tasks.

Configure the Raw ISR Support

In some systems, there may only be a single actual (raw) ISR to handle all interrupts. In this sort of system, most of the Interrupt System Service Library may be implemented in software, with only the highest level interrupt being supported by hardware. In other systems, all interrupts may be supported by separate ISRs and vector selection and prioritization will be supported by hardware.

ISRs may be dynamically linked to specific interrupt sources or they may be statically linked at build time. If a dynamic interrupt library is used (by defining the constant `SYS_INT_DYNAMIC`), the calls to the SYS_INT_DynamicRegister function will register a pointer to the given Tasks routine for each registered interrupt source in an internal table. The dynamic library will then determine the source of the interrupt and call the given Tasks routine.

If a static configuration is desired, the "raw" ISR support must be implemented so that it directly calls (using static, build-time linkage) the appropriate module's Tasks routine. This requires the system implementer or integrator to implement the raw ISR, but it reduces the amount of overhead necessary to handle interrupts, reducing both interrupt latency and code size.

Static Configuration

When statically configuring raw ISR support, the system implementer or integrator must directly implement the raw ISRs in an appropriate manner for the selected processor. The raw ISR, must then call the appropriate Tasks routine to properly handle and clear the interrupt source.

Description

A static configuration of the raw ISR support for MPLAB Harmony requires processor-family-specific knowledge. Or, more accurately, it requires compiler-specific knowledge. The following example shows how to implement a raw ISR for the PIC32 family of devices. Refer to the compiler manual for details of how to implement an ISR.

Raw ISR Responsibilities:

- Identify the interrupt source
- Call the appropriate module's Tasks routine

The first thing a raw ISR must do is identify the source of the interrupt. Each interrupt source has its own interrupt "vector". This means that the only time a specific ISR is called is when a specific source has caused an interrupt. Therefore, the raw ISR can assume that every time it is called, its source has caused an interrupt. Once the raw ISR has identified the interrupt source, it must call the appropriate module's Tasks routine to service and clear the interrupt.

Example: PIC32 Timer1 Raw ISR

```
void __ISR ( _TIMER_1_VECTOR ) _InterruptHandler_TMR_1_stub( void )
{
    /* Call the timer driver's "Tasks" routine */
    DRV_TMR_Tasks ( gTMRObject );
}
```

In the example, gTMRObject holds the return value from the DRV_TMR_Initialize function.

The SYS_INT_DynamicRegister and SYS_INT_DynamicDeregister functions are macro switched to compile away to nothing if a static configuration is chosen.

Dynamic Configuration

When dynamically configuring raw ISR support, the system implementer or integrator must register each interrupt-driven driver or module's Tasks routine with the dynamic system interrupt service for the appropriate interrupt source. The dynamic SYS INT service will then ensure that the appropriate Tasks routine is called when an interrupt occurs.

Description

When using the dynamic system interrupt (SYS INT) service, it is not necessary to implement raw ISRs for interrupt-driven modules. The processor-family-specific, dynamic SYS INT implementation provided with MPLAB Harmony implements the raw ISRs so the system developer or integrator does not have to. Instead, the system developer must register the module's Tasks" routine using the SYS_ModuleRegister function after registering the module in the module registration routine (described in the SYS INIT documentation). The following example shows how a module must register its ISR Tasks routine.

Example: Dynamic Registration of an Interrupt-Driven Module

```
// Register the TMR driver's "Tasks" routine with the SYS INT service
SYS_INT_DynamicRegister(object, DRV_TMR_Tasks, PLIB_INT_SOURCE_TIMER_1);
```

The module init routine must register the module's Tasks routine with the SYS INT service instead of the SYS TASKS service. To do this, it calls the SYS_INT_DynamicRegister function, passing in the object (the same object handle returned by the module's initialization routine), along with a pointer to the module's Tasks routine and the interrupt source with which it will be associated.

Note: Dynamic interrupt registration functionality is currently not supported in the Interrupt System Service.

Building the Library

This section lists the files that are available in the Interrupt System Service Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/system/int`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
sys_int.h	Interrupt System Service Library API header file.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/sys_int_pic32.c	Interrupt System Service Library implementation.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The Interrupt System Service does not depend on any other modules.

Library Interface

a) Interrupt System Setup Functions

	Name	Description
	SYS_INT_Initialize	Configures and initializes the interrupt subsystem.
	SYS_INT_DynamicDeregister	Deregisters the current ISR from the given interrupt source.
	SYS_INT_DynamicRegister	Registers an Interrupt "Tasks" Routine for the specified interrupt source or trap).
	SYS_INT_ShadowRegisterAssign	Assigns a shadow register set for an interrupt priority level.
	SYS_INT_ShadowRegisterGet	Gets the shadow register set assigned for an interrupt priority level.
	SYS_INT_StatusGetAndDisable	Disables interrupts to the processor and return the previous status.
	SYS_INT_StatusRestore	Restores the processor status.

b) Global Interrupt Management Functions

	Name	Description
	SYS_INT_Disable	Disables interrupts to the processor.
	SYS_INT_Enable	Enables global interrupts to the processor.
	SYS_INT_IsEnabled	Identifies if interrupts are currently enabled or disabled at the top level.
	SYS_INT_ExternalInterruptTriggerSet	Sets the external interrupt trigger type.

c) Interrupt Source Management Functions

	Name	Description
	SYS_INT_SourceDisable	Disables the specified source from generating interrupts to the processor.
	SYS_INT_SourceEnable	Enables the specified source to generate interrupts to the processor.

	SYS_INT_SourceIsEnabled	Identifies if the specified source is enabled or disabled.
	SYS_INT_SourceStatusClear	Clears the interrupt request for the specified interrupt source.
	SYS_INT_SourceStatusGet	Determines the status of the specified interrupt source.
	SYS_INT_SourceStatusSet	Sets the specified interrupt source.
	SYS_INT_VectorPrioritySet	Sets the given interrupt vector to the specified priority.
	SYS_INT_VectorSubprioritySet	Sets the specified interrupt vector to the given sub priority.

d) Data Types and Constants

	Name	Description
	SYS_INT_TASKS_POINTER	Pointer to an interrupt-handling "Tasks" routine.
	INT_EXTERNAL_EDGE_TRIGGER	Lists the available external interrupt trigger options.
	SYS_INT_PROCESSOR_STATUS	CPU Processor status

Description

This section describes the APIs of the Interrupt System Service Library.

Refer to each section for a detailed description.

a) Interrupt System Setup Functions

SYS_INT_Initialize Function

Configures and initializes the interrupt subsystem.

File

sys_int.h

C

```
void SYS_INT_Initialize();
```

Returns

None.

Description

This function configures and initializes the interrupt subsystem appropriately for the current system design.

Remarks

None.

The System Interrupt library must be initialized by calling the SYS_INT_Initialize routine. This is normally done in the "SYS_Initialize" routine before any interrupt support is used. If the dynamic interrupt system service is not used, the "SYS_Initialize" routine must be implemented by the system designer or integrator as required by the system design and is not implemented by the System Interrupt library. The global interrupts are enabled as a part the call to "SYS_INT_Initialize". However, before enabling the generation of interrupts to the processor, each individual module (driver, library, or application) must have a "Tasks" routine to in place (statically linked to the raw ISR) to handle the interrupt before it enables it's own interrupt.

Example: Initializing the System Interrupt Library

```
SYS_INT_Initialize();
```

Preconditions

None.

Example

```
// Initialize the interrupt system. This needs to done in the initialization
// code.
SYS_INT_Initialize();
```

Function

void SYS_INT_Initialize (void)

SYS_INT_DynamicDeregister Function

Deregisters the current ISR from the given interrupt source.

File

sys_int.h

C

```
void SYS_INT_DynamicDeregister(INT_SOURCE source);
```

Returns

None.

Description

This function deregisters the current Interrupt Service Routine (ISR), if any, from the specified interrupt source.

Remarks

It is safe to call this routine, even of no ISR has been registered for the given interrupt source.

Calling this routine is optional. If the system is designed such that the given ISR is expected to always be available once the system has been initialized, this routine does not need to be called.

Preconditions

SYS_INT_Initialize must have been called.

Example

```
SYS_INT_DynamicDeregister(SYS_INT_TIMER_1);
```

Parameters

Parameters	Description
source	Identifier for the desired interrupt source

Function

void SYS_INT_DynamicDeregister (INT_SOURCE source)

SYS_INT_DynamicRegister Function

Registers an Interrupt "Tasks" Routine for the specified interrupt source or trap).

File

sys_int.h

C

```
void SYS_INT_DynamicRegister(INT_SOURCE source, SYS_INT_TASKS_POINTER tasks, SYS_MODULE_OBJ object);
```

Returns

None.

Description

This function registers an Interrupt "Tasks" Routine for the specified interrupt source or trap).

Remarks

This routine only generates executable code when a driver is configured to register dynamically its "Tasks" routine with the system interrupt service. However, it should be called even if the ISR-to-source association is defined statically at compile time to maintain source code compatibility. A device driver normally registers its own ISR from its initialization routine.

In the example code, the macros MY_DRIVER_INTERRUPT_SOURCE would be defined in the appropriate configuration header, which would be included by the driver source file where the "DRV_MYDEV_Tasks" routine and the MyParam data would be defined.

It is safe to call this routine without first calling SYS_INT_DynamicDeregister, even if a previous ISR has been registered. The effect will be that the new ISR supplants the old one.

The System Interrupt library must be initialized by calling the SYS_INT_Initialize routine. This is normally done in the "SYS_Initialize" routine before any interrupt support is used.

If the dynamic interrupt system service is not used, the "SYS_Initialize" routine must be implemented by the system designer or integrator as

required by the system design and is not implemented by the System Interrupt library.

Once the library has been initialized, call the function SYS_INT_Enable to enable interrupts to the processor. However, before enabling the generation of interrupts to the processor, each individual module (driver, library, or application) must have a "Tasks" routine to in place (either registered with SYS_INT_DynamicRegister or statically linked to the raw ISR) to handle the interrupt before it enables it's own interrupt.

Example: Initializing the System Interrupt Library

```
// Initialize the interrupt system.
SYS_INT_Initialize();
// Initialize all interrupt-aware software modules
SYS_INT_Enable();
```

Preconditions

SYS_INT_Initialize must have been called.

Example

```
SYS_INT_Initialize();
SYS_INT_DynamicRegister(MY_DRIVER_INTERRUPT_SOURCE, DRV_MYDEV_Tasks, MyObject);
```

Parameters

Parameters	Description
source	Identifier for the desired interrupt source
tasks	Pointer to the tasks routine
object	Handle to the module instance

Function

void SYS_INT_DynamicRegister(INT_SOURCE source,
SYS_INT_TASKS_POINTER tasks,
SYS_MODULE_OBJ object)

SYS_INT_ShadowRegisterAssign Function

Assigns a shadow register set for an interrupt priority level.

File

sys_int.h

C

```
void SYS_INT_ShadowRegisterAssign(INT_PRIORITY_LEVEL priority, INT_SHADOW_REGISTER shadowRegister);
```

Returns

None.

Description

The function assigns a shadow register set for an interrupt priority level.

Remarks

This feature may not be available on all devices.

Preconditions

None.

Example

```
SYS_INT_ShadowRegisterAssign( INT_PRIORITY_LEVEL5, INT_SHADOW_REGISTER_5 );
```

Parameters

Parameters	Description
priority	Interrupt priority level for which the shadow register set has to be assigned.
shadowRegister	Shadow register set number.

Function

void SYS_INT_ShadowRegisterAssign (INT_PRIORITY_LEVEL priority,
INT_SHADOW_REGISTER shadowRegister)

SYS_INT_ShadowRegisterGet Function

Gets the shadow register set assigned for an interrupt priority level.

File

sys_int.h

C

```
INT_SHADOW_REGISTER SYS_INT_ShadowRegisterGet(INT_PRIORITY_LEVEL priority);
```

Returns

None.

Description

The function gets the shadow register set assigned for an interrupt priority level.

Remarks

This feature may not be available on all devices. Refer to the specific device data sheet to determine availability.

Preconditions

None.

Example

```
INT_SHADOW_REGISTER shadowReg;

shadowReg = SYS_INT_ShadowRegisterGet( INT_PRIORITY_LEVEL5 );
```

Parameters

Parameters	Description
priority	Interrupt priority level for which the shadow register set has to be assigned.

Function

INT_SHADOW_REGISTER SYS_INT_ShadowRegisterGet (INT_MODULE_ID index,
INT_PRIORITY_LEVEL priority)

SYS_INT_StatusGetAndDisable Function

Disables interrupts to the processor and return the previous status.

File

sys_int.h

C

```
SYS_INT_PROCESSOR_STATUS SYS_INT_StatusGetAndDisable();
```

Returns

- SYS_INT_PROCESSOR_STATUS - 32 bit value holding the processor status before disabling the interrupt

Description

This function disables interrupts to the processor at the top level. This function can be called to prevent any source from being able to generate an interrupt. It returns the processor status (which includes global interrupt status and Interrupt Priority status) before disabling the interrupts.

Remarks

Previous Master interrupt status can be found by checking 0th bit of the returned value.

This function should be paired with the use of SYS_INT_StatusRestore(). The value returned from this function should be passed into SYS_INT_StatusRestore() function.

Preconditions

SYS_INT_Initialize must have been called.

Example

```
SYS_INT_PROCESSOR_STATUS  processorStatus;

// Save the processor status (which includes global interrupt status)
// and Disable the global interrupts
processorStatus = SYS_INT_StatusGetAndDisable();

{
    // Do something critical
}

// set the processor status back to the one which was there before
// disabling the global interrupt
SYS_INT_StatusRestore(processorStatus);
```

Function

SYS_INT_PROCESSOR_STATUS SYS_INT_StatusGetAndDisable (void)

SYS_INT_StatusRestore Function

Restores the processor status.

File

sys_int.h

C

```
void SYS_INT_StatusRestore(SYS_INT_PROCESSOR_STATUS processorStatus);
```

Returns

None.

Description

This function sets the processor status based on the 32 bit value passed as a parameter. 0th bit of the status is for Master Interrupt status.

Remarks

This function should be paired with the use of SYS_INT_GetStateAndDisable(). The value returned from SYS_INT_GetStateAndDisable() should be passed into this function.

Preconditions

None.

Example

```
SYS_INT_PROCESSOR_STATUS processorStatus;

processorStatus = SYS_INT_GetStateAndDisable();
{
    // do some critical work
}
SYS_INT_StatusRestore(processorStatus);
```

Parameters

Parameters	Description
processorStatus	value returned from previous call to SYS_INT_StatusGetAndDisable().

Function

void SYS_INT_StatusRestore (SYS_INT_PROCESSOR_STATUS processorStatus)

b) Global Interrupt Management Functions

SYS_INT_Disable Function

Disables interrupts to the processor.

File

sys_int.h

C

```
bool SYS_INT_Disable();
```

Returns

true - Global Interrupts are enabled (before the call to disable) false - Global Interrupts are disabled (before the call to disable)

Description

This function disables interrupts to the processor at the top level. This function can be called to prevent any source from being able to generate an interrupt. It returns the global interrupt status before disabling the interrupts.

Remarks

This API will be deprecated. Use "SYS_INT_StatusGetAndDisable" instead.

Preconditions

SYS_INT_Initialize must have been called.

Example

```
// Interrupt enable status
bool flag;
// Disable the global interrupts
flag = SYS_INT_Disable();
// Do something critical
// Check if interrupts were disabled/enabled
if (flag)
{
    // enable the global interrupts if they were enabled before the
    // call to SYS_INT_Disable()
    SYS_INT_Enable();
}
```

Function

bool SYS_INT_Disable (void)

SYS_INT_Enable Function

Enables global interrupts to the processor.

File

sys_int.h

C

```
void SYS_INT_Enable();
```

Returns

None.

Description

This function enables interrupts to the processor at the top level, allowing any currently enabled source to generate an interrupt. This function must be called before any source will be able to generate an interrupt.

Remarks

SYS_INT_Enable is called from the SYS_INT_Initialize() function.

Preconditions

None.

Example

```
// Check if global interrupts are enabled
if(!SYS_INT_IsEnabled())
{
    // Enable the global interrupts.
    SYS_INT_Enable();
}
```

Function

void SYS_INT_Enable (void)

SYS_INT_IsEnabled Function

Identifies if interrupts are currently enabled or disabled at the top level.

File

sys_int.h

C

```
bool SYS_INT_IsEnabled();
```

Returns

- true - If the interrupts are currently enabled
- false - If the interrupts are currently disabled

Description

This function identifies if interrupts are enabled or disabled at the top level.

Remarks

None.

Preconditions

SYS_INT_Initialize must have been called.

Example

```
// Check if global interrupts are enabled
if ( SYS_INT_IsEnabled() )
{
    // Interrupt enable status
    bool flag;
    // Disable the global interrupts.
    flag = SYS_INT_Disable();
}
```

Function

bool SYS_INT_IsEnabled (void)

SYS_INT_ExternalInterruptTriggerSet Function

Sets the external interrupt trigger type.

File

sys_int.h

C

```
void SYS_INT_ExternalInterruptTriggerSet(INT_EXTERNAL_SOURCES source, INT_EXTERNAL_EDGE_TRIGGER
edgeTrigger);
```

Returns

None.

Description

This function sets the External interrupt trigger type. User can set for multiple sources in a single call.

Remarks

Not supported for all interrupt sources. Check the specific data sheet to know the supported interrupt sources.

Preconditions

None.

Example

```
SYS_INT_ExternalInterruptTriggerSet (   INT_EXTERNAL_INT_SOURCE0|INT_EXTERNAL_INT_SOURCE0,
                                        INT_EDGE_TRIGGER_RISING );
```

Parameters

Parameters	Description
source	Identifier for the desired interrupt source

Function

void SYS_INT_ExternalInterruptTriggerSet (INT_EXTERNAL_SOURCES source,
INT_EXTERNAL_EDGE_TRIGGER edgeTrigger)

c) Interrupt Source Management Functions

SYS_INT_SourceDisable Function

Disables the specified source from generating interrupts to the processor.

File

sys_int.h

C

```
bool SYS_INT_SourceDisable(INT_SOURCE source);
```

Returns

- true - The Interrupt source is enabled (before the call to SYS_INT_SourceDisable)
- false - The Interrupt source is disabled (before the call to SYS_INT_SourceDisable)

Description

This function disables the given source from generating interrupts the processor when events occur.It returns the interrupt source enable/disable status before disabling the interrupt source.

Remarks

None.

Preconditions

SYS_INT_Initialize must have been called.

Example

```
// interrupt source enable/disable status.
bool flag
// Initialize the interrupt system.This needs to done in the initialization
// code.
SYS_INT_Initialize();
// Disable the interrupt source
flag = SYS_INT_SourceDisable(INT_SOURCE_PARALLEL_PORT);
// before enabling the source check the enable/disable status
if(flag)
{
    SYS_INT_SourceEnable(INT_SOURCE_PARALLEL_PORT);
}
```

Parameters

Parameters	Description
source	Identifier for the desired interrupt source.

Function

bool SYS_INT_SourceDisable (INT_SOURCE source)

SYS_INT_SourceEnable Function

Enables the specified source to generate interrupts to the processor.

File

sys_int.h

C

```
void SYS_INT_SourceEnable(INT_SOURCE source);
```

Returns

None.

Description

This function enables the specified source to generate interrupts to the processor when events occur.

Remarks

An Interrupt Service Routine (ISR) for the given interrupt source must be ready to receive the call before the source is enabled.

Preconditions

SYS_INT_Initialize must have been called and an ISR must have been registered for the source.

Example

```
// Initialize the interrupt system. This needs to done in the initialization
// code.
SYS_INT_Initialize();
// Enable the interrupt source
SYS_INT_SourceEnable(INT_SOURCE_PARALLEL_PORT);
```

Parameters

Parameters	Description
source	Identifier for the desired interrupt source

Function

void SYS_INT_SourceEnable (INT_SOURCE source)

SYS_INT_SourceIsEnabled Function

Identifies if the specified source is enabled or disabled.

File

sys_int.h

C

```
bool SYS_INT_SourceIsEnabled(INT_SOURCE source);
```

Returns

- true - If the given source is currently enabled.
- false - If the given source is currently disabled.

Description

This function identifies if the specified source is currently enabled or is currently disabled.

Remarks

None.

Preconditions

SYS_INT_Initialize must have been called.

Example

```
// Initialize the interrupt system. This needs to done in the initialization
// code.
SYS_INT_Initialize();
// Check if the required interrupt source is enabled
if ( SYS_INT_SourceIsEnabled(INT_SOURCE_PARALLEL_PORT))
{
    // App code
}
```

Parameters

Parameters	Description
source	Identifier for the desired interrupt source.

Function

bool SYS_INT_SourceIsEnabled (INT_SOURCE source)

SYS_INT_SourceStatusClear Function

Clears the interrupt request for the specified interrupt source.

File

sys_int.h

C

```
void SYS_INT_SourceStatusClear(INT_SOURCE source);
```

Returns

None.

Description

This function clears the interrupt request for the specified interrupt source.

Remarks

None.

Preconditions

SYS_INT_Initialize must have been called.

Example

```
// Initialize the interrupt system. This needs to done in the initialization
// code.
SYS_INT_Initialize();
// Check if the interrupt source flag is set
if ( SYS_INT_SourceStatusGet(INT_SOURCE_PARALLEL_PORT) )
{
    // Clear the interrupt flag
    SYS_INT_SourceStatusClear(INT_SOURCE_PARALLEL_PORT);
}
```

Parameters

Parameters	Description
source	Identifier for the desired interrupt source

Function

void SYS_INT_SourceStatusClear (INT_SOURCE source)

SYS_INT_SourceStatusGet Function

Determines the status of the specified interrupt source.

File

sys_int.h

C

```
bool SYS_INT_SourceStatusGet(INT_SOURCE source);
```

Returns

- true - If the given interrupt source is currently set
- false - If the given interrupt source is not currently set

Description

This function determines the current status of the interrupt source.

Remarks

Works even if the interrupt source or interrupts in general have not been enabled, so it can be used for polling implementations.

Preconditions

SYS_INT_Initialize must have been called.

Example

```
// Initialize the interrupt system.This needs to done in the initialization
// code.
SYS_INT_Initialize();
// Check if the required interrupt source is set
if ( SYS_INT_SourceStatusGet(INT_SOURCE_PARALLEL_PORT) )
{
    // Handle interrupt
}
```

Parameters

Parameters	Description
source	Identifier for the desired interrupt source

Function

bool SYS_INT_SourceStatusGet (INT_SOURCE source)

SYS_INT_SourceStatusSet Function

Sets the specified interrupt source.

File

sys_int.h

C

```
void SYS_INT_SourceStatusSet(INT_SOURCE source);
```

Returns

None.

Description

This function sets the specified interrupt source, causing the processor to be interrupted if interrupts are enabled, the source has been enabled, and the priority is higher than the current priority.

Remarks

Not supported for all interrupt sources. Check the specific data sheet for software clear only interrupt sources.

The driver, middleware, or application's interrupt-handling "Tasks" routine must do two things at a minimum, in the following order.

1. Remove the cause of the interrupt

2. Clear the interrupt source by calling the function SYS_INT_SourceStatusClear

Exactly what actions are necessary to remove the cause of an interrupt is completely dependent on the source of the interrupt. This is normally the main purpose of the driver itself and is beyond the scope of this section. Refer to the documentation for the peripheral being managed.

WARNING! The cause of the interrupt must be removed before clearing the interrupt source or the interrupt may re-occur immediately after the source is cleared potentially causing an infinite loop. An infinite loop may also occur if the source is not cleared before the interrupt-handler returns.

Example: Handling Interrupts

```
void DRV_MYDEV_Tasks( SYS_MODULE_OBJ object )
{
    // Remove the cause of the interrupt
    //...

    // Clear Interrupt source
    SYS_INT_SourceStatusClear(myIntSourceID);
}
```

Note: the value of "myIntSourceID" is usually either a static or dynamic configuration option. Refer to the documentation for the specific device driver to identify how to define the interrupt source ID.

Testing Interrupt

Some times it is necessary to cause an interrupt in software, possibly for testing purposes. To support this, the function SYS_INT_SourceStatusSet is provided.

Example: Causing an Interrupt in Software

```
SYS_INT_SourceStatusSet(MY_DRIVER_INTERRUPT_SOURCE);
```

Note: This feature is not available for all interrupt sources on all Microchip microcontrollers. Refer to the data sheet for the microcontroller being used to determine if it is possible for software to set a specific interrupt source.

Preconditions

SYS_INT_Initialize must have been called and an ISR must have been registered for the source (if interrupts and the source are enabled).

Example

```
// Initialize the interrupt system. This needs to done in the initialization
// code.
SYS_INT_Initialize();
// Check if interrupt source flag is set
if ( !SYS_INT_SourceStatusGet(INT_SOURCE_PARALLEL_PORT) )
{
    // Set the interrupt source flag
    SYS_INT_SourceStatusSet(INT_SOURCE_PARALLEL_PORT);
}
```

Parameters

Parameters	Description
source	Identifier for the desired interrupt source

Function

void SYS_INT_SourceStatusSet (INT_SOURCE source)

SYS_INT_VectorPrioritySet Function

Sets the given interrupt vector to the specified priority.

File

sys_int.h

C

```
void SYS_INT_VectorPrioritySet(INT_VECTOR vector, INT_PRIORITY_LEVEL priority);
```

Returns

None.

Description

This routine sets the given interrupt vector to the specified priority.

Remarks

This feature is not supported on all devices. Refer to the specific device data sheet or family reference manual to determine whether this feature is supported.

In the example code, the macros MY_DRIVER_INTERRUPT_VECTOR, MY_DRIVER_ISR_PRIORITY would be defined appropriately during configuration.

Preconditions

SYS_INT_Initialize must have been called.

Example

```
#define MY_DRIVER_INTERRUPT_VECTOR  INT_VECTOR_T1
#define MY_DRIVER_ISR_PRIORITY      INT_PRIORITY_LEVEL2
// Initialize the interrupt system.This needs to done in the initialization
// code.
SYS_INT_Initialize();
// Assign priority to the interrupt vector
SYS_INT_VectorPrioritySet(MY_DRIVER_INTERRUPT_VECTOR, MY_DRIVER_ISR_PRIORITY);
```

Parameters

Parameters	Description
vector	Identifier for the desired interrupt vector
priority	Priority (if supported)

Function

void SYS_INT_VectorPrioritySet (INT_VECTOR vector, INT_PRIORITY_LEVEL priority)

SYS_INT_VectorSubprioritySet Function

Sets the specified interrupt vector to the given sub priority.

File

sys_int.h

C

```
void SYS_INT_VectorSubprioritySet(INT_VECTOR vector, INT_SUBPRIORITY_LEVEL subpriority);
```

Returns

None.

Description

This function sets the specified interrupt vector to the specified sub-priority.

Remarks

This feature is not supported on all devices. Refer to the specific device data sheet or family reference manual to determine whether this feature is supported.

In the example code, the macros MY_DRIVER_INTERRUPT_VECTOR, MY_DRIVER_ISR_SUB_PRIORITY would be defined appropriately during configuration.

Preconditions

SYS_INT_Initialize must have been called.

Example

```
#define MY_DRIVER_INTERRUPT_VECTOR  INT_VECTOR_T1
#define MY_DRIVER_ISR_PRIORITY      INT_PRIORITY_LEVEL2
#define MY_DRIVER_ISR_SUB_PRIORITY  INT_SUBPRIORITY_LEVEL1
// Initialize the interrupt system.This needs to done in the initialization
// code.
SYS_INT_Initialize();
// Assign priority to the interrupt vector
SYS_INT_VectorPrioritySet(MY_DRIVER_INTERRUPT_VECTOR, MY_DRIVER_ISR_PRIORITY);
// Assign sub-priority to the interrupt vector
SYS_INT_VectorSubprioritySet(MY_DRIVER_INTERRUPT_VECTOR, MY_DRIVER_ISR_SUB_PRIORITY);
```

Parameters

Parameters	Description
vector	Identifier for the desired interrupt vector
subpriority	Subpriority (if supported)

Function

void SYS_INT_VectorSubprioritySet(INT_VECTOR vector,
INT_SUBPRIORITY_LEVEL subpriority)

d) Data Types and Constants

SYS_INT_TASKS_POINTER Type

Pointer to an interrupt-handling "Tasks" routine.

File

sys_int.h

C

```
typedef void (* SYS_INT_TASKS_POINTER)(SYS_MODULE_OBJ object);
```

Description

Interrupt Tasks Routine Pointer

This data type defines a pointer to an interrupt-handling "Tasks" routine. The form of a tasks routine is as follows:

void My_Tasks (SYS_MODULE_OBJ object);

Where "MyTasks" is the name of the tasks routine and object is a Handle to the module instance.

Remarks

"Tasks" is normally defined by a device driver, middleware, or system layer.

The term Interrupt Service Routine (ISR) is used for the "raw" ISR code that is either located directly at the interrupt vector address or whose address is loaded from the interrupt vector. The term "Tasks" routine is used to identify the driver-specific routine that is called by the actual ISR to perform the tasks necessary to handle and clear the interrupt.

INT_EXTERNAL_EDGE_TRIGGER Enumeration

Lists the available external interrupt trigger options.

File

sys_int.h

C

```
typedef enum {
  INT_EDGE_TRIGGER_FALLING,
  INT_EDGE_TRIGGER_RISING
} INT_EXTERNAL_EDGE_TRIGGER;
```

Members

Members	Description
INT_EDGE_TRIGGER_FALLING	External interrupt trigger on falling edge
INT_EDGE_TRIGGER_RISING	External interrupt trigger on rising edge

Description

Interrupt external edge selection.

This enumeration lists all of the available external interrupt trigger options.

Remarks

None.

SYS_INT_PROCESSOR_STATUS Type

CPU Processor status

File

sys_int.h

C

```
typedef uint32_t SYS_INT_PROCESSOR_STATUS;
```

Description

Interrupt Processor Status

This data type holds the status of CPU register 2

Remarks

None.

Files

Files

Name	Description
sys_int.h	Interrupt System Service.

Description

This section lists the source and header files used by the library.

sys_int.h

Interrupt System Service.

Enumerations

	Name	Description
	INT_EXTERNAL_EDGE_TRIGGER	Lists the available external interrupt trigger options.

Functions

	Name	Description
	SYS_INT_Disable	Disables interrupts to the processor.
	SYS_INT_DynamicDeregister	Deregisters the current ISR from the given interrupt source.
	SYS_INT_DynamicRegister	Registers an Interrupt "Tasks" Routine for the specified interrupt source or trap).
	SYS_INT_Enable	Enables global interrupts to the processor.
	SYS_INT_ExternalInterruptTriggerSet	Sets the external interrupt trigger type.
	SYS_INT_Initialize	Configures and initializes the interrupt subsystem.
	SYS_INT_IsEnabled	Identifies if interrupts are currently enabled or disabled at the top level.
	SYS_INT_ShadowRegisterAssign	Assigns a shadow register set for an interrupt priority level.
	SYS_INT_ShadowRegisterGet	Gets the shadow register set assigned for an interrupt priority level.
	SYS_INT_SourceDisable	Disables the specified source from generating interrupts to the processor.
	SYS_INT_SourceEnable	Enables the specified source to generate interrupts to the processor.
	SYS_INT_SourceIsEnabled	Identifies if the specified source is enabled or disabled.
	SYS_INT_SourceStatusClear	Clears the interrupt request for the specified interrupt source.
	SYS_INT_SourceStatusGet	Determines the status of the specified interrupt source.
	SYS_INT_SourceStatusSet	Sets the specified interrupt source.
	SYS_INT_StatusGetAndDisable	Disables interrupts to the processor and return the previous status.
	SYS_INT_StatusRestore	Restores the processor status.
	SYS_INT_VectorPrioritySet	Sets the given interrupt vector to the specified priority.
	SYS_INT_VectorSubprioritySet	Sets the specified interrupt vector to the given sub priority.

Types

	Name	Description
	SYS_INT_PROCESSOR_STATUS	CPU Processor status
	SYS_INT_TASKS_POINTER	Pointer to an interrupt-handling "Tasks" routine.

Description

Interrupt System Service Library Interface Definition

This file contains the interface definition for the Interrupt System Service. It provides a way to interact with the interrupt subsystem to manage the occurrence of interrupts for sources supported by the system.

File Name

sys_int.h

Company

Microchip Technology Inc.

Memory System Service Library

This section describes the Memory System Service Library.

Introduction

Introduction to the Memory System Service.

Description

The Memory System Service provides support for the initialization of external memory and external memory controllers. It is configured to run in static mode by the MPLAB Harmony Configurator (MHC). When an external memory interface is enabled by MHC, the initialization code for the controller is generated and added to the system initialization sequence in the application. The specific timing parameters for the external memory to be used are selected by the user via MHC.

Using the Library

This topic describes the basic architecture of the Memory System Service Library and provides information and examples on its use.

Description

Interface Header File: `sys_memory.h`

The interface to the Memory System Service library is defined in the `sys_memory.h` header file, which is included by the `system.h` system service header file. Any C language source (`.c`) file that uses the Memory System Service library should include `system.h`.

Please refer to the What is MPLAB Harmony? section for how the library interacts with the framework.

Abstraction Model

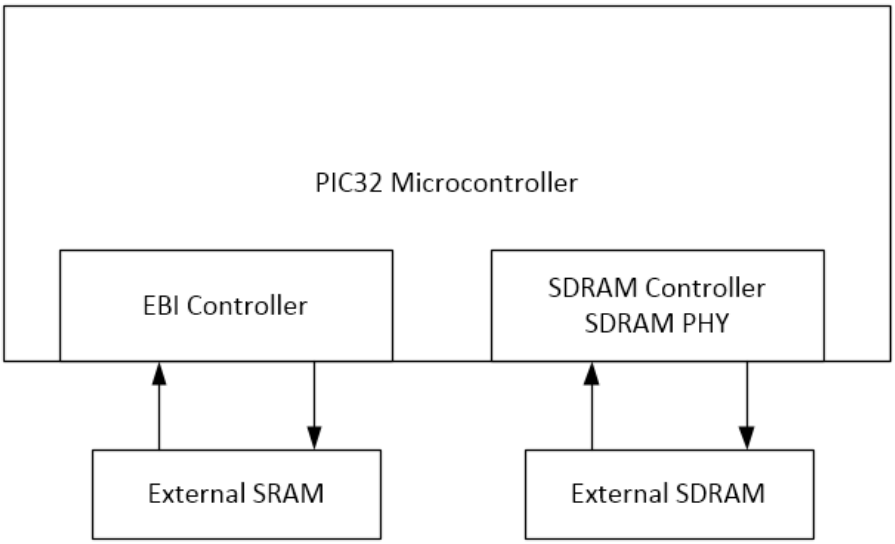
Provides information on the abstraction model for the Memory System Service.

Description

The Memory System Service manages the initialization of interfaces to external memory devices on some PIC32 microcontrollers. The initialization is performed during the system initialization sequence, so the memory is available to the application when the application tasks are initiated. The memory devices accessed via the interfaces initialized by this service are mapped into the virtual address space, and once initialized, are accessed directly just like internal SRAM. The type and number of external memory devices, as well as the virtual address mapping may vary between devices. Please refer to the specific device data sheet for details of a particular device.

The following figure provides the abstraction model for the Memory System Service.

Memory System Service Abstraction Model



Library Overview

Please refer to the System Service Introduction for a detailed description of MPLAB Harmony system services.

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Memory System Service.

How the Library Works

The Memory System Service Library can be used by a device driver, middleware layer, or application to provide access to, and control over, interrupts to the processor.

Description

Initialization

Once the service is initialized, there is no further run-time configuration or operation required. The external memory is simply accessed via virtual address, just like internal SRAM. Therefore, there is a single API that manages the initialization of the selected external memory devices: SYS_MEMORY_Initialize.

The SYS_MEMORY_Initialize API will invoke the initialization function(s) of external memory devices enabled via MHC. There are presently two external memory controllers supported on some PIC32 microcontrollers, the External Bus Interface (EBI) and the SDRAM controller. The EBI can interface with external asynchronous SRAM or NOR Flash, while the SDRAM controller can interface with external DDR2 SDRAM.

```
SYS_MEMORY_EBI_Initialize();
SYS_MEMORY_DDR_Initialize();
```

Configuring the Library

The configuration of the Memory System Service is based on the file `system_config.h`.

This header file contains the configuration selection for the Memory System service. Based on the selections made, the Memory System Service may support the selected features. These configuration settings will apply to all instances of the Memory System Service.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

Building the Library

This section lists the files that are available in the Memory System Service Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/system/memory`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
sys_memory.h	Memory System Service Library API header file.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
N/A	No source files are available for this library.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The Memory System Service is not dependent upon other modules.

Library Interface

a) Functions

	Name	Description
	SYS_MEMORY_DDR_Initialize	Initializes and Enables the DDR External Memory Controller.
	SYS_MEMORY_EBI_Initialize	Initializes and Enables the EBI External Memory Controller.
	SYS_MEMORY_Initialize	Initializes and Enables the External Memory Controller(s).

Description

This section describes the APIs of the Memory System Service Library.

a) Functions

SYS_MEMORY_DDR_Initialize Function

Initializes and Enables the DDR External Memory Controller.

File

sys_memory.h

C

```
void SYS_MEMORY_DDR_Initialize();
```

Returns

None.

Description

This function Enables the external DDR memory controller module.

Remarks

This routine must be called before any attempt to access external DDR memory.

Not all features are available on all devices. Refer to the specific device data sheet to determine availability.

Preconditions

None.

Example

```
SYS_MEMORY_DDR_Initialize(NULL);
```

Parameters

Parameters	Description
data	Pointer to the data structure containing any data necessary to initialize the hardware. This pointer may be null if no data is required and default initialization is to be used.

Function

void SYS_MEMORY_DDR_Initialize (void * data)

SYS_MEMORY_EBI_Initialize Function

Initializes and Enables the EBI External Memory Controller.

File

sys_memory.h

C

```
void SYS_MEMORY_EBI_Initialize();
```

Returns

None.

Description

This function Enables the external EBI memory controller module.

Remarks

This routine must be called before any attempt to access external EBI memory.

Not all features are available on all devices. Refer to the specific device data sheet to determine availability.

Preconditions

None.

Example

```
SYS_MEMORY_EBI_Initialize(NULL);
```

Parameters

Parameters	Description
data	Pointer to the data structure containing any data necessary to initialize the hardware. This pointer may be null if no data is required and default initialization is to be used.

Function

void SYS_MEMORY_EBI_Initialize (void * data)

SYS_MEMORY_Initialize Function

Initializes and Enables the External Memory Controller(s).

File

sys_memory.h

C

```
void SYS_MEMORY_Initialize();
```

Returns

None.

Description

This function Enables the external memory controller module(s).

Remarks

This routine must be called before any attempt to access external memory.

Not all features are available on all devices. Refer to the specific device data sheet to determine availability.

Preconditions

None.

Example

```
SYS_MEMORY_Initialize(NULL);
```

Parameters

Parameters	Description
data	Pointer to the data structure containing any data necessary to initialize the hardware. This pointer may be null if no data is required and default initialization is to be used.

Function

void SYS_MEMORY_Initialize (void * data)

Files

Files

Name	Description
sys_memory.h	Memory System Service Implementation.

Description

This section lists the source and header files used by the library.

sys_memory.h

Memory System Service Implementation.

Functions

	Name	Description
	SYS_MEMORY_DDR_Initialize	Initializes and Enables the DDR External Memory Controller.
	SYS_MEMORY_EBI_Initialize	Initializes and Enables the EBI External Memory Controller.
	SYS_MEMORY_Initialize	Initializes and Enables the External Memory Controller(s).

Description

Memory System Service Implementation

The Memory System Service provides a simple interface to manage the memory controllers. This file implements the core interface routines for the Memory System Service.

File Name

Microchip Technology Inc.

Messaging System Service Library

This section describes the Messaging System Service Library.

Introduction

This library provides intra-process and inter-process communication by the sending and receiving of simple messages. The format of these messages is under developer control, providing flexibility to tune message format for each application. The number and size of message queues is under developer control, with a message priority scheme implemented by multiple queues. Each priority queue has an configurable size. The number of message types and the number of receiving mailboxes is also configurable.

Description

This library provides intra-process and inter-process communication by the sending and receiving of simple messages. The format of these messages is under developer control, providing flexibility to tune message format for each application. The number and size of message queues is under developer control, with a message priority scheme implemented by multiple queues. Each priority queue has an configurable size. The number of message types and the number of receiving mailboxes is also configurable.

Consider an application that combines graphics on a display screen, with a touch overlay on top of the screen, and several buttons. System messages can be used by touch software to alert the graphics part of the application to update the screen as well as alert other parts of the application to perhaps change the audio volume whenever a slider value has changed. This is easily supported by the Messaging System Services Library.

Using the Library

This topic describes the basic architecture of the Messaging System Service Library and provides information and examples on its use.

Description

Interface Header File: `sys_msg.h`

The interface to the Messaging System Service library is defined in the `sys_msg.h` header file, which is included by the `system.h` system service header file. Any C language source (`.c`) file that uses the Messaging System Service library should include `system.h`.

Please refer to the What is MPLAB Harmony? section for how the library interacts with the framework.

Abstraction Model

This library provides an abstraction of the messaging subsystem that is used by device drivers, middleware libraries and applications to receive and control interrupts in real time.

This library uses `calloc` to allocate memory for:

- Message queues for each priority as part of SYS_MSG_Initialize
- Mailbox definition objects
- Message type objects

If calls to `calloc` fails to allocate the needed memory then object handles are returned with a value of `SYS_OBJ_HANDLE_INVALID`.

Library Overview

Please refer to the System Service Introduction for a detailed description of MPLAB Harmony system services.

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Messaging System Service module

Library Interface Section	Description
Initialization, Tasks, and Versioning Functions	Provides configuration and control functions.
Mailbox Functions	Provides mailbox APIs.
Message Type Functions	Provides messaging type APIs.
Message Send/Receive Functions	Provides messaging send and receive APIs.
Utility Functions	Provides messaging utility APIs.

How the Library Works

The Messaging System Service Library can be used by a device driver, middleware layer, or application to provide access to, and control over, interrupts to the processor.

Description

Note: Not all modes are available on all devices. Please refer to the specific device data sheet to determine the modes supported for your device.

The following example can be run on any PIC32 starter kit:

```
#include <sys/appio.h>
#include <GenericTypeDefs.h>

#include "system/common/sys_module.h"
#include "system/msg/sys_msg.h"
```

```
#include "system/msg/src/sys_msg_local.h"

// Strawman callback functions for three mailboxes
void myCallBack0( SYS_MSG_OBJECT *pMessage )
{
    DBPRINTF("CallBack0:: Message Type: %d, nSource: %d\r\n"
             "            param 0: %d, param1: %d, param2: %d \r\n",
             pMessage->nMessageTypeID,
             pMessage->nSource, pMessage->param0,
             pMessage->param1,  pMessage->param2
            );
}

void myCallBack1( SYS_MSG_OBJECT *pMessage )
{
    DBPRINTF("CallBack1:: Message Type: %d, nSource: %d\r\n"
             "            param 0: %d, param1: %d, param2: %d \r\n",
             pMessage->nMessageTypeID,
             pMessage->nSource, pMessage->param0,
             pMessage->param1,  pMessage->param2
            );
}

void myCallBack2( SYS_MSG_OBJECT *pMessage )
{
    DBPRINTF("CallBack2:: Message Type: %d, nSource: %d\r\n"
             "            param 0: %d, param1: %d, param2: %d \r\n",
             pMessage->nMessageTypeID,
             pMessage->nSource, pMessage->param0,
             pMessage->param1,  pMessage->param2
            );
}

int main(void)
{
    SYS_MSG_MESSAGING_OBJECT oSysMsg;
    SYS_OBJ_HANDLE hSysMsg, hMsgType[5], hMailbox[3];
    SYS_MSG_INSTANCE iSysMsg = SYS_MSG_0;
    SYS_MSG_OBJECT myMessage[5];

    {// SYS_MSG_Initialize
        uint8_t nQSizes[] = SYS_MSG_BUFFER_SIZES;

        // Initialize the messaging system. This needs to done in the initialization code.
        hSysMsg = SYS_MSG_Initialize(iSysMsg,SYS_MSG_MAX_PRIORITY+1,nQSizes);

        SYS_ASSERT( SYS_OBJ_HANDLE_INVALID != hSysMsg,"Bad hSysMsg!" );
    }

    // Create the message types to be used
    //                                    ID:    :Priority
    hMsgType[0] = SYS_MSG_TypeCreate(iSysMsg,1<<0,0);
    hMsgType[1] = SYS_MSG_TypeCreate(iSysMsg,1<<1,1);
    hMsgType[2] = SYS_MSG_TypeCreate(iSysMsg,1<<2,2);
    hMsgType[3] = SYS_MSG_TypeCreate(iSysMsg,1<<3,3);
    hMsgType[4] = SYS_MSG_TypeCreate(iSysMsg,1<<4,4);

    // Create the mailboxes to be used
    hMailbox[0] = SYS_MSB_MailboxOpen( iSysMsg, &myCallBack0 );
    hMailbox[1] = SYS_MSB_MailboxOpen( iSysMsg, &myCallBack1 );
    hMailbox[2] = SYS_MSB_MailboxOpen( iSysMsg, &myCallBack2 );

 // Identify which messages are of interest for each mailbox.
    SYS_MSG_MailboxMsgAdd(hMailbox[0],hMsgType[0]);
    SYS_MSG_MailboxMsgAdd(hMailbox[0],SYS_MSG_ID2hMsgType(iSysMsg,1<<1));
    SYS_MSG_MailboxMsgAdd(hMailbox[0],SYS_MSG_ID2hMsgType(iSysMsg,1<<2));
    SYS_MSG_MailboxMsgAdd(hMailbox[0],SYS_MSG_ID2hMsgType(iSysMsg,1<<3));
```

```
SYS_MSG_MailboxMsgAdd(hMailbox[0],SYS_MSG_ID2hMsgType(iSysMsg,1<<4));
SYS_MSG_MailboxMsgAdd(hMailbox[1],hMsgType[0]);
SYS_MSG_MailboxMsgAdd(hMailbox[2],hMsgType[0]);

        // Preemptively read all Mailbox Zero messages
        while ( NULL != (pMessage = SYS_MSG_MailboxMessagesGet(hMailbox[0])) )
        {
            // "Process" message.
            DBPRINTF("Mailbox Zero: Message Type: %d, nSource: %d\r\n"
                     "              param 0: %d, param1: %d, param2: %d \r\n",
                     pMessage->nMessageTypeID,
                     pMessage->nSource, pMessage->param0,
                     pMessage->param1,  pMessage->param2
                    );
        }

        // Deliver messages for all mailboxes.
        DBPRINTF("\r\nGot Messages: %d\r\n",SYS_MSG_GotMessages(iSysMsg));
        for (iPriority=0;iPriority<=SYS_MSG_MAX_PRIORITY;iPriority++)
        {
            qStatus[iPriority] =
               SYS_MSG_QueueStatus((SYS_OBJ_HANDLE)iSysMsg,iPriority);
        }
        DBPRINTF("Queue Status (4:-1:0): %d, %d, %d, %d, %d\r\n\r\n",
                  qStatus[4],qStatus[3],qStatus[2],qStatus[1],qStatus[0]);
        while ( (pQElement = SYS_MSG_MessageReceive(iSysMsg)) != NULL )
        {
            SYS_MSG_MessageDeliver(iSysMsg,pQElement);
            for (iPriority=0;iPriority<=SYS_MSG_MAX_PRIORITY;iPriority++)
            {
                qStatus[iPriority] =
                   SYS_MSG_QueueStatus((SYS_OBJ_HANDLE)iSysMsg,iPriority);
            }
            DBPRINTF("Queue Status (4:-1:0): %d, %d, %d, %d, %d\r\n\r\n",
                      qStatus[4],qStatus[3],qStatus[2],qStatus[1],qStatus[0]);
        }
        DBPRINTF("Got Messages: %d\r\n",SYS_MSG_GotMessages(iSysMsg));
    }

    return 0;
}
```

Configuring the Library

The file `sys_msg_config.h` file provides configuration parameters that the implementer can use to adapt the Messaging System Service Library to a particular application.

Macros

	Name	Description
	SYS_MSG_BUFFER_SIZES	define SYS_MSG_BUFFER_SIZES { 4, 4, 4, 4, 1
	SYS_MSG_MAX_MAILBOXES	Specifies the maximum number of mailboxes possible.
	SYS_MSG_MAX_MSGS_DELIVERED	Specifies the maximum number of messages delivered per each call to SYS_MSG_Tasks.
	SYS_MSG_MAX_PRIORITY	Specifies the maximum message priority.
	SYS_MSG_MAX_TYPES	Specifies the maximum number of message types possible.
	_SYS_MSG_CONFIG_TEMPLATE__H	This is macro _SYS_MSG_CONFIG_TEMPLATE__H.

Description

By default, the system message format provides 64 bits of information in a message:

```
    typedef union
    {
```

```
        struct
        {
            uint16_t         param0; // Message parameter zero
            uint16_t         param1; // Message parameter one
            uint16_t         param2; // Message parameter two
            uint16_t nMessageTypeID; // Message type identifier
        };
        struct
        {
            uint16_t        nSource; // Message source identifier
            uintptr_t      *  pData; // Pointer to additional message data
        };
    } SYS_MSG_OBJECT;
```

The only required field in the message format definition is `nMessageTypeID`. However, it does not need to be 16 bits long.

The maximum number of mailboxes is defined by:

```
#define SYS_MSG_MAX_MAILBOXES  (32)
```

The minimum number of mailboxes is one.

The maximum number of message types is defined by:

```
#define SYS_MSG_MAX_TYPES  (32)
```

The minimum number of message types is one.

Message priorities run from zero to SYS_MSG_MAX_PRIORITY, which is defined by:

```
#define SYS_MSG_MAX_PRIORITY   (4)
```

For each message priority from 0,1, to SYS_MSG_MAX_PRIORITY a queue is created. The size of each queue is defined by:

```
//           Message Priority:  0   1   2   3  4
#define SYS_MSG_BUFFER_SIZES { 64, 32, 16,  8, 4 }
```

In this example there are five priorities, 0, 1, ..4, and the sizes of each message queue is provided in the definition of SYS_MSB_BUFFER_SIZES.

Then, this information is used when initializing the Messaging System Service in the application start-up code:

```
SYS_OBJ_HANDLE hSysMsg;
{//SYS_MSG_Initialize
    uint16_t nQSizes[] = SYS_MSG_BUFFER_SIZES;
    hSysMsg = SYS_MSG_Initialize(SYS_MSG_MAX_PRIORITY+1,nQSizes);
    SYS_ASSERT( SYS_OBJ_HANDLE_INVALID != hSysMsg,"Bad hSysMsg!" );
}
```

SYS_MSG_BUFFER_SIZES Macro

File

sys_msg_config.h

C

```
#define SYS_MSG_BUFFER_SIZES { 16 }
```

Description

define SYS_MSG_BUFFER_SIZES { 4, 4, 4, 4, 1

SYS_MSG_MAX_MAILBOXES Macro

Specifies the maximum number of mailboxes possible.

File

sys_msg_config.h

C

```
#define SYS_MSG_MAX_MAILBOXES (2)
```

Description

System Messaging Max Number of Mailboxes

Specifies the maximum number of mailboxes possible.

Remarks

Minimum number is 1 mailbox.

SYS_MSG_MAX_MSGS_DELIVERED Macro

Specifies the maximum number of messages delivered per each call to SYS_MSG_Tasks.

File

sys_msg_config.h

C

```
#define SYS_MSG_MAX_MSGS_DELIVERED (1)
```

Description

System Messaging Maximum Number of Messages Delivered per call to SYS_MSG_Tasks

Specifies the maximum number of messages delivered per each call to SYS_MSG_Tasks. If zero then all message queues are emptied before the tasks routine finishes execution.

Remarks

0 implies all queues are empty after SYS_MSG_Tasks is done.

SYS_MSG_MAX_PRIORITY Macro

Specifies the maximum message priority.

File

sys_msg_config.h

C

```
#define SYS_MSG_MAX_PRIORITY (0)
```

Description

System Messaging Maximum Priority

Specifies the maximum message priority.

Remarks

Message priorities run from 0 to SYS_MSG_MAX_PRIORITIES. The number of message queues is SYS_MSG_MAX_PRIORITIES+1.

SYS_MSG_MAX_TYPES Macro

Specifies the maximum number of message types possible.

File

sys_msg_config.h

C

```
#define SYS_MSG_MAX_TYPES (2)
```

Description

System Messaging Max Number of Message Types

Specifies the maximum number of message types possible.

Remarks

Minimum number is 1.

_SYS_MSG_CONFIG_TEMPLATE__H Macro

File

sys_msg_config.h

C

```
#define _SYS_MSG_CONFIG_TEMPLATE__H
```

Description

This is macro _SYS_MSG_CONFIG_TEMPLATE__H.

Building the Library

This section lists the files that are available in the Messaging System Service Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/system/msg`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`sys_msg.h`	Messaging System Service Library API header file.
`/src/sys_msg_local.h`	System messaging local declarations and definitions.
`/config/sys_msg_config.h`	System messaging configuration.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/sys_msg.c`	Messaging System Service Library implementation.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The Messaging System Service is not dependent upon other modules.

Library Interface

a) Initialization, Tasks, and Versioning Functions

	Name	Description
	SYS_MSG_Deinitialize	Deinitializes System Messaging Instance.
	SYS_MSG_Initialize	Configures and initializes the messaging subsystem.
	SYS_MSG_Tasks	System Messaging Service Tasks routine.

b) Mailbox Functions

	Name	Description
	SYS_MSG_MailboxMessagesGet	Gets queued messages for a mailbox.
	SYS_MSG_MailboxMsgAdd	Adds a message type to the list of messages received by a mailbox.
	SYS_MSG_MailboxMsgRemove	Removes a message type from the list of messages received by a mailbox.
	SYS_MSG_MailboxClose	Closes (destroys) a mailbox previously opened with SYS_MSG_MailboxOpen.
	SYS_MSG_MailboxOpen	Opens a system messaging mailbox.
	SYS_MSG_MailboxReinit	Reinitializes a previously opened mailbox.

c) Message Type Functions

	Name	Description
	SYS_MSG_TypeCreate	Creates a new message type.
	SYS_MSG_TypeRemove	Removes an existing message type.

d) Message Send/Receive Functions

	Name	Description
	SYS_MSG_GotMessages	Returns true if system messaging has undelivered messages, false otherwise.
	SYS_MSG_MessageDeliver	Delivers messages to mailboxes.
	SYS_MSG_MessageReceive	Receives the next message in the message queues.
	SYS_MSG_MessageSend	Sends a message, as defined by a message structure.

e) Utility Functions

	Name	Description
	SYS_MSG_ID2hMsgType	Translates message type identifier into handle of corresponding message type object.
	SYS_MSG_QueueStatus	Returns the message queue status for a given message priority.

f) Data Types and Constants

	Name	Description
	SYS_MSG_INIT	Contains all the data necessary to initialize an instance of the System Messaging Service.
	SYS_MSG_INSTANCE	System Messaging instances numbering is from 0,1, to SYS_MSG_MAX_INSTANCE.
	SYS_MSG_OBJECT	This is type SYS_MSG_OBJECT.
	SYS_MSG_QUEUE_STATUS	Messaging queue status enumeration.
	SYS_MSG_RECEIVE_CALLBACK	Pointer to the System message received callback function.
	SYS_MSG_RESULTS	Enumeration of message send results.
	SYS_MSGQ_ELEMENT	Defines queue element for message queue belonging to each priority.
	SYS_MSG_MAILBOXES_ADDONE	don't need to round up the number of bitmaps
	SYS_MSG_NUM_MAILBOX_BITMAPS	This is macro SYS_MSG_NUM_MAILBOX_BITMAPS.
	SYS_OBJ_HANDLE_INVALID	This is macro SYS_OBJ_HANDLE_INVALID.
	SYS_OBJ_HANDLE_STATIC	This is macro SYS_OBJ_HANDLE_STATIC.
	SYS_OBJ_HANDLE	SYS_MODULE_OBJ was poorly named. It should be SYS_MODULE_OBJ_HANDLE or something shorter. For brevity, it was renamed to SYS_OBJ_HANDLE.

Description

This section describes the APIs of the Messaging System Service Library.

Refer to each section for a detailed description.

a) Initialization, Tasks, and Versioning Functions

SYS_MSG_Deinitialize Function

Deinitializes System Messaging Instance.

File

sys_msg.h

C

```
void SYS_MSG_Deinitialize(SYS_OBJ_HANDLE handleSysMsg);
```

Returns

None.

Description

This function deinitializes the System Messaging Instance and frees up allocated memory for it.

Remarks

None.

Preconditions

None.

Example

```
SYS_OBJ_HANDLE hSysMsg;
uint16_t nQSizes[] = SYS_MSG_BUFFER_SIZES;

// Initialize the messaging system. This needs to done in the initialization code.
// Choose System Messaging instance that supports 8 byte messages
hSysMsg = SYS_MSG_Initialize(SYS_MSG_8Bytes,SYS_MSG_MAX_PRIORITY+1,nQSizes);

if (SYS_OBJ_HANDLE_INVALID == hSysMsg)
{
    // Handle error
}
.
.
.
// Remove this instance.
SYS_MSG_Deinitialize( hSysMsg );
```

Parameters

Parameters	Description
hSysMsg	handle to System Messaging Object for instance to be removed.

Function

void SYS_MSG_Deinitialize (SYS_OBJ_HANDLE hSysMsg)

SYS_MSG_Initialize Function

Configures and initializes the messaging subsystem.

File

sys_msg.h

C

```
SYS_OBJ_HANDLE SYS_MSG_Initialize(const SYS_MSG_INSTANCE iSysMsg, SYS_OBJ_HANDLE pInitializeSysMsg);
```

Returns

Handle to the System Messaging object created. Returns SYS_OBJ_HANDLE_INVALID if allocation of data structure fails. Returns SYS_OBJ_HANDLE_INVALID if pointer to initialization data structure is NULL.

Description

This function configures and initializes the messaging subsystem appropriately for the current system design.

Remarks

None.

Preconditions

None.

Example

```
  SYS_OBJ_HANDLE hSysMsg;
  SYS_MSG_INIT sInitSysMsg = { 0, (SYS_MSG_MAX_PRIORITY+1), { SYS_MSG_BUFFER_SIZES } };
//uint16_t nQSizes[] = SYS_MSG_BUFFER_SIZES;

  // Initialize the messaging system. This needs to done in the initialization code.
  // Choose System Messaging instance that supports 8 byte messages
  hSysMsg = SYS_MSG_Initialize(SYS_MSG_8Bytes,&sInitSysMsg);
```

```
if (SYS_OBJ_HANDLE_INVALID == hSysMsg)
{
    // Handle error
}
```

Parameters

Parameters	Description
iSysMsg	Index of System Messaging Service to be initialized.
pInitSysMsg	Pointer to System Messaging initialization data structure. If NULL default config values are used.

Function

SYS_OBJ_HANDLE SYS_MSG_Initialize (const SYS_MSG_INSTANCE iSysMsg,
SYS_OBJ_HANDLE pInitSysMsg)

SYS_MSG_Tasks Function

System Messaging Service Tasks routine.

File

sys_msg.h

C

```
void SYS_MSG_Tasks(SYS_OBJ_HANDLE handleSysMsg);
```

Returns

None.

Description

This function is the System Messaging Service Tasks routine.

Remarks

None.

Preconditions

hSysMsg must have been returned from a call to SYS_MSG_Initialize.

Example

```
while ( SYS_MSG_GotMessages(iSysMsg) )
{
    SYS_MSG_Tasks(hSysMsg);
}
```

Parameters

Parameters	Description
hSysMsg	handle to System Messaging Object.

Function

void SYS_MSG_Tasks (SYS_OBJ_HANDLE hSysMsg)

b) Mailbox Functions

SYS_MSG_MailboxMessagesGet Function

Gets queued messages for a mailbox.

File

sys_msg.h

C

```
SYS_MSG_OBJECT * SYS_MSG_MailboxMessagesGet(SYS_OBJ_HANDLE hMailbox);
```

Returns

Pointer to next message in the queue(s) that is of interest to the mailbox. Function returns NULL if no messages are found in the queue.

Description

This function gets the queued messages for a mailbox. Messages returned by this function will not be received via the mailbox's callback function.

Remarks

None.

Preconditions

hMailbox provided by call to SYS_MSG_MailboxOpen.

Example

```
SYS_MSG_OBJECT *pNextMessage;
while ( NULL != (pNextMessage = SYS_MSG_MailboxMessagesGet(hMyMailbox)) )
{
    // Process message at *pNextMessage.
}
```

Parameters

Parameters	Description
hMailbox	Object handle to mailbox

Function

SYS_MSG_OBJECT *SYS_MSG_MailboxMessagesGet(SYS_OBJ_HANDLE hMailbox)

SYS_MSG_MailboxMsgAdd Function

Adds a message type to the list of messages received by a mailbox.

File

sys_msg.h

C

```
void SYS_MSG_MailboxMsgAdd(SYS_OBJ_HANDLE hMailbox, SYS_OBJ_HANDLE hMsgType);
```

Returns

None.

Description

This function adds a message type to the list of messages received by a mailbox.

Remarks

When the message type handle is unknown but the message ID is known use SYS_MSG_ID2hMsgType to provide the message type handle. See code example.

Preconditions

hMailbox provided by call to SYS_MSG_MailboxOpen.

Example

```
const SYS_MSG_INSTANCE iSysMsg;
SYS_OBJ_HANDLE hMsgType[5], hMailbox[3];

// Create three mailboxes
hMailbox[0] = SYS_MSG_MailboxOpen( iSysMsg, &myCallBack0 );
hMailbox[1] = SYS_MSG_MailboxOpen( iSysMsg, &myCallBack1 );
hMailbox[2] = SYS_MSG_MailboxOpen( iSysMsg, &myCallBack2 );

// Create five message types
//                              Message ID:  :Priority
hMsgType[0] = SYS_MSG_TypeCreate(iSysMsg,1<<0,0);
hMsgType[1] = SYS_MSG_TypeCreate(iSysMsg,1<<1,1);
hMsgType[2] = SYS_MSG_TypeCreate(iSysMsg,1<<2,2);
```

```
hMsgType[3] = SYS_MSG_TypeCreate(iSysMsg,1<<3,3);
hMsgType[4] = SYS_MSG_TypeCreate(iSysMsg,1<<4,4);

// Add messages to each mailbox
SYS_MSG_MailboxMsgAdd(hMailbox[0],hMsgType[0]);
SYS_MSG_MailboxMsgAdd(hMailbox[1],hMsgType[1]);
SYS_MSG_MailboxMsgAdd(hMailbox[2],hMsgType[2]);

SYS_MSG_MailboxMsgAdd(hMailbox[0],SYS_MSG_ID2hMsgType(iSysMsg,1<<1));
SYS_MSG_MailboxMsgAdd(hMailbox[0],SYS_MSG_ID2hMsgType(iSysMsg,1<<2));
SYS_MSG_MailboxMsgAdd(hMailbox[0],SYS_MSG_ID2hMsgType(iSysMsg,1<<3));
SYS_MSG_MailboxMsgAdd(hMailbox[0],SYS_MSG_ID2hMsgType(iSysMsg,1<<4));
```

Parameters

Parameters	Description
hMailbox	Object handle to mailbox
hMsgType	Handle to message type of interest for this mailbox.

Function

void SYS_MSG_MailboxMsgAdd(SYS_OBJ_HANDLE hMailbox, SYS_OBJ_HANDLE hMsgType)

SYS_MSG_MailboxMsgRemove Function

Removes a message type from the list of messages received by a mailbox.

File

sys_msg.h

C

```
void SYS_MSG_MailboxMsgRemove(SYS_OBJ_HANDLE hMailbox, SYS_OBJ_HANDLE hMsgType);
```

Returns

None.

Description

This function removes a message type from the list of messages received by a mailbox.

Remarks

When the message type handle is unknown but the message ID is known use SYS_MSG_ID2hMsgType to provide the message type handle. See code example.

Preconditions

hMailbox provided by call to SYS_MSG_MailboxOpen.

Example

```
const SYS_MSG_INSTANCE iSysMsg;
SYS_OBJ_HANDLE hMsgType[5], hMailbox[3];

// Create three mailboxes
hMailbox[0] = SYS_MSG_MailboxOpen( iSysMsg, &myCallBack0 );
hMailbox[1] = SYS_MSG_MailboxOpen( iSysMsg, &myCallBack1 );
hMailbox[2] = SYS_MSG_MailboxOpen( iSysMsg, &myCallBack2 );

// Create five message types
//                              Message ID:  :Priority
hMsgType[0] = SYS_MSG_TypeCreate(iSysMsg,1<<0,0);
hMsgType[1] = SYS_MSG_TypeCreate(iSysMsg,1<<1,1);
hMsgType[2] = SYS_MSG_TypeCreate(iSysMsg,1<<2,2);
hMsgType[3] = SYS_MSG_TypeCreate(iSysMsg,1<<3,3);
hMsgType[4] = SYS_MSG_TypeCreate(iSysMsg,1<<4,4);

// Add messages to each mailbox
SYS_MSG_MailboxMsgAdd(hMailbox[0],hMsgType[0]);
SYS_MSG_MailboxMsgAdd(hMailbox[1],hMsgType[1]);
SYS_MSG_MailboxMsgAdd(hMailbox[2],hMsgType[2]);
```

```
SYS_MSG_MailboxMsgAdd(hMailbox[0],SYS_MSG_ID2hMsgType(iSysMsg,1<<1));
SYS_MSG_MailboxMsgAdd(hMailbox[0],SYS_MSG_ID2hMsgType(iSysMsg,1<<2));
SYS_MSG_MailboxMsgAdd(hMailbox[0],SYS_MSG_ID2hMsgType(iSysMsg,1<<3));
SYS_MSG_MailboxMsgAdd(hMailbox[0],SYS_MSG_ID2hMsgType(iSysMsg,1<<4));
```

Parameters

Parameters	Description
hMailbox	Object handle to mailbox
hMsgType	Handle to message type to be ignored by this mailbox.

Function

void SYS_MSG_MailboxMsgRemove(SYS_OBJ_HANDLE hMailbox, SYS_OBJ_HANDLE hMsgType)

SYS_MSG_MailboxClose Function

Closes (destroys) a mailbox previously opened with SYS_MSG_MailboxOpen.

File

sys_msg.h

C

```
void SYS_MSG_MailboxClose(SYS_OBJ_HANDLE hMailbox);
```

Returns

None.

None.

Description

This function closes (destroys) a mailbox previously opened with SYS_MSG_MailboxOpen.

Preconditions

hMailbox provided by call to SYS_MSG_MailboxOpen.

Example

```
SYS_OBJ_HANDLE hMyMailbox;

hMyMailbox = SYS_MSG_MailboxOpen( iSysMsg, &myCallBackFunction );
SYS_MSG_MailboxClose(hMyMailbox);
```

Parameters

Parameters	Description
hMailbox	Handle to mailbox that is to be closed (destroyed).

Function

void SYS_MSG_MailboxClose(SYS_OBJ_HANDLE hMailbox)

SYS_MSG_MailboxOpen Function

Opens a system messaging mailbox.

File

sys_msg.h

C

```
SYS_OBJ_HANDLE SYS_MSG_MailboxOpen(const SYS_MSG_INSTANCE iSysMsg, SYS_MSG_RECEIVE_CALLBACK
msgCallBackFunction);
```

Returns

Handle to new system messaging mailbox.

Description

This function opens a system messaging mailbox, providing a message callback function that is called whenever a message is received.

Remarks

A null callback function disables messaging callbacks.

Preconditions

iSysMsg must have been used in a call to SYS_MSG_Initialize. Message callback function will not be called until SYS_MSG_MailboxSignUp has been used to sign up the mailbox for messages of interest.

Example

```
SYS_OBJ_HANDLE hMyMailbox;

hMyMailbox = SYS_MSG_MailboxOpen( iSysMsg, &myCallBackFunction );
if (SYS_OBJ_HANDLE_INVALID == SYS_MSG_TypeRemove)
{
    // Handle error
}
```

Parameters

Parameters	Description
iSysMsg	Index of System Messaging Service instance.
msgCallBackFunction	pointer to message callback function

Function

SYS_OBJ_HANDLE SYS_MSG_MailboxOpen(const SYS_MSG_INSTANCE iSysMsg,
SYS_MSG_RECEIVE_CALLBACK msgCallBackFunction);

SYS_MSG_MailboxReinit Function

Reinitializes a previously opened mailbox.

File

sys_msg.h

C

```
void SYS_MSG_MailboxReinit(SYS_OBJ_HANDLE hMailbox, SYS_MSG_RECEIVE_CALLBACK msgCallBackFunction);
```

Returns

None.

Description

This function reinitializes a previously opened mailbox by providing a new callback function and clearing all message type assignments.

Remarks

A null callback function disables messaging callbacks.

Preconditions

hMailbox provided by call to SYS_MSG_MailboxOpen.

Example

```
SYS_OBJ_HANDLE hMyMailbox;

hMyMailbox = SYS_MSG_MailboxOpen( iSysMsg, &myCallBackFunction );
SYS_MSG_MailboxReinit(hMyMailbox,&anotherCallBackFunction );
```

Parameters

Parameters	Description
hMailbox	Object handle to mailbox
msgCallBackFunction	pointer to new message callback function

Function

void SYS_MSG_MailboxReinit(SYS_OBJ_HANDLE hMailbox,
SYS_MSG_RECEIVE_CALLBACK msgCallBackFunction);

c) Message Type Functions

SYS_MSG_TypeCreate Function

Creates a new message type.

File

sys_msg.h

C

```
SYS_OBJ_HANDLE SYS_MSG_TypeCreate(const SYS_MSG_INSTANCE iSysMsg, uint8_t nMessageTypeID, uint8_t
nMessagePriority);
```

Returns

Handle to new message type definition.

Description

This function creates a new message type, defining an integer message type and priority.

Remarks

None.

Preconditions

iSysMsg must have been used in a call to SYS_MSG_Initialize.

Example

```
SYS_OBJ_HANDLE hMsgType;
hMsgType = SYS_MSG_TypeCreate( iSysMsg, 1, 3 );
if (SYS_OBJ_HANDLE_INVALID == hMsgType)
{
    // Handle error
}
```

Parameters

Parameters	Description
iSysMsg	Index of System Messaging Service instance.
nMessageTypeID	Integer message type identifier
nMessagePriority	Message priority, between 0 and SYS_MSG_MAX_PRIORITIES

Function

SYS_OBJ_HANDLE SYS_MSG_TypeCreate(const SYS_MSG_INSTANCE iSysMsg,
uint8_t nMessageTypeID,
uint8_t nMessagePriority)

SYS_MSG_TypeRemove Function

Removes an existing message type.

File

sys_msg.h

C

```
void SYS_MSG_TypeRemove(SYS_OBJ_HANDLE hMsgType);
```

Returns

None.

Description

This function removes an existing message type.

Remarks

When the message type handle is unknown but the message ID is known use SYS_MSG_ID2hMsgType to provide the message type handle. See code example.

Preconditions

None.

Example

```
SYS_OBJ_HANDLE hMsgType;
hMsgType = SYS_MSG_TypeCreate( iSysMsg, 1, 3 );
SYS_MSG_TypeRemove( hMsgType );
```

Alternately:

```
SYS_OBJ_HANDLE hMsgType;
hMsgType = SYS_MSG_TypeCreate( iSysMsg, 1, 3 );
SYS_MSG_TypeRemove( SYS_MSG_ID2hMsgType(iSysMsg,1) );
```

Parameters

Parameters	Description
hMsgType	Handle to message type that is to be removed

Function

void SYS_MSG_TypeRemove(SYS_OBJ_HANDLE hMsgType)

d) Message Send/Receive Functions

SYS_MSG_GotMessages Function

Returns true if system messaging has undelivered messages, false otherwise.

File

sys_msg.h

C

```
bool SYS_MSG_GotMessages(const SYS_MSG_INSTANCE iSysMsg);
```

Returns

- true - Undelivered system messages exist
- false - No undelivered system messages exist

Description

This function returns the status when system messaging has undelivered messages.

Remarks

None.

Preconditions

iSysMsg must have been used in a call to SYS_MSG_Initialize.

Example

```
DBPRINTF("rnGot Messages: %drn",SYS_MSG_GotMessages(iSysMsg));
while ( (pNextMessage = SYS_MSG_MessageReceive(iSysMsg)) != NULL )
{
    SYS_MSG_MessageDeliver(iSysMsg,pNextMessage);
    DBPRINTF("rn");
}
```

```
DBPRINTF("Got Messages: %drn",SYS_MSG_GotMessages(ihSysMsg));
```

Parameters

Parameters	Description
iSysMsg	Index of System Messaging Service instance.

Function

bool SYS_MSG_GotMessages(const SYS_MSG_INSTANCE iSysMsg)

SYS_MSG_MessageDeliver Function

Delivers messages to mailboxes.

File

sys_msg.h

C

```
void SYS_MSG_MessageDeliver(const SYS_MSG_INSTANCE iSysMsg, SYS_MSGQ_ELEMENT * pQElement);
```

Returns

None.

Description

This function delivers messages to mailboxes, and removes the message from the queue when done.

Remarks

None.

Preconditions

iSysMsg must have been used in a call to SYS_MSG_Initialize.

Example

```
SYS_MSGQ_ELEMENT *pQElement;
SYS_MSG_OBJECT nextMessage;
while ( (pQElement = SYS_MSG_MessageReceive(iSysMsg)) != NULL )
{
    // In case you desire to examine message before delivering it.
    nextMessage = pQElement->sMessage;

    // Deliver message to all interested mailboxes
    SYS_MSG_MessageDeliver(iSysMsg,pQElement);
}
```

Parameters

Parameters	Description
iSysMsg	Index of System Messaging Service instance.
pQElement	pointer to queue element to be delivered.

Function

void SYS_MSG_MessageDeliver(const SYS_MSG_INSTANCE iSysMsg, SYS_MSGQ_ELEMENT *pQElement);

SYS_MSG_MessageReceive Function

Receives the next message in the message queues.

File

sys_msg.h

C

```
SYS_MSGQ_ELEMENT * SYS_MSG_MessageReceive(const SYS_MSG_INSTANCE iSysMsg);
```

Returns

Pointer to next message, as found in a message queue element, NULL if there are no messages.

Description

This function receives the next message in the message queues, returning NULL if the queues are empty.

Remarks

None.

Preconditions

iSysMsg must have been used in a call to SYS_MSG_Initialize.

Example

```
SYS_MSGQ_ELEMENT *pQElement;
SYS_MSG_OBJECT nextMessage;
while ( (pQElement = SYS_MSG_MessageReceive(iSysMsg)) != NULL )
{
    // In case you desire to examine message before delivering it.
    nextMessage = pQElement->sMessage;

    // Deliver message to all interested mailboxes
    SYS_MSG_MessageDeliver(iSysMsg,pQElement);
}
```

Parameters

Parameters	Description
iSysMsg	Index of System Messaging Service instance.

Function

SYS_MSGQ_ELEMENT *SYS_MSG_MessageReceive(const SYS_MSG_INSTANCE iSysMsg)

SYS_MSG_MessageSend Function

Sends a message, as defined by a message structure.

File

sys_msg.h

C

```
SYS_MSG_RESULTS SYS_MSG_MessageSend(const SYS_MSG_INSTANCE iSysMsg, SYS_MSG_OBJECT * pMessage);
```

Returns

Message result from SYS_MSG_RESULTS enumeration.

Description

This function sends a message, as defined by a message structure.

Remarks

None.

Preconditions

iSysMsg must have been used in a call to SYS_MSG_Initialize.

Example

```
SYS_MSG_OBJECT myMessage;
SYS_MSG_RESULTS myMessageStatus;
SYS_OBJ_HANDLE hMyMsgType;

hMyMsgType = SYS_MSG_TypeCreate( iSysMsg, 1, 3 );
if (SYS_OBJ_HANDLE_INVALID == hMyMsgType)
{
    // Handle error
}
```

```
myMessage.hMsgType = hMyMsgType;
myMessage.nSource  = myMsgSource;
myMessage.param1   = parameterOneValue;
myMessage.param1   = parameterTwoValue;

myMessageStatus = SYS_MSG_MessageSend(iSysMsg,&myMessage);
SYS_ASSERT( myMessageStatus > 0, "Bad message status!" );
```

Parameters

Parameters	Description
iSysMsg	Index of System Messaging Service instance.
pMessage	Pointer to message definition.

Function

SYS_MSG_RESULTS SYS_MSG_MessageSend(const SYS_MSG_INSTANCE iSysMsg,
SYS_MSG_OBJECT *pMessage)

e) Utility Functions

SYS_MSG_ID2hMsgType Function

Translates message type identifier into handle of corresponding message type object.

File

sys_msg.h

C

```
SYS_OBJ_HANDLE SYS_MSG_ID2hMsgType(const SYS_MSG_INSTANCE iSysMsg, uint8_t nMessageTypeID);
```

Returns

Handle to message type definition object corresponding to the message type identifier. Returns NULL if the message type is not defined.

Description

This function translates the message type identifier into the handle of the corresponding message type object.

Remarks

This function is useful in situations where the message type identifier is known but the message type handle is not. This allows applications to statically define message type IDs and use them in code instead of having to wait until message handles are known and then dynamically sharing message handles via global variables.

Preconditions

iSysMsg must have been used in a call to SYS_MSG_Initialize.

Example

```
#define MY_MESSAGE_TYPE_ID 1;

  // Create message type
  SYS_OBJ_HANDLE hMsgType;
  uint8_t nPriority = 3;
  hMsgType = SYS_MSG_TypeCreate( iSysMsg, MY_MESSAGE_TYPE_ID, nPriority );
  if (SYS_OBJ_HANDLE_INVALID == hMsgType)
  {
      // Handle error
  }
  .
  .
  .
  // Remove message type without knowing message type handle
  SYS_MSG_TypeRemove(iSysMsg,SYS_MSG_ID2hMsgType(iSysMsg,MY_MESSAGE_TYPE_ID));
```

Parameters

Parameters	Description
iSysMsg	Index of System Messaging Service instance.
nMessageTypeID	Integer message type identifier.

Function

SYS_OBJ_HANDLE SYS_MSG_ID2hMsgType(const SYS_MSG_INSTANCE iSysMsg,
uint8_t nMessageTypeID)

SYS_MSG_QueueStatus Function

Returns the message queue status for a given message priority.

File

sys_msg.h

C

```
SYS_MSG_QUEUE_STATUS SYS_MSG_QueueStatus(const SYS_MSG_INSTANCE iSysMsg, uint8_t nMessagePriority);
```

Returns

Number of messages in queue if not full or SYS_MSG_QUEUE_FULL if full. If message priority is not legal, returns SYS_MSG_QUEUE_BAD.

Description

This function returns the message queue status for a given message priority.

Remarks

None.

Preconditions

iSysMsg must have been used in a call to SYS_MSG_Initialize.

Example

Parameters

Parameters	Description
iSysMsg	Index of System Messaging Service instance.
nMessagePriority	message priority of interest, from zero to SYS_MSG_MAX_PRIORITIES.

Function

SYS_MSG_QUEUE_STATUS SYS_MSG_QueueStatus(const SYS_MSG_INSTANCE iSysMsg, uint8_t nMessagePriority)

f) Data Types and Constants

SYS_MSG_INIT Structure

Contains all the data necessary to initialize an instance of the System Messaging Service.

File

sys_msg.h

C

```
typedef struct {
  uint8_t nMaxMsgsDelivered;
  uint8_t nMessagePriorities;
  uint16_t * nQSizes;
} SYS_MSG_INIT;
```

Members

Members	Description
uint8_t nMaxMsgsDelivered;	Maximum number of messages delivered per call to SYS_MSG_Tasks
uint8_t nMessagePriorities;	Number of message priorities desired
uint16_t * nQSizes;	Array of queue sizes for priorities 0,1,...SYS_MSG_MAX_PRIORITY

Description

System Messaging Service Initialization Data

This data type contains all of the data necessary to initialize an instance of the System Messaging Service.

Remarks

A pointer to a structure of this format containing the desired initialization data must be passed into the SYS_MSG_Initialize routine. If nMaxMsgsDelivered == 0. ALL messages in priority queues are delivered each time SYS_MSG_Tasks is called.

SYS_MSG_INSTANCE Enumeration

System Messaging instances numbering is from 0,1, to SYS_MSG_MAX_INSTANCE.

File

sys_msg.h

C

```
typedef enum {
  SYS_MSG_0,
  SYS_MSG_1,
  SYS_MSG_2,
  SYS_MSG_3,
  SYS_MSG_4,
  SYS_MSG_NUM_INSTANCES
} SYS_MSG_INSTANCE;
```

Description

Enumeration of the Allowable of System Messaging Instances

System Messaging instances numbering is from 0,1, to SYS_MSG_MAX_INSTANCE.

Remarks

None.

SYS_MSG_OBJECT Structure

File

sys_msg.h

C

```
typedef struct {
  union {
    struct {
      uint8_t nMessageTypeID;
      uint8_t nSource;
      uint16_t param0;
      uint16_t param1;
      uint16_t param2;
    }
    struct {
      uint16_t dummy;
      uint16_t nSizeData;
      uintptr_t * pData;
    }
  }
} SYS_MSG_OBJECT;
```

Members

Members	Description
uint8_t nMessageTypeID;	Message type identifier
uint8_t nSource;	Message source identifier
uint16_t param0;	Message parameter zero
uint16_t param1;	Message parameter one
uint16_t param2;	Message parameter two
uint16_t nSizeData;	Size of data that pData identifies
uintptr_t * pData;	Pointer to additional message data

Description

This is type SYS_MSG_OBJECT.

SYS_MSG_QUEUE_STATUS Enumeration

Messaging queue status enumeration.

File

sys_msg.h

C

```
typedef enum {
  SYS_MSG_QUEUE_BAD,
  SYS_MSG_QUEUE_FULL,
  SYS_MSG_QUEUE_EMPTY
} SYS_MSG_QUEUE_STATUS;
```

Members

Members	Description
SYS_MSG_QUEUE_BAD	QUEUE Status: full
SYS_MSG_QUEUE_FULL	QUEUE Status: full
SYS_MSG_QUEUE_EMPTY	QUEUE Status: empty

Description

System Messaging Queue Status Enumeration

This enumeration provides the messaging queue status. Positive values indicate the number of messages in the queue.

Remarks

None.

SYS_MSG_RECEIVE_CALLBACK Type

Pointer to the System message received callback function.

File

sys_msg.h

C

```
typedef void (* SYS_MSG_RECEIVE_CALLBACK)(SYS_MSG_OBJECT *pMessage);
```

Description

Pointer to the System Message Received Callback Function

This data type is a pointer to the function provided for each system messaging mailbox that is called when a system message is received for each mailbox.

SYS_MSG_RESULTS Enumeration

Enumeration of message send results.

File

sys_msg.h

C

```
typedef enum {
  SYS_MSG_NOT_SENT_QFULL,
  SYS_MSG_BAD_PRIORITY,
  SYS_MSG_BAD_MSGTYPE,
  SYS_MSG_NOT_SENT,
  SYS_MSG_SENT
} SYS_MSG_RESULTS;
```

Members

Members	Description
SYS_MSG_NOT_SENT_QFULL	Message could not be sent, no room available in priority queues
SYS_MSG_BAD_PRIORITY	Message could not be sent, Message Message priority bad
SYS_MSG_BAD_MSGTYPE	Message could not be sent, Message type bad
SYS_MSG_NOT_SENT	Message could not be sent, no other information available
SYS_MSG_SENT	Message sent

Description

System Messaging Results Enumeration

This enumeration provides message send results.

Remarks

SYS_MSG_SENT aligns with SYS_MSGQ_Success. SYS_MSG_NOT_SENT aligns with SYS_MSGQ_Failure

SYS_MSGQ_ELEMENT Structure

Defines queue element for message queue belonging to each priority.

File

sys_msg.h

C

```
typedef struct {
  SYS_MSG_OBJECT sMessage;
  uint16_t mailboxInterestBitMap[SYS_MSG_NUM_MAILBOX_BITMAPS];
} SYS_MSGQ_ELEMENT;
```

Members

Members	Description
SYS_MSG_OBJECT sMessage;	System Message Bit map for mailboxes interested in this message type, modified as each mailbox is notified.

Description

System Messaging Queues Element

This data type defines the queue element for the message queue belonging to each priority.

Remarks

None.

SYS_MSG_MAILBOXES_ADDONE Macro

File

sys_msg.h

C

```
#define SYS_MSG_MAILBOXES_ADDONE 0
```

Description

don't need to round up the number of bitmaps

SYS_MSG_NUM_MAILBOX_BITMAPS Macro

File

sys_msg.h

C

```
#define SYS_MSG_NUM_MAILBOX_BITMAPS (SYS_MSG_MAX_MAILBOXES/16 + SYS_MSG_MAILBOXES_ADDONE)
```

Description

This is macro SYS_MSG_NUM_MAILBOX_BITMAPS.

SYS_OBJ_HANDLE_INVALID Macro

File

sys_msg.h

C

```
#define SYS_OBJ_HANDLE_INVALID ( (SYS_OBJ_HANDLE) -1 )
```

Description

This is macro SYS_OBJ_HANDLE_INVALID.

SYS_OBJ_HANDLE_STATIC Macro

File

sys_msg.h

C

```
#define SYS_OBJ_HANDLE_STATIC ( (SYS_OBJ_HANDLE)  0 )
```

Description

This is macro SYS_OBJ_HANDLE_STATIC.

SYS_OBJ_HANDLE Type

SYS_MODULE_OBJ was poorly named. It should be SYS_MODULE_OBJ_HANDLE or something shorter. For brevity, it was renamed to SYS_OBJ_HANDLE.

File

sys_msg.h

C

```
typedef uintptr_t SYS_OBJ_HANDLE;
```

Description

SYS_MODULE_OBJ Rename

SYS_MODULE_OBJ was poorly named. It should be SYS_MODULE_OBJ_HANDLE or something shorter. For brevity, it was renamed to SYS_OBJ_HANDLE.

Remarks

None.

Files

Files

Name	Description
sys_msg.h	System Service for the messaging module.
sys_msg_config.h	System Messaging Configuration definitions file

Description

This section lists the source and header files used by the library.

sys_msg.h

System Service for the messaging module.

Enumerations

	Name	Description
	SYS_MSG_INSTANCE	System Messaging instances numbering is from 0,1, to SYS_MSG_MAX_INSTANCE.
	SYS_MSG_QUEUE_STATUS	Messaging queue status enumeration.
	SYS_MSG_RESULTS	Enumeration of message send results.

Functions

	Name	Description
	SYS_MSG_Deinitialize	Deinitializes System Messaging Instance.
	SYS_MSG_GotMessages	Returns true if system messaging has undelivered messages, false otherwise.
	SYS_MSG_ID2hMsgType	Translates message type identifier into handle of corresponding message type object.
	SYS_MSG_Initialize	Configures and initializes the messaging subsystem.
	SYS_MSG_MailboxClose	Closes (destroys) a mailbox previously opened with SYS_MSG_MailboxOpen.
	SYS_MSG_MailboxMessagesGet	Gets queued messages for a mailbox.
	SYS_MSG_MailboxMsgAdd	Adds a message type to the list of messages received by a mailbox.
	SYS_MSG_MailboxMsgRemove	Removes a message type from the list of messages received by a mailbox.
	SYS_MSG_MailboxOpen	Opens a system messaging mailbox.
	SYS_MSG_MailboxReinit	Reinitializes a previously opened mailbox.
	SYS_MSG_MessageDeliver	Delivers messages to mailboxes.
	SYS_MSG_MessageReceive	Receives the next message in the message queues.
	SYS_MSG_MessageSend	Sends a message, as defined by a message structure.
	SYS_MSG_QueueStatus	Returns the message queue status for a given message priority.
	SYS_MSG_Tasks	System Messaging Service Tasks routine.
	SYS_MSG_TypeCreate	Creates a new message type.
	SYS_MSG_TypeRemove	Removes an existing message type.

Macros

	Name	Description
	SYS_MSG_MAILBOXES_ADDONE	don't need to round up the number of bitmaps
	SYS_MSG_NUM_MAILBOX_BITMAPS	This is macro SYS_MSG_NUM_MAILBOX_BITMAPS.
	SYS_OBJ_HANDLE_INVALID	This is macro SYS_OBJ_HANDLE_INVALID.
	SYS_OBJ_HANDLE_STATIC	This is macro SYS_OBJ_HANDLE_STATIC.

Structures

	Name	Description
	SYS_MSG_INIT	Contains all the data necessary to initialize an instance of the System Messaging Service.
	SYS_MSG_OBJECT	This is type SYS_MSG_OBJECT.
	SYS_MSGQ_ELEMENT	Defines queue element for message queue belonging to each priority.

Types

	Name	Description
	SYS_MSG_RECEIVE_CALLBACK	Pointer to the System message received callback function.
	SYS_OBJ_HANDLE	SYS_MODULE_OBJ was poorly named. It should be SYS_MODULE_OBJ_HANDLE or something shorter. For brevity, it was renamed to SYS_OBJ_HANDLE.

Description

Messaging System Service Library Interface Definitions

This file contains the interface definition for the messaging system service. It provides a way to interact with the messaging subsystem.

File Name

sys_msg.h

Company

Microchip Technology Inc.

sys_msg_config.h

System Messaging Configuration definitions file

Macros

	Name	Description
	_SYS_MSG_CONFIG_TEMPLATE__H	This is macro _SYS_MSG_CONFIG_TEMPLATE__H.
	SYS_MSG_BUFFER_SIZES	define SYS_MSG_BUFFER_SIZES { 4, 4, 4, 4, 1
	SYS_MSG_MAX_MAILBOXES	Specifies the maximum number of mailboxes possible.
	SYS_MSG_MAX_MSGS_DELIVERED	Specifies the maximum number of messages delivered per each call to SYS_MSG_Tasks.
	SYS_MSG_MAX_PRIORITY	Specifies the maximum message priority.
	SYS_MSG_MAX_TYPES	Specifies the maximum number of message types possible.

Description

System Messaging Configuration Definitions

These definitions statically define the operation of the System Messaging service.

Microchip Technology Inc.

Ports System Service Library

This section describes the Ports System Service Library.

Introduction

This library provides an interface to manage and control general purpose input or output ports controlled by the Ports modules on the Microchip families of microcontrollers.

Description

One challenge designers of general purpose microcontroller devices face is to provide a large set of available peripheral features on parts with a limited number of I/O pins. To help meet this challenge and to provide flexibility for board designers, many devices provide an ability to route I/O signals for selected peripherals to different I/O pins. However, in some cases, general purpose I/O (GPIO) pins must be used to implement the desired functionality under direct software control. The purpose of the ports system service is to provide direct control if general purpose I/O pins and to support the selection of the desired peripheral functionality for supported I/O pins and ports.

General purpose I/O pins can be controlled individually, but they are also grouped together in sets and can be controlled together as a unit. These groups of GPIO pins are called "ports" on Microchip microcontrollers and this library provides the ability to read and write data patterns to or from them in sets or as individual pins. In addition peripheral IO routing and pin/port control, this library provides the ability to select and configure several other features of the I/O pins and ports available on Microchip microcontrollers, as follows.

Other Features

- Individual output pin/port open-drain enable/disable
- Individual input pin/port pull-up enable/disable
- Monitor select inputs and generate interrupt on mismatch condition [Change Notification]
- Operate during Sleep and Idle modes
- Port line Analog/Digital Selection
- Port slew rate control

Note: Trademarks and Intellectual Property are property of their respective owners. Customers are responsible for obtaining appropriate licensing or rights before using this software. Refer to the MPLAB Harmony *Software License Agreement* for complete licensing information. A copy of this agreement is available in the `<install-dir>/doc` folder of your MPLAB Harmony installation.

Using the Library

This topic describes the basic architecture of the Ports System Service Library and provides information and examples on its use.

Description

Interface Header File: `sys_ports.h`

The interface to the Ports System Service Library is defined in the `sys_ports.h` header file, which is included by the `sys.h` header file.

Any C language source (`.c`) file that uses the Ports System Service must include `sys.h`.

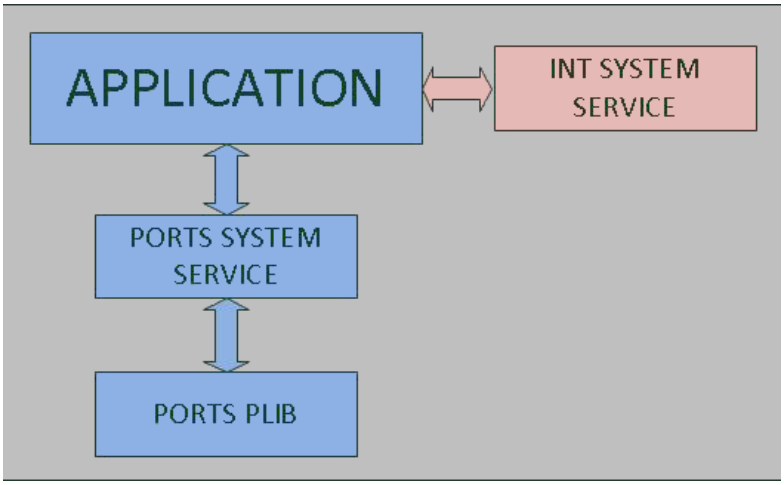
Please refer to the What is MPLAB Harmony? section for how the library interacts with the framework.

Abstraction Model

This library provides a low-level abstraction of the Ports System Service Library. This topic describes how that abstraction is modeled in software and introduces the library's interface.

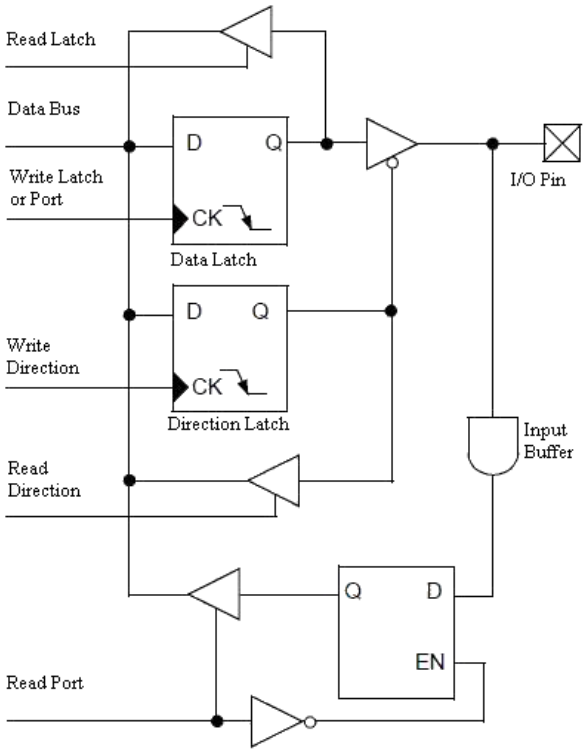
Description

This model explains how the system interfaces with the Ports System Service and the application as illustrated in the following diagram.



General Purpose I/O

All port pins have three registers directly associated with their operation as digital I/O. The Data Direction register determines whether the pin is an input or an output. If the data direction bit is a '1', the pin is an input. All port pins are defined as inputs after a Reset. Reads from the Output Latch register, read the latch, while writes to the latch, write the latch. Reads from the port, read the port pins, while writes to the port pins, write the latch.



The *pull-ups* act as a current source or sink source connected to the pin, and eliminates the need for external resistors when push-button or keypad devices are connected. These *pull-ups* prevent floating state of the pins by providing voltage to it. These features are available on some pins and some parts. Please refer to the specific device data sheet for further information.

The *open-drain* feature allows the generation of outputs higher than VDD (e.g., 5V) on any desired digital only pins by using external pull-up resistors. The maximum open-drain voltage allowed is the same as the maximum VIH specification.

The *input change notification* function of the I/O ports allows the microcontrollers to generate interrupt requests to the processor in response to a change of state on selected input pins. This feature is capable of detecting input change of states even in Sleep mode, when the clocks are disabled.

The *Alternate Pin Function selections* are used to steer specific peripheral input and output functions between different pins.

The *output slew rate* of each port is programmable to select either the standard transition rate or a reduced transition rate of x times the standard to minimize EMI. The reduced transition time is the default slew rate for all ports.

Peripheral Pin Select

Available Pins:

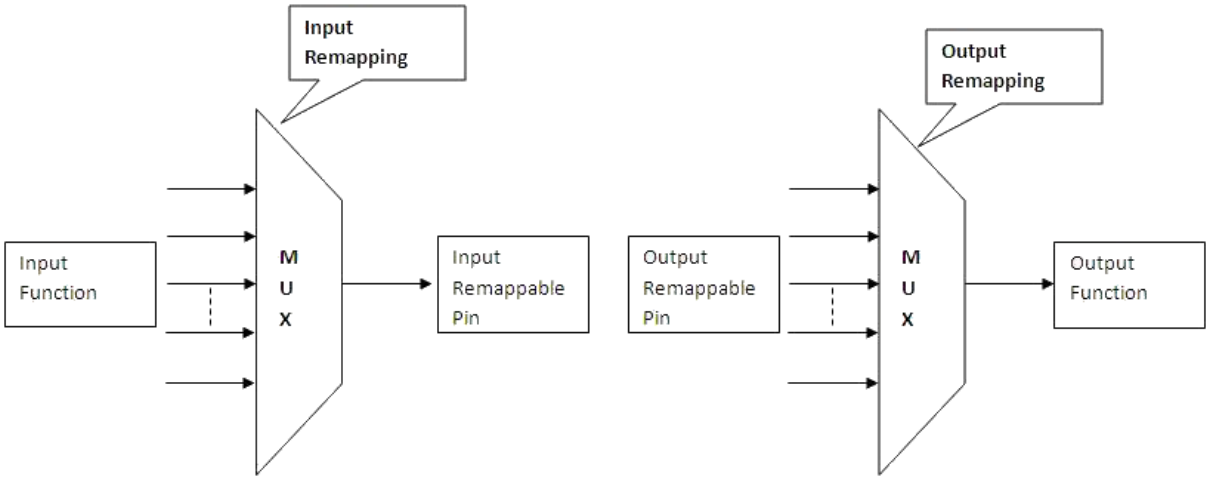
The number of available pins is dependent on the particular device and its pin count. Pins that support the peripheral pin select feature include the designation "RPn" in their full pin designation, where "RP" designates a remappable peripheral and "n" is the remappable port number.

Available Peripherals:

The peripherals managed by the peripheral pin select are all digital-only peripherals. These include general serial communications (UART and SPI), general purpose timer clock inputs, timer-related peripherals (Input Capture and Output Compare) and interrupt-on-change inputs.

In comparison, some digital-only peripheral modules are never included in the peripheral pin select feature. This is because the peripheral's function requires special I/O circuitry on a specific port and cannot be easily connected to multiple pins. These modules include I2C among others. A similar requirement excludes all modules with analog inputs, such as the A/D converter. A key difference between remappable and non-remappable peripherals is that remappable peripherals are not associated with a default I/O pin. The peripheral must always be assigned to a specific I/O pin before it can be used. In contrast, non-remappable peripherals are always available on a default pin, assuming that the peripheral is active and not conflicting with another peripheral.

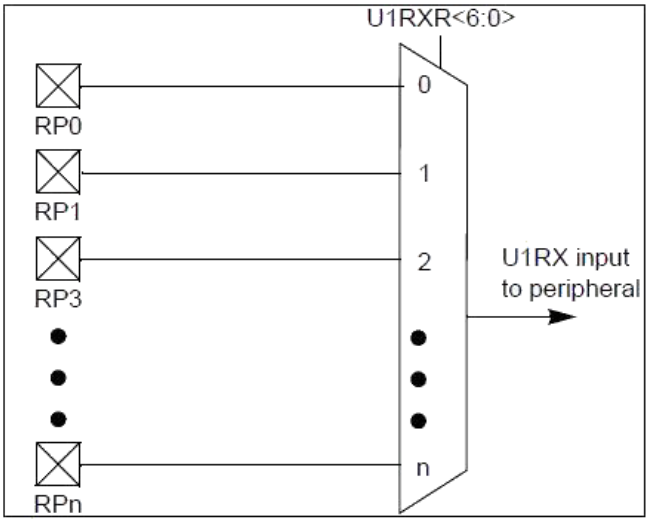
When a remappable peripheral is active on a given I/O pin, it takes priority over all other digital I/O and digital communication peripherals associated with the pin. Priority is given regardless of the type of peripheral that is mapped. Remappable peripherals never take priority over any analog functions associated with the pin.



Input Mapping:

The inputs of the peripheral pin select options are mapped on the basis of the peripheral. That is, a control register associated with a peripheral dictates to which pin it will be mapped.

Remappable Input Example for USART 1 Receive

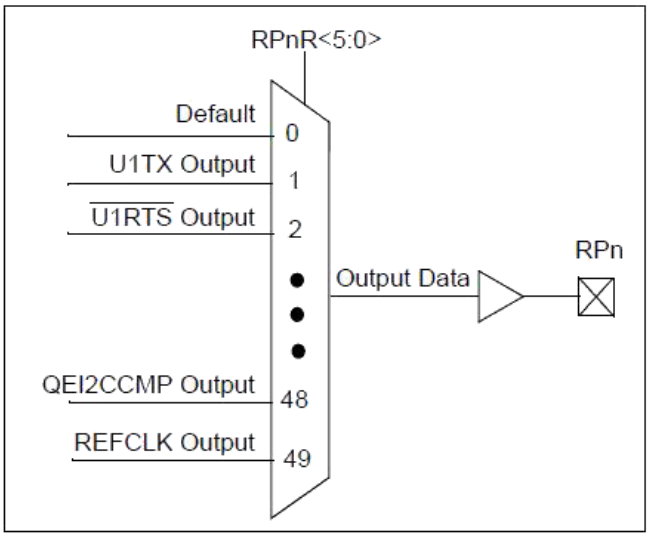


Note: For input only, peripheral pin select functionality does not have priority over I/O port settings. Therefore, when configuring Remappable Pin for input,the corresponding bit in the I/O port register must also be configured for input (set to '1').

Output Mapping:

In contrast to inputs, the outputs of the peripheral pin select options are mapped on the basis of the pin. In this case, a control register associated with a particular pin dictates the peripheral output to be mapped.

Multiplexing of Remappable Output for RPn



Mapping Limitations:

The control schema of the peripheral select pins is not limited to a small range of fixed peripheral configurations. There are no mutual or hardware-enforced lockouts between any of the peripheral mapping SFRs. Literally any combination of peripheral mappings across any or all of the RPn pins is possible. This includes both many-to-one and one-to-many mappings of peripheral inputs and outputs to pins. While such mappings may be technically possible from a configuration point of view, they may not be supportable from an electrical point of view.

Library Overview

Please refer to the System Service Introduction for a detailed description of MPLAB Harmony system services.

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Ports System Service Library.

Library Interface Section	Description
Pin Control Functions	Port bit/pin read/write/toggle/clear/set interfaces.
Ports Control Functions	Port access read/write/toggle/clear/set interfaces.
Change Notification Functions	Interface routines for Port line change notification.
Peripheral Pin Select Functions	Interface routines for mapping the digital input/output to a specific PPS Remappable input/output pin.

How the Library Works

Pin Control

Pins Functions Usage

- **Pin Read:** Port pin can be read at bit/pin level using SYS_PORTS_PinRead with appropriate parameters
- **Pin Write:** Port pin can be written at bit/pin level using SYS_PORTS_PinWrite with appropriate parameters
- **Pin Clear:** Port pin can be cleared at bit/pin level using SYS_PORTS_PinClear with appropriate parameters
- **Pin Set:** Port pin can be set at bit/pin level using SYS_PORTS_PinSet with appropriate parameters
- **Pin Direction Control:** Port pin direction can be set at bit/pin level using SYS_PORTS_PinDirectionSelect with appropriate parameters. The Direction information can be obtained through the interface SYS_PORTS_DirectionGet.
- **Pin Toggle:** Port pin can be toggled at bit/pin level using SYS_PORTS_PinToggle with appropriate parameters
- **Pin Open Drain:** Port pin can be enabled open drain functionality at bit/pin level using SYS_PORTS_PinOpenDrainEnable with appropriate parameters. Similarly, the Port pin can be disabled open drain functionality at bit/pin level using SYS_PORTS_PinOpenDrainDisable with appropriate parameters.

Example:

```
// PORT Direction setting for output
SYS_PORTS_PinDirectionSelect(MY_PORTS_INSTANCE, SYS_PORTS_DIRECTION_OUTPUT, MY_CHANNEL, MY_PINNUM);
```

```
// PORT Direction setting for input
SYS_PORTS_PinDirectionSelect(MY_PORTS_INSTANCE, SYS_PORTS_DIRECTION_INPUT, MY_CHANNEL, MY_PINNUM);
// Writing a value into a PORT
SYS_PORTS_PinWrite(MY_PORTS_INSTANCE, MY_CHANNEL, MY_PINNUM, MY_VALUE);
// Reading back the previously written value
bool readData = SYS_PORTS_PinRead(MY_PORTS_INSTANCE, MY_CHANNEL, MY_PINNUM);
// Clearing the PORT
SYS_PORTS_PinClear(MY_PORTS_INSTANCE, MY_CHANNEL, MY_PINNUM);
// Setting the port
SYS_PORTS_PinSet(MY_PORTS_INSTANCE, MY_CHANNEL, MY_PINNUM);
// Toggling a PORT
SYS_PORTS_PinToggle(MY_PORTS_INSTANCE, MY_CHANNEL, MY_PINNUM);
```

Note: Not all features are available on all devices. Please refer to the specific device data sheet to determine availability.

Ports Control

Port Functions Usage

- **Port Read:** Ports can be read at byte/word level using the interface SYS_PORTS_Read with appropriate parameters
- **Port Write:** Ports can be written to at byte/word level using the interface SYS_PORTS_Write appropriate parameters
- **Port Clear:** Ports can be cleared at byte/word level using the interface SYS_PORTS_Clear with appropriate parameters
- **Port Set:** Ports can be set at byte/word level using the interface SYS_PORTS_Set with appropriate parameters
- **Port Direction Control:** Ports direction can be set at byte/word level using the interface SYS_PORTS_DirectionSelect with appropriate parameters. The Direction information can be obtained through the interface SYS_PORTS_DirectionGet.
- **Port Toggle:** Ports can be toggled at byte/word level using the interface SYS_PORTS_Toggle with appropriate parameters
- **Port Open Drain:** Ports can be enabled open drain functionality at byte/word level using the interface SYS_PORTS_OpenDrainEnable with appropriate parameters. Similarly, the Ports can be disabled open drain functionality at byte/word level using the interface SYS_PORTS_OpenDrainDisable with appropriate parameters.

Example:

```
// PORT Direction setting for output
SYS_PORTS_DirectionSelect(MY_PORTS_INSTANCE, SYS_PORTS_DIRECTION_OUTPUT, MY_CHANNEL,
(PORTS_DATA_MASK)0xFFFF);
// PORT Direction setting for input
SYS_PORTS_DirectionSelect(MY_PORTS_INSTANCE, SYS_PORTS_DIRECTION_INPUT, MY_CHANNEL,
(PORTS_DATA_MASK)0xFFFF);
// Writing a value into a PORT
SYS_PORTS_Write(MY_PORTS_INSTANCE, MY_CHANNEL, (PORTS_DATA_TYPE)0x1234)
// Reading back the previously written value
PORTS_DATA_TYPE readData = SYS_PORTS_Read(MY_PORTS_INSTANCE, MY_CHANNEL);
// Clearing the PORT
SYS_PORTS_Clear(MY_PORTS_INSTANCE, MY_CHANNEL, (PORTS_DATA_MASK)0x00FF);
// Setting the port
SYS_PORTS_Set(MY_PORTS_INSTANCE, MY_CHANNEL, 0x1234, (PORTS_DATA_MASK)0x00FF);
// Toggling a PORT
SYS_PORTS_Toggle(MY_PORTS_INSTANCE, MY_CHANNEL, (PORTS_DATA_MASK)0x00FF);
```

Note: Not all features are available on all devices. Please refer to the specific device data sheet to determine availability.

Change Notification

Change Notification Feature Usage

The change notification feature can be enabled using "SYS_PORTS_ChangeNotificationEnable". This routine performs the following operations:

- Change notification can be disabled after the successful usage using the interface SYS_PORTS_ChangeNotificationDisable
- Certain microcontrollers support the global control over the change notification feature using the following interfaces SYS_PORTS_ChangeNotificationGlobalEnable and SYS_PORTS_ChangeNotificationGlobalDisable
- If there are any requirements to control the pull-ups SYS_PORTS_ChangeNotificationPullUpEnable and SYS_PORTS_ChangeNotificationPullUpDisable could be used

Change Notification Operation in Sleep and Idle Modes

The change notification module continues to operate during Sleep or Idle mode. Its operation can be enabled and disabled using the interfaces SYS_PORTS_ChangeNotificationInIdleModeEnable and SYS_PORTS_ChangeNotificationInIdleModeDisable, respectively.

Example:

```
// Enabling the global change notification
SYS_PORTS_ChangeNotificationGlobalEnable(MY_PORTS_INSTANCE);
// Enabling weak pull-ups for the change notification PIN 10
SYS_PORTS_ChangeNotificationPullUpEnable(MY_PORTS_INSTANCE, PORTS_CHANGE_NOTICE_PIN_10);
// Enabling change notification on PIN 10
SYS_PORTS_ChangeNotificationEnable(MY_PORTS_INSTANCE, PORTS_CHANGE_NOTICE_PIN_10, SYS_PORTS_PULLUP_ENABLE);
// Enabling the change notification in idle mode.
SYS_PORTS_ChangeNotificationInIdleModeEnable(MY_PORTS_INSTANCE);
```

Note: Not all features are available on all devices. Please refer to the specific device data sheet to determine availability.

Peripheral Pin Select

Ports Remapping or Peripheral Pin Select Usage

Input/Output Function Remapping:

The SYS_PORTS_RemapInput and SYS_PORTS_RemapOutput functions with appropriate parameters can be used to remap a particular port pin as input/output for a peripheral.

Example:

```
// Remapping input function 'Input Capture 1' to the Remappable input pin 'RPD2'
SYS_PORTS_RemapInput (PORTS_ID_0, INPUT_FUNC_IC1, INPUT_PIN_RPD2 );
// Remapping output function 'UART1 Transmit' to the Remappable output pin 'RPA14'
SYS_PORTS_RemapInputOutput(PORTS_ID_0, OUTPUT_FUNC_U1TX, OUTPUT_PIN_RPA14);
```

Note: Not all features are available on all devices. Please refer to the specific device data sheet to determine availability.

Miscellaneous

Other Usage

Slew Rate:

Slew rate of a particular port can be controlled though the interfaces SYS_PORTS_SlewRateSetReduced and SYS_PORTS_SlewRateSetStandard.

Open Drain:

Peripheral based open drain can be controlled through the interfaces SYS_PORTS_PeripheralOpenDrainEnable and SYS_PORTS_PeripheralOpenDrainDisable.

Note: Not all features are available on all devices. Please refer to the specific device data sheet to determine availability.

Special Considerations

Note on Ports Usage:

1. Setting a port pin as an analog input also requires that the corresponding direction be set. If the direction is set to output, the digital output level (VOH or VOL) will be outputted.
2. When reading the port register, all pins configured as analog input channels will read as cleared.
3. Pins configured as digital inputs will not output an analog input. Analog levels on any pin that is defined as a digital input may cause the input buffer to consume current that exceeds the device specifications.
4. Pull-ups and pull-downs on change notification pins should always be disabled when the port pin is configured as a digital output.

Considerations for the Peripheral Pin Select:

The ability to control Peripheral Pin Select options introduces several considerations into application design that could be overlooked. This is particularly true for several common peripherals that are available only as remappable peripherals.

The main consideration is that the Peripheral Pin Selects are not available on default pins in the device's default (Reset) state, all Peripheral Pin Select inputs are tied to Vss and all Peripheral Pin Select outputs are disconnected. This situation requires the user to initialize the device with the proper peripheral configuration before any other application code is executed. For application safety, however, it is best to lock the configuration after writing to the control registers.

A final consideration is that Peripheral Pin Select functions neither override analog inputs, nor reconfigure pins with analog functions for digital I/O. If a pin is configured as an analog input on device Reset, it must be explicitly reconfigured as digital I/O when used with a Peripheral Pin Select.

Note: Not all features are available on all devices. Please refer to the specific device data sheet to determine availability.

Configuring the Library

The configuration of the Ports System Service is based on the file `system_config.h`.

This header file contains the configuration selection for the Ports System Service. Based on the selections made, the Ports System Service may support the selected features. These configuration settings will apply to all instances of the Ports System Service.

This header can be placed anywhere, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

Building the Library

This section lists the files that are available in the Ports System Service Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/system/ports`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
sys_ports.h	Ports System Service Library API header file.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/sys_ports.c	Ports System Service Library implementation.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The Reset System Service Library depends on the following modules:

- Ports Peripheral Library
- Device Control Peripheral Library

Library Interface

a) Pin Control Functions

	Name	Description
	SYS_PORTS_PinModeSelect	Enables the selected pin as analog or digital. **Implementation:** Dynamic
	SYS_PORTS_PinOpenDrainDisable	Disables the open-drain functionality for the selected pin. **Implementation:** Dynamic
	SYS_PORTS_PinOpenDrainEnable	Enables the open-drain functionality for the selected pin. **Implementation:** Dynamic
	SYS_PORTS_PinRead	Reads the selected digital pin. **Implementation:** Dynamic
	SYS_PORTS_PinSet	Sets the selected digital pin/latch. **Implementation:** Dynamic

	SYS_PORTS_PinToggle	Toggles the selected digital pin. **Implementation:** Dynamic
	SYS_PORTS_PinWrite	Writes the selected digital pin. **Implementation:** Dynamic
	SYS_PORTS_PinClear	Clears the selected digital pin. **Implementation:** Dynamic
	SYS_PORTS_PinDirectionSelect	Enables the direction for the selected pin. **Implementation:** Dynamic

b) Ports Control Functions

	Name	Description
	SYS_PORTS_Clear	Clears the selected digital port. **Implementation:** Dynamic
	SYS_PORTS_DirectionGet	Reads the direction for the selected port. **Implementation:** Dynamic
	SYS_PORTS_DirectionSelect	Enables the direction for the selected port. **Implementation:** Dynamic
	SYS_PORTS_OpenDrainDisable	Disables the open-drain functionality for the selected port. **Implementation:** Dynamic
	SYS_PORTS_OpenDrainEnable	Enables the open-drain functionality for the selected port. **Implementation:** Dynamic
	SYS_PORTS_Read	Reads the data from the I/O port. **Implementation:** Dynamic
	SYS_PORTS_Set	Sets the selected digital port/latch based on the mask. **Implementation:** Dynamic
	SYS_PORTS_Toggle	Toggles the selected digital port pins. **Implementation:** Dynamic
	SYS_PORTS_Write	Writes the data to the I/O port. **Implementation:** Dynamic
	SYS_PORTS_Initialize	Initializes PORT Pins/Channels. **Implementation:** Static/Dynamic

c) Change Notification Functions

	Name	Description
	SYS_PORTS_ChangeNotificationDisable	Disables the change notification for the selected port. **Implementation:** Dynamic
	SYS_PORTS_ChangeNotificationEnable	Enables the change notification for the selected port. **Implementation:** Dynamic
	SYS_PORTS_ChangeNotificationGlobalDisable	Globally disables the change notification for the selected port. **Implementation:** Dynamic
	SYS_PORTS_ChangeNotificationGlobalEnable	Globally enables the change notification for the selected port. **Implementation:** Dynamic
	SYS_PORTS_ChangeNotificationInIdleModeDisable	Disables the change notification for the selected port in Sleep or Idle mode. **Implementation:** Dynamic
	SYS_PORTS_ChangeNotificationInIdleModeEnable	Enables the change notification for the selected port in Sleep or Idle mode. **Implementation:** Dynamic
	SYS_PORTS_ChangeNotificationPullUpDisable	Disables a weak pull-up on the change notification pin. **Implementation:** Dynamic
	SYS_PORTS_ChangeNotificationPullUpEnable	Enables a weak pull-up on the change notification pin. **Implementation:** Dynamic

d) Peripheral Pin Select Functions

	Name	Description
	SYS_PORTS_RemapInput	Input/Output (I/O) function remapping. **Implementation:** Dynamic
	SYS_PORTS_RemapOutput	Input/Output (I/O) function remapping. **Implementation:** Dynamic

e) Data Types and Constants

	Name	Description
	SYS_PORTS_PIN_DIRECTION	Defines the direction of the port pins.
	SYS_PORTS_PULLUP_PULLDOWN_STATUS	Provides the pull-up and pull-down status.

Description

This section describes the APIs of the Ports System Service Library.

Refer to each section for a detailed description.

a) Pin Control Functions

SYS_PORTS_PinModeSelect Function

Enables the selected pin as analog or digital.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_PinModeSelect(PORTS_MODULE_ID index, PORTS_ANALOG_PIN pin, PORTS_PIN_MODE mode);
```

Returns

None.

Description

This function enables the selected pin as analog or digital.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
// MY_PIN       - PORTS_ANALOG_PIN_AN0
// MY_PIN_MODE  - PORTS_PIN_MODE_ANALOG
SYS_PORTS_PinModSYS_PORTS_PinModeSelecteSelect( MY_PORTS_INSTANCE, MY_PIN, MY_PIN_MODE );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
pin	Possible values of PORTS_ANALOG_PIN
mode	Possible values of PORTS_PIN_MODE

Function

void SYS_PORTS_PinModeSelect (PORTS_MODULE_ID index,
PORTS_ANALOG_PIN pin,
PORTS_PIN_MODE mode)

SYS_PORTS_PinOpenDrainDisable Function

Disables the open-drain functionality for the selected pin.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_PinOpenDrainDisable(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);
```

Returns

None.

Description

This function disables the open-drain functionality for the selected pin.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
// MY_PINNUM - PORTS_PIN_10
SYS_PORTS_PinOpenDrainDisable(MY_PORTS_INSTANCE, MY_PINNUM);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the PORT channel: A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS

Function

void SYS_PORTS_PinOpenDrainDisable (PORTS_MODULE_ID index,
PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos)

SYS_PORTS_PinOpenDrainEnable Function

Enables the open-drain functionality for the selected pin.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_PinOpenDrainEnable(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);
```

Returns

None.

Description

This function enables the open-drain functionality for the selected pin.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
```

```
// MY_PINNUM - PORTS_PIN_10
SYS_PORTS_PinOpenDrainEnable( MY_PORTS_INSTANCE, MY_CHANNEL, MY_PINNUM );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the PORT channel: A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS

Function

void SYS_PORTS_PinOpenDrainEnable (PORTS_MODULE_ID index,
PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos)

SYS_PORTS_PinRead Function

Reads the selected digital pin.

Implementation: Dynamic

File

sys_ports.h

C

```
bool SYS_PORTS_PinRead(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);
```

Returns

The status of the port pin.

Description

This function reads the selected digital pin, not the Latch.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
// MY_PINNUM - PORTS_PIN_10
bool bitStatus = SYS_PORTS_PinRead(MY_PORTS_INSTANCE, MY_CHANNEL, MY_PINNUM);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the PORT channel: A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS

Function

bool SYS_PORTS_PinRead (PORTS_MODULE_ID index,
PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos)

SYS_PORTS_PinSet Function

Sets the selected digital pin/latch.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_PinSet(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);
```

Returns

None.

Description

This function sets the selected digital pin/latch.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
// MY_PINNUM - PORTS_PIN_10
SYS_PORTS_PinSet(MY_PORTS_INSTANCE, MY_CHANNEL, MY_PINNUM);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the PORT channel: A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS

Function

void SYS_PORTS_PinSet(PORTS_MODULE_ID index,
PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos)

SYS_PORTS_PinToggle Function

Toggles the selected digital pin.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_PinToggle(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);
```

Returns

None.

Description

This function toggles the selected digital pin.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
```

```
// MY_PINNUM - PORTS_PIN_10
SYS_PORTS_PinToggle( MY_PORTS_INSTANCE, MY_CHANNEL, MY_PINNUM );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the PORT channel: A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS

Function

void SYS_PORTS_PinToggle (PORTS_MODULE_ID index,
PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos)

SYS_PORTS_PinWrite Function

Writes the selected digital pin.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_PinWrite(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos, bool value);
```

Returns

None.

Description

This function writes the selected digital pin.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
// MY_PINNUM - PORTS_PIN_10
SYS_PORTS_PinWrite(MY_PORTS_INSTANCE, MY_CHANNEL, MY_PINNUM, value);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the PORT channel: A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS
value	Value to be written to the specific pin/latch: • true - Sets the bit • false - Clears the bit

Function

void SYS_PORTS_PinWrite (PORTS_MODULE_ID index,
PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos
bool value)

SYS_PORTS_PinClear Function

Clears the selected digital pin.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_PinClear(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);
```

Returns

None.

Description

This function clears the selected digital pin.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
// MY_PINNUM - PORTS_IO_PIN_10
SYS_PORTS_PinClear( MY_PORTS_INSTANCE, MY_CHANNEL, MY_PINNUM );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the PORT channel: A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS

Function

void SYS_PORTS_PinClear (PORTS_MODULE_ID index,
PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos)

SYS_PORTS_PinDirectionSelect Function

Enables the direction for the selected pin.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_PinDirectionSelect(PORTS_MODULE_ID index, SYS_PORTS_PIN_DIRECTION pinDir, PORTS_CHANNEL
channel, PORTS_BIT_POS bitPos);
```

Returns

None.

Description

This function enables the direction for the selected pin.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
// MY_PINNUM - PORTS_PIN_10
SYS_PORTS_PIN_DIRECTION pinDir;
pinDir = SYS_PORTS_DIRECTION_INPUT;
SYS_PORTS_PinDirectionSelect(MY_PORTS_INSTANCE, pinDir, MY_CHANNEL, MY_PINNUM);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
pinDir	Pin direction
channel	Identifier for the PORT channel: A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS

Function

void SYS_PORTS_PinDirectionSelect (PORTS_MODULE_ID index,
SYS_PORTS_PIN_DIRECTION pinDir,
PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos)

b) Ports Control Functions

SYS_PORTS_Clear Function

Clears the selected digital port.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_Clear(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_MASK clearMask);
```

Returns

None.

Description

This function clears the selected digital port.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
PORTS_DATA_MASK clearMask = (PORTS_DATA_MASK)0x00FF;
SYS_PORTS_Clear( MY_PORTS_INSTANCE, MY_CHANNEL, clearMask );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the PORT channel: A, B, C, etc.

clearMask	Identifies the bits to be cleared

Function

void SYS_PORTS_Clear (PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_MASK clearMask)

SYS_PORTS_DirectionGet Function

Reads the direction for the selected port.

Implementation: Dynamic

File

sys_ports.h

C

```
PORTS_DATA_MASK SYS_PORTS_DirectionGet(PORTS_MODULE_ID index, PORTS_CHANNEL channel);
```

Returns

Direction of the port.

Description

This function reads the direction for the selected port.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
PORTS_DATA_MASK value;
value = SYS_PORTS_DirectionGet( MY_PORTS_INSTANCE, MY_CHANNEL );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the PORT channel: A, B, C, etc.

Function

PORTS_DATA_MASK SYS_PORTS_DirectionGet(PORTS_MODULE_ID index, PORTS_CHANNEL channel)

SYS_PORTS_DirectionSelect Function

Enables the direction for the selected port.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_DirectionSelect(PORTS_MODULE_ID index, SYS_PORTS_PIN_DIRECTION pinDir, PORTS_CHANNEL
channel, PORTS_DATA_MASK mask);
```

Returns

None

Description

This function enables the direction for the selected port.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
SYS_PORTS_PIN_DIRECTION pinDir;
pinDir = SYS_PORTS_DIRECTION_INPUT;
PORTS_DATA_MASK myMask = (PORTS_DATA_MASK)0x00FF;
SYS_PORTS_DirectionSelect(MY_PORTS_INSTANCE, pinDir, MY_CHANNEL, myMask );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
pinDir	Pin direction
channel	Identifier for the PORT channel: A, B, C, etc.
mask	Mask for the direction of width PORTS_DATA_MASK

Function

void SYS_PORTS_DirectionSelect(PORTS_MODULE_ID index,
SYS_PORTS_PIN_DIRECTION pinDir,
PORTS_CHANNEL channel,
PORTS_DATA_MASK mask)

SYS_PORTS_OpenDrainDisable Function

Disables the open-drain functionality for the selected port.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_OpenDrainDisable(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_MASK mask);
```

Returns

None.

Description

This function disables the open-drain functionality for the selected port.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
SYS_PORTS_PeripheralOpenDrainDisable( MY_PORTS_INSTANCE, MY_CHANNEL, (PORTS_DATA_MASK)0x00FF );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the PORT channel: A, B, C, etc.
mask	Mask of type PORTS_DATA_MASK

Function

void SYS_PORTS_OpenDrainDisable(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_MASK mask)

SYS_PORTS_OpenDrainEnable Function

Enables the open-drain functionality for the selected port.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_OpenDrainEnable(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_MASK mask);
```

Returns

None.

Description

This function enables the open-drain functionality for the selected port.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
SYS_PORTS_OpenDrainEnable( MY_PORTS_INSTANCE, MY_CHANNEL, (PORTS_DATA_MASK)0x00FF );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the PORT channel: A, B, C, etc.
mask	Mask of type PORTS_DATA_MASK

Function

void SYS_PORTS_OpenDrainEnable(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_MASK mask)

SYS_PORTS_Read Function

Reads the data from the I/O port.

Implementation: Dynamic

File

sys_ports.h

C

```
PORTS_DATA_TYPE SYS_PORTS_Read(PORTS_MODULE_ID index, PORTS_CHANNEL channel);
```

Returns

Returns the data read from the port.

Description

This function reads the data from the I/O port.

Remarks

None.

Preconditions

The direction of the port to be set as input.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
PORTS_DATA_TYPE readData;
readData = SYS_PORTS_Read( MY_PORTS_INSTANCE, MY_CHANNEL );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the PORT channel: A, B, C, etc.

Function

PORTS_DATA_TYPE SYS_PORTS_Read(PORTS_MODULE_ID index, PORTS_CHANNEL channel)

SYS_PORTS_Set Function

Sets the selected digital port/latch based on the mask.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_Set(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_TYPE value, PORTS_DATA_MASK
mask);
```

Returns

None.

Description

This function Sets the selected digital port/latch relative to the mask.

This function "AND" value and mask parameters and then set the bits in the port channel that were set in the result of the ANDing operation.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
// MY_VALUE - 0x1234
PORTS_DATA_MASK myMask = (PORTS_DATA_MASK)0x00FF;

// Set the MY_CHANNEL bit positions 2,4 and 5 (0x0034 = b0000 0000 0011 0100)
SYS_PORTS_Set(MY_PORTS_INSTANCE, MY_CHANNEL, MY_VALUE, myMask);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the PORT channel: A, B, C, etc.
value	Consists of information about which port bit has to be set
mask	Identifies the bits which could be intended for setting

Function

void SYS_PORTS_Set(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_TYPE value,
PORTS_DATA_MASK mask)

SYS_PORTS_Toggle Function

Toggles the selected digital port pins.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_Toggle(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_MASK toggleMask);
```

Returns

None.

Description

This function toggles the selected digital port pins.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
PORTS_DATA_MASK toggleMask = (PORTS_DATA_MASK)0x00FF;
SYS_PORTS_Toggle( MY_PORTS_INSTANCE, MY_CHANNEL, toggleMask );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the PORT channel: A, B, C, etc.
toggleMask	Identifies the bits to be toggled

Function

void SYS_PORTS_Toggle(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_MASK toggleMask)

SYS_PORTS_Write Function

Writes the data to the I/O port.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_Write(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_TYPE value);
```

Returns

None.

Description

This function writes the data to the I/O port.

Remarks

None.

Preconditions

The direction of the port to be set as output.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
PORTS_DATA_TYPE writeData;
SYS_PORTS_Write( MY_PORTS_INSTANCE, MY_CHANNEL, MY_VALUE );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the PORT channel: A, B, C, etc.
value	Value to be written into a port of width PORTS_DATA_TYPE

Function

void SYS_PORTS_Write(PORTS_MODULE_ID index,
PORTS_CHANNEL channel,
PORTS_DATA_TYPE value)

SYS_PORTS_Initialize Function

Initializes PORT Pins/Channels.

Implementation: Static/Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_Initialize();
```

Returns

None.

Description

This function initializes different port pins/channels to the desired state. It also remaps the pins to the desired specific function.

Remarks

This API must be be called at the time of system initialization to initialize the ports pins.

Preconditions

None.

Example

```
SYS_PORTS_Initialize();
```

Function

void SYS_PORTS_Initialize()

c) Change Notification Functions

SYS_PORTS_ChangeNotificationDisable Function

Disables the change notification for the selected port.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_ChangeNotificationDisable(PORTS_MODULE_ID index, PORTS_CHANGE_NOTICE_PIN pinNum);
```

Returns

None.

Description

This function disables the change notification for the selected port.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
PORTS_CHANGE_NOTICE_PIN pinNum;
SYS_PORTS_ChangeNotificationDisable( index, pinNum );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
pinNum	Possible values of PORTS_CHANGE_NOTICE_PIN

Function

void SYS_PORTS_ChangeNotificationDisable(PORTS_MODULE_ID index,
PORTS_CHANGE_NOTICE_PIN pinNum)

SYS_PORTS_ChangeNotificationEnable Function

Enables the change notification for the selected port.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_ChangeNotificationEnable(PORTS_MODULE_ID index, PORTS_CHANGE_NOTICE_PIN pinNum,
SYS_PORTS_PULLUP_PULLDOWN_STATUS value);
```

Returns

None.

Description

This function enables the change notification for the selected port.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
SYS_PORTS_PULLUP_PULLDOWN_STATUS value;
```

```
PORTS_CHANGE_NOTICE_PIN pinNum;
SYS_PORTS_ChangeNotificationEnable( index, pinNum, value );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
value	Pull-up enable or disable value
pinNum	Possible values of PORTS_CHANGE_NOTICE_PIN

Function

void SYS_PORTS_ChangeNotificationEnable(PORTS_MODULE_ID index,
PORTS_CHANGE_NOTICE_PIN pinNum,
SYS_PORTS_PULLUP_PULLDOWN_STATUS value)

SYS_PORTS_ChangeNotificationGlobalDisable Function

Globally disables the change notification for the selected port.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_ChangeNotificationGlobalDisable(PORTS_MODULE_ID index);
```

Returns

None.

Description

This function globally disables the change notification for the selected port.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
SYS_PORTS_ChangeNotificationGlobalDisable( MY_PORTS_INSTANCE);
```

Function

void SYS_PORTS_ChangeNotificationGlobalDisable(PORTS_MODULE_ID index);

SYS_PORTS_ChangeNotificationGlobalEnable Function

Globally enables the change notification for the selected port.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_ChangeNotificationGlobalEnable(PORTS_MODULE_ID index);
```

Returns

None.

Description

This function globally enables the change notification for the selected port.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
SYS_PORTS_ChangeNotificationGlobalEnable( MY_PORTS_INSTANCE );
```

Function

void SYS_PORTS_ChangeNotificationGlobalEnable(PORTS_MODULE_ID index)

SYS_PORTS_ChangeNotificationInIdleModeDisable Function

Disables the change notification for the selected port in Sleep or Idle mode.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_ChangeNotificationInIdleModeDisable(PORTS_MODULE_ID index);
```

Returns

None.

Description

This function disables the change notification for the selected port in Sleep or Idle mode.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
SYS_PORTS_ChangeNotificationInIdleModeDisable( MY_PORTS_INSTANCE );
```

Function

void SYS_PORTS_ChangeNotificationInIdleModeDisable(PORTS_MODULE_ID index);

SYS_PORTS_ChangeNotificationInIdleModeEnable Function

Enables the change notification for the selected port in Sleep or Idle mode.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_ChangeNotificationInIdleModeEnable(PORTS_MODULE_ID index);
```

Returns

None.

Description

This function enables the change notification for the selected port in Sleep or Idle mode.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
SYS_PORTS_ChangeNotificationInIdleModeEnable( MY_PORTS_INSTANCE );
```

Function

void SYS_PORTS_ChangeNotificationInIdleModeEnable(PORTS_MODULE_ID index);

SYS_PORTS_ChangeNotificationPullUpDisable Function

Disables a weak pull-up on the change notification pin.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_ChangeNotificationPullUpDisable(PORTS_MODULE_ID index, PORTS_CHANGE_NOTICE_PIN pinNum);
```

Returns

None.

Description

This function Disables a weak pull-up on the change notification pin.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
// MY_PINNUM - PORTS_CHANGE_NOTICE_PIN_10
SYS_PORTS_ChangeNotificationPullUpDisable( MY_PORTS_INSTANCE, MY_PINNUM );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
pinNum	Possible values of PORTS_CHANGE_NOTICE_PIN

Function

void SYS_PORTS_ChangeNotificationPullUpDisable (PORTS_MODULE_ID index,
PORTS_CHANGE_NOTICE_PIN pinNum)

SYS_PORTS_ChangeNotificationPullUpEnable Function

Enables a weak pull-up on the change notification pin.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_ChangeNotificationPullUpEnable(PORTS_MODULE_ID index, PORTS_CHANGE_NOTICE_PIN pinNum);
```

Returns

None.

Description

This function enables a weak pull-up on the change notification pin.

Remarks

Not all features are available on all devices. Refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
// MY_PINNUM - PORTS_CHANGE_NOTICE_PIN_10
SYS_PORTS_ChangeNotificationPullUpEnable( MY_PORTS_INSTANCE, MY_PINNUM );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
pinNum	Possible values of PORTS_CHANGE_NOTICE_PIN

Function

void SYS_PORTS_ChangeNotificationPullUpEnable (PORTS_MODULE_ID index,
PORTS_CHANGE_NOTICE_PIN pinNum)

d) Peripheral Pin Select Functions

SYS_PORTS_RemapInput Function

Input/Output (I/O) function remapping.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_RemapInput(PORTS_MODULE_ID index, PORTS_REMAP_INPUT_FUNCTION function, PORTS_REMAP_INPUT_PIN
remapPin);
```

Returns

None.

Description

This function controls the I/O function remapping.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use SYS_PORTS_ExistsRemapInputOutput in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
```

```
// Remapping input function 'Input Capture 1' to the Remappable pin 'RPD2'
SYS_PORTS_RemapInput(MY_PORTS_INSTANCE, INPUT_FUNC_IC1, INPUT_PIN_RPD2 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void SYS_PORTS_RemapInput(PORTS_MODULE_ID index,
PORTS_REMAP_INPUT_FUNCTION function,
PORTS_REMAP_INPUT_PIN remapPin)

One of the possible values of PORTS_REMAP_INPUT_FUNCTION

remapPin - One of the possible values of PORTS_REMAP_INPUT_PIN

SYS_PORTS_RemapOutput Function

Input/Output (I/O) function remapping.

Implementation: Dynamic

File

sys_ports.h

C

```
void SYS_PORTS_RemapOutput(PORTS_MODULE_ID index, PORTS_REMAP_OUTPUT_FUNCTION function,
PORTS_REMAP_OUTPUT_PIN remapPin);
```

Returns

None.

Description

This function controls the I/O function remapping.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use SYS_PORTS_ExistsRemapInputOutput in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_PORTS_INSTANCE, is the ports instance selected for use by the
// application developer.
// Remapping output function 'UART3 Transmit' to the Remappable pin 'RPA14'
SYS_PORTS_RemapInputOutput(MY_PORTS_INSTANCE, OUTPUT_FUNC_U3TX, OUTPUT_PIN_RPA14);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void SYS_PORTS_RemapOutput(PORTS_MODULE_ID index,
PORTS_REMAP_OUTPUT_FUNCTION function,
PORTS_REMAP_OUTPUT_PIN remapPin)

One of the possible values of PORTS_REMAP_OUTPUT_FUNCTION

remapPin - One of the possible values of PORTS_REMAP_OUTPUT_PIN

e) Data Types and Constants

SYS_PORTS_PIN_DIRECTION Enumeration

Defines the direction of the port pins.

File

sys_ports.h

C

```
typedef enum {
  SYS_PORTS_DIRECTION_OUTPUT,
  SYS_PORTS_DIRECTION_INPUT
} SYS_PORTS_PIN_DIRECTION;
```

Members

Members	Description
SYS_PORTS_DIRECTION_OUTPUT	Direction as output
SYS_PORTS_DIRECTION_INPUT	Direction as input

Description

SYS PORTS PIN DIRECTION

These constants provide the port pin direction definitions.

Remarks

None.

SYS_PORTS_PULLUP_PULLDOWN_STATUS Enumeration

Provides the pull-up and pull-down status.

File

sys_ports.h

C

```
typedef enum {
  SYS_PORTS_PULLUP_DISABLE,
  SYS_PORTS_PULLUP_ENABLE
} SYS_PORTS_PULLUP_PULLDOWN_STATUS;
```

Members

Members	Description
SYS_PORTS_PULLUP_DISABLE	PULLUP Disable
SYS_PORTS_PULLUP_ENABLE	PULLUP Enable

Description

SYS PORTS PULLUP status

These constants provide the pull-up or pull-down status definitions.

Remarks

None.

Ports System Service interface definitions

Enumerations

	Name	Description
	SYS_PORTS_PIN_DIRECTION	Defines the direction of the port pins.
	SYS_PORTS_PULLUP_PULLDOWN_STATUS	Provides the pull-up and pull-down status.

Functions

	Name	Description
	SYS_PORTS_ChangeNotificationDisable	Disables the change notification for the selected port. **Implementation:** Dynamic
	SYS_PORTS_ChangeNotificationEnable	Enables the change notification for the selected port. **Implementation:** Dynamic
	SYS_PORTS_ChangeNotificationGlobalDisable	Globally disables the change notification for the selected port. **Implementation:** Dynamic
	SYS_PORTS_ChangeNotificationGlobalEnable	Globally enables the change notification for the selected port. **Implementation:** Dynamic
	SYS_PORTS_ChangeNotificationInIdleModeDisable	Disables the change notification for the selected port in Sleep or Idle mode. **Implementation:** Dynamic
	SYS_PORTS_ChangeNotificationInIdleModeEnable	Enables the change notification for the selected port in Sleep or Idle mode. **Implementation:** Dynamic
	SYS_PORTS_ChangeNotificationPullUpDisable	Disables a weak pull-up on the change notification pin. **Implementation:** Dynamic
	SYS_PORTS_ChangeNotificationPullUpEnable	Enables a weak pull-up on the change notification pin. **Implementation:** Dynamic
	SYS_PORTS_Clear	Clears the selected digital port. **Implementation:** Dynamic
	SYS_PORTS_DirectionGet	Reads the direction for the selected port. **Implementation:** Dynamic
	SYS_PORTS_DirectionSelect	Enables the direction for the selected port. **Implementation:** Dynamic
	SYS_PORTS_Initialize	Initializes PORT Pins/Channels. **Implementation:** Static/Dynamic
	SYS_PORTS_OpenDrainDisable	Disables the open-drain functionality for the selected port. **Implementation:** Dynamic
	SYS_PORTS_OpenDrainEnable	Enables the open-drain functionality for the selected port. **Implementation:** Dynamic
	SYS_PORTS_PinClear	Clears the selected digital pin. **Implementation:** Dynamic
	SYS_PORTS_PinDirectionSelect	Enables the direction for the selected pin. **Implementation:** Dynamic
	SYS_PORTS_PinModeSelect	Enables the selected pin as analog or digital. **Implementation:** Dynamic
	SYS_PORTS_PinOpenDrainDisable	Disables the open-drain functionality for the selected pin. **Implementation:** Dynamic
	SYS_PORTS_PinOpenDrainEnable	Enables the open-drain functionality for the selected pin. **Implementation:** Dynamic
	SYS_PORTS_PinRead	Reads the selected digital pin. **Implementation:** Dynamic
	SYS_PORTS_PinSet	Sets the selected digital pin/latch. **Implementation:** Dynamic
	SYS_PORTS_PinToggle	Toggles the selected digital pin. **Implementation:** Dynamic
	SYS_PORTS_PinWrite	Writes the selected digital pin. **Implementation:** Dynamic

	SYS_PORTS_Read	Reads the data from the I/O port. **Implementation:** Dynamic
	SYS_PORTS_RemapInput	Input/Output (I/O) function remapping. **Implementation:** Dynamic
	SYS_PORTS_RemapOutput	Input/Output (I/O) function remapping. **Implementation:** Dynamic
	SYS_PORTS_Set	Sets the selected digital port/latch based on the mask. **Implementation:** Dynamic
	SYS_PORTS_Toggle	Toggles the selected digital port pins. **Implementation:** Dynamic
	SYS_PORTS_Write	Writes the data to the I/O port. **Implementation:** Dynamic

Description

Ports System Service Interface Definition

This file contains the interface definition for the Ports system service. It provides a way to interact with the Ports subsystem to manage the timing requests supported by the system

Microchip Technology Inc.

Random Number Generator (RNG) System Service Library

This section describes the Random Number Generator (RNG) System Service Library.

Introduction

This library provides a Random Number Generator (RNG) service with a convenient C language interface.

Description

The Random Number Generator (RNG) System Service provides a simple C-language interface for generating random numbers at both pseudo-random and cryptographic strengths.

Using the Library

This topic describes the basic architecture of the RNG System Service Library and provides information and examples on its use.

Description

Interface Header File: `sys_random.h`

The interface to the RNG System Service library is defined in the `sys_random.h` header file.

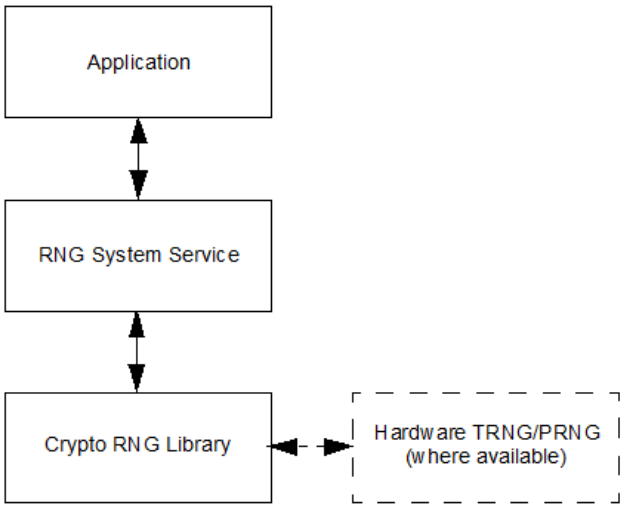
Please refer to the What is MPLAB Harmony? section for how the RNG System Service interacts with the framework.

Abstraction Model

This topic provides a description of the software abstraction for the RNG System Service.

Description

This model explains how the system interfaces with the RNG System Service and the application, as illustrated in the following diagram.



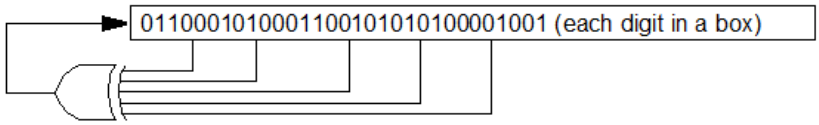
Random Numbers

Random numbers are often desired in systems in order to provide a change in the system that cannot necessarily be predicted. For example, a game might use random numbers for a dice roll or a playing card shuffle. Another example is when a collision occurs in an Ethernet network. A delay is inserted in the next attempt to communicate on the network, and the length of the delay is determined by a random number.

Pseudo Random Numbers (PRN)

Due to the deterministic nature of computer systems, it is actually very difficult to produce true randomness in number generation. For many systems, a pseudo-random number is sufficient. Typically, the pseudo-random number is generated via a Linear Feedback Shift Register (LFSR). The LFSR takes a seed value, and generates a new number typically by having taps on the LFSR in different places and XORing the bits together. This new bit is appended to the beginning of the number after the original number has been shifted one bit to the right.

And example of a LFSR is shown in the following figure.



Cryptographically-secure Pseudo Random Numbers (CSPRN)

Because pseudo-random numbers can be predicted if an attacker knows the setup of the LFSR, it is desired in certain applications to have a way of minimizing the predictability of the random numbers. To accomplish this, a sub-set of PRNGs are run through statistical tests to determine their security in cryptographic applications. A Cryptographically-secure Pseudo Random Number generator is one that has passed all such statistical tests.

True Random Number Generator (TRNG)

To provide seed values for the PRNG, and in applications that require true randomness, there are hardware options for a true random number generator (TRNG). These generators use ring oscillators and the inherent thermal noise within silicon to create the individual bits of a number. Because of the nature of these oscillators, it is not possible to predict the generated numbers.

Library Overview

Please refer to the System Service Introduction for a detailed description of MPLAB Harmony system services.

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Random Number Generator module.

Library Interface Section	Description
Random Number Generator Functions	Provides system module APIs. Device initialization, deinitialization, reinitialization and status functions.
Data Types and Constants	Device-specific enumerations, structures, and constants.

How the Library Works

Describes how the RNG Library works.

Description

Service Initialization

To begin using the Random Number System Service, it is necessary to initialize the service using the SYS_RANDOM_Initialize function.

Example:

```
// Initialization data for the RNG
SYS_RANDOM_INIT rngInit = { 0x12345678, NULL, 32 };
// Initialize the System Random Service
SYS_RANDOM_Initialize( 0, rngInit );
```

Pseudo-Random Numbers

The Pseudo-Random Number functions use the C-language functions seed() and rand() to provide the pseudo-random numbers.

Example:

```
// Seed the PRNG
SYS_RANDOM_PseudoSeedSet(0x876543210);
// Get a Pseudo-random Number
uint32_t myRandomNum = SYS_RANDOM_PseudoGet();
```

Cryptographic Pseudo-Random Numbers

The Cryptographic Random Number functions use the Crypto RNG library functions to seed and generate numbers. On PIC32 devices with a PRNG/TRNG module, it will use the hardware to generate the numbers.

Example:

```
// Get a 32-bit Crypto Random Number
uint32_t myRandomNum = SYS_RANDOM_CryptoGet();
// Fill an array of random numbers
uint32_t myRandomNumArray[10];
SYS_RANDOM_CryptoBlockGet(myRandomNumArray, 10);
// Get a 1-byte Random Number
uint8_t myRandomByte = SYS_RANDOM_CryptoByteGet();
```

Configuring the Library

Macros

	Name	Description
	SYS_RANDOM_CRYPTO_SEED_SIZE	

Description

The configuration of the RNG System Service is based on the file `system_config.h`.

This header file contains the configuration selection for the Random Number Generator System Service. Based on the selections made, the Random Number Generator System Service may support the selected features. These configuration settings will apply to all instances of the Random Number Generator System Service.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

SYS_RANDOM_CRYPTO_SEED_SIZE Macro

File

sys_random_config_template.h

C

```
#define SYS_RANDOM_CRYPTO_SEED_SIZE (256/8)
```

Description

Cryptographic Quality Seed Value

Building the Library

This section lists the files that are available in the Random Number Generator System Service Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/system/random`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`sys_random.h`	Random Number Generator System Service Library API header file.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/sys_random.c`	Random Number Generator System Service Library implementation.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this system service.

Module Dependencies

The Random Number Generator System Service is dependent upon the following modules:

- Cryptographic (Crypto) Library

Library Interface

a) Random Number Generator Functions

	Name	Description
	SYS_RANDOM_CryptoBlockGet	Generates a sequence of random bytes using the cryptographic quality Random Number Generator.
	SYS_RANDOM_CryptoByteGet	Returns a random byte from the cryptographic quality Random Number Generator.
	SYS_RANDOM_CryptoEntropyAdd	Adds randomness to the cryptographic quality Random Number Generator.
	SYS_RANDOM_CryptoGet	Returns a random 32 bit value from the cryptographic quality Random Number Generator.
	SYS_RANDOM_CryptoSeedSet	Reseeds the cryptographic quality Random Number Generator.
	SYS_RANDOM_CryptoSeedSizeGet	Reseeds the cryptographic quality Random Number Generator.
	SYS_RANDOM_Deinitialize	Deinitializes the Random Number Generator system service.
	SYS_RANDOM_Initialize	Initializes the Random Number Generator system service.
	SYS_RANDOM_PseudoGet	Returns a random value from the Pseudo-random Number Generator.
	SYS_RANDOM_PseudoSeedSet	Reseeds the Pseudo-random Number Generator.

b) Data Types and Constants

	Name	Description
	SYS_RANDOM_INIT	Random Number Generator Service Initialization Data

Description

This section describes the APIs of the RNG System Service Library.

Refer to each section for a detailed description.

a) Random Number Generator Functions

SYS_RANDOM_CryptoBlockGet Function

Generates a sequence of random bytes using the cryptographic quality Random Number Generator.

File

sys_random.h

C

```
void SYS_RANDOM_CryptoBlockGet(void * buffer, size_t size);
```

Returns

None.

Description

This function uses the Cryptographic-quality Random Number Generator to fill a block of data with random numbers.

Remarks

When run, it will fill the memory starting at buffer with size bytes of random numbers.

Preconditions

System service must be initialized by calling SYS_RANDOM_Initialize before this function is called.

Example

```
#define RNG_DATA_SIZE   32

uint8_t randomData[RNG_DATA_SIZE];
SYS_MODULE_OBJ rngObject;

rngObject = SYS_RANDOM_Initialize();
...
SYS_RANDOM_CryptoBlockGet((void *)randomData, RNG_DATA_SIZE);
```

Parameters

Parameters	Description
buffer	Pointer to the memory location to fill with random data.
size	The amount of random data, in bytes, to put in memory.

Function

void SYS_RANDOM_CryptoBlockGet(uint8_t buffer, size_t bufferSize);

SYS_RANDOM_CryptoByteGet Function

Returns a random byte from the cryptographic quality Random Number Generator.

File

sys_random.h

C

```
uint8_t SYS_RANDOM_CryptoByteGet();
```

Returns

Returns one byte of cryptographic-quality random data.

Description

This function returns a single byte from the Cryptographic-quality Random Number Generator.

Remarks

None.

Preconditions

System service must be initialized by calling SYS_RANDOM_Initialize before this function is called.

Example

```
uint8_t randomData;
SYS_MODULE_OBJ rngObject;

rngObject = SYS_RANDOM_Initialize();
randomData = SYS_RANDOM_CryptoByteGet();
```

Function

uint8_t SYS_RANDOM_CryptoByteGet(void);

SYS_RANDOM_CryptoEntropyAdd Function

Adds randomness to the cryptographic quality Random Number Generator.

File

sys_random.h

C

```
void SYS_RANDOM_CryptoEntropyAdd(uint8_t data);
```

Returns

None.

Description

This function adds entropy to the Cryptographic-quality Random Number Generator in order to adjust the randomness of the generated numbers.

Remarks

This function currently does not function.

Preconditions

None.

Example

```
SYS_MODULE_OBJ rngObject;

rngObject = SYS_RANDOM_Initialize();
SYS_RANDOM_CryptoEntropyAdd(23);
```

Parameters

Parameters	Description
data	8-bit value to add to the entropy calculation.

Function

void SYS_RANDOM_CryptoEntropyAdd(uint8_t data);

SYS_RANDOM_CryptoGet Function

Returns a random 32 bit value from the cryptographic quality Random Number Generator.

File

sys_random.h

C

```
uint32_t SYS_RANDOM_CryptoGet();
```

Returns

32-bit random number.

Description

This function returns a 32-bit random number from the Cryptographic- quality Random Number Generator.

Remarks

On PIC32MZ devices with a hardware Random Number Generator, this function returns a value from that generator. Other devices will use a software library to generate the random number.

Preconditions

System service must be initialized by calling SYS_RANDOM_Initialize before this function is called.

Example

```
SYS_MODULE_OBJ rngObject;
uint32_t rngData;

rngObject = SYS_RANDOM_Initialize();
...
rngData = SYS_RANDOM_CryptoGet();
```

Function

uint32_t SYS_RANDOM_CryptoGet(void);

SYS_RANDOM_CryptoSeedSet Function

Reseeds the cryptographic quality Random Number Generator.

File

sys_random.h

C

```
void SYS_RANDOM_CryptoSeedSet(void * seed, size_t size);
```

Returns

None.

Description

This function inserts a seed value into the Cryptographic-quality Random Number Generator. The value will be used to generate the next random number.

Remarks

None.

Preconditions

System service must be initialized by calling SYS_RANDOM_Initialize before this function is called.

Example

```
SYS_MODULE_OBJ rngObject;
uint8_t rngSeed[SYS_RANDOM_CRYPTO_SEED_SIZE];

rngObject = SYS_RANDOM_Initialize();
// Fill the rngSeed
SYS_RANDOM_CryptoSeedSet(rngSeed, sizeof(rngSeed));
```

Parameters

Parameters	Description
seed	Pointer to the memory location containing the new seed.
size	Must be less or equal to SYS_RANDOM_CRYPTO_SEED_SIZE

Function

void SYS_RANDOM_CryptoSeedSet(void *seed, size_t size);

SYS_RANDOM_CryptoSeedSizeGet Function

Reseeds the cryptographic quality Random Number Generator.

File

sys_random.h

C

```
size_t SYS_RANDOM_CryptoSeedSizeGet();
```

Returns

Returns the size (in bytes) of the most recently set seed value for the cryptographic strength random number generator.

Description

This function returns the current size of the seed used in the Cryptographic- quality Random Number Generator.

Remarks

None.

Preconditions

System service must be initialized by calling SYS_RANDOM_Initialize before this function is called.

Example

```
SYS_MODULE_OBJ rngObject;
size_t seedSize;

rngObject = SYS_RANDOM_Initialize();
...
seedSize = SYS_RANDOM_CryptoSeedSizeGet();
```

Function

size_t SYS_RANDOM_CryptoSeedSizeGet(void);

SYS_RANDOM_Deinitialize Function

Deinitializes the Random Number Generator system service.

File

sys_random.h

C

```
void SYS_RANDOM_Deinitialize(SYS_MODULE_OBJ object);
```

Returns

None.

Description

This function deinitializes the Random Number Generator system service.

Remarks

None.

Preconditions

System service must be initialized by calling SYS_RANDOM_Initialize before this function is called.

Example

```
SYS_MODULE_OBJ rngObject;

rngObject = SYS_RANDOM_Initialize();
```

Parameters

Parameters	Description
object	SYS RANDOM object handle, returned from SYS_RANDOM_Initialize

Function

void SYS_RANDOM_Deinitialize(SYS_MODULE_OBJ object);

SYS_RANDOM_Initialize Function

Initializes the Random Number Generator system service.

File

sys_random.h

C

```
SYS_MODULE_OBJ SYS_RANDOM_Initialize(const SYS_MODULE_INDEX index, const SYS_MODULE_INIT * const init);
```

Returns

If successful, returns a valid handle to an object. Otherwise, it returns SYS_MODULE_OBJ_INVALID.

Description

This function initializes the Random Number System service, including seeding the Pseudo Random Number Generator, the Crypto RNG library, and setting the seed size.

Remarks

None.

Preconditions

None.

Example

```
SYS_MODULE_OBJ rngObject;

rngObject = SYS_RANDOM_Initialize();
SYS_RANDOM_Deinitialize(rngObject);
```

Parameters

Parameters	Description
index	Module instance index.
init	initialization data for the random system service (cast of a pointer to a SYS_RANDOM_INIT structure to a SYS_MODULE_INDEX structure pointer).

Function

SYS_MODULE_OBJ SYS_RANDOM_Initialize(const SYS_RANDOM_INIT* const randomInit);

SYS_RANDOM_PseudoGet Function

Returns a random value from the Pseudo-random Number Generator.

File

sys_random.h

C

```
uint32_t SYS_RANDOM_PseudoGet();
```

Returns

A 32-bit pseudo-random number.

Description

This function returns one 32-bit Pseudo-random Number.

Remarks

None.

Preconditions

None.

Example

```
uint32_t rngNumber;

rngNumber = SYS_RANDOM_PseudoGet();
```

Function

uint32_t SYS_RANDOM_PseudoGet(void);

SYS_RANDOM_PseudoSeedSet Function

Reseeds the Pseudo-random Number Generator.

File

sys_random.h

C

```
void SYS_RANDOM_PseudoSeedSet(uint32_t seed);
```

Returns

None.

Description

This function inserts a seed value into the Pseudo-Random Number Generator. The value will be used to generate the next random number.

Preconditions

None.

Example

```
uint32_t rngSeed = 0x12345678;

SYS_RANDOM_PseudoSeedSet(rngSeed);
Remarks:   None.
```

Parameters

Parameters	Description
seed	32-bit value to use as the seed for the Pseudo RNG.

Function

void SYS_RANDOM_PseudoSeedSet(uint32_t seed);

b) Data Types and Constants

SYS_RANDOM_INIT Structure

File

sys_random.h

C

```
typedef struct {
  uint32_t seedPseudo;
  void * seedCrypto;
  size_t seedCryptoSize;
} SYS_RANDOM_INIT;
```

Reset System Service Library

This section describes the Reset System Service Library.

Introduction

This library provides an interface to manage the Reset module on the Microchip family of microcontrollers during different modes of operation.

Description

The Reset System Service Library is a MPLAB Harmony system service that can be used to identify the reason for the most recent processor reset, manage the system's reset reason status flags, and even cause a reset under software control if the processor in use supports that functionality.

Using the Library

This topic describes the basic architecture of the Reset System Service and provides information and examples on its use.

Description

Interface Header File: `sys_reset.h`

The interface to the Clock System Service is defined in the `sys_reset.h` header file, which is included by the `sys.h` header file.

Any C language source (`.c`) file that uses the Reset System Service must include `sys.h`.

Abstraction Model

This topic describes the basic abstraction model and functionality of the Reset System Service.

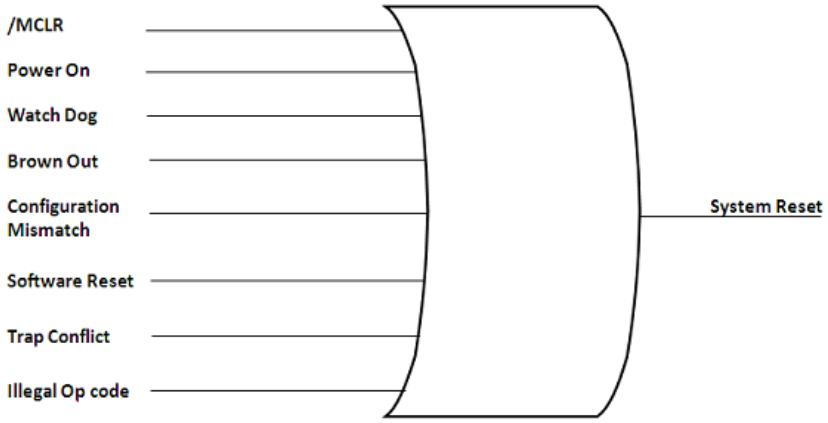
Description

The Reset System Service Library provides the following functionality:

- Microcontroller Reset Reason Management
- Triggering Software Reset

When one of the sources described in the following section asserts a reset request or the software requests a reset using this library, the microcontroller will be immediately reset.

The following figure illustrates the hardware abstraction model for the reset system service,



Reset Sources

- **/MCLR:** Whenever the /MCLR pin is driven low, the device asynchronously asserts reset. The processor continues to use the existing clock source that was in use before the /MCLR Reset occurred.
- **Power On [POR]:** A power-on event generates an internal power-on reset pulse when a VDD rise is detected above POR voltage. In particular, VDD must fall below POR voltage before a new POR is initiated.
- **Watch Dog Timer [WDT]:** Whenever a watchdog timer time-out occurs, the device asynchronously asserts system reset. The clock source

remains unchanged. Note that a WDT time-out during Sleep or Idle mode will wake-up the processor, but will not reset the processor.

- **Brown Out:** If the voltage supplied to the internal regulator is inadequate to maintain a regulated level, the regulator reset circuitry will generate a Brown-Out Reset (BOR). Brown out reset is applicable only when the regulator is enabled.
- **Configuration Mismatch:** To maintain the integrity of the stored configuration values, all device configuration bits are implemented as a complementary set of register bits. For each bit, as the actual value of the register is written as '1', a complementary value, '0', is stored in its corresponding background register and vice versa. The bit pairs are compared every time, including sleep mode. During this comparison, if the configuration bit values are not found opposite to each other, a configuration mismatch event is generated which causes a device reset.
- **Software Reset:** Whenever the reset instruction or a reset sequence is executed, the device asserts system reset. This reset state does not reinitialize the clock. The clock source that is in effect prior to the reset instruction or reset sequence execution remains in effect.
- **Trap Conflict:** A trap conflict reset occurs when a hard and a soft trap occur at the same time.
- **Illegal Opcode:** A device reset is generated if the device attempts to execute an illegal opcode value that was fetched from program memory.

Note: For more information on the electrical specifications, refer to the "**Electrical Characteristics"** chapter of the specific device data sheet.

Library Overview

Please refer to the System Service Introduction for a detailed description of MPLAB Harmony system services.

The library interface routines are divided into the following sub-sections, which address one of the blocks or the overall operation of the Reset System Service Library.

Library Interface Section	Description
Functions	Provides functions to read the reset reason and clear the respective status, to trigger the software reset, and reset the NMI delay count.

How the Library Works

Reset Reason Management

Describes how to use the library to identify and clear the reason a reset occurred.

Description

Reset Reason

Other software modules may identify the reason for the most recent system reset using the SYS_RESET_ReasonGet function. After obtaining the reset reason, its status flag can be cleared using the SYS_RESET_ReasonClear function.

Example: Identifying and Clearing Reset Reason

```
RESET_REASON reasonType;

reasonType = SYS_RESET_ReasonGet();
if( reasonType == RESET_REASON_MCLR )
{
    // Take some reset reason specific action
    // ...

    // Clear the reset reason status flag
    SYS_RESET_ReasonClear( RESET_REASON_MCLR );
}
```

Example: Clearing Multiple Reset Reasons

```
// Clear multiple reason flags
SYS_RESET_ReasonClear( RESET_REASON_MCLR|RESET_REASON_POWERON );

// Clear all current reason flags
SYS_RESET_ReasonClear( RESET_REASON_ALL );
```

Note: Not every reset reason is supported by every device, refer to the device specific information for more information.

Triggering a Software Reset

Describes how to use the Reset System Service Library to cause a system reset.

Description

Software Reset Trigger

Software can trigger the a system reset by using the SYS_RESET_SoftwareReset function.

Example

```
SYS_RESET_SoftwareReset();
```

Note: On devices that support software reset functionality, this routine never returns. Execution continues from the reset vector, following the reset. On devices that do not support software reset, calling this routine will give a build warning and execution will continue immediately following this function.

Configuring the Library

Describes how to configure the system reset library.

Description

The configuration of the Reset System Service is affected by the following:

- Processor Selection
- System Configuration

Processor Selection

Different processors support different reset reasons. Not all reset reasons are defined for all processors. Refer to the specific device data sheet or family reference manual for the processor in use to identify which reset reasons it supports.

System Configuration

Many MPLAB Harmony libraries provide configuration options that can be selected by defining their desired values at build-time using the C-language preprocessor "#define" statement. To obtain these definitions, MPLAB Harmony libraries include a file named "system_config.h" that must be defined as part of the over-all system configuration and placed in the compiler's include file search path.

Refer to the Applications Help section for more details.

System Reset Library Configuration Options

This library does not support any build-time configuration items.

Building the Library

This section lists the files that are available in the Reset System Service Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/system/reset`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
sys_reset.h	Reset System Service Library API header file.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/sys_reset.c	Reset System Service Library implementation.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The Reset System Service Library depends on the following modules:

- Reset Peripheral Library
- Device Control Peripheral Library

Library Interface

a) Functions

	Name	Description
	SYS_RESET_ReasonClear	Clears the status flag for the specified reset reason.
	SYS_RESET_ReasonGet	Returns the reason for the reset.
	SYS_RESET_SoftwareReset	Triggers a software reset.
	SYS_RESET_NMIDelayCountSet	Sets the Delay for WDT/DMT NMI reset events.

Description

This section describes the APIs of the Reset System Service Library.

Refer to each section for a detailed description.

a) Functions

SYS_RESET_ReasonClear Function

Clears the status flag for the specified reset reason.

File

sys_reset.h

C

```
void SYS_RESET_ReasonClear(RESET_REASON reason);
```

Returns

None.

Description

This function clears the specified status flag(s) that were previously set by the processor to identify the reason for the most recent reset.

Remarks

None.

Preconditions

Hardware should have set the reset reason.

Example

```
// To clear a single reset reason,
SYS_RESET_ReasonClear( RESET_REASON_MCLR );

// To clear more than one reason,
SYS_RESET_ReasonClear( RESET_REASON_MCLR|RESET_REASON_POWERON );
```

```
// To clear all the reasons,
SYS_RESET_ReasonClear( RESET_REASON_ALL );
```

Parameters

Parameters	Description
reason	One of the possible values of the enum RESET_REASON

Function

void SYS_RESET_ReasonClear(RESET_REASON reason)

SYS_RESET_ReasonGet Function

Returns the reason for the reset.

File

sys_reset.h

C

```
RESET_REASON SYS_RESET_ReasonGet();
```

Returns

A value identifying the reason for the most recent reset.

Description

This function identifies the reason that the most recent reset occurred.

Remarks

None.

Preconditions

None.

Example

```
RESET_REASON reasonType;
reasonType = SYS_RESET_ReasonGet();
```

Function

RESET_REASON SYS_RESET_ReasonGet(void)

SYS_RESET_SoftwareReset Function

Triggers a software reset.

File

sys_reset.h

C

```
void SYS_RESET_SoftwareReset();
```

Returns

None.

Description

This function triggers a processor.

Remarks

The software reset feature must be supported by the processor in use.

Preconditions

None.

Example

```
SYS_RESET_SoftwareReset();
```

Function

void SYS_RESET_SoftwareReset(void)

SYS_RESET_NMIDelayCountSet Function

Sets the Delay for WDT/DMT NMI reset events.

File

sys_reset.h

C

```
void SYS_RESET_NMIDelayCountSet(RESET_NMI_COUNT_TYPE nmi_count);
```

Returns

None

Description

This function sets the NMI counter value, that is equivalent to the number of SYSCLK cycles needed for the device Reset to occur when a WDT/DMT NMI event is triggered. This NMI reset counter is only applicable to these two specific NMI events only.

Remarks

The NMI feature must be supported by the processor in use.

Preconditions

None.

Example

```
SYS_RESET_NMIDelayCountSet( 0x54 );
```

Parameters

Parameters	Description
nmi_count	NMI counter value.

Function

void SYS_RESET_NMIDelayCountSet(RESET_NMI_COUNT_TYPE nmi_count)

Files

Files

Name	Description
sys_reset.h	Reset System Service interface definition.

Description

sys_reset.h

Reset System Service interface definition.

Functions

	Name	Description
	SYS_RESET_NMIDelayCountSet	Sets the Delay for WDT/DMT NMI reset events.
	SYS_RESET_ReasonClear	Clears the status flag for the specified reset reason.
	SYS_RESET_ReasonGet	Returns the reason for the reset.
	SYS_RESET_SoftwareReset	Triggers a software reset.

Timer System Service Library

This section describes the Timer System Service Library.

Introduction

This library provides interfaces to manage alarms and/or delays.

Description

The Timer System Service Library is capable of providing periodic or one-shot alarm delays to the user. It works as a client for the Timer driver and opens one of the instances of the driver to perform the activities. The periodicity or the delay is an integer multiple of the Timer driver alarm period.

Using the Library

This topic describes the basic architecture of the Timer System Service Library and provides information and examples on its use.

Description

Interface Header File: `sys_tmr.h`

The interface to the Timer System Service library is defined in the `sys_tmr.h` header file, which is included by the `sys.h` system service header file. Any C language source (`.c`) file that uses the Timer System Service library should include `sys.h`.

Please refer to the What is MPLAB Harmony? section for how the System Service interacts with the framework.

Abstraction Model

The Timer System Service module uses the Timer driver abstraction layer to provide the following functionalities,

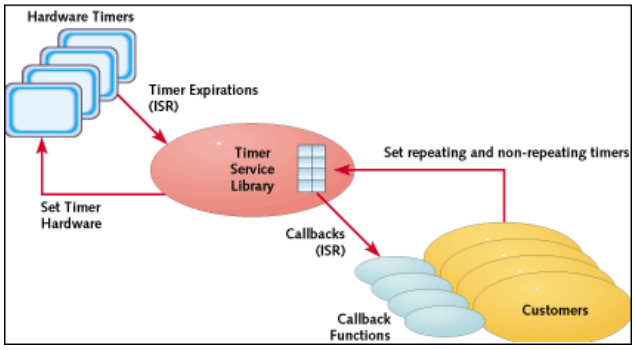
- Periodic Callback
- One Shot/Single Callback
- Delays

Note: The Timer System Service will work in both the polling and interrupt driven environments; however, Interrupt mode is recommended.

Description

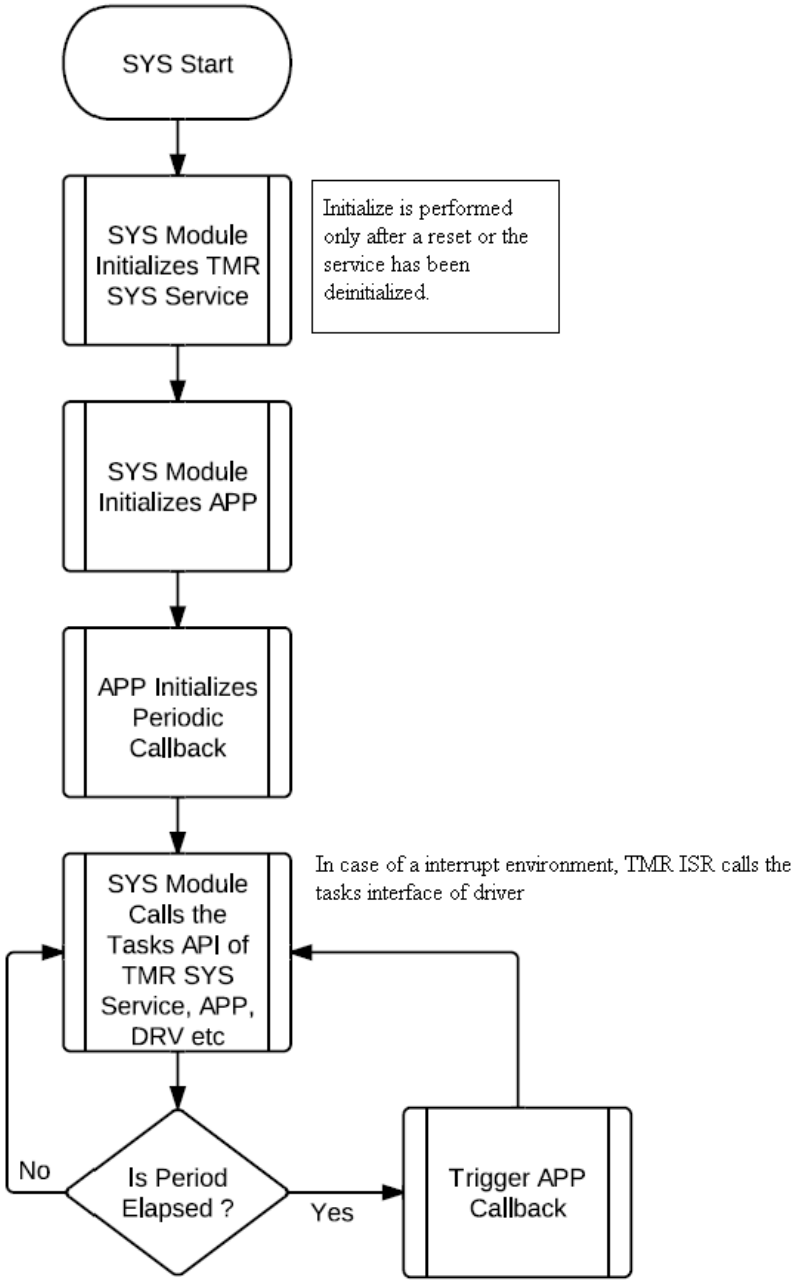
Abstraction Model

The following diagram depicts the Timer System Service abstraction model.



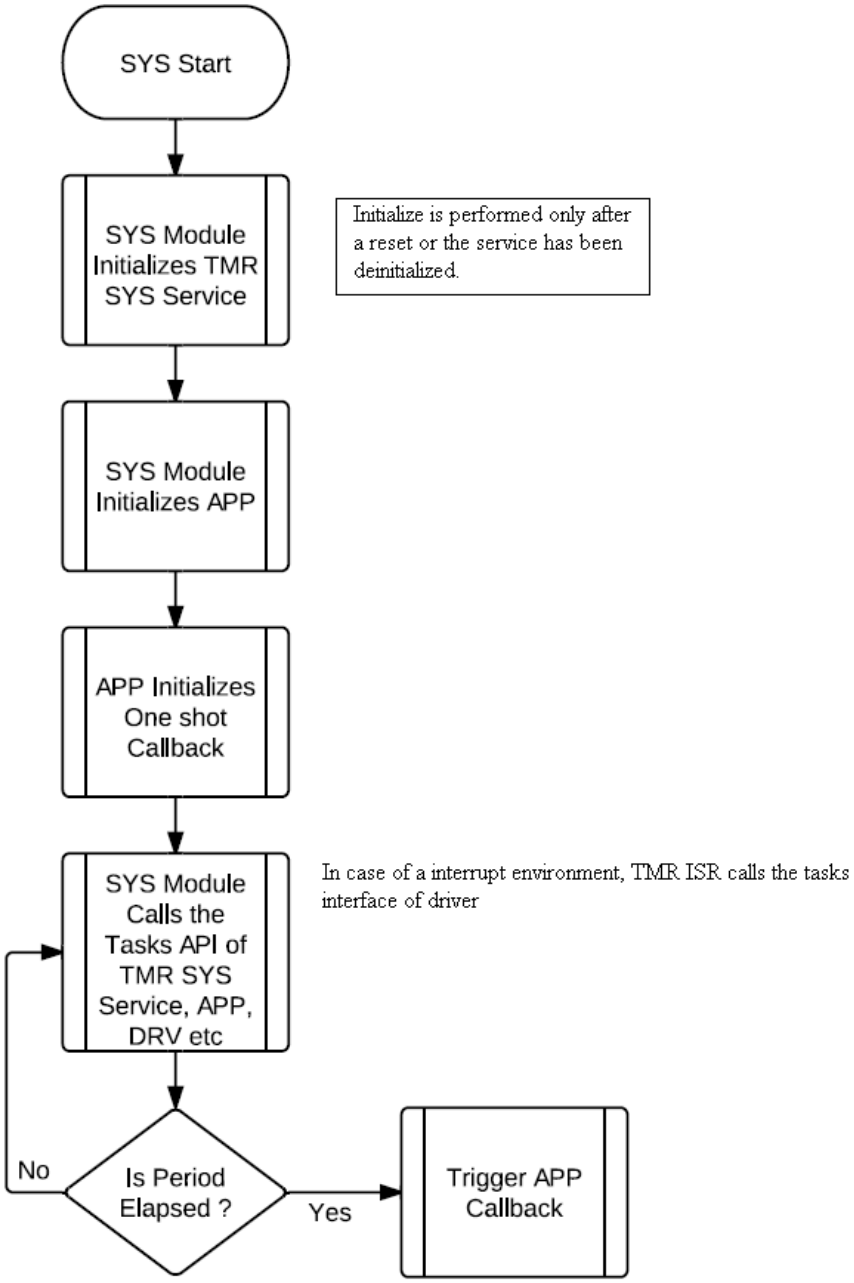
Periodic Callback

The following flow diagram depicts the Periodic Callback usage model.



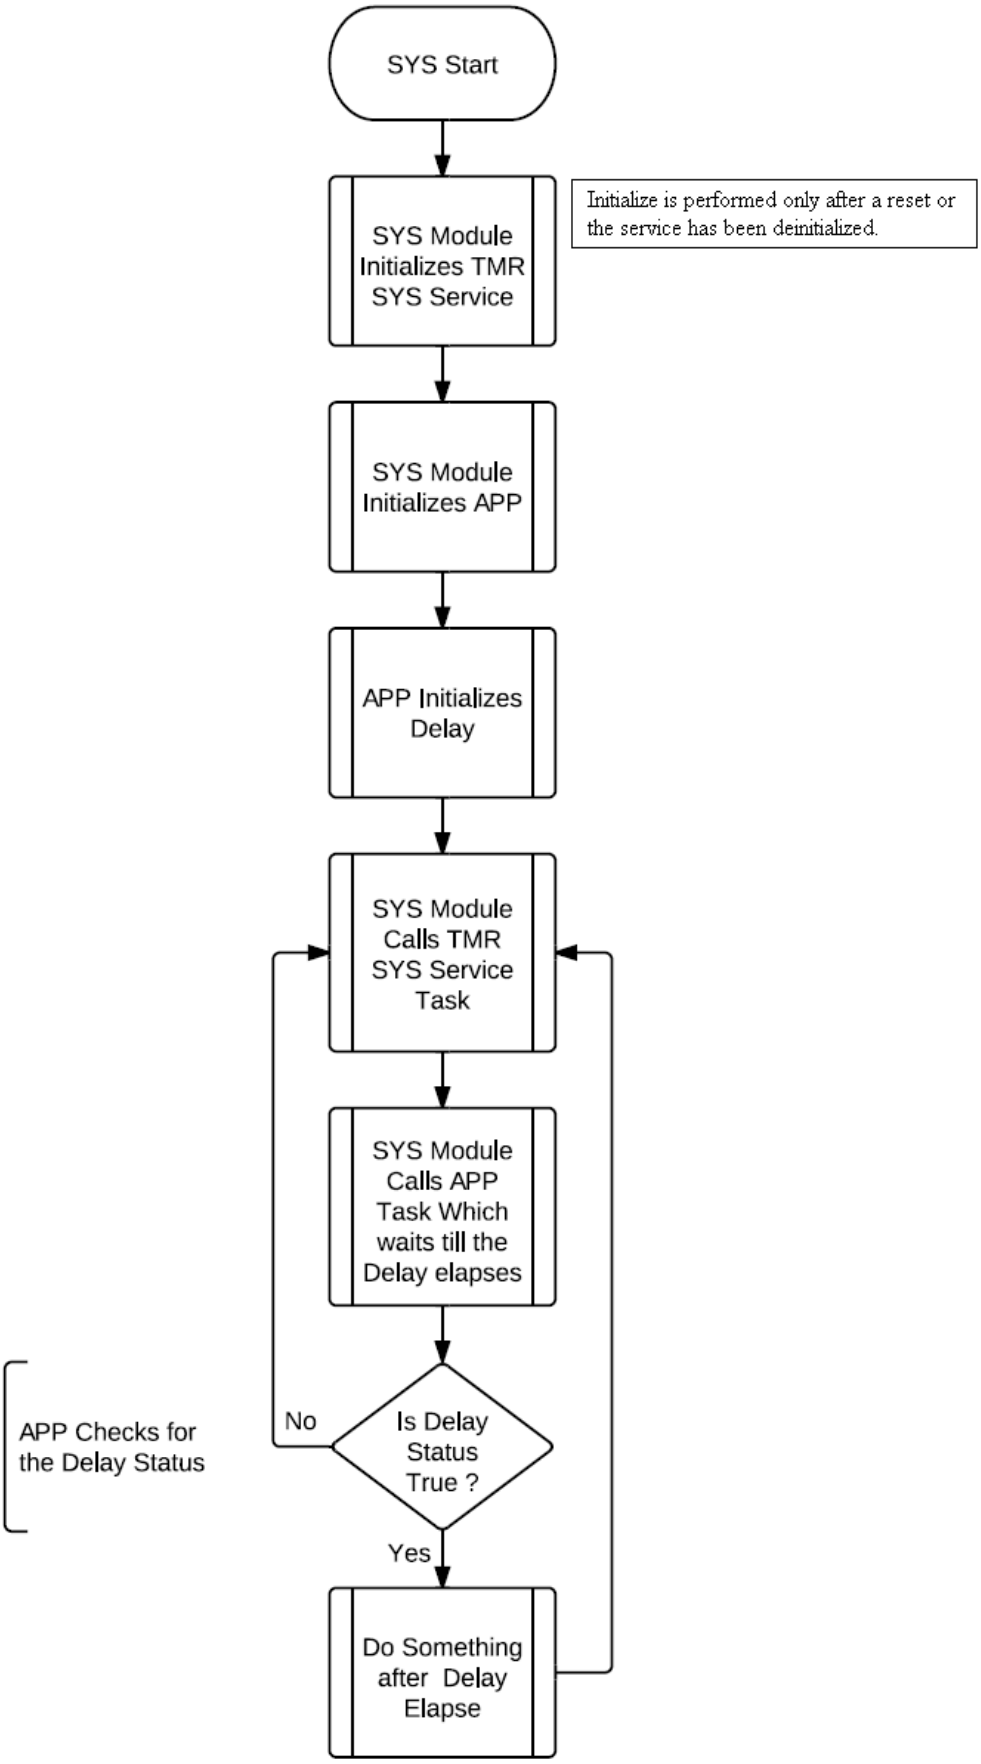
One-Shot Callback

The following flow diagram depicts the One-Shot Callback usage model.



Delay

The following flow diagram depicts the Delay usage model.



SYS Start
SYS Module Initializes TMR SYS Service
Initialize is performed only after a reset or the service has been deinitialized.
SYS Module Initializes APP
APP Initializes Delay
SYS Module Calls TMR SYS Service Task
SYS Module Calls APP Task Which waits till the Delay elapses
APP Checks for the Delay Status
No
Is Delay Status True ?
Yes
Do Something after Delay Elapse

Library Overview

Please refer to the System Service Introduction for a detailed description of MPLAB Harmony system services.

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Timer System Service Library.

Library Interface Section	Description
System Level Interaction Functions	Provides system module APIs. Device initialization, deinitialization, reinitialization and status functions.
Timed Callback Functions	Provides interfaces to handle timed periodic or one shot callbacks
Timed Delay Functions	Provides interfaces to handle timed delays
Miscellaneous Functions	Provides interfaces for timer tick counts, etc.

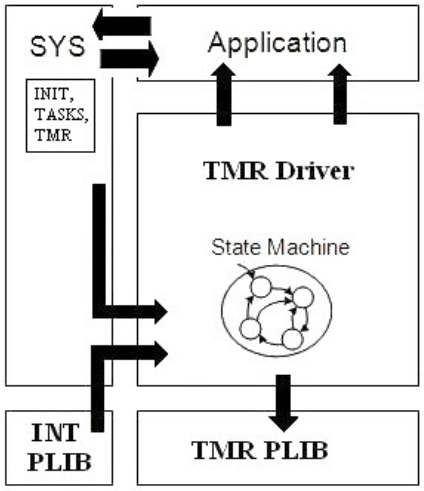
How the Library Works

The library provides interfaces to support:

- System Interaction
- Periodic Callback
- One shot/Single Callback
- Delays
- Tick count Information

Description

The following model gives information on interaction between various modules.



Note: The arrows in the diagram indicate the dependencies or support.

Module interaction occurs in the following order:

1. The initialization, reinitialization, deinitialization are handled by the SYS INIT module.
2. The Timer System Service Initialization function initializes the library's internal data structures.
3. After the initialization, Timer System Service Tasks function would be called by the SYS Tasks module to open the Timer Driver and do other configuration activities. Once the Timer driver is ready to be used the Timer System Service Tasks API makes the system ready to be used by setting the status of the Timer System Service module to SYS_STATUS_READY.
4. The application can now enable either periodic callback or one-shot callback or enable delays.

Notes:

1. It is possible to have multiple clients access the system timer service, each with different periodic or single callbacks or delays.
2. If the underlying Timer Driver uses Interrupt mode, it is the responsibility of the user or the application to ensure that the Interrupt system module has been initialized and that priorities have been set accordingly.
3. Ensure that the selected timer clock source is DRV_TMR_CLKSOURCE_INTERNAL, as the Timer System Service will not function if the timer clock source is external.

System Interaction

Initialization and Reinitialization:

The SYS module performs the initialization and the reinitialization of the Timer System Service. During initialization the following information is populated into the internal data structures from the init structure SYS_TMR_INIT passed as a parameter:

Initialization Member	Description
moduleInit	System module initialization of the power state
drvIndex	Timer driver module/instance index, the same index used to initialize the timer driver
tmrFreq	Required System Timer frequency in Hertz, which is the base frequency for all of the system time-keeping.

The SYS_TMR_Initialize API returns a handle of the type SYS_MODULE_OBJ. After this, the object handle returned by the Initialize interface would be used by the other system interfaces such as SYS_TMR_Reinitialize, SYS_TMR_Deinitialize, SYS_TMR_Status, and SYS_TMR_Tasks.

Note: If an attempt is made to initialize the SYS TMR module if it is already initialized, will safely return without modifying the behavior of the system.

Example for Timer System Service initialization:

```
SYS_MODULE_OBJ  objectHandle;
SYS_TMR_INIT    initConfig;

// Populate the SYS TMR initialization structure
initConfig.moduleInit.value     = SYS_MODULE_POWER_RUN_FULL;
initConfig.drvIndex             = DRV_TMR_INDEX_0;
initConfig.tmrFreq          = 1000;

objectHandle = SYS_TMR_Initialize( SYS_TMR_INDEX_0, ( SYS_MODULE_INIT * )&initConfig );
if( SYS_MODULE_OBJ_INVALID == objectHandle )
{
    // Handle error
}
```

Sample initialization sequence in polling environment:

```
void SYS_Initialize( SYS_INIT_DATA *data )
{
    /* Application Initialization */
    App_Init();

    /* Initialize the Timer driver */
    drvTmrObject = DRV_TMR_Initialize( DRV_TMR_INDEX_0, (SYS_MODULE_INIT *)&tmrInitData );

    /* Initialize the SYS TMR Module */
    sysTmrObject = SYS_TMR_Initialize( SYS_TMR_INDEX_0, (SYS_MODULE_INIT *)&sysTmrInitData );
}
```

Sample initialization sequence in an interrupt driven environment:'

```
void SYS_Initialize( SYS_INIT_DATA *data )
{
    /* Application Initialization */
    App_Init();

    /* Initialize the Timer driver */
    drvTmrObject = DRV_TMR_Initialize( DRV_TMR_INDEX_0, ( SYS_MODULE_INIT * )&tmrInitData );

    /* Initialize the SYS TMR Module */
    sysTmrObject = SYS_TMR_Initialize( SYS_TMR_INDEX_0, ( SYS_MODULE_INIT * )&sysTmrInitData );

/* Set the Timer Interrupt priority, sub-priority if supported by the device */
    SYS_INT_VectorPrioritySet(INT_VECTOR_T1, INT_PRIORITY_LEVEL1 );
    SYS_INT_VectorSubprioritySet(INT_VECTOR_T1, INT_SUBPRIORITY_LEVEL1 );

    /* Initialize the interrupt sub system module */
    SYS_INT_Initialize();
}
```

Deinitialization:

The deinitialize operation (SYS_TMR_Deinitialize) places the module in inactive state. Once the initialize operation has been called, the deinitialize

operation must be called before the initialize is called again. If the operation requires time to allow the hardware to complete, this will be reported by the SYS_TMR_Status operation.

Status:

Status of the system timer module can be checked using SYS_TMR_Status interface. After the initialization, reinitialization or the deinitialization activities the System timer Service status can be retrieved and checked for further actions.

Tasks Routine:

The system will call SYS_TMR_Tasks from System Task Service. This interface gets the system timer module into running mode. This interface needs to be called after the timer driver is successfully initialized.

Sample call order:

```
void SYS_Tasks( void )
{
    /* Call Driver TMR Tasks API */
    DRV_TMR_Tasks( drvTmrObject );

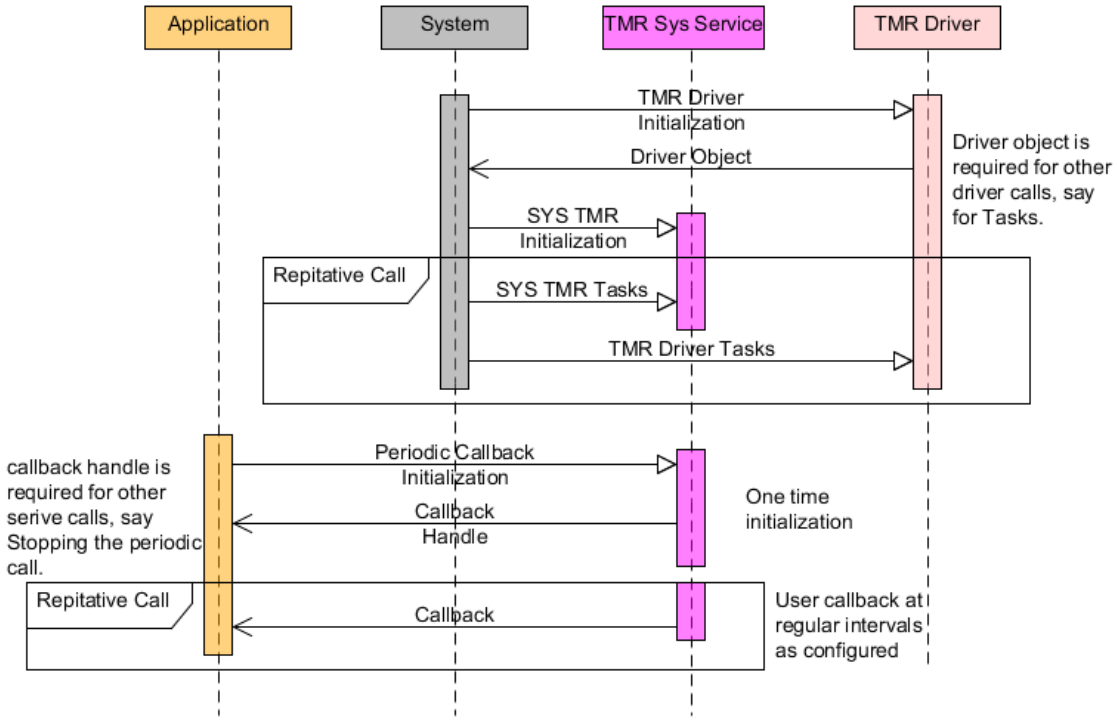
    /* Call SYS TMR Tasks API */
    SYS_TMR_Tasks( sysTmrObject );

    /* Call the Application Tasks */
    App_Tasks();
}
```

Periodic Callback

This section describes the periodic callback registration and its usage.

The following diagram depicts the interaction across various modules for the periodic callback feature,



Steps involved in registering and using the feature:

1. The Timer System Service should be in a ready state. Use the SYS_TMR_STATUS function to verify that the service is in this state.
2. Register the periodic callback feature using the SYS_TMR_CallbackPeriodic function with the period, a context pointer, and the pointer to the callback routine. The interface SYS_TMR_CallbackPeriodic returns a valid handle after successful registration.

Notes:

1. The handle can be later used by the user to stop the periodic callback by the user using the interface SYS_TMR_CallbackStop. Based on the periodicity set by the user the respective callback would be triggered repetitively after it elapses.
2. The period parameter will be adjusted internally to match the Timer System running frequency.

Example:

```
void SYS_Initialize ( SYS_INIT_DATA *data )
{
    /* Initialize the Timer driver */
    drvTmrObject = DRV_TMR_Initialize ( SYS_INDEX, (SYS_MODULE_INIT *)&tmrInitData );

    /* Initialize the SYS TMR Module */
    sysTmrObject = SYS_TMR_Initialize ( SYS_INDEX, (SYS_MODULE_INIT *)&sysTmrInitData );

    /* Application Initialization */
    App_Initialize ();

}

void SYS_Tasks(void)
{
    /* Call Driver TMR Tasks API */
    DRV_TMR_Tasks ( drvTmrObject );

    /* Call SYS TMR Tasks API */
    SYS_TMR_Tasks ( sysTmrObject );

    /* Call the App Tasks */
    App_Tasks ();
}

void App_Tasks ( void )
{
    switch (testState)
    {
        /* Wait in Init state until the SYS TMR Module is in running mode */
        case TEST_STATE_Init:
                if (SYS_STATUS_READY == SYS_TMR_Status(sysTmrObject))
                {
                    /* SYS TMR is in running mode */
                    testState = TEST_STATE_Config_Periodic;
                }
                else
                {
                    testState = TEST_STATE_Init;
                }
            break;

        case TEST_STATE_Config_Periodic:
                /* Activate periodic callback */
                handle = SYS_TMR_CallbackPeriodic (120, 0, &Test_Callback);
                testState = TEST_STATE_Count_Read;
             break;

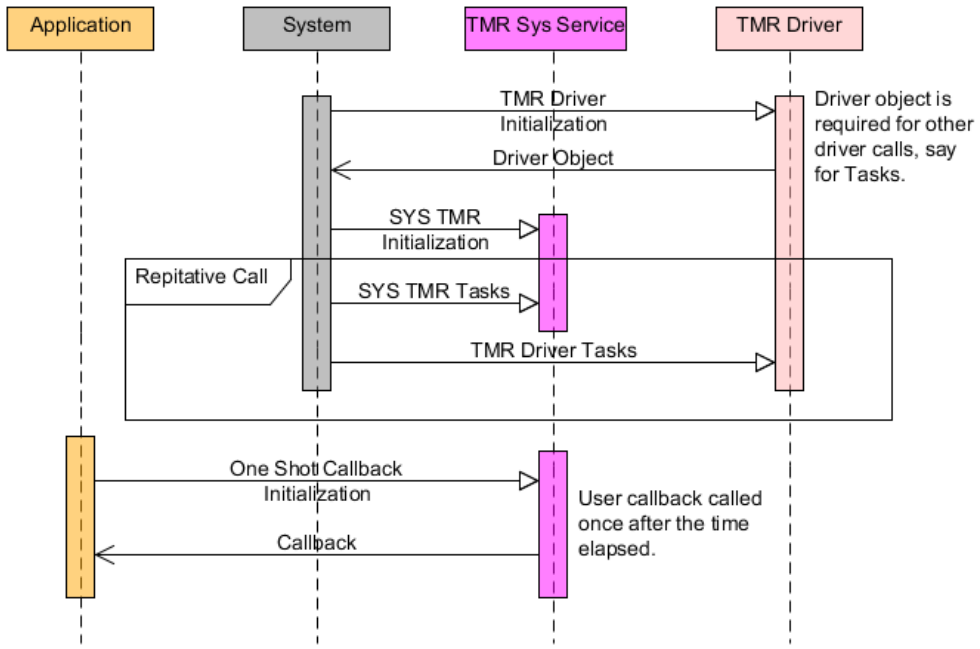
        case TEST_STATE_Count_Read:
                testCount1 = SYS_TMR_TickCountGet ();
            break;
    }
}

// Callback which will be called repetitively after the configured
// time elapses
void Test_Callback ( uintptr_t context, uint32_t currTick )
{
    PORTA = ~PORTA;
}
```

One Shot Callback

This section describes the one-shot/single callback registration and its usage.

The following diagram depicts the interaction across various modules for the one-shot callback feature,



Steps involved in registering and using the feature:

1. Initial requirement is to have the Timer System Service module in the SYS_STATUS_READY state. The user can call the function SYS_TMR_Status to get the current status information of the module.
2. One-shot/Single callback feature can be registered by calling the function SYS_TMR_CallbackSingle with the parameters periodicity of the callback, a context pointer, and a pointer to the user's callback routine.

Based on the periodicity set by the user, the respective callback would be triggered once after it elapses.

Notes:

1. The handle can be later used by the user to stop the one-shot callback by the user using the interface SYS_TMR_CallbackStop.
2. The period parameter will be adjusted internally to match the Timer System running frequency.

Example:

```
void SYS_Initialize ( SYS_INIT_DATA *data )
{
    /* Initialize the Timer driver */
    drvTmrObject = DRV_TMR_Initialize ( SYS_INDEX, (SYS_MODULE_INIT *)&tmrInitData );

    /* Initialize the SYS TMR Module */
    sysTmrObject = SYS_TMR_Initialize ( SYS_INDEX, (SYS_MODULE_INIT *)&sysTmrInitData );

    /* Application Initialization */
    App_Initialize ();

}

void SYS_Tasks(void)
{
    /* Call Driver TMR Tasks API */
    DRV_TMR_Tasks ( drvTmrObject );

    /* Call SYS TMR Tasks API */
    SYS_TMR_Tasks ( sysTmrObject );

    /* Call the App Tasks */
    App_Tasks ();
}

void App_Tasks ( void )
{
    switch (testState)
    {
```

```
        /* Wait in Init state until the SYS TMR Module is in running mode */
        case TEST_STATE_Init:
                if (SYS_STATUS_READY == SYS_TMR_Status(sysTmrObject))
                {
                    /* SYS TMR is in running mode */
                    testState = TEST_STATE_Config_Single;
                }
                else
                {
                    testState = TEST_STATE_Init;
                }
            break;

        case TEST_STATE_Config_Single:
                /* Activate one shot/single callback */
                handle = SYS_TMR_CallbackSingle (120, 0, &Test_Callback);
                testState = TEST_STATE_Count_Read;
             break;

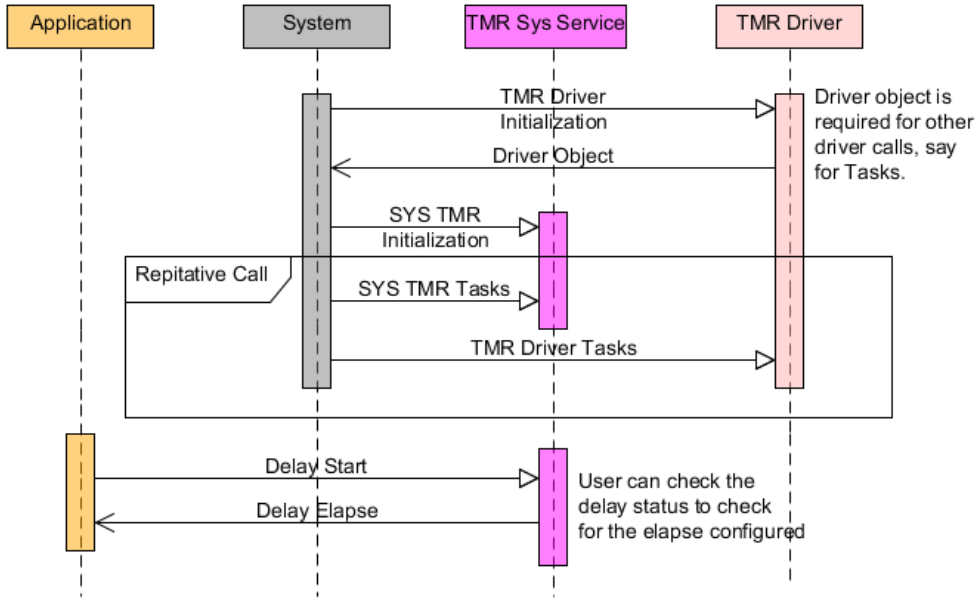
        case TEST_STATE_Count_Read:
                testCount1 = SYS_TMR_TickCountGet ();
            break;
    }
}

// Callback which will be called repetitively after the configured
// time elapses
void Test_Callback ( uintptr_t context, uint32_t currTick )
{
    PORTA = ~PORTA;
}
```

Delays

This section describes the delay registration and its usage. The mechanism depicted supports only non-blocking delays.

The following diagram depicts the interaction across various modules for the delay feature.



Steps involved in registering and using the feature:

1. Initial requirement is to have the Timer System Service module in the SYS_STATUS_READY state. The user can call the function SYS_TMR_Status to get the current status information of the module.
2. Delay feature can be registered by calling the function SYS_TMR_DelayMS with the delay parameter.

Notes:

1. The API SYS_TMR_DelayMS returns a valid handle after successful registration. This handle can be later used by the user to check the status of the delay using the API SYS_TMR_DelayStatusGet.
2. The period parameter will be adjusted internally to match the Timer System running frequency.

Example:

```
case DELAY_START_STATE:
    handle = SYS_TMR_DelayMS (500);
    state = DELAY_CHECKSTATE;
break;

case DELAY_CHECKSTATE:
    if (true == SYS_TMR_DelayStatusGet(handle))
    {
        state = DELAY_START_STATE;
    }
    else
    {
        state = DELAY_CHECKSTATE;
    }
break;
```

Miscellaneous

Tick Counts Information: The API SYS_TMR_TickCountGet provides the current tick information.

Examples

Sample Application Tasks

Periodic callback with only one period with 120 ms period:

```
switch (state)
{
  case STATE_Init:
    if (SYS_STATUS_READY == SYS_TMR_Status(sysTmrObject))
    {
      state = STATE_Config_Periodic;
    }
    else
    {
      state = STATE_Init;
    }
  break;

  case STATE_Config_Periodic:
    handle = SYS_TMR_CallbackPeriodic (120, 0, &Test_Callback);
    state = STATE_Count_Read;
  break;

  case STATE_Count_Read:
    testCount = SYS_TMR_TickCountGet ();
    state = STATE_Count_Read;
  break;
}
```

Periodic callback with multiple periods 120 ms and 250 ms:

```
switch (state)
{
  case STATE_Init:
    if (SYS_STATUS_READY == SYS_TMR_Status(sysTmrObject))
    {
      state = STATE_Config_Periodic;
    }
    else
    {
      state = STATE_Init;
    }
  break;
```

```
  case STATE_Config_Periodic:
    handle1 = SYS_TMR_CallbackPeriodic (120, 0, &Test_Callback1);
    handle2 = SYS_TMR_CallbackPeriodic (250, 0, &Test_Callback2);
    state = STATE_Count_Read;
  break;

  case STATE_Count_Read:
    testCount = SYS_TMR_TickCountGet ();
    state = STATE_Count_Read;
  break;
}

void Test_Callback1 ( uintptr_t context, uint32_t currTick )
{
  /* Assume RA0 is connected to one LED */
  PORTAbits.RA0 = ~PORTAbits.RA0;
}

void Test_Callback2 ( uintptr_t context, uint32_t currTick )
{
  /* Assume RA1 is connected to another LED */
    PORTAbits.RA1 = ~PORTAbits.RA1;
}
```

One-Shot Callback:

```
switch (state)
{
  case STATE_Init:
    if (SYS_STATUS_READY == SYS_TMR_Status(sysTmrObject))
    {
      state = STATE_Config_Single;
    }
    else
    {
      state = STATE_Init;
    }
  break;

  case STATE_Config_Single:
    SYS_TMR_CallbackSingle (500, 0, &Test_Callback);
    state = STATE_Count_Read;
  break;

  case STATE_Count_Read:
    testCount = SYS_TMR_TickCountGet ();
    state = STATE_Count_Read;
  break;
}
```

Delay:

```
switch (state)
{
  case STATE_Init:
    if (SYS_STATUS_READY == SYS_TMR_Status(sysTmrObject))
    {
      state = STATE_DelayStart;
    }
    else
    {
      state = STATE_Init;
    }
  break;

  case STATE_DelayStart:
    dlHandle = SYS_TMR_DelayMS (500);
    state = STATE_DelayCheck;
  break;

  case STATE_DelayCheck:
    if (SYS_TMR_DELAY_EXPIRED == SYS_TMR_DelayStatusGet(dlHandle))
```

```
      {
        state = STATE_DelayStart;
      }
      else
      {
        state = STATE_DelayCheck;
      }
    break;
  }
```

Configuring the Library

Macros

	Name	Description
	_SYS_TMR_CONFIG_TEMPLATE_H	This is macro _SYS_TMR_CONFIG_TEMPLATE_H.

Description

The configuration of the Timer System Service is based on the file `system_config.h`.

This header file contains the configuration selection for the Timer System Service build. Based on the selections made, the Timer System Service may support the selected features. These configuration settings will apply to all instances of the Timer System Service.

This header can be placed anywhere, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

_SYS_TMR_CONFIG_TEMPLATE_H Macro

File

sys_tmr_config_template.h

C

```
#define _SYS_TMR_CONFIG_TEMPLATE_H
```

Description

This is macro _SYS_TMR_CONFIG_TEMPLATE_H.

Building the Library

This section lists the files that are available in the Timer System Service Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/system/timer`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using #include) by any code that uses this library.

Source File Name	Description
`sys_tmr.h`	Timer System Service Library API header file.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/dynamic/sys_tmr.c`	Timer System Service Library implementation.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	There are no optional files for this library.

Module Dependencies

The Timer System Service Library depends on the following modules:

- Timer Driver Library

Library Interface

a) System Level Interaction Functions

	Name	Description
	SYS_TMR_Deinitialize	Deinitializes the specific module instance of the TMR module
	SYS_TMR_Initialize	Initializes hardware and data for the instance of the Timer module and opens the specific module instance.
	SYS_TMR_Status	Returns status of the specific instance of the Timer module.
	SYS_TMR_Tasks	Maintains the system timer's state machine and implements its ISR.

b) Timed Callback Functions

	Name	Description
	SYS_TMR_CallbackStop	Stops a periodic timer object.
	SYS_TMR_CallbackPeriodic	Creates a permanent timer object that calls back to the client periodically.
	SYS_TMR_CallbackSingle	Creates a one-shot/single callback timer object.

c) Timed Delay Functions

	Name	Description
	SYS_TMR_DelayStatusGet	Checks the status of the previously requested delay timer object.
	SYS_TMR_DelayMS	Creates a timer object that times out after the specified delay.

d) Timed Object Functions

	Name	Description
	SYS_TMR_ObjectCountGet	Returns the current millisecond count of a timer object.
	SYS_TMR_ObjectCreate	Creates a new timer object.
	SYS_TMR_ObjectDelete	Deletes an existent timer object.
	SYS_TMR_ObjectReload	Reloads an existing timer object.

e) Miscellaneous Functions

	Name	Description
	SYS_TMR_TickCountGet	Provides the current counter value.
	SYS_TMR_TickCountGetLong	Provides the current counter value with 64-bit resolution.
	SYS_TMR_TickCounterFrequencyGet	Provides the number of ticks per second
	SYS_TMR_SystemCountGet	Provides the current system time count value.
	SYS_TMR_SystemCountFrequencyGet	Provides the current system count frequency.
	SYS_TMR_ModuleStatusGet	Returns status of the specific instance of the Timer module.

f) Data Types and Constants

	Name	Description
	SYS_TMR_CALLBACK	This data type defines a pointer callback function.
	SYS_TMR_HANDLE	Identifies a client timer object.
	SYS_TMR_INIT	Identifies the system timer initialize structure.
	SYS_TMR_HANDLE_INVALID	Identifies the invalid handle of the system timer.
	SYS_TMR_INDEX_0	Timer System Service index definitions.
	SYS_TMR_FLAGS	Defines the types and flags supported by a client timer object.
	SYS_TMR_CLIENT_TOLERANCE	Sets the accepted client tolerance in %.
	SYS_TMR_DRIVER_INDEX	Sets the default timer driver object to be used by the system timer service.
	SYS_TMR_FREQUENCY	Specifies the operating frequency for the system timer, Hz.

	SYS_TMR_FREQUENCY_TOLERANCE	Sets the error tolerance in %.
	SYS_TMR_INTERRUPT_NOTIFICATION	Activates the notification mechanism from within the timer interrupt.
	SYS_TMR_MAX_CLIENT_OBJECTS	Sets the maximum number of timer clients that can be active at a given time.
	SYS_TMR_MODULE_INIT	Sets the default module init value by the system timer service.
	SYS_TMR_UNIT_RESOLUTION	Specifies the internal units for the time keeping.

Description

This section describes the APIs of the Timer System Service Library.

Refer to each section for a detailed description.

a) System Level Interaction Functions

SYS_TMR_Deinitialize Function

Deinitializes the specific module instance of the TMR module

File

sys_tmr.h

C

```
void SYS_TMR_Deinitialize(SYS_MODULE_OBJ object);
```

Returns

None.

Description

This function deinitializes the specific module instance disabling its operation (and any hardware for driver modules). Resets all of the internal data structures and fields for the specified instance to the default settings.

Remarks

Once the Initialize operation has been called, the De-initialize operation must be called before the Initialize operation can be called again.

Preconditions

The SYS_TMR_Initialize function should have been called before calling this function.

Example

```
SYS_MODULE_OBJ      object;     //  Returned from SYS_TMR_Initialize
SYS_STATUS          status;

SYS_TMR_Deinitialize (object);

status = SYS_TMR_Status (object);

if (SYS_MODULE_UNINITIALIZED == status)
{
    // Check again later if you need to know
    // when the SYS TMR is deinitialized.
}
```

Parameters

Parameters	Description
object	SYS TMR object handle, returned from SYS_TMR_Initialize

Function

void SYS_TMR_Deinitialize (SYS_MODULE_OBJ object)

SYS_TMR_Initialize Function

Initializes hardware and data for the instance of the Timer module and opens the specific module instance.

File

sys_tmr.h

C

```
SYS_MODULE_OBJ SYS_TMR_Initialize(const SYS_MODULE_INDEX index, const SYS_MODULE_INIT * const init);
```

Returns

If successful, returns a valid handle to an object. Otherwise, it returns SYS_MODULE_OBJ_INVALID. The returned object must be passed as argument to SYS_TMR_Reinitialize, SYS_TMR_Deinitialize, SYS_TMR_Tasks and SYS_TMR_Status routines.

Description

This function initializes hardware for the instance of the Timer module, using the specified hardware initialization data. It also initializes any internal data structures.

Remarks

This routine should only be called once during system initialization.

Preconditions

None.

Example

```
SYS_MODULE_OBJ  objectHandle;
SYS_TMR_INIT    initConfig;

// Populate the timer initialization structure
initConfig.moduleInit.value     = SYS_MODULE_POWER_RUN_FULL;
initConfig.drvIndex             = DRV_TMR_INDEX_0;
initConfig.tmrFreq              = 1000;

objectHandle = SYS_TMR_Initialize (SYS_TMR_INDEX_0, (SYS_MODULE_INIT*)&initConfig);
if (SYS_MODULE_OBJ_INVALID == objectHandle)
{
    // Handle error
}
```

Parameters

Parameters	Description
index	Index for the instance to be initialized
init	Pointer to a data structure containing any data necessary to initialize the sys timer. This pointer may be null if no data is required because static overrides have been provided.

Function

SYS_MODULE_OBJ SYS_TMR_Initialize (const SYS_MODULE_INDEX index,
const SYS_MODULE_INIT * const init)

SYS_TMR_Status Function

Returns status of the specific instance of the Timer module.

File

sys_tmr.h

C

```
SYS_STATUS SYS_TMR_Status(SYS_MODULE_OBJ object);
```

Returns

- SYS_STATUS_READY - Indicates that the driver initialization is complete and ready to be used.

Description

This function returns the status of the specific module instance.

Remarks

Any value greater than SYS_STATUS_READY is also a normal running state in which the driver is ready to accept new operations

- SYS_STATUS_ERROR - Indicates that the driver is in an error state.

Any value less than SYS_STATUS_ERROR is also an error state.

- SYS_MODULE_UNINITIALIZED - Indicates that the driver has been deinitialized.

This value is less than SYS_STATUS_ERROR.

None.

Preconditions

The SYS_TMR_Initialize function should have been called before calling this function.

Example

```
SYS_MODULE_OBJ      object;     // Returned from SYS_TMR_Initialize
SYS_STATUS          tmrStatus;

tmrStatus = SYS_TMR_Status (object);

if ( SYS_STATUS_ERROR <= tmrStatus )
{
    // Handle error
}
```

Parameters

Parameters	Description
object	SYS TMR object handle, returned from SYS_TMR_Initialize

Function

SYS_STATUS SYS_TMR_Status (SYS_MODULE_OBJ object)

SYS_TMR_Tasks Function

Maintains the system timer's state machine and implements its ISR.

File

sys_tmr.h

C

```
void SYS_TMR_Tasks(SYS_MODULE_OBJ object);
```

Returns

None.

Description

This function is used to maintain the system timer's internal state machine. It should be always be called from 'Sys_Tasks' function.

Remarks

This function is normally not called directly by an application. It is called by the system's Tasks routine (SYS_Tasks) or by the appropriate raw ISR.

Preconditions

The SYS_TMR_Initialize function must have been called for the specified TMR driver instance.

Example

```
SYS_MODULE_OBJ      object;     // Returned from SYS_TMR_Initialize

while (true)
{
    SYS_TMR_Tasks ( object );

    // Do other tasks
}
```

Parameters

Parameters	Description
object	SYS TMR object handle, returned from SYS_TMR_Initialize

Function

void SYS_TMR_Tasks (SYS_MODULE_OBJ object)

b) Timed Callback Functions

SYS_TMR_CallbackStop Function

Stops a periodic timer object.

File

sys_tmr.h

C

```
void SYS_TMR_CallbackStop(SYS_TMR_HANDLE handle);
```

Returns

None.

Description

This function deletes a previously created periodic timer object. All the associated resources are released.

Remarks

This function is equivalent to SYS_TMR_ObjectDelete(handle);.

Preconditions

The SYS_TMR_CallbackPeriodic function should have been called to obtain a valid timer handle.

Example

```
int count, state;
void Test_Callback ( uintptr_t context, uint32_t currTick )
{
    count++;
}

void DelayTask ( )
{
    SYS_TMR_HANDLE handle;
    switch (state)
    {
        case 1:
            handle = SYS_TMR_CallbackPeriodic ( 20, 1, Test_Callback );
            state++;
            break;
        case 2:
            if ( count > 100 )
            {
                SYS_TMR_CallbackStop ( handle );
                state++;
            }
            count++;
            break;
    }
}
```

Parameters

Parameters	Description
handle	A valid periodic timer handle, returned by a SYS_TMR_CallbackPeriodic call.

Function

void SYS_TMR_CallbackStop (SYS_TMR_HANDLE handle)

SYS_TMR_CallbackPeriodic Function

Creates a permanent timer object that calls back to the client periodically.

File

sys_tmr.h

C

```
SYS_TMR_HANDLE SYS_TMR_CallbackPeriodic(uint32_t periodMs, uintptr_t context, SYS_TMR_CALLBACK callback);
```

Returns

A valid timer object handle of type SYS_TMR_HANDLE if the call succeeds. SYS_TMR_HANDLE_INVALID otherwise.

Description

This function creates a timer object that will continuously notify the client once the time-out occurs. The timer object will be deleted by a call to SYS_TMR_CallbackStop

Remarks

The created timer object is persistent and needs to be deleted with SYS_TMR_CallbackStop when no longer needed.

This function is equivalent to SYS_TMR_ObjectCreate(periodMs, context, callback, SYS_TMR_FLAG_PERIODIC);

Preconditions

The SYS_TMR_Initialize function should have been called before calling this function.

Example

```
SYS_TMR_HANDLE handle20ms, handle30ms;

void Test_Callback ( uintptr_t context, uint32_t currTick );

handle20ms = SYS_TMR_CallbackPeriodic ( 20, 1, Test_Callback );
handle30ms = SYS_TMR_CallbackPeriodic ( 20, 2, Test_Callback );

void Test_Callback ( uintptr_t context, uint32_t currTick )
{
    if ( context == 1 )
    {
        //20 ms
    }
    else
    {
        //30 ms
    }
}
```

Parameters

Parameters	Description
periodMs	Periodic delay in milliseconds
context	A client parameter that's passed in the callback function. This will help to identify the callback.
callback	Pointer to a callback routine that will be called periodically once the time-out occurs.

Function

SYS_TMR_HANDLE SYS_TMR_CallbackPeriodic (uint32_t periodMs, uintptr_t context,
SYS_TMR_CALLBACK callback)

SYS_TMR_CallbackSingle Function

Creates a one-shot/single callback timer object.

File

sys_tmr.h

C

```
SYS_TMR_HANDLE SYS_TMR_CallbackSingle(uint32_t periodMs, uintptr_t context, SYS_TMR_CALLBACK callback);
```

Returns

A valid timer object handle of type SYS_TMR_HANDLE if the call succeeds. SYS_TMR_HANDLE_INVALID otherwise.

Description

This function creates a self-destroying one-shot/single timer object that will notify the client once the time-out occurs. Once the time-out occurs and the notification is sent the timer object will be invalidated.

Remarks

The timer object will delete itself and free the associated resources. The SYS_TMR_HANDLE will be no longer valid.

However, SYS_TMR_CallbackStop() can be called to kill the timer object before its time-out expires, if not needed anymore.

This function is equivalent to SYS_TMR_ObjectCreate(periodMs, context, callback, SYS_TMR_FLAG_SINGLE | SYS_TMR_FLAG_AUTO_DELETE);

Preconditions

The SYS_TMR_Initialize function should have been called before calling this function.

Example

```
SYS_TMR_HANDLE handle;
void Test_Callback20ms ( uintptr_t context, uint32_t currTick );

handle = SYS_TMR_CallbackSingle ( 20, 1, Test_Callback20ms );
```

Parameters

Parameters	Description
periodMs	Periodic delay in milliseconds
context	A client parameter that's passed in the callback function. This will help to identify the callback.
callback	Pointer to a callback routine which will be called once

Function

SYS_TMR_HANDLE SYS_TMR_CallbackSingle (uint32_t periodMs, uintptr_t context,
SYS_TMR_CALLBACK callback)

c) Timed Delay Functions

SYS_TMR_DelayStatusGet Function

Checks the status of the previously requested delay timer object.

File

sys_tmr.h

C

```
bool SYS_TMR_DelayStatusGet(SYS_TMR_HANDLE handle);
```

Returns

- true - If the delay is elapsed
- false - If the delay is not elapsed

Description

This function checks the status of the previously requested delay timer object.

Remarks

Once the required delay is achieved and SYS_TMR_DelayStatusGet returns true the SYS_TMR_HANDLE will be no longer valid and the created timer object is deleted.

Preconditions

The SYS_TMR_DelayMS function should have been called before calling this function.

Example

```
SYS_TMR_HANDLE tmrHandle;

case APP_ADD_DELAY:
    tmrHandle = SYS_TMR_DelayMS ( 50 );
    state = APP_CHECK_DELAY;
    break;
case APP_CHECK_DELAY:
    if ( SYS_TMR_DelayStatusGet ( tmrHandle ) == true )
    {
        state = APP_DELAY_COMPLETE;
    }
    break;
```

Parameters

Parameters	Description
handle	A valid timer object handle, returned by SYS_TMR_DelayMS

Function

bool SYS_TMR_DelayStatusGet (SYS_TMR_HANDLE handle)

SYS_TMR_DelayMS Function

Creates a timer object that times out after the specified delay.

File

sys_tmr.h

C

```
SYS_TMR_HANDLE SYS_TMR_DelayMS(uint32_t delayMs);
```

Returns

A valid timer handler of type SYS_TMR_HANDLE is returned if the call is successful. SYS_TMR_HANDLE_INVALID otherwise.

Description

This function creates a self-destroying timer object that times out after the required delay. The delay status can be checked using SYS_TMR_DelayStatusGet();

Remarks

Once the required delay is achieved and SYS_TMR_DelayStatusGet() returns true the SYS_TMR_HANDLE will be no longer valid and the created timer object is deleted.

However, SYS_TMR_CallbackStop() can be called to kill the timer object before its time-out expires, if not needed anymore.

This function is equivalent to SYS_TMR_ObjectCreate(delayMs, 0, 0, SYS_TMR_FLAG_SINGLE | SYS_TMR_FLAG_AUTO_DELETE);

Preconditions

The SYS_TMR_Initialize function should have been called before calling this function.

Example

```
SYS_TMR_HANDLE tmrHandle;

case APP_ADD_DELAY:
    tmrHandle = SYS_TMR_DelayMS ( 50 );
    state = APP_CHECK_DELAY;
    break;
case APP_CHECK_DELAY:
    if ( SYS_TMR_DelayStatusGet (tmrHandle ) == true )
    {
        state = APP_DELAY_COMPLETE;
    }
    break;
```

Parameters

Parameters	Description
delayMs	Indicates the delay required in milliseconds

Function

SYS_TMR_HANDLE SYS_TMR_DelayMS (uint32_t delayMs)

d) Timed Object Functions

SYS_TMR_ObjectCountGet Function

Returns the current millisecond count of a timer object.

File

sys_tmr.h

C

```
uint32_t SYS_TMR_ObjectCountGet(SYS_TMR_HANDLE handle, uint32_t* pRateMs);
```

Returns

- > 0 - the current timer object millisecond count
- = 0 - time-out has occurred
- < 0 - if invalid timer object

Description

This function returns the current count and the time-out values of a timer object, in milliseconds.

Remarks

This function will destroy the auto-delete timer objects if the time-out has occurred.

Preconditions

The SYS_TMR_ObjectCreate function should have been called to get a valid timer object handle.

Parameters

Parameters	Description
handle	A valid timer handle, returned by a SYS_TMR_ObjectCreate call.
pRateMs	pointer to address to store the current object reload rate, in milliseconds. Could be NULL, if not needed.

Function

uint32_t SYS_TMR_ObjectCountGet (SYS_TMR_HANDLE handle, uint32_t* pRateMs)

SYS_TMR_ObjectCreate Function

Creates a new timer object.

File

sys_tmr.h

C

```
SYS_TMR_HANDLE SYS_TMR_ObjectCreate(uint32_t periodMs, uintptr_t context, SYS_TMR_CALLBACK callback,
SYS_TMR_FLAGS flags);
```

Returns

A valid timer object handle of type SYS_TMR_HANDLE if the call succeeds. SYS_TMR_HANDLE_INVALID otherwise.

Description

This function creates a new timer object of requested type. If a callback is supplied, it will notify the user once the time-out occurs. The timer object will be deleted by a call to SYS_TMR_ObjectDelete

Remarks

The created timer object needs to be deleted with SYS_TMR_ObjectDelete when no longer needed (unless is auto-delete type).

The auto-delete objects are deleted if the time-out has occurred and the client has been notified, meaning:

- The object has a notification/callback function, which has been called upon time-out.
- SYS_TMR_ObjectCountGet()/SYS_TMR_DelayStatusGet has been called

Preconditions

The SYS_TMR_Initialize function should have been called before calling this function.

Example

```
SYS_TMR_HANDLE handle20ms, handle30ms;

void Test_Callback ( uintptr_t context, uint32_t currTick );

handle20ms = SYS_TMR_ObjectCreate ( 20, 1, Test_Callback, SYS_TMR_FLAG_PERIODIC );
handle30ms = SYS_TMR_ObjectCreate ( 30, 2, Test_Callback, SYS_TMR_FLAG_PERIODIC );

void Test_Callback ( uintptr_t context, uint32_t currTick )
{
    if ( context == 1 )
    {
        //20 ms
    }
    else
    {
        //30 ms
    }
}

// when done with the timer objects
SYS_TMR_ObjectDelete(handle20ms);
SYS_TMR_ObjectDelete(handle30ms);
```

Parameters

Parameters	Description
periodMs	Periodic delay in milliseconds
context	A client parameter that's passed in the callback function. This will help to identify the callback. Can be 0 if not needed.
callback	Pointer to a callback routine that will be called periodically once the time-out occurs. Can be NULL if not needed.
flags	multiple flags specifying what type of object is created: • SYS_TMR_FLAG_PERIODIC - a periodic timer object is requested • SYS_TMR_FLAG_SINGLE - a single timer object is requested • SYS_TMR_FLAG_AUTO_DELETE - auto-delete object (SYS_TMR_FLAG_SINGLE only)

Function

SYS_TMR_HANDLE SYS_TMR_ObjectCreate (uint32_t periodMs, uintptr_t context,
SYS_TMR_CALLBACK callback, SYS_TMR_FLAGS flags)

SYS_TMR_ObjectDelete Function

Deletes an existent timer object.

File

sys_tmr.h

C

```
void SYS_TMR_ObjectDelete(SYS_TMR_HANDLE handle);
```

Returns

None.

Description

This function deletes a timer object and release the associated resources.

Remarks

The created timer objects need to be deleted when it is no longer needed (unless of auto-delete type).

Preconditions

The SYS_TMR_ObjectCreate function should have been called to get a valid timer object handle.

Parameters

Parameters	Description
handle	A valid timer handle, returned by a SYS_TMR_ObjectCreate call.

Function

void SYS_TMR_ObjectDelete (SYS_TMR_HANDLE handle)

SYS_TMR_ObjectReload Function

Reloads an existing timer object.

File

sys_tmr.h

C

```
bool SYS_TMR_ObjectReload(SYS_TMR_HANDLE handle, uint32_t periodMs, uintptr_t context, SYS_TMR_CALLBACK callback);
```

Returns

- true - If the call succeeds
- false - If the call fails

Description

This function changes the parameters for an already existing timer object. The timer object should be valid.

Remarks

The function works for any kind of timer object. It will fail if the timer object was auto-delete type and the time-out has already expired.

Preconditions

The SYS_TMR_ObjectCreate function should have been called to get a valid timer object handle.

Parameters

Parameters	Description
handle	A valid timer handle, returned by a SYS_TMR_ObjectCreate call.
periodMs	Periodic delay in milliseconds
context	A client parameter that's passed in the callback function. This will help to identify the callback. Can be '0' if not needed.
callback	Pointer to a callback routine that will be called periodically once the time-out occurs. Can be NULL if not needed.

Function

bool SYS_TMR_ObjectReload (SYS_TMR_HANDLE handle, uint32_t periodMs,
uintptr_t context, SYS_TMR_CALLBACK callback)

e) Miscellaneous Functions

SYS_TMR_TickCountGet Function

Provides the current counter value.

File

sys_tmr.h

C

```
uint32_t SYS_TMR_TickCountGet();
```

Returns

The current system timer tick count value.

Description

This function provides the current tick counter value.

Remarks

None.

Preconditions

The SYS_TMR_Initialize function should have been called before calling this function.

Example

```
uint32_t count;
count = SYS_TMR_TickCountGet ();
```

Function

uint32_t SYS_TMR_TickCountGet(void)

SYS_TMR_TickCountGetLong Function

Provides the current counter value with 64-bit resolution.

File

sys_tmr.h

C

```
uint64_t SYS_TMR_TickCountGetLong();
```

Returns

The current system timer tick count value.

Description

This function provides the current tick counter value as a 64-bit value.

Remarks

None.

Preconditions

The SYS_TMR_Initialize function should have been called before calling this function.

Example

```
uint64_t lCount;
lCount = SYS_TMR_TickCountGetLong ();
```

Function

uint64_t SYS_TMR_TickCountGetLong(void)

SYS_TMR_TickCounterFrequencyGet Function

Provides the number of ticks per second

File

sys_tmr.h

C

```
uint32_t SYS_TMR_TickCounterFrequencyGet();
```

Returns

The current system timer ticks per second.

Description

This function provides the system tick resolution, the number of ticks per second

Remarks

None.

Preconditions

The SYS_TMR_Initialize function should have been called before calling this function.

Example

```
uint32_t tickFrequencyHz;

tickFrequencyHz = SYS_TMR_TickCounterFrequencyGet ( );
```

Function

uint32_t SYS_TMR_TickCounterFrequencyGet (void)

SYS_TMR_SystemCountGet Function

Provides the current system time count value.

File

sys_tmr.h

C

```
uint64_t SYS_TMR_SystemCountGet();
```

Returns

The current system count value.

Description

This function provides the current system time count value with the greatest possible resolution. It is the number of counts from the system start up as counted with the system count frequency (SYS_TMR_SystemCountFrequencyGet).

Remarks

None.

Preconditions

The SYS_TMR_Initialize function should have been called before calling this function.

Example

```
uint64_t sysCount;
sysCount = SYS_TMR_SystemCountGet ();
// the system has been running for sysCount/SYS_TMR_SystemCountFrequencyGet seconds
```

Function

uint64_t SYS_TMR_SystemCountGet(void)

SYS_TMR_SystemCountFrequencyGet Function

Provides the current system count frequency.

File

sys_tmr.h

C

```
uint32_t SYS_TMR_SystemCountFrequencyGet();
```

Returns

The current system frequency value in Hertz.

Description

This function provides the current system count frequency in Hz. The tick count measurement is based on this value. This is the resolution of the system time base.

Remarks

None.

Preconditions

The SYS_TMR_Initialize function should have been called before calling this function.

Example

```
uint32_t sysCountFreq;
sysCountFreq = SYS_TMR_SystemCountFrequencyGet ();
```

Function

uint32_t SYS_TMR_SystemCountFrequencyGet(void)

SYS_TMR_ModuleStatusGet Function

Returns status of the specific instance of the Timer module.

File

sys_tmr.h

C

```
SYS_STATUS SYS_TMR_ModuleStatusGet(const SYS_MODULE_INDEX index);
```

Returns

- SYS_STATUS_READY - Indicates that the service initialization is complete and the timer is ready to be used.
- SYS_STATUS_ERROR - Indicates that the timer service is in an error state

Description

This function returns the status of the specific module instance. It uses the index of the instance rather than an object handle.

Remarks

Any value less than SYS_STATUS_ERROR is also an error state.

- SYS_MODULE_UNINITIALIZED - Indicates that the timer service has been deinitialized

None.

Preconditions

The SYS_TMR_Initialize function should have been called before calling this function.

Example

```
SYS_STATUS tmrStatus = SYS_TMR_ModuleStatusGet (SYS_TMR_INDEX_0);

if ( SYS_STATUS_ERROR <= tmrStatus )
{
    // Handle error
}
```

Parameters

Parameters	Description
object	SYS TMR object handle, returned from SYS_TMR_Initialize

Function

SYS_STATUS SYS_TMR_ModuleStatusGet (const SYS_MODULE_INDEX index)

f) Data Types and Constants

SYS_TMR_CALLBACK Type

This data type defines a pointer callback function.

File

sys_tmr.h

C

```
typedef void (* SYS_TMR_CALLBACK)(uintptr_t context, uint32_t currTick);
```

Description

SYS TMR Callback Function

Defines a pointer to a client notification function that's called when a timer object times out.

Remarks

The client notification function should be kept as short as possible and non blocking. It is meant for some quick operation (like flag setting) and not for extensive operation. It can be called within interrupt context.

Parameters

Parameters	Description
context	A client parameter that's passed in the callback function. This will help to identify the callback.
currTick	The current system tick when the notification is called.

SYS_TMR_HANDLE Type

Identifies a client timer object.

File

sys_tmr.h

C

```
typedef uintptr_t SYS_TMR_HANDLE;
```

Description

SYS TMR Handle

This handle identifies a registered instance of a client timer object. Access to a timer object parameters and functionality has to use a valid client timer handle.

Remarks

None.

SYS_TMR_INIT Structure

Identifies the system timer initialize structure.

File

sys_tmr.h

C

```
typedef struct {
  SYS_MODULE_INIT moduleInit;
  SYS_MODULE_INDEX drvIndex;
  uint32_t tmrFreq;
} SYS_TMR_INIT;
```

Members

Members	Description
SYS_MODULE_INIT moduleInit;	System module initialization
SYS_MODULE_INDEX drvIndex;	Driver Module index
uint32_t tmrFreq;	System timer required frequency, Hz This is the base frequency for all time keeping

Description

SYS TMR Initialize structure

This structure identifies the system timer initialize structure.

Remarks

None.

SYS_TMR_HANDLE_INVALID Macro

Identifies the invalid handle of the system timer.

File

sys_tmr.h

C

```
#define SYS_TMR_HANDLE_INVALID ( ( uintptr_t ) -1 )
```

Description

SYS Timer invalid handle macro definition

This enumeration identifies the invalid handle of the system timer.

Remarks

None.

SYS_TMR_INDEX_0 Macro

Timer System Service index definitions.

File

sys_tmr.h

C

```
#define SYS_TMR_INDEX_0 0
```

Description

SYS Timer Module Index Numbers

These constants provide Timer System Service index definitions.

Remarks

These constants should be used in place of hard-coded numeric literals.

SYS_TMR_FLAGS Enumeration

Defines the types and flags supported by a client timer object.

File

sys_tmr.h

C

```
typedef enum {
  SYS_TMR_FLAG_PERIODIC = 0x0001,
  SYS_TMR_FLAG_SINGLE = 0x0000,
  SYS_TMR_FLAG_AUTO_DELETE = 0x1000
} SYS_TMR_FLAGS;
```

Members

Members	Description
SYS_TMR_FLAG_PERIODIC = 0x0001	the timer is of periodic type as the time-out is achieved the timer is reloaded so it will periodically provide notifications
SYS_TMR_FLAG_SINGLE = 0x0000	the timer is a single shot type it fires just once, when the time-out occurs
SYS_TMR_FLAG_AUTO_DELETE = 0x1000	as time-out occurs, the timer deletes itself only SINGLE and DELAY timer types support this feature

Description

SYS TMR Flags

This enumerated type describes the types and run time flags supported by a client timer object.

Remarks

Multiple flags can be ORed.

SYS_TMR_CLIENT_TOLERANCE Macro

Sets the accepted client tolerance in %.

File

sys_tmr_config_template.h

C

```
#define SYS_TMR_CLIENT_TOLERANCE (10)
```

Description

Client accepted Tolerance configuration

This macro sets the percentage of the accepted tolerance for the requested client delay. If the system timer cannot achieve a delay within the specified tolerance it will reject the client request.

Remarks

This error depends on the actual frequency that the system timer uses as a time base.

SYS_TMR_DRIVER_INDEX Macro

Sets the default timer driver object to be used by the system timer service.

File

sys_tmr_config_template.h

C

```
#define SYS_TMR_DRIVER_INDEX (DRV_TMR_INDEX_0)
```

Description

Default timer driver object configuration

This macro sets the default timer driver object to be used by the system timer service.

Remarks

This value can be overridden by a run time initialization value.

SYS_TMR_FREQUENCY Macro

Specifies the operating frequency for the system timer, Hz.

File

sys_tmr_config_template.h

C

```
#define SYS_TMR_FREQUENCY (1250)
```

Description

System timer running frequency

This macro sets the operating frequency for the system timer, in Hz. All the timing is maintained based on this frequency. This is actually the rate of the interrupt that's requested to the hardware timer that the system timer uses.

The higher the rate, the better time keeping but the operation of the CPU will be interrupted more frequently (if the underlying timer driver is working in interrupts) and the result will be a greater overhead. Therefore is is not recommended to go higher than 1 KHz (below 1 ms) when the timer driver works in interrupts.

Remarks

The system timer cannot obtain timing with a finer resolution than this frequency.

This value can be overridden by a run time initialization value.

The actual running frequency depends on the timer driver running frequency. Select a value that makes sense to minimize the error (see SYS_TMR_FREQUENCY_TOLERANCE notes).

SYS_TMR_FREQUENCY_TOLERANCE Macro

Sets the error tolerance in %.

File

sys_tmr_config_template.h

C

```
#define SYS_TMR_FREQUENCY_TOLERANCE (10)
```

Description

Error Tolerance configuration

This macro sets the accepted tolerance percentage for the requested system timer frequency (SYS_TMR_FREQUENCY).

Remarks

This error depends on the time base that the system timer uses (i.e. the underlying timer driver timing frequency). The actual running frequency for the system timer may be slighlty different from the requested SYS_TMR_FREQUENCY.

SYS_TMR_INTERRUPT_NOTIFICATION Macro

Activates the notification mechanism from within the timer interrupt.

File

sys_tmr_config_template.h

C

```
#define SYS_TMR_INTERRUPT_NOTIFICATION (false)
```

Description

Interrupt Notification Mode configuration

This macro enables/disables the notification towards the timer clients to be delivered directly from the underlying time base interrupt routine(the routine that notifies the system timer itself that another system tick has elapsed).

Enabling interrupt notifications provide a more accurate and responsive callback towards the clients. However the client callbacks need to be non blocking and as short as possible (the client callback are meant for setting a flag to indicate that further processing is needed and not to execute lengthy processing inside the callback itself).

- true - Client notification in interrupt enabled
- false - Client notification in interrupt disabled

Remarks

None.

SYS_TMR_MAX_CLIENT_OBJECTS Macro

Sets the maximum number of timer clients that can be active at a given time.

File

sys_tmr_config_template.h

C

```
#define SYS_TMR_MAX_CLIENT_OBJECTS (5)
```

Description

Maximum client timer objects configuration

This macro sets the maximum number of clients that the Timer system service can support.

Remarks

None.

SYS_TMR_MODULE_INIT Macro

Sets the default module init value by the system timer service.

File

sys_tmr_config_template.h

C

```
#define SYS_TMR_MODULE_INIT (SYS_MODULE_POWER_RUN_FULL)
```

Description

Default module init object configuration

This macro sets the default module init value by the system timer service.

Remarks

This value can be overridden by a run time initialization value.

SYS_TMR_UNIT_RESOLUTION Macro

Specifies the internal units for the time keeping.

File

sys_tmr_config_template.h

C

```
#define SYS_TMR_UNIT_RESOLUTION (10000)
```

Description

System timer internal units resolution

This macro sets the system timer internal time units, in Hz. The higher the value, the better resolution but the range of the delays that can be obtained is shortened.

A value too low will limit the resolution of delays that can be obtained. In order to be able to obtain milliseconds delays the value should be greater than 1000 Hz.

The internal timing calculation is done with integer arithmetic so in order to do a precise enough calculation for ms values, a finer time unit needs to be used.

Remarks

10000 Hz (meaning 0.1 ms units) is the recommended value because the delays than need to be achieved are in the ms range.

The service tries to achieve enough resolution for delays in the range of milliseconds. That means that this value cannot be < 1000 and the service will fail to initilize if such a value is attempted.

The setting affects the range of delays that can be obtained. delay < (2^32 -1)/SYS_TMR_RESOLUTION gives the maximum delay value, in seconds, that can be achieved For example: delay < 119.3 hours (for SYS_TMR_RESOLUTION == 10000).

Enumerations

	Name	Description
	SYS_TMR_FLAGS	Defines the types and flags supported by a client timer object.

Functions

	Name	Description
	SYS_TMR_CallbackPeriodic	Creates a permanent timer object that calls back to the client periodically.
	SYS_TMR_CallbackSingle	Creates a one-shot/single callback timer object.
	SYS_TMR_CallbackStop	Stops a periodic timer object.
	SYS_TMR_Deinitialize	Deinitializes the specific module instance of the TMR module
	SYS_TMR_DelayMS	Creates a timer object that times out after the specified delay.
	SYS_TMR_DelayStatusGet	Checks the status of the previously requested delay timer object.
	SYS_TMR_Initialize	Initializes hardware and data for the instance of the Timer module and opens the specific module instance.
	SYS_TMR_ModuleStatusGet	Returns status of the specific instance of the Timer module.
	SYS_TMR_ObjectCountGet	Returns the current millisecond count of a timer object.
	SYS_TMR_ObjectCreate	Creates a new timer object.
	SYS_TMR_ObjectDelete	Deletes an existent timer object.
	SYS_TMR_ObjectReload	Reloads an existing timer object.
	SYS_TMR_Status	Returns status of the specific instance of the Timer module.
	SYS_TMR_SystemCountFrequencyGet	Provides the current system count frequency.
	SYS_TMR_SystemCountGet	Provides the current system time count value.
	SYS_TMR_Tasks	Maintains the system timer's state machine and implements its ISR.
	SYS_TMR_TickCounterFrequencyGet	Provides the number of ticks per second
	SYS_TMR_TickCountGet	Provides the current counter value.
	SYS_TMR_TickCountGetLong	Provides the current counter value with 64-bit resolution.

Touch System Service Library

The Touch System Service is a thin layer specifically for abstracting input from various touch drivers. It is designed to interpret the data from the touch driver and translate it into single-touch behavior that can be used by other modules in the framework, such as the Graphics Library.

The Touch System Service supports both resistive touch driver (ADC10BIT) and capacitive touch drivers (MTCH6301 and MTCH36303).

Currently, the Touch System Service is only available to support non-gestural single finger touch screen input.

Introduction

This library provides a low-level abstraction of the Device Control System Service Library that is available on the Microchip family of PIC32 microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, there by hiding differences from one microcontroller variant to another.

Description

The Touch System Service is accessed via the Message System Service. For details on how to register to the Message System Service, please refer to its section.

Note: The MPLAB Harmony Graphics Composer is designed to automatically configure the Touch System Service and the Message System Service based on the user's request for touch screen input.

Using the Library

This topic describes the basic architecture of the Touch System Service Library and provides information and examples on its use.

Description

Interface Header File: `sys_touch.h`

The interface to the Touch System Service library is defined in the `sys_touch.h` header file.

Please refer to the What is MPLAB Harmony? section for how the Touch System Service interacts with the framework.

Library Overview

A client needs to register a callback to allow the Messaging System Service to send messages of type "TYPE_TOUCHSCREEN" to it. Since it is a dependency, the Messaging System Service is automatically enabled in the MPLAB Harmony Configurator configuration tree when the Touch System Service is enabled.

For detail with how to interface the Message System Service, please refer to the Messaging System Service Library section.

Configuring the Library

No configuration is required for the Touch System Service.

Building the Library

This section lists the files that are available in the Touch System Service Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/system/touch`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`sys_touch.h`	Touch System Service Library API header file.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/sys_touch.c`	Touch System Service Library implementation.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for the library.

Module Dependencies

The Touch System Service Library is not dependent upon other modules.

Library Interface

a) Functions

	Name	Description
	SYS_TOUCH_CalibrationSet	Sets the calibration values for Touch client specified by moduleIndex.
	SYS_TOUCH_Initialize	Initializes and Enables the Touch Controller.
	SYS_TOUCH_Open	Opens the touch service specified by the moduleIndex and returns a handle to it.
	SYS_TOUCH_TouchMsgGet	Populates the Graphics Object Library (GOL) message structure.
	SYS_TOUCH_Tasks	Maintains the system service's state machine.

b) Data Types and Constants

	Name	Description
	NVM_READ_FUNC	typedef for read function pointer
	NVM_SECTORERASE_FUNC	typedef for sector erase function pointer
	NVM_WRITE_FUNC	typedef for write function pointer
	SYS_TOUCH_HANDLE	Handle for requested Touch interface.
	SYS_TOUCH_INDEX	Identifies the Touch System Service module index definitions.
	SYS_TOUCH_INIT	Identifies the touch attributes supported
	SYS_TOUCH_STATUS	Identifies the current status/state of touch.
	SYS_TOUCH_HANDLE_INVALID	Invalid touch handle.
	TouchShowMessage	macro to draw repeating text
	SYS_INPUT_DEVICE_TYPE	Specifies the different user input devices supported in the library.
	SYS_INPUT_DEVICE_EVENT	Specifies the different user input device events supported in the library.
	_SYS_TOUCH_H	This is macro _SYS_TOUCH_H.

Description

This section describes the APIs of the Touch System Service Library.

a) Functions

SYS_TOUCH_CalibrationSet Function

Sets the calibration values for Touch client specified by moduleIndex.

File

sys_touch.h

C

```
void SYS_TOUCH_CalibrationSet(SYS_MODULE_INDEX moduleIndex, DRV_TOUCH_SAMPLE_POINTS * samplePoints);
```

Returns

none.

Description

This function sets the calibration values provided by samplePoints for the specified client.

Remarks

None.

Preconditions

Function SYS_TOUCH_Open must have been called before calling this function.

Example

```
SYS_MODULE_INDEX moduleIndex;
SYS_TOUCH_SAMPLE_POINTS samplePoints;
SYS_TOUCH_CalibrationSet( moduleIndex,  samplePoints);
```

Parameters

Parameters	Description
moduleIndex	Identifier for the touch to be opened
samplePoints	sample points

Function

void SYS_TOUCH_CalibrationSet(SYS_MODULE_INDEX moduleIndex,
DRV_TOUCH_SAMPLE_POINTS * samplePoints)

SYS_TOUCH_Initialize Function

Initializes and Enables the Touch Controller.

File

sys_touch.h

C

```
SYS_MODULE_OBJ SYS_TOUCH_Initialize(const SYS_MODULE_INDEX moduleIndex, const SYS_MODULE_INIT * const init);
```

Returns

If successful, returns a valid handle to the DMA module object. Otherwise, it returns SYS_MODULE_OBJ_INVALID.

Description

This function Enables the Touch module. Enable/Disable stop in idle mode feature based on the passed parameter value.

This routine initializes the Touch module making it ready for clients to open and use it. The initialization data is specified by the init parameter.

Remarks

This routine must be called before any other TOUCH systems service routines are called.

Not all features are available on all devices. Refer to the specific device data sheet to determine availability.

Preconditions

None.

Example

```
SYS_MODULE_OBJ objectHandle;
SYS_TOUCH_INIT touchInit;

objectHandle = SYS_TOUCH_Initialize(SYS_TOUCH_INDEX_1,
                                    (SYS_MODULE_INIT*)touchInit);
if (SYS_MODULE_OBJ_INVALID == objectHandle)
{
    // Handle error
}
```

Parameters

Parameters	Description
init	Pointer to the data structure containing any data necessary to initialize the hardware. This pointer may be null if no data is required and default initialization is to be used.

Function

SYS_MODULE_OBJ SYS_TOUCH_Initialize (const SYS_MODULE_INIT * const init)

SYS_TOUCH_Open Function

Opens the touch service specified by the moduleIndex and returns a handle to it.

File

sys_touch.h

C

```
SYS_TOUCH_HANDLE SYS_TOUCH_Open(SYS_MODULE_INDEX moduleIndex);
```

Returns

If successful, the routine returns a valid open-instance handle (a number identifying both the caller and the module instance).

If an error occurs, the return value is SYS_TOUCH_HANDLE_INVALID.

Description

This function opens the touch service specified by the index and provides a handle that must be provided to all other client-level operations to identify the caller.

Remarks

The handle returned is valid until the SYS_TOUCH_lose routine is called.

Preconditions

The SYS_TOUCH_Initialize function must have been called before calling this function.

Example

```
SYS_TOUCH_HANDLE handle;

handle = SYS_TOUCH_Open(SYS_TOUCH_INDEX_0);
if (SYS_TOUCH_HANDLE_INVALID == handle)
{
    // Unable to open the service
    // May be the service is not initialized or the initialization
    // is not complete.
}
```

Parameters

Parameters	Description
moduleIndex	Identifier for the touch to be opened

Function

SYS_TOUCH_HANDLE SYS_TOUCH_Open(SYS_MODULE_INDEX moduleIndex)

SYS_TOUCH_TouchMsgGet Function

Populates the Graphics Object Library (GOL) message structure.

File

sys_touch.h

C

```
void SYS_TOUCH_TouchMsgGet(SYS_MODULE_INDEX moduleIndex);
```

Returns

None.

Description

This function populates the GOL message structure.

Remarks

None.

Preconditions

None.

Function

void SYS_TOUCH_TouchMsgGet(SYS_MODULE_INDEX moduleIndex)

SYS_TOUCH_Tasks Function

Maintains the system service's state machine.

File

sys_touch.h

C

```
void SYS_TOUCH_Tasks(SYS_MODULE_OBJ object);
```

Returns

None.

Description

This function is used to maintain the Touch system service's internal state machine. This function is specifically designed for non interrupt trigger implementations(polling mode), and should be used only in polling mode. this function should be called from the SYS_Tasks() function.

Remarks

This function is normally not called directly by an application. It is called by the system's Tasks routine (SYS_Tasks).

Preconditions

Touch should have been initialized by calling SYS_Touch_Initialize.

Example

```
// 'object' Returned from SYS_Touch_Initialize

while (true)
{
    SYS_Touch_Tasks ((object) );

    // Do other tasks
}
```

Parameters

Parameters	Description
object	Object handle for the Touch module (returned from SYS_Touch_Initialize)

Function

void SYS_Touch_Tasks(SYS_MODULE_OBJ object);

b) Data Types and Constants

NVM_READ_FUNC Type

File

sys_touch.h

C

```
typedef uint16_t (* NVM_READ_FUNC)(uint32_t);
```

Description

typedef for read function pointer

NVM_SECTORERASE_FUNC Type

File

sys_touch.h

C

```
typedef void (* NVM_SECTORERASE_FUNC)(uint32_t);
```

Description

typedef for sector erase function pointer

NVM_WRITE_FUNC Type

File

sys_touch.h

C

```
typedef void (* NVM_WRITE_FUNC)(uint16_t, uint32_t);
```

Description

typedef for write function pointer

SYS_TOUCH_HANDLE Type

Handle for requested Touch interface.

File

sys_touch.h

C

```
typedef uintptr_t SYS_TOUCH_HANDLE;
```

Description

Touch System Service handle

A Touch handle is returned by a call to the SYS_TOUCH_Open function. This handle is an identification for the associated touch interface.

The handle once assigned to a client expires when the client calls SYS_TOUCH_Close.

Remarks

None.

SYS_TOUCH_INDEX Enumeration

Identifies the Touch System Service module index definitions.

File

sys_touch.h

C

```
typedef enum {
  SYS_TOUCH_INDEX_0,
  SYS_TOUCH_INDEX_1
} SYS_TOUCH_INDEX;
```

Members

Members	Description
SYS_TOUCH_INDEX_0	First Touch service instance
SYS_TOUCH_INDEX_1	Second Touch service

Description

SYS TOUCH Module Index Numbers

These constants provide the Touch System Service index definitions.

Remarks

These constants should be used in place of hard-coded numeric literals.

These values should be passed into the SYS_TOUCH_Initialize and function to identify the driver instance in use.

SYS_TOUCH_INIT Structure

Identifies the touch attributes supported

File

sys_touch.h

C

```
typedef struct {
  SYS_MODULE_INDEX driverModuleIndex;
} SYS_TOUCH_INIT;
```

Members

Members	Description
SYS_MODULE_INDEX driverModuleIndex;	The Module index of the driver to which touch is attached.

Description

Touch System Service Initialization

This data type defines the touch id and relate with the driver that should be used to initialize touch system.

These functions help to align touch with hardware touch driver specific driver function calls.

Remarks

None.

SYS_TOUCH_STATUS Enumeration

Identifies the current status/state of touch.

File

sys_touch.h

C

```
typedef enum {
  SYS_TOUCH_ERROR = -1,
  SYS_TOUCH_UNINITIALIZED = 0,
  SYS_TOUCH_BUSY = 1,
  SYS_TOUCH_READY = 2
} SYS_TOUCH_STATUS;
```

Members

Members	Description
SYS_TOUCH_ERROR = -1	An unspecified error has occurred.
SYS_TOUCH_UNINITIALIZED = 0	The module has not yet been initialized
SYS_TOUCH_BUSY = 1	An operation is currently in progress
SYS_TOUCH_READY = 2	Any previous operations have succeeded and the service is ready for additional operations

Description

Touch System Service status

Identifies the current status/state of touch.

Remarks

This enumeration is the return type for the status routine.

SYS_TOUCH_HANDLE_INVALID Macro

Invalid touch handle.

File

sys_touch.h

C

```
#define SYS_TOUCH_HANDLE_INVALID (((SYS_TOUCH_HANDLE) -1))
```

Description

Invalid Touch Handle

If the touch system service is unable to allow an additional clients to use it, it must then return the special value SYS_TOUCH_HANDLE_INVALID. Callers should check the handle returned for this value to ensure this value was not returned before attempting to call any other driver routines using the handle.

Remarks

None.

TouchShowMessage Macro

File

sys_touch.h

C

```
#define TouchShowMessage( pStr, color, x, y, width, height) \
                {                                           \
                    GFX_ColorSet(gfxIndex, color);                    \
                    while(GFX_TextStringBoxDraw(gfxIndex, x,y,width,height,pStr, 0, GFX_ALIGN_LEFT) ==
GFX_STATUS_FAILURE);        \
                }
```

Description

macro to draw repeating text

SYS_INPUT_DEVICE_TYPE Enumeration

Specifies the different user input devices supported in the library.

File

sys_touch.h

C

```
typedef enum {
  TYPE_UNKNOWN = 0,
  TYPE_KEYBOARD,
  TYPE_TOUCHSCREEN
} SYS_INPUT_DEVICE_TYPE;
```

Members

Members	Description
TYPE_UNKNOWN = 0	Unknown device.
TYPE_KEYBOARD	Keyboard.
TYPE_TOUCHSCREEN	Touchscreen.

Description

Input Device Type: SYS_INPUT_DEVICE_TYPE

This enumeration specifies the different user input devices supported in the library.

Remarks

Beta. The enum will be relocated to SYS_INPUT when available.

SYS_INPUT_DEVICE_EVENT Enumeration

Specifies the different user input device events supported in the library.

File

sys_touch.h

C

```
typedef enum {
  EVENT_INVALID = 0,
  EVENT_MOVE,
  EVENT_PRESS,
  EVENT_STILLPRESS,
```

```
    EVENT_RELEASE,
    EVENT_KEYSCAN,
    EVENT_CHARCODE,
    EVENT_SET,
    EVENT_SET_STATE,
    EVENT_CLR_STATE
} SYS_INPUT_DEVICE_EVENT;
```

Members

Members	Description
EVENT_INVALID = 0	Invalid event.
EVENT_MOVE	Move event.
EVENT_PRESS	Press event.
EVENT_STILLPRESS	Continuous press event.
EVENT_RELEASE	Release event.
EVENT_KEYSCAN	Key scan event, parameters for the object ID and keyboard scan code will be sent with this event in the GFX_GOL_MESSAGE as parameter.
EVENT_CHARCODE	Character code event. The actual character code will be sent with this event in the GFX_GOL_MESSAGE as parameter.
EVENT_SET	Generic set event.
EVENT_SET_STATE	Generic set state event.
EVENT_CLR_STATE	Generic clear state event.

Description

Input device event: INPUT_DEVICE_EVENT

This enumeration specifies the different user input device events supported in the graphics library.

Remarks

None.

_SYS_TOUCH_H Macro

File

sys_touch.h

C

```
#define _SYS_TOUCH_H
```

Description

This is macro _SYS_TOUCH_H.

Files

Files

Name	Description
sys_touch.h	Touch System Service Implementation.

Description

This section lists the source and header files used by the library.

sys_touch.h

Touch System Service Implementation.

Enumerations

	Name	Description
	SYS_INPUT_DEVICE_EVENT	Specifies the different user input device events supported in the library.
	SYS_INPUT_DEVICE_TYPE	Specifies the different user input devices supported in the library.
	SYS_TOUCH_INDEX	Identifies the Touch System Service module index definitions.

	SYS_TOUCH_STATUS	Identifies the current status/state of touch.

Functions

	Name	Description
	SYS_TOUCH_CalibrationSet	Sets the calibration values for Touch client specified by moduleIndex.
	SYS_TOUCH_Initialize	Initializes and Enables the Touch Controller.
	SYS_TOUCH_Open	Opens the touch service specified by the moduleIndex and returns a handle to it.
	SYS_TOUCH_Tasks	Maintains the system service's state machine.
	SYS_TOUCH_TouchMsgGet	Populates the Graphics Object Library (GOL) message structure.

Macros

	Name	Description
	_SYS_TOUCH_H	This is macro _SYS_TOUCH_H.
	SYS_TOUCH_HANDLE_INVALID	Invalid touch handle.
	TouchShowMessage	macro to draw repeating text

Structures

	Name	Description
	SYS_TOUCH_INIT	Identifies the touch attributes supported

Types

	Name	Description
	NVM_READ_FUNC	typedef for read function pointer
	NVM_SECTORERASE_FUNC	typedef for sector erase function pointer
	NVM_WRITE_FUNC	typedef for write function pointer
	SYS_TOUCH_HANDLE	Handle for requested Touch interface.

Description

Touch System Service Implementation

The Touch System Service provides a simple interface to manage the touch screen drivers. This file implements the core interface routines for the Touch System Service. This is a resistive touch screen driver that is using the Microchip Graphics Library. The calibration values are automatically checked (by reading a specific memory location on the non-volatile memory) when initializing the module if the function pointers to the read and write callback functions are initialized. If the read value is invalid calibration will automatically be executed. Otherwise, the calibration values will be loaded and used. The driver assumes that the application side provides the read and write routines to a non-volatile memory. If the callback functions are not initialized, the calibration routine will always be called at startup to initialize the global calibration values. This driver assumes that the Graphics Library is initialized and will be using the default font of the library.

Watchdog Timer System Service Library

This section describes the Watchdog Timer (WDT) System Service Library.

Introduction

This library provides a low-level abstraction of the Watchdog Timer System Service Library that is available on the Microchip family of microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, there by abstracting differences from one microcontroller variant to another.

Description

The primary function of the Watchdog Timer (WDT) is to reset the microcontroller, in the event of a software malfunction, by resetting the device if it has not been cleared by software. To ensure that application does not hang, the application is required to reset the timer periodically. It can also be used to wake the device from Sleep or Idle mode. The WDT is a free-running timer which uses the low-power RC oscillator and requires no external components. Therefore, the WDT will continue to operate even if the system’s primary clock source is stopped.

Using the Library

This topic describes the basic architecture of the Watchdog Timer System Service Library and provides information and examples on its use.

Description

Interface Header File: `sys_wdt.h`

The interface to the Watchdog Timer System Service library is defined in the `sys_wdt.h` header file. This file is included by the `sys.h` file. Any C language source (`.c`) file that uses the Watchdog Timer System Service library should include `sys.h`.

Please refer to the What is MPLAB Harmony? section for how the System Service interacts with the framework.

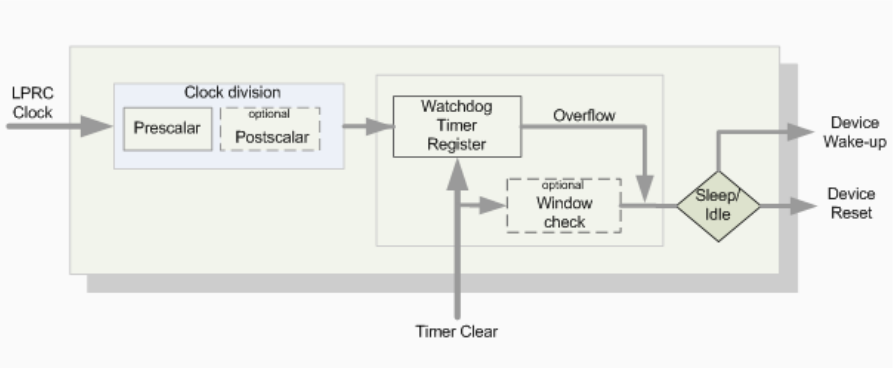
Abstraction Model

This library provides a low-level abstraction of the Watchdog Timer System Service Library. This topic describes how that abstraction is modeled in software and introduces the library's interface.

Description

The Watchdog Timer uses the internal Low-Power RC (LPRC) Oscillator as the source of clock. The clock is divided by the configured prescaler value. There may be one more postscaler divisors and these should be set through the Configuration bits. The divided clock is then used to increment a counter. If the software does not clear the counter in time, the counter overflows and that will result in reset in normal mode. In Sleep or Idle mode, the overflow will result in a device wake-up. In Windowed mode, resetting the counter when the count is not in the specified window will also lead to a reset.

Watchdog Timer Software Abstraction Block Diagram



Library Overview

Refer to the System Service Introduction section for how the system services operates in a system.

The library interface routines are divided into various sub-sections, which address one of the blocks of the overall operation of the Watchdog Timer module.

Library Interface Section	Description
Enable and Disable Functions	APIs to enable and disable the Watchdog Timer
Clearing the Timer Functions	API to clear the Watchdog Timer

How the Library Works

Provides information on how the library works.

Description

Watchdog Timer Initialization:

For devices that have Windowed mode, use the argument to control the mode. The argument will be discarded for devices that do not have Windowed mode.

```
//Enable the Watchdog Timer with Window mode enabled
SYS_WDT_Enable(true);

//Enable the Watchdog Timer with Window mode disabled
SYS_WDT_Enable(false);
```

```
//Some code
SYS_WDT_Disable();
```

Note: The previous code example will not work if the Watchdog Timer is controlled through the Configuration bits.

Service the Watchdog Timer:

To ensure the normal operation of the system, the software must periodically clear the Watchdog Timer.
`SYS_WDT_TimerClear();`

Note: Not all modes are available on all devices. Please refer to the specific device data sheet to determine the supported modes.

Configuring the Library

Macros

	Name	Description
	WDT_PLIB_ID	Configures the module's ID used by the peripheral library.

Description

The configuration of the Watchdog Timer System Service is based on the file `system_config.h`.

This header file contains the configuration selection for the Watchdog Timer System Service. Based on the selections made, the Watchdog Timer System Service may support the selected features. These configuration settings will apply to all instances of the Watchdog Timer System Service.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

WDT_PLIB_ID Macro

Configures the module's ID used by the peripheral library.

File

sys_wdt_config.h

C

```
#define WDT_PLIB_ID WDT_ID_1
```

Description

Watchdog timer module ID used by the Peripheral Library

This macro configures the module's ID used by the peripheral library.

Remarks

None.

Building the Library

This section lists the files that are available in the Watchdog Timer System Service Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/system/wdt`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`sys_wdt.h`	Watchdog Timer System Service Library API header file.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/sys_wdt.c	Watchdog Timer System Service Library implementation.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The Watchdog Timer System Service is not dependent upon other modules.

Library Interface

a) Enable and Disable Functions

	Name	Description
	SYS_WDT_Disable	Disables the WDT if it is enabled in software.
	SYS_WDT_Enable	Enables the WDT. The argument 'windowModeEnable' will be used only for those devices that support 'window mode'. Otherwise, it will be discarded.

b) Clearing the Timer Functions

	Name	Description
	SYS_WDT_TimerClear	Reset the WDT.

Description

This section describes the Application Programming Interface (API) functions of the Watchdog Timer System Service.

Refer to each section for a detailed description.

a) Enable and Disable Functions

SYS_WDT_Disable Function

Disables the WDT if it is enabled in software.

File

sys_wdt.h

C

```
void SYS_WDT_Disable();
```

Returns

None.

Description

This function disables the WDT if it is enabled in software. If the WDT is enabled through 'configuration bits' it cannot be disabled using this function.

Remarks

The example code doesn't include the settings that should be done through configuration bits.

Preconditions

The WDT should be disabled through 'configuration bits'.

Example

```
SYS_WDT_Disable();
```

Function

void SYS_WDT_Disable (void)

SYS_WDT_Enable Function

Enables the WDT. The argument 'windowModeEnable' will be used only for those devices that support 'window mode'. Otherwise, it will be discarded.

File

sys_wdt.h

C

```
void SYS_WDT_Enable(bool windowModeEnable);
```

Returns

None.

Description

This function enables the WDT. The argument 'windowModeEnable' will be used only for those devices that support 'window mode'. Otherwise, the argument will be discarded. This function could be called multiple times to enable/disable the 'window mode'.

Remarks

Calling this function is not necessary if the WDT is enabled through Configuration bits.

Preconditions

None.

Example

```
bool windowModeEnable = true;

SYS_WDT_Enable(windowModeEnable);
```

Parameters

Parameters	Description
windowModeEnable	A flag indicates whether to enable/disable the 'window mode'. • true - Enable the 'window mode' • false - Disable the 'window mode'

Function

void SYS_WDT_Enable (bool windowModeEnable)

b) Clearing the Timer Functions

SYS_WDT_TimerClear Function

Reset the WDT.

File

sys_wdt.h

C

```
void SYS_WDT_TimerClear();
```

Returns

None.

Description

This function clears the WDT counter. The WDT should be cleared periodically before the count overflows and forces the device to Reset.

Remarks

Clearing the WDT before the count reaches the window, will cause a reset in Windowed mode.

The example code doesn't include the settings that should be done through Configuration bits.

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is supported.

Preconditions

None.

Example

```
//Application loop
while(1)
{
    SYS_WDT_TimerClear();
    //user code
}
```

Function

void SYS_WDT_TimerClear (void)

TCP/IP Stack Libraries Help

This section provides information on the TCP/IP Stack Library and its modules that are available in MPLAB Harmony.

TCP/IP Stack Library Overview

This section provides an overview of the TCP/IP Stack libraries that are available in MPLAB Harmony.

Introduction

This topic provides an overview of the TCP/IP Stack in MPLAB Harmony.

Description

The MPLAB Harmony TCP/IP Stack provides a foundation for embedded network applications by handling most of the interaction required between the physical network port and your application. It includes modules for several commonly used application layers, including HTTP for serving web pages, SMTP for sending e-mails, SNMP for providing status and control, Telnet, TFTP, Serial-to-Ethernet, and much more. In addition, the stack includes light-weight and high-performance implementations of the TCP and UDP transport layers, as well as other supporting modules such as IP, ICMP, DHCP, ARP, and DNS.

Network Metrics

This topic provides TCP/IP network metrics information for PIC32MX and PIC32MZ devices.

Description

Network Metrics for the PIC32MX

Test Setup:

- PIC32 MZ Embedded Connectivity Starter Kit
- PIC32 MX Ethernet Starter Kit II
- Starter Kit I/O Expansion Board
- Fast 100 Mbps Ethernet PICtail Plus
- Windows 7 PC
- TX buffer: 7350 bytes
- RX buffer: 4400 bytes

Iperf Bandwidth Measurements

All bandwidth numbers are in kilobits per second.

Table 1: Internal MAC Measurements for PIC32MX Devices

Type	-O0	-O1	-O2	-O3	-Os
TCP Client	25,963	47,652	53,650	56,682	50,191
TCP Server	29,046	45,193	50,484	52,603	45,659
UDP Client	33,795	60,997	71,105	72,049	63,298
UDP Server	36,451	78,546	86,994	88,757	80,948

UDP Server	7,849	9,651	10,358	10,371	9,722

Table 4: Internal MAC Measurements for PIC32MX + MIPS16 Devices

Type	-O0	-O1	-O2	-O3	-Os
TCP Client	19,748	29,707	32,488	33,920	30,206
TCP Server	17,369	23,294	25,945	28,018	23,421
UDP Client	23,901	34,285	38,598	51,959	36,252
UDP Server	27,720	37,914	39,186	60,143	37,401

Table 5: ENCx24J600 MAC Measurements for PIC32MX + MIPS16 Devices

Type	-O0	-O1	-O2	-O3
TCP Client	5,480	6,232	6,985	6,345
TCP Server	4,984	6,262	6,454	6,644
UDP Client	6,370	7,727	8,069	8,586
UDP Server	7,109	8,471	8,702	9,289

Commands

The following commands were used to generate the network performance numbers as measured with Iperf:

UDP/IP Client:

PIC32 Board	Personal Computer
`iperf -c <PC IP Address> -u -b 100M -i 5 -t 20`	`iperf -s -u -i 5`

UDP/IP Server:

PIC32 Board	Personal Computer
`iperf -s -u -i 5`	`iperf -c mchpboard_e -u -b 100M -i 5 -t 20`

TCP/IP Client:

PIC32 Board	Personal Computer
`iperf -c <PC IP Address> -t 10 -i 5 -l 1024 -x 100M -M 1460`	`iperf -s -i 5 -m -w 10K –N`

TCP/IP Server:

PIC32 Board	Personal Computer
`iperf -s -i 5 -x 100M`	`iperf -c mchpboard_e -t 10 -i 5 -l 1024`

Flash and RAM Usage

Provides information on Flash and RAM usage by device family.

Description

Flash and RAM Usage

Table 1 and Table 2 provide Flash and RAM usage for PIC32MX and PIC32MZ devices, respectively.

Table 1: PIC32MX Device Flash and Ram Usage

Optimization	0	0	1	1	2	2	3	3	s	s

Note: wolfSSL is built with the following features:

- SSL 3.0, TLS 1.0, TLS 1.1, TLS 1.2
- Ciphers: AES, ARC4, DES, DH, DSA, HMAC, rabbit, RSA
- Hashes: md4, md5, sha, sha256

Getting Help

This topic provides information for requesting support assistance with the TCP/IP Stack.

Description

The TCP/IP Stack is supported through Microchip's standard support channels. If you encounter difficulties, you may submit ticket requests at http://support.microchip.com.

The Microchip forums are also an excellent source of information, with a very lively community dedicated specifically to Ethernet and TCP/IP discussions at http://forum.microchip.com.

Microchip also offers embedded network classes through Regional Training Centers. For more information, visit http://techtrain.microchip.com/rtcv2/.

Building the Library

This section lists the files that are available in the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	File that includes all of the TCP/IP modules.

Required File(s)

MHC ***All of the required files listed in the following table are automatically loaded into the MPLAB X IDE project by the MHC.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/common/big_int.c`	Library for integers greater than 32 bits.
`/src/common/hashes.c`	Utility file for MD5 and SHA-1 hash generation.
`/src/common/helpers.c`	Helper functions for string manipulation and binary to string.
`/src/common/lfsr.c`	Simple Linear Feedback Shift Register implementation.
`/src/hash_fnv.c`	FNV Hash routines

/src/ohash.c	Hash Table manipulation routines.
/src/tcpip_heap_alloc.c	Memory heap management for the TCP/IP Stack Library.
/src/tcpip_helpers.c	Network string helper functions (i.e., IP address string to IP).
/src/tcpip_managers.c	Central manager for TCP/IP Stack Library.
/src/tcpip_notify.c	Functions to handle the notification heap.
/src/tcpip_packet.c	Functions for managing the preallocated packet memory.
/src/system/system_debug.c	Temporary implementation of the system debug server.
/src/system/drivers/db_appio.c	Temporary driver implementation for application debug input/output.
/src/system/drivers/usart.c	Temporary driver implementation for the UART.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
/src/system/system_commands.c	Temporary implementation of the debug command processor.

Module Dependencies

The TCP/IP Stack Library depends on the following modules:

- Ethernet MAC Driver Library (if using the Ethernet interface)
- Ethernet PHY Driver Library (if using the Ethernet interface)
- MRF24WG Wi-Fi Driver Library (if using the Wi-Fi interface)
- SPI Driver Library (if using the Wi-Fi interface)
- Operating System Abstraction Layer (OSAL) Library Help
- Clock System Service Library
- System Service Library
- Console System Service Library
- File System Service Library
- Interrupt System Service Library
- Timer System Service Library
- Random Number Generator System Service Library
- Debug System Service Library

TCP/IP Stack Library Porting Guide

This section provides porting information for the TCP/IP Stack libraries.

Introduction

This section provides information for porting from a previous version of the TCP/IP Stack to the TCP/IP Stack within MPLAB Harmony.

Upgrading from the V5 TCP/IP Stack to the MPLAB Harmony TCP/IP Stack

The MPLAB Harmony TCP/IP Stack is a completely new distribution, which is included as part of the MPLAB Harmony installation. No files need to be maintained from an existing V5 TCP/IP Stack installation.

MPLAB Harmony TCP/IP Stack Key Features

This topic provides a description of some of the key features of the MPLAB Harmony TCP/IP Stack that are not available in the V5 version of the stack.

Description

Note: The PIC18 device family is not supported by the MPLAB Harmony TCP/IP Stack.

The following are the key features of the MPLAB Harmony TCP/IP Stack:

- Multiple interfaces - Ethernet and/or Wi-Fi interfaces are supported

- Dual stack with IPv4 and/or IPv6 support:
- UDP and TCP sockets are capable of supporting either/or IPv4/IPv6 connections
- Fully dynamic:
- Stack initialization/deinitialization
- Up/down interface
- Resource management
- Module configuration
- Improved modularity and stack layout:
- The stack uses the drivers and services provided by the MPLAB Harmony framework (e.g., the SPI driver for the Wi-Fi interface). This improvement offers better isolation, modularity, and maintainability of the stack.
- Run-time configuration through the TCP/IP console:
- The stack uses the System Console and Debug system services
- Interrupt driven operation
- RTOS friendly, with easy RTOS integration:
- OSAL calls are added in all stack modules for multi-threading support
- The BSD layer compatibility has been greatly improved, new dynamic socket options have been added as well as IPv6 support.
- Run time benchmarking support using standard industry tools - Iperf
- The MPLAB Harmony file system (SYS FS) is used by the HTTP, FTP, SNMP, modules, among others. This makes the stack independent of the specific file structure of a particular media and allows web page storage on a multitude of storage media.
- The stack uses the high performance MPLAB Harmony Cryptographic Library, which is a very efficient and modern implementation supporting the latest encryption and key exchanges algorithms
- The stack security has been greatly improved by adding support of the modern wolfSSL TLS libraries

All of these features bring flexibility and many new options that were not present in the previous V5 MLA TCP/IP implementation.

Please note that a direct comparison of the code size between demo applications using the V5 and the MPLAB Harmony TCP/IP stack can be misleading because of the multitude of the extra options, features, and services that are included as part of a standard Harmony distribution. Many of the features can be disabled from the build of the stack and the comparison of the results will be more realistic.

MPLAB Harmony TCP/IP Stack Structure

This topic describes the structure of the MPLAB Harmony TCP/IP Stack.

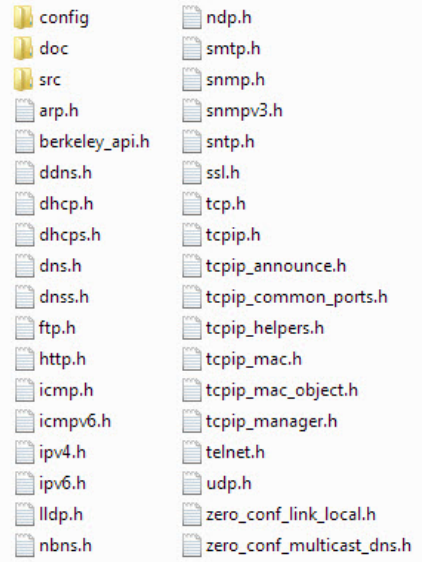
Description

The MPLAB Harmony TCP/IP Stack consists of the following structure:

- Lowercase file names
- Underscores are used (e.g., `tcpip_manager.h`)
- Private headers are no longer exposed and have been moved to the source folder
- System services have been removed from the stack, such as:
- Interrupts
- Drivers
- Timer services
- File system
- Board Support Package (BSP)

By default, the TCP/IP Stack is placed into the following location during installation of MPLAB Harmony on a Windows® system: `C:\Microchip\harmony\<version>\framework\tcpip`.

The following figure shows the list of files in the `tcpip` folder.



MPLAB Harmony TCP/IP Stack Design

This topic discusses the design of the MPLAB Harmony TCP/IP Stack.

Description

The MPLAB Harmony TCP/IP Stack is designed as a part of a system running other applications, middleware, etc. Therefore, it makes use of the system services that are available to other modules in the system or to the application, such as:

- File system
- System interrupts
- System driver services
- System timers
- System device drivers
- System command processor
- System console
- System debug services

Refer to the `./framework/tcpip/src/system` folder for the header files that expose the system wide available API.

MPLAB Harmony TCP/IP Stack API Changes

This topic discusses the reasons behind the API changes to the MPLAB Harmony TCP/IP Stack.

Description

For most modules, the API should be backward compatible to the V5 TCP/IP Stack.

The changes in the stack API have been minimized so that the porting process is straightforward. However, new functionality has been added because of new features, such as IPv6 support, multiple network interfaces, and the dynamic configuration of the stack. Other than these new features, the changes to the API were only made when an existing V5 TCP/IP Stack function did not support the required parameters/flexibility, or they were confusing.

The API changes are at the TCP, UDP, ARP, HTTP, SMTP, and stack access and initialization level.

TCP Changes

This topic discusses the changes made to the `tcp.h` file.

Description

TCP Changes

The TCP/IP Stack include header file, `tcp.h`, has been updated as follows.

- *DNS Resolution* - DNS resolution is no longer performed automatically when opening a TCP socket. The TCP layer takes only an IP address as an input parameter. If you need a DNS resolution, you have to perform it before opening a socket (see `dns.h`).
- *IPv6 Support* - Support for IPv6 has been added

Opening TCP Sockets

To open TCP sockets, the required functions are now:

```
TCP_SOCKET TCPIP_TCP_ServerOpen(IP_ADDRESS_TYPE addType, TCP_PORT localPort, IP_MULTI_ADDRESS* localAddress)
```

and

```
TCP_SOCKET TCPIP_TCP_ClientOpen(IP_ADDRESS_TYPE addType, TCP_PORT remotePort, IP_MULTI_ADDRESS*
remoteAddress)
```

These two new functions replace the V5 TCP/IP Stack TCPOpen function. The application code must replace the calls to TCPOpen with TCP_SOCKET TCPIP_TCP_ServerOpen or TCP_SOCKET TCPIP_TCP_ClientOpen, as appropriate.

The new calls add the possibility to use IPV6 addresses and make clear the choice of parameters for server or client sockets. The parameters are:

typedef union

```
{
IPV4_ADDR v4Add;
IPV6_ADDR v6Add;
}IP_MULTI_ADDRESS;
```

typedef enum

```
{
IP_ADDRESS_TYPE_ANY = 0, // either IPv4 or IPv6; unspecified;
IP_ADDRESS_TYPE_IPV4 = 1, // IPv4 address type
IP_ADDRESS_TYPE_IPV6 // IPv6 address type
}IP_ADDRESS_TYPE;
```

Note: Currently, `IP_ADDRESS_TYPE_ANY` is only supported for server sockets.

Disconnecting a Socket

The functions to disconnect a socket have changed to include added functionality:

```
TCPIP_TCP_Disconnect(TCP_SOCKET hTCP)
```

This function closes the TX side of a connection by sending a FIN (if currently connected) to the remote node of the connection. It no longer sends a RST signal to the remote node so that a sequence of two sequential calls to the function is no longer needed.

If the socket has the Linger option set (default), the queued TX data transmission will be attempted before sending the FIN. If the Linger option is off, the queued TX data will be discarded.

No more data can be sent by this socket, but more data can be received (the socket will be eventually closed when a FIN is received from the remote node or by a time-out dictated by the TCP_FIN_WAIT_2_TIMEOUT value in `tcp_config.h`).

Please note that this call may fail in which case it can be reissued.

Setting the socket options is done using the function TCPIP_TCP_OptionsSet.

```
TCPIP_TCP_Abort(TCP_SOCKET hTCP, bool killSocket)
```

This function aborts a connection to a remote node by sending a RST (if currently connected). Any pending TX/RX data is discarded.

A client socket will always be closed and the associated resources released. The socket cannot be used again after this call.

A server socket will abort the current connection if:

- `killSocket == false` (the socket will remain listening)
- `killSocket == true` (the socket will be closed and all associated resources released. The socket cannot be used again after this call.)

```
TCPIP_TCP_Close(TCP_SOCKET hTCP)
```

This function disconnects an open socket and destroys the socket handle, releasing the associated resources.

If the graceful option is set for the socket (default) a `TCPIP_TCP_Disconnect` will be tried (FIN will be sent):

- If the linger option is set (default) the `TCPIP_TCP_Disconnect` will attempt to send any queued TX data before issuing the FIN
- If the FIN send operation fails or the socket is not connected, an abort is generated
- If the graceful option is not set, or the previous step could not send the FIN:
- A TCPIP_TCP_Abort(is called, sending a RST to the remote node and communication is closed. The socket is no longer valid and the associated resources are freed.

Setting the socket options is done using the call TCPIP_TCP_OptionsSet();.

Adjusting Socket Size

The function to adjust the size of a socket's RX and TX buffers has changed to include added functionality:

```
TCPIP_TCP_FifoSizeAdjust(TCP_SOCKET hTCP, uint16_t wMinRXSize, uint16_t wMinTXSize, TCP_ADJUST_FLAGS vFlags)
```

The TX and RX FIFOs (buffers) associated with a socket are now completely separate and independent.

Two new flags, TCP_ADJUST_TX_ONLY and TCP_ADJUST_RX_ONLY, have been added, which allow changing the size of TX and RX buffers independently. This is the preferred option.

However, when either flag is not set, for the purpose of this function, the TX and RX FIFOs are considered to be contiguous so that the total FIFO space is divided between the TX and RX FIFOs. This provides backward compatibility with previous versions of this function.

Note: The TX or RX associated buffer sizes can be independently changed too using the socket options. See the `TCPIP_TCP_OptionsSet` function for more information.

UDP Changes

This topic discusses the changes made to the udp.h file.

Description

UDP Changes

The TCP/IP Stack include header file, udp.h, has been updated as follows.

- *DNS Resolution* - DNS resolution is no longer performed automatically when opening a UDP socket. The UDP layer takes only an IP address as an input parameter. If you need a DNS resolution, you have to perform it before opening a socket (see dns.h).
- *IPv6 Support* - Support for IPv6 has been added

Opening UDP Sockets

To open UDP sockets, the required functions are now:

```
UDP_SOCKET TCPIP_UDP_ServerOpen(IP_ADDRESS_TYPE addType, UDP_PORT localPort, IP_MULTI_ADDRESS*
localAddress);
```

and

```
UDP_SOCKET TCPIP_UDP_ClientOpen(IP_ADDRESS_TYPE addType, UDP_PORT remotePort, IP_MULTI_ADDRESS*
remoteAddress);
```

These two new functions replace the V5 TCP/IP Stack UDPOpen function.

The application code must replace any calls to UDPOpen with UDP_SOCKET TCPIP_UDP_ServerOpen or UDP_SOCKET TCPIP_UDP_ClientOpen, as appropriate.

Note: Currently, IP_ADDRESS_TYPE_ANY is only supported for server sockets.

ARP Changes

This topic discusses the changes made to the arp.h file.

Description

ARP Changes

The header file, arp.h, has been updated as follows.

The ARP module has been redesigned to support multiple network interfaces and to implement internal storage (caches) per interface for eliminating the need for frequent access to the network.

Some of the most important changes include:

- Manipulation/control of the cache entries (TCPIP_ARP_EntryGet, TCPIP_ARP_EntrySet, TCPIP_ARP_EntryRemove) with permanent entries support
- Dynamic notification mechanism (TCPIP_ARP_HandlerRegister, TCPIP_ARP_HandlerDeRegister) for signaling of the ARP events
- Resolution calls (TCPIP_ARP_Resolve, TCPIP_ARP_Probe, TCPIP_ARP_IsResolved)

Normally, the application does not need access to the ARP module. The address resolution is performed internally by the stack.

The ARP module cache manipulation access is meant for TCP/IP Stack control and configuration depending on the actual network topology.

Berkeley Changes

This topic discusses the changes made to the Berkeley API file.

Description

The Berkeley API include file has been renamed to berkeley_api.h (formerly BerkeleyAPI.h). The following changes are included:

- IPv6 Support – Support for IPv6 has been added
- setsockopt, getsockopt, gethostbyname have been added

API functionality has changed in the following ways to bring the MPLAB Harmony implementation to be more in line with industry standard Berkeley Socket API specification.

- *errno* – APIs now report specific error codes through a global variable: errno. This variable is only valid between calls to the Berkeley API, and is currently not tread safe, there is on errno variable shared across all threads.
- *bind* – bind now supports binding to a specific IP address. If an invalid address is specified the function will now return an error and set errno accordingly
- *accept* – accept no longer returns INVALID_SOCKET on error but SOCKET_ERROR and errno is set to the specific error.
- *connect* - connect no longer returns INVALID_SOCKET on error but SOCKET_ERROR and errno is set to the specific error. In addition, connect does not return SOCKET_CNXN_IN_PROGRESS; instead, SOCKET_ERROR is returned and errno is set to EINPROGRESS. Finally,

connect now supports setting a specific local IP address; if the IP address is invalid, the SOCKET_ERROR is returned and errno is set with the error.

- *sendto* – sendto now supports sending from a specific IP address. If an invalid address is specified, the function returns SOCKET_ERROR and sets errno.

HTTP Changes

This topic discusses the changes made to the `http.h` file.

Note: This file was named `http2.h` in the V6 Beta TCP/IP Stack.

Description

HTTP Changes

The TCP/IP Stack include header file, `http.h`, has been updated as follows.

Function Name Changes

Prior Function Name	New Function Name
HTTPExecutePost	TCPIP_HTTP_PostExecute
HTTPExecuteGet	TCPIP_HTTP_GetExecute
HTTPNeedsAuth	TCPIP_HTTP_FileAuthenticate
HTTPCheckAuth	TCPIP_HTTP_UserAuthenticate
HTTPReadPostPair	TCPIP_HTTP_PostReadPair
HTTPPrint_varname(...)	TCPIP_HTTP_Print_varname(…)

All of the functions that the HTTP exposes as its API now take a first parameter, a HTTP connection handle, named HTTP_CONN_HANDLE. This allows a cleaner and better behavior in both multi-threaded environments and in the situation where we it may be desired to run multiple instances of the HTTP process itself, allowing for serving multiple independent connections.

For example, the HTTP functions now appear as:

- TCPIP_HTTP_FileInclude(HTTP_CONN_HANDLE connHandle, const uint8_t* cFile) ;
- TCPIP_HTTP_GetExecute(HTTP_CONN_HANDLE connHandle);
- TCPIP_HTTP_PostExecute(HTTP_CONN_HANDLE connHandle);
- TCPIP_HTTP_CurrentConnectionFileGet(HTTP_CONN_HANDLE connHandle);
- TCPIP_HTTP_CurrentConnectionCallbackPosGet(HTTP_CONN_HANDLE connHandle);

Support has been added for the HTTP module client to store/retrieve its own connection related data. For example:

- TCPIP_HTTP_CurrentConnectionUserDataSet(HTTP_CONN_HANDLE connHandle, const void* uData);
- TCPIP_HTTP_CurrentConnectionUserDataGet(HTTP_CONN_HANDLE connHandle);

HTTP Print

Also, the functions exposed in `http_print.h` take the connection handle parameter. For example:

- TCPIP_HTTP_Print(HTTP_CONN_HANDLE connHandle, uint32_t callbackID);
- TCPIP_HTTP_Print_hellomsg(HTTP_CONN_HANDLE connHandle);

These changes affect all of the function calls in the file, `custom_http_app.c`, such as:

- TCPIP_HTTP_GetExecute(HTTP_CONN_HANDLE connHandle);
- TCPIP_HTTP_PostExecute(HTTP_CONN_HANDLE connHandle);

To port an existing application, the extra parameter will have to be added. The connection handle is passed to the application as part of the HTTP callback. The modifications should be minimal and possible using an editor without any other impact.

Please note that the MPFS2 generator utility (`mpfs2.jar`) has been updated to support the new HTTP API.

See the list of the complete API changes in `http.h` and `http_print.h`.

MPLAB Harmony TCP/IP Stack Storage Changes

This topic describes the storage changes in the MPLAB Harmony TCP/IP Stack.

Description

MPLAB Harmony TCP/IP Stack Storage Changes

The V5 TCP/IP Stack include header file, `tcpip_storage.h`, *does not* exist in the MPLAB Harmony TCP/IP Stack.

The TCP/IP Stack storage has become obsolete and is no longer maintained. This is mainly due to the way the dynamic initialization of the

stack is done in the V5 TCP/IP Stack:

- Each module has its own initialization data
- There are many parameters that could be relevant for an application and that may require storage besides the IP address, IP Mask, or SSID, etc.
- The data is passed dynamically at the stack initialization. There is no longer a "build time" set of parameters against which to check at stack configuration (although support for a default configuration set at build time is present). The actual data contents are the application's responsibility.
- A system database service will be added that will use the File System. The database service will maintain configurations for all the modules in the system, including the TCP/IP. The system database service API will be available to the applications as well for storing/retrieving proprietary information.
- The parameter, TCPIP_STACK_USE_STORAGE, in the file, `tcpip_config.h`, should not be enabled. Future plans call for this service to be removed from the distribution.

MPLAB Harmony TCP/IP Stack Configuration Changes

This topic describes the configuration changes in the MPLAB Harmony TCP/IP Stack.

Description

The stack configuration has a completely *new* structure. Each project has its own configuration folder that stores multiple configurations based on CPU platforms and hardware boards.

Note: V5 TCP/IP Stack configuration files *cannot* be reused in the MPLAB Harmony TCP/IP Stack.

The following is a list of the most important features:

- `system_config` folder for projects – all profiles are stored in this location
- Multiple profiles per project, which are separated by CPU platform. The TCP/IP profile is usually common.
- `tcpip_config.h` – selects modules that are part of the build
- Each module has its own profile: `arp_config.h`, `tcp_config.h`, `ssl_config.h`, etc.
- BSP profiles per development board containing:
- `hardware_config.h` – the BSP specific hardware settings
- `media_storage_config.h` – storage media and partitioning settings
- `sys_fs_config.h` – file system configuration and settings
- `mpfs_config.h` – MPFS file system settings
- `network_config.h` – configuration for every network interface: NetBIOS names, default IP addresses, etc.
- `system_config.h` – system configuration (i.e, system tick, system console selection, system debug services, etc.)

MPLAB Harmony TCP/IP Stack Configuration

This topic provides information on the configuration of the MPLAB Harmony TCP/IP Stack.

Description

MPLAB Harmony TCP/IP Stack Configuration

The presented structure is simply a model and a different layout can be chosen. The only requirement is to use the proper path in your project so that the necessary configuration files are found at build time.

For example, depending on your exact hardware platform or development board, a path similar to the following can be added to your project path:

```
..\harmony\<version>\apps\tcpip\tcpip_web_server_demo_app\firmware\src\system_config\pic32_eth_sk_int_dyn\tcpip_profile
```

MPLAB Harmony TCP/IP Stack Heap Configuration

This topic provides information on the heap configuration of the MPLAB Harmony TCP/IP Stack.

Description

MPLAB Harmony TCP/IP Stack Heap Configuration

The MPLAB Harmony TCP/IP Stack uses dynamic memory for both initialization and run time buffers. Therefore, there are two requirements for a project containing the stack to work properly.

The first requirement is that the TCP/IP stack should be configured with enough heap space. The amount of heap used by the stack is specified by the TCPIP_STACK_DRAM_SIZE parameter in the `tcpip_config.h` file.

The value of the required TCP/IP heap for a project is application dependent. Some of the most important factors that impact the heap size are:

- Number of TCP sockets
- By default, each TCP socket requires 512 bytes for a RX buffer and 512 bytes for a TX buffer. These parameters can be adjusted by modifying the values specified in `tcp_config.h` or dynamically through the TCPIP_TCP_OptionsSet function.
- Number of UDP sockets:
- For each UDP socket that needs to initiate a transmission, the IP layer will have to allocate the required space (suggested by the functions, UDPv4IsTxPutReady or UDPv4IsTxPutReady
- Once the UDP buffering will be added, each socket will have its own RX and TX buffers. These parameters can be adjusted by modifying the values specified in the file, `udp_config.h`, or dynamically through the TCPIP_UDP_OptionsSet function
- The type of Ethernet MAC that is used:
- The PIC32MX6XX/7XX devices with a built-in 100 Mbps Ethernet controller use system memory for buffering incoming RX traffic. For sustained 100 Mbps operation, adequate RX buffer space must be provided. This parameter can be adjusted by modifying the values specified in the file, `network_config.h`, using the array, TCPIP_HOSTS_CONFIGURATION.
- If SSL is enabled, it will require additional buffering for encryption/decryption at run-time. The SSL module buffering requirement is dependent on the RSA key length specified in `ssl_config.h`.

The second requirement is that the project that includes the MPLAB Harmony TCP/IP Stack must be built with sufficient heap size to accommodate the stack (at a minimum, the project needs the TCPIP_STACK_DRAM_SIZE bytes of heap). This parameter is adjusted on the Linker tab in the project properties.

In general, for a TCP/IP project running on a PIC32MX device with an embedded Ethernet controller, at least 8 KB of heap space is needed by the stack. However, the following is implied:

- 100 Mbps traffic is not sustained
- No SSL
- Relatively few sockets

A typical value for comfortably handling 100 Mbps Ethernet traffic would be 40 KB of TCP/IP heap space.

The amount of the required heap is less for an external Ethernet MAC.

Keep in mind the following when assigning heap space:

- If there is not enough heap space the stack initialization may fail
- If there is not enough heap space some run time buffer allocation may fail and some packets transmission will have to be deferred until a later time, thus impacting the stack performance
- It is always a good idea to have a reserve, at least an extra 2 KB of heap space above the total amount of space that is used
- A very useful tool in understanding the heap allocation and how the space is distributed among the stack modules is the TCP/IP command processor

By enabling the parameter, TCPIP_STACK_DRAM_DEBUG_ENABLE, in the `tcpip_config.h` file, the stack will output debug messages when it runs out of memory. Then, using the `heapinfo` command at the TCP/IP command processor prompt will return a snapshot of the current TCP/IP heap status and can help in early detection of problems.

Optionally, enabling the parameter, TCPIP_STACK_DRAM_TRACE_ENABLE in the `tcpip_config.h` file, will instruct the TCP/IP heap allocation module to store trace information that will be displayed with the `heapinfo` command.

New MPLAB Harmony TCP/IP Stack API Functions

This topic describes some of the important new API functions in the MPLAB Harmony TCP/IP Stack.

Description

There are many new functions available that have been introduced to take advantage of new features, such as IPv6 and support of multiple interfaces. However, there is no concern for the porting process regarding the new API calls as the previous stack implementation did not support this kind of service.

A new API function should be added to the application only when the access to the new feature is needed.

Existent applications should port easily without using the new API.

For reference, the following are a few of the most important new API functions that could prove useful in the porting of your application:

- Initialization of the stack network interfaces:
- TCPIP_STACK_NetUp()
- TCPIP_STACK_NetDown()
- Default interface selection:
- TCPIP_STACK_NetDefaultGet()
- TCPIP_STACK_NetDefaultSet()
- TCP/UDP multiple interface support:
- TCPIP_TCP_Bind()
- TCPIP_TCP_RemoteBind()
- TCPIP_TCP_SocketNetGet()
- TCPIP_TCP_SocketNetSet()
- TCPIP_UDPBind()
- TCPIP_UDP_RemoteBind()

- TCPIP_UDP_SocketNetGet()
- TCPIP_UDP_SocketNetSet()

Refer to the file, `tcpip_manager.h`, for a complete list of all new network interface APIs.

Main Program Changes

This topic describes the main program changes in the MPLAB Harmony TCP/IP Stack.

Description

Main Program Changes

There are few changes that the main program loop has to take care of. A full working example is given with the file, `main_demo.c`, which is provided with the stack distribution.

The main program should call the following functions:

- SYS_Initialize() – This function is what initializes the system and runs the Board Support Package (BSP) specific code
- SYS_Tasks() – This is the function that takes care of the system tasks and must be called periodically
- TCPIP_STACK_Task() – This is the TCP/IP stack tasks function that runs all of the state machines that are part of the TCP/IP stack. This function must be called periodically. Please note the name change.

To gain access to a network interface the TCPIP_STACK_NetHandle("iname") function should be used. Examples are provided in the previous section.

MPLAB Harmony TCP/IP Stack Initialization Changes

This topic describes the initialization updates to the MPLAB Harmony TCP/IP Stack.

Description

The TCP/IP Stack include header file, `tcpip_manager.h`, has been updated as follows.

To initialize the stack the call is now:

```
TCPIP_STACK_Initialize(const TCPIP_NETWORK_CONFIG* pNetConf, int nNets, TCPIP_STACK_MODULE_CONFIG*
pModConfig, int nModules);
```

Where:

- `pNetConf` – is a pointer to an array of configurations for all the initialized network interfaces
- `nNets` – is the number of the network interfaces that the stack is to support
- `pModConfig` – is a pointer to an table storing configuration data for the TCP/IP stack modules
- `nModules` – is the number of entries in this table, (i.e., the number of initialized modules)

The default TCP/IP stack configuration is provided with the stack distribution and consists of:

- `network_config.h`: TCPIP_HOSTS_CONFIGURATION[] – an array of TCPIP_NETWORK_CONFIG entries describing the default configuration of each network interface
- `tcpip_modules_config.h`: TCPIP_STACK_MODULE_CONFIG_TBL[] – an array of TCPIP_STACK_MODULE_CONFIG entries storing the default configuration data for each module of the TCP/IP stack. This is just an aggregate of all the default configurations per module found in the module configuration header files, such as `tcp_config.h`, `udp_config.h`, `arp_config.h`, and so on.

These tables are defined by default in the configuration files. See MPLAB Harmony TCP/IP Stack Configuration Changes for details.

You can change the parameters of these structures as appropriate.

An example of the TCP/IP initialization is part of the distributed file, `main_demo.c`. This file is located in the following Windows® path:

`.\harmony<version>\apps\tcpip\tcpip_web_server_demo_app\firmware\src`

Note: The stack initialization may fail. The application code must check the result of this call to detect if the stack failed to initialize properly.

MPLAB Harmony TCP/IP Stack Access Changes

This topic describes the stack access updates that were made to the MPLAB Harmony TCP/IP Stack.

Description

The TCP/IP Stack include header file, `tcpip_manager.h`, has been updated as follows.

Direct access to the internally maintained stack structures has been removed. To access the information for a specific network interface a handle must be obtained using the interface name. For example:

```
TCPIP_NET_HANDLE hNet = TCPIP_STACK_NetHandleGet("PIC32INT");
```

or

```
TCPIP_NET_HANDLE hNet = TCPIP_STACK_NetHandleGet("MRF24W");
```

Once a handle to the interface has been obtained, different parameters of that network interface can be queried and set. For example:

- TCPIP_STACK_NetAddress(TCPIP_NET_HANDLE netH) – returns the network interface address
- TCPIP_STACK_NetAddressGateway(TCPIP_NET_HANDLE netH) – returns the interface gateway address

Refer to the `tcpip_manager.h` file for a complete list of functions.

Note: The TCPIP_NET_HANDLE is an opaque data type.

The well known names of the network interfaces are currently in the file, `tcpip.h`.

The exact header file that exposes the network interfaces names may change in the future; however, the names of the supported network interfaces will be retained.

Use the file, `network_config.h`, as an example.

Refer to the file, `main_demo.c`, for an example of how to use the interface handle functions.

MPLAB Harmony TCP/IP Stack Utilities

This topic describes the MPLAB Harmony TPC/IP Stack utilities.

Description

The MPLAB Harmony TCP/IP Stack includes the following utilities:

- MPFS2 - The MPFS2 Java utility that assists the application in generating the MPFS image of the files needed by the Web server has been updated. This utility supports both the V5 and MPLAB Harmony versions of the TCP/IP stack with improved functionality. The V5 TCP/IP Stack utility can still be used; however, some minor adjustments may need to be done manually. Refer to the MPFS2 Utility section for more information.
- TCP/IP Discoverer - The TCP/IP Discoverer Java utility has been updated to support not only the MPLAB Harmony TCP/IP Stack, but also IPV6. This utility is up and running and is backward compatible with the V5 TCP/IP Stack. Refer to the TCP/IP Discoverer Utility section for more information.
- TCP/IP Configuration - The TCP/IP Configuration utility is currently not supported. The need of individually configuring TCP and UDP sockets is no longer needed, as all sockets behave similarly and they are allocated dynamically as needed.

MPLAB Harmony TCP/IP Stack SSL/RSA Usage

This topic provides information regarding the usage of SSL and RSA.

Description

The SSL design has been updated to support multiple interfaces. The same is true for the RSA engine. However, the SSL module does not currently use the Microchip Cryptographic (Crypto) Library. Until the proper Crypto Library support is added to SSL, the stack is distributed with the RSA and RC4 code embedded into the stack.

In the future, the Crypto Library will be completely removed from the TCP/IP stack, and the stack will be just a client to the Crypto Library.

Porting Applications from the V6 Beta TCP/IP Stack to the MPLAB Harmony TCP/IP Stack

Porting an application from the V6 Beta TCP/IP Stack to the TCP/IP Stack within MPLAB Harmony consists of updating existing TCP/IP Stack function names in your application to the new MPLAB Harmony function names.

MPLAB Harmony TCP/IP Stack Function Name Compliance

This topic provides header file function mapping tables that show the V6 Beta TCP/IP Stack function name and the compliant name within the MPLAB Harmony TCP/IP Stack.

Description

The replacement names chosen to make existing TCP/IP Stack functions compliant with MPLAB Harmony are shown in individual tables per header file name.

The files listed in the tables are located in the following two MPLAB Harmony installation folders:

`.\harmony\<version>\framework\tcpip`

`.\harmony\<version>\framework\tcpip\src`

Each table shows the original and new names used. Note that other than name changes, no other modifications were made to the middleware functions.

Header File: arp.h

V6 Beta TCP/IP Stack Name	MPLAB Harmony Compliant Name
ARP_ENTRY_QUERY	TCPIP_ARP_ENTRY_QUERY

Development Information (Advance Information)

This *advance information* is specifically provided to assist MPLAB Harmony driver development for porting the existing Ethernet Controller Library and MAC/PHY drivers to the new platform.

Porting the MPLAB Harmony Drivers and Peripheral Library

This topic provides function mapping tables that show the V6 Beta TCP/IP Stack function name and the compliant name within the MPLAB Harmony TCP/IP Stack for the purpose of porting to the MPLAB Harmony Ethernet Drivers and Ethernet Peripheral Library.

Description

Note: This content in this section is considered to be *Advance Information*.

Porting the MPLAB Harmony Ethernet Drivers and the MPLAB Harmony Ethernet Peripheral Library involves replacing the Ethernet Controller Library with calls to MPLAB Harmony equivalents. This information is listed in Table 1. Please note that function arguments were modified in some instances.

To understand how a function of the Ethernet Controller Library is different from its equivalent MPLAB Harmony function, the header of the MPLAB Harmony function should be examined. The MPLAB Harmony function header always lists the Ethernet Controller Library function(s) that the new MPLAB Harmony function replaces, including the arguments of the old function.

Table 1: TCP/IP Stack Function Mapping

Announce Module

This section describes the TCP/IP Stack Library Announce module.

Introduction

TCP/IP Stack Library Announce Module for Microchip Microcontrollers

This library provides the API of the Announce Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

This module will facilitate device discovery on DHCP enabled networks by broadcasting a UDP message on port 30303 whenever the local IP address changes.

Using the Library

This topic describes the basic architecture of the Announce TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `tcpip_announce_config.h`

The interface to the Announce TCP/IP Stack library is defined in the `tcpip_announce_config.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the Announce TCP/IP Stack library should include `tcpip.h`.

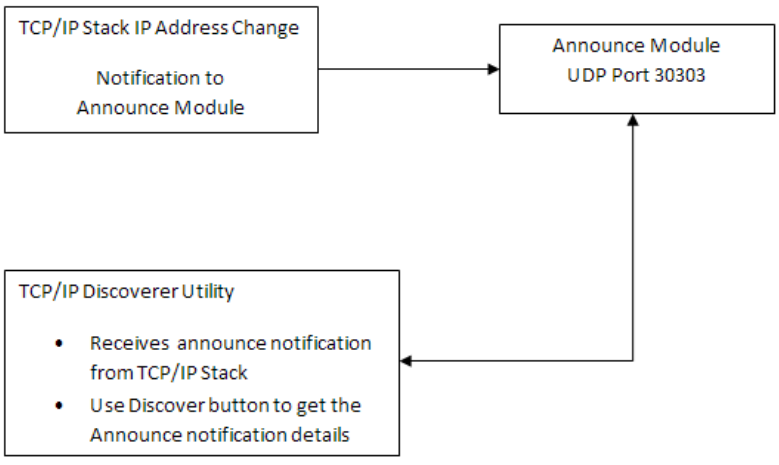
Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

This library provides the API of the Announce TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

Announce Software Abstraction Block Diagram



Discovering the Board

Provides information on how the Announce module works in conjunction with the TCP/IP Discoverer personal computer utility to display an interface's MAC and IPv4/IPv6 addresses.

Description

The Announce module provides an easy way to determine useful parameters for your TCP/IP node's interfaces. This module works in conjunction with the TCP/IP Discoverer personal computer utility to display an interface's MAC and IPv4/IPv6 addresses, IPv6 multicast listeners, NBNS host name, and MAC type. During stack operation several events may cause an Announce packet to be broadcast on a particular interface. These include:

- Reception of an Announce packet request on that interface
- A DHCP event on that interface (i.e., the interface has configured a new IPv4 address using DHCP)
- The addition or removal of an IPv6 Unicast Address from an interface (after Duplicate Address Detection)
- The addition or removal of an IPv6 Multicast Listener from an interface
- A user call to the ANNOUNCE_Notify function specifying the interface to which you want to send parameters

Each Announce packet is a UDP packet broadcast from the corresponding interface's IPv4 address. The payload is a series of fields beginning with an 8-bit field ID, followed by field information, followed by a field terminator (0x0D 0x0A). The current field IDs and information formats are:

- 0x01 – This field ID indicates that not all of the interface's address information could be transmitted in one packet. There is no field information for this ID.
- 0x01 0x0A 0x0D
- 0x02 – MAC address (6 bytes).
- 0x02 0x00 0x04 0xA3 0x12 0x0f 0x94 0x0D 0x0A
- 0x03 – MAC type. The field information for this ID is a variable length string describing the MAC type of this interface – "ENCJ60", "ENCJ600", "97J60", "PIC32INT", "MRF24W".
- 0x03 'P' 'I' 'C' '3' '2' 'I' 'N' 'T' 0x0D 0x0A
- 0x04 – Host name. The NBNS host name of the interface, with trailing spaces.
- 0x04 'M' 'C' 'H' 'P' 'B' 'O' 'A' 'R' 'D' ' ' ' ' ' ' ' ' ' ' ' ' ' ' ' ' 0x0D 0x0A
- 0x05 – The interface's IPv4 address (4 bytes, big-endian).
- 0x05 0x0A 0x00 0x01 0x03 0x0D 0x0A
- 0x06 – One of the interface's IPv6 unicast addresses (16 bytes, big-endian). Note that the interface may have more than one of these. The interface also has a corresponding solicited-node multicast address listener for every unicast address that is given. The interface may have static IP address.
- 0x06 0xFE 0x80 0x00 0x00 0x00 0x00 0x00 0x00 0x02 0x04 0xA3 0xFF 0xFE 0x12 0x0F 0x94 0x0D 0x0A
- 0x06 0xFD 0xFE 0xDC 0xDA 0x98 0x76 0x00 0x01 0x02 0x04 0xA3 0xFF 0xAA 0xAA 0xAA 0xAA 0x0D 0x0A
- 0x07 – One of the interface's IPv6 multicast address listeners (16 bytes, big-endian). The solicited-node multicast address listeners will not be included.
- 0x07 0xFF 0x02 0x00 0x00 0x00 0x00 0x00 0x00 0x00 0x00 0x00 0x00 0x00 0x00 0x00 0x01 0x0D 0x0A
- 0x08 – One of the interface's IPv6 default router address (16 bytes, big-endian).
- 0x08 0xFD 0xFE 0xDC 0xDA 0x98 0x76 0x00 0x01 0x00 0x00 0x00 0x00 0x00 0x00 0x00 0x00 0x01 0x0D 0x0A
- 0x09 – One of the interface's IPv6 default gateway address (16 bytes, big-endian).
- 0x08 0xFD 0xFE 0xDC 0xDA 0x98 0x76 0x00 0x01 0x00 0x00 0x00 0x00 0x00 0x00 0x00 0x00 0x01 0x0D 0x0A

Configuring the Library

Macros

	Name	Description
	TCPIP_ANNOUNCE_TASK_RATE	announce task rate, millseconds The default value is 333 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_ANNOUNCE_MAX_PAYLOAD	Maximum size of a payload sent once

Description

The configuration of the Announce TCP/IP Stack Library is based on the file `tcpip_config.h`.

This header file contains the configuration selection for the Announce TCP/IP Stack Library. Based on the selections made, the Announce TCP/IP Stack Library may support the selected features. These configuration settings will apply to all instances of the Announce TCP/IP Stack Library.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_ANNOUNCE_TASK_RATE Macro

File

tcpip_announce_config.h

C

```
#define TCPIP_ANNOUNCE_TASK_RATE 333
```

Description

announce task rate, millseconds The default value is 333 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

TCPIP_ANNOUNCE_MAX_PAYLOAD Macro

File

tcpip_announce_config.h

C

```
#define TCPIP_ANNOUNCE_MAX_PAYLOAD (512)
```

Description

Maximum size of a payload sent once

Building the Library

This section lists the files that are available in the Announce module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/tcpip_announce.c`	Announce implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The Announce module depends on the following modules:

- TCP/IP Stack Library
- UDP Module

Files

Files

Name	Description
tcpip_announce_config.h	Announce configuration file

Description

ARP Module

This section describes the TCP/IP Stack Library ARP Module.

Introduction

TCP/IP Stack Library Address Resolution Protocol (ARP) Module for Microchip Microcontrollers

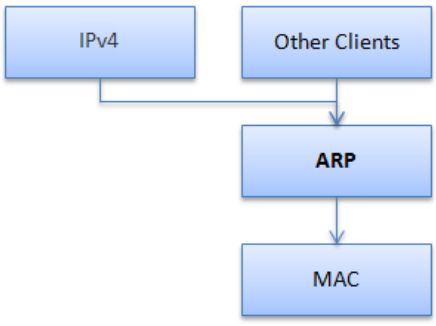
This library provides the API of the ARP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

The Address Resolution Protocol, or ARP, is a foundation layer of TCP/IP. It translates IP addresses to physical MAC addresses

TCP and UDP applications will not need to access ARP directly. The IPv4 module will handle the ARP operations transparently.

Responses to incoming ARP requests are processed automatically. Resolution of ARP requests follows a simple state machine, as indicated in the following diagram.



Using the Library

This topic describes the basic architecture of the ARP TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `arp.h`

The interface to the arp TCP/IP Stack library is defined in the `arp.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the ARP TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

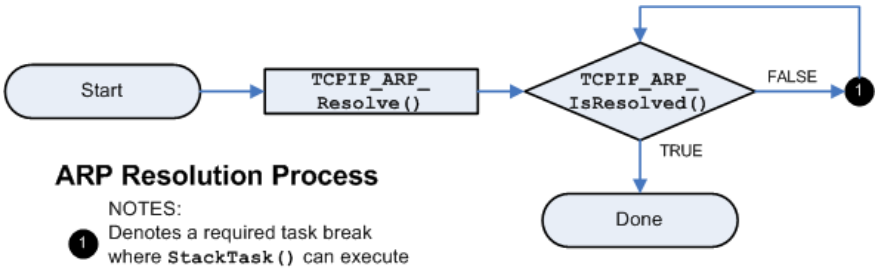
Abstraction Model

This library provides the API of the ARP TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

ARP Software Abstraction Block Diagram

This module provides software abstraction of the ARP module existent in any TCP/IP Stack implementation. It removes the overhead of address resolution from all other modules in the stack.



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the ARP module.

Library Interface Section	Description
General Functions	Functions exported by the ARP library interface.
Cache Manipulation Functions	This section provides an interface to the internal data storage (cache) that the ARP module implements.
Data Types and Constants	Derived types and enumerations used by the ARP library interface.

How the Library Works

The ARP module provides address resolution capabilities for the TCP/IP stack.

The ARP module is an independent module that maintains its state across calls and updates its state machine. A data storage (cache) is maintained and updated internally for each interface existent in the system. The number of entries in each cache is configurable at initialization time.

The ARP state machine can remove entries from the cache and can provide signals when a specific entry has been resolved or has timed out. The purging of the cache is done internally base on a time-out parameter that is dynamically configurable.

The module provides a notification mechanism which simplifies the design of the ARP clients. The most important client of the ARP module is the IPv4 layer.

Configuring the Library

Macros

	Name	Description
	ARP_CACHE_DELETE_OLD	On initialization, delete the old cache if still in place Else don't re-initialize Default should be 1
	TCPIP_ARP_CACHE_ENTRIES	Number of entries in the cache. Default number of entries per interface.
	TCPIP_ARP_CACHE_ENTRY_RETRIES	Number of ARP requests generated for resolving an entry.
	TCPIP_ARP_CACHE_PENDING_ENTRY_TMO	Timeout for a cache entry pending to be solved, in seconds. The entry will be removed if the tmo elapsed and the entry has not been solved. A solved entry moves to the solved entries timeout.
	TCPIP_ARP_CACHE_PENDING_RETRY_TMO	Timeout for resending an ARP request for a pending entry. In order to prevent the ARP flooding the standard recommends it to be greater than 1 sec. It should be less than TCPIP_ARP_CACHE_PENDING_ENTRY_TMO
	TCPIP_ARP_CACHE_PERMANENT_QUOTA	Max percentage of permanent entries in the cache. Note that since permanent entries cannot be removed they tend to degrade the efficiency of the cache look up.
	TCPIP_ARP_CACHE_PURGE_QUANTA	The number of entries to delete, once the threshold is reached.
	TCPIP_ARP_CACHE_PURGE_THRESHOLD	Default purge threshold, percentage Once the number of resolved entries in the cache gets beyond the threshold some resolved entries will be purged.
	TCPIP_ARP_CACHE_SOLVED_ENTRY_TMO	Timeout for a solved entry in the cache, in seconds. The entry will be removed if the tmo elapsed and the entry has not been referenced again
	TCPIP_ARP_GRATUITOUS_PROBE_COUNT	Number of ARP requests generated when sending a gratuitous ARP probe. Default value should be 1.
	TCPIP_ARP_TASK_PROCESS_RATE	ARP task processing rate, in seconds. The ARP module will process a timer event with this rate for maintaining its own queues, processing timeouts, etc. Choose it so that the other ARP_CACHE_xxx_TMO are multiple of this The default value is 2 seconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

Description

The configuration of the TCP/IP Stack ARP is based on the file `system_config.h` (which may include the file `arp_config.h`).

This header file contains the configuration selection for the TCP/IP Stack ARP. Based on the selections made, the TCP/IP Stack ARP may support the selected features. These configuration settings will apply to the single instance of the TCP/IP Stack ARP.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

ARP_CACHE_DELETE_OLD Macro

File

arp_config.h

C

```
#define ARP_CACHE_DELETE_OLD 1
```

Description

On initialization, delete the old cache if still in place Else don't re-initialize Default should be 1

TCPIP_ARP_CACHE_ENTRIES Macro

File

arp_config.h

C

```
#define TCPIP_ARP_CACHE_ENTRIES 5
```

Description

Number of entries in the cache. Default number of entries per interface.

TCPIP_ARP_CACHE_ENTRY_RETRIES Macro

File

arp_config.h

C

```
#define TCPIP_ARP_CACHE_ENTRY_RETRIES 3
```

Description

Number of ARP requests generated for resolving an entry.

TCPIP_ARP_CACHE_PENDING_ENTRY_TMO Macro

File

arp_config.h

C

```
#define TCPIP_ARP_CACHE_PENDING_ENTRY_TMO (1 * 60)
```

Description

Timeout for a cache entry pending to be solved, in seconds. The entry will be removed if the tmo elapsed and the entry has not been solved. A solved entry moves to the solved entries timeout.

TCPIP_ARP_CACHE_PENDING_RETRY_TMO Macro

File

arp_config.h

C

```
#define TCPIP_ARP_CACHE_PENDING_RETRY_TMO (2)
```

Description

Timeout for resending an ARP request for a pending entry. In order to prevent the ARP flooding the standard recommends it to be greater than 1 sec. It should be less than TCPIP_ARP_CACHE_PENDING_ENTRY_TMO

TCPIP_ARP_CACHE_PERMANENT_QUOTA Macro

File

arp_config.h

C

```
#define TCPIP_ARP_CACHE_PERMANENT_QUOTA 50
```

Description

Max percentage of permanent entries in the cache. Note that since permanent entries cannot be removed they tend to degrade the efficiency of the cache look up.

TCPIP_ARP_CACHE_PURGE_QUANTA Macro

File

arp_config.h

C

```
#define TCPIP_ARP_CACHE_PURGE_QUANTA 3
```

Description

The number of entries to delete, once the threshold is reached.

TCPIP_ARP_CACHE_PURGE_THRESHOLD Macro

File

arp_config.h

C

```
#define TCPIP_ARP_CACHE_PURGE_THRESHOLD 75
```

Description

Default purge threshold, percentage Once the number of resolved entries in the cache gets beyond the threshold some resolved entries will be purged.

TCPIP_ARP_CACHE_SOLVED_ENTRY_TMO Macro

File

arp_config.h

C

```
#define TCPIP_ARP_CACHE_SOLVED_ENTRY_TMO (20 * 60)
```

Description

Timeout for a solved entry in the cache, in seconds. The entry will be removed if the tmo elapsed and the entry has not been referenced again

TCPIP_ARP_GRATUITOUS_PROBE_COUNT Macro

File

arp_config.h

C

```
#define TCPIP_ARP_GRATUITOUS_PROBE_COUNT 1
```

Description

Number of ARP requests generated when sending a gratuitous ARP probe. Default value should be 1.

TCPIP_ARP_TASK_PROCESS_RATE Macro

File

arp_config.h

C

```
#define TCPIP_ARP_TASK_PROCESS_RATE (2)
```

Description

ARP task processing rate, in seconds. The ARP module will process a timer event with this rate for maintaining its own queues, processing timeouts, etc. Choose it so that the other ARP_CACHE_xxx_TMO are multiple of this The default value is 2 seconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

Building the Library

This section lists the files that are available in the ARP module of the TCP/IP Stack Library

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
/tcpip.h	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/arp.c	ARP implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The ARP module depends on the following modules:

- TCP/IP Stack Library

Library Interface

a) General Functions

	Name	Description
	TCPIP_ARP_EntryGet	Gets the current mapping for an IP address.
	TCPIP_ARP_EntryRemove	Removes the mapping of an address, even a permanent one
	TCPIP_ARP_EntryRemoveNet	Removes all the entries belonging to a network interface.
	TCPIP_ARP_HandlerDeRegister	Deregisters the event handler
	TCPIP_ARP_HandlerRegister	Register an ARP resolve handler.
	TCPIP_ARP_IsResolved	Determines if an ARP request has been resolved yet.
	TCPIP_ARP_Probe	Transmits an ARP probe to resolve an IP address.
	TCPIP_ARP_Resolve	Transmits an ARP request to resolve an IP address.
	TCPIP_ARP_Task	Standard TCP/IP stack module task function.
	TCPIP_ARP_EntrySet	Adds an ARP cache entry for the specified interface.

b) Cache Manipulation Functions

	Name	Description
	TCPIP_ARP_CacheEntriesNoGet	Used to retrieve the number of entries for a specific interface.
	TCPIP_ARP_CacheThresholdSet	Sets the cache threshold for the specified interface in percent.
	TCPIP_ARP_EntryQuery	Queries an ARP cache entry using the index of the cache line.
	TCPIP_ARP_EntryRemoveAll	Removes all the mapping belonging to an interface.

c) Data Types and Constants

	Name	Description
	TCPIP_ARP_ENTRY_QUERY	ARP entry query.
	TCPIP_ARP_ENTRY_TYPE	Type of ARP entry.
	TCPIP_ARP_EVENT_HANDLER	Notification handler that can be called when a specific entry is resolved.
	TCPIP_ARP_EVENT_TYPE	Events reported by ARP.
	TCPIP_ARP_HANDLE	ARP handle.
	TCPIP_ARP_OPERATION_TYPE	Type of ARP operation.
	TCPIP_ARP_RESULT	ARP results (success and failure codes).
	TCPIP_ARP_MODULE_CONFIG	This is type TCPIP_ARP_MODULE_CONFIG.

Description

This section describes the Application Programming Interface (API) functions of the ARP module.

Refer to each section for a detailed description.

a) General Functions

TCPIP_ARP_EntryGet Function

Gets the current mapping for an IP address.

File

arp.h

C

```
TCPIP_ARP_RESULT TCPIP_ARP_EntryGet(TCPIP_NET_HANDLE hNet, IPV4_ADDR* ipAdd, TCPIP_MAC_ADDR* pHwAdd, bool probe);
```

Returns

- ARP_RES_ENTRY_SOLVED - if the required entry is already solved
- ARP_RES_ENTRY_QUEUED - if the required entry was already queued
- ARP_RES_ENTRY_NEW - if the operation succeeded and a new entry was added (and queued for resolving)
- ARP_RES_CACHE_FULL - if new entry could not be inserted, the cache was full
- ARP_RES_BAD_ADDRESS - bad address specified
- ARP_RES_NO_INTERFACE - no such interface

Description

If probe == false The function behaves identical to TCPIP_ARP_IsResolved(): If the corresponding MAC address exists in the cache it is copied to the user supplied pHwAdd

If probe == true The function behaves identical to TCPIP_ARP_Resolve():

- If the corresponding MAC address does not exist in the cache

this function transmits and ARP request. Upon the address resolution it calls the registered handler (if available) with the supplied notification parameter (if != 0)

- If the hardware address exists in the cache, the result is written to pHwAdd

and no network ARP request is sent

Remarks

Similar to TCPIP_ARP_Resolve + TCPIP_ARP_IsResolved, it avoids a double hash search when the mapping exists.

Preconditions

The ARP module should have been initialized.

Parameters

Parameters	Description
hNet	Interface to use
ipAdd	The IP address to get entries from
pHwAdd	pointer to store the hardware address
probe	boolean to specify if ARP probing is initiated or not

Function

TCPIP_ARP_RESULT TCPIP_ARP_EntryGet(TCPIP_NET_HANDLE hNet, IPV4_ADDR* ipAdd,
TCPIP_MAC_ADDR* pHwAdd, bool probe)

TCPIP_ARP_EntryRemove Function

Removes the mapping of an address, even a permanent one

File

arp.h

C

```
TCPIP_ARP_RESULT TCPIP_ARP_EntryRemove(TCPIP_NET_HANDLE hNet, IPV4_ADDR* ipAdd);
```

Returns

TCPIP_ARP_RESULT

- On Success - ARP_RES_OK
- On Failure - ARP_RES_NO_ENTRY (if no such mapping exists) ARP_RES_NO_INTERFACE (if no such interface exists)

Description

This function removes an existent mapping from the selected interface cache.

Remarks

None.

Preconditions

The ARP module should have been initialized.

Parameters

Parameters	Description
hNet	Interface to use
ipAdd	IP Address to remove entries for

Function

TCPIP_ARP_RESULT TCPIP_ARP_EntryRemove(TCPIP_NET_HANDLE hNet, IPV4_ADDR* ipAdd);

TCPIP_ARP_EntryRemoveNet Function

Removes all the entries belonging to a network interface.

File

arp.h

C

```
TCPIP_ARP_RESULT TCPIP_ARP_EntryRemoveNet(TCPIP_NET_HANDLE hNet, IPV4_ADDR* ipAdd, IPV4_ADDR* mask,
TCPIP_ARP_ENTRY_TYPE type);
```

Returns

TCPIP_ARP_RESULT

- On Success - ARP_RES_OK
- On Failure - ARP_RES_BAD_TYPE (if no such type exists) ARP_RES_NO_INTERFACE (if no such interface exists)

Description

This function removes all existent mappings belonging to a network interface. The performed operation: if(entry->type == type and entry->ipAdd & mask == ipAdd & mask) then remove entry

Remarks

None.

Preconditions

The ARP module should have been initialized.

Parameters

Parameters	Description
hNet	Interface handle to use
ipAdd	IP address
mask	IP address of mask

type	valid types of entries to remove: • ARP_ENTRY_TYPE_PERMANENT • ARP_ENTRY_TYPE_COMPLETE • ARP_ENTRY_TYPE_INCOMPLETE • ARP_ENTRY_TYPE_ANY

Function

TCPIP_ARP_RESULT TCPIP_ARP_EntryRemoveNet(TCPIP_NET_HANDLE hNet, IPV4_ADDR* ipAdd, IPV4_ADDR* mask, TCPIP_ARP_ENTRY_TYPE type)

TCPIP_ARP_HandlerDeRegister Function

Deregisters the event handler

File

arp.h

C

```
bool TCPIP_ARP_HandlerDeRegister(TCPIP_ARP_HANDLE hArp);
```

Returns

Boolean

- On Success - true
- On Failure - false (If no such handler registered)

Description

Deregisters a previously registered ARP handler

Remarks

None.

Preconditions

The ARP module should have been initialized.

Parameters

Parameters	Description
hArp	ARP Handle

Function

bool TCPIP_ARP_HandlerDeRegister(TCPIP_ARP_HANDLE hArp)

TCPIP_ARP_HandlerRegister Function

Register an ARP resolve handler.

File

arp.h

C

```
TCPIP_ARP_HANDLE TCPIP_ARP_HandlerRegister(TCPIP_NET_HANDLE hNet, TCPIP_ARP_EVENT_HANDLER handler, const void* hParam);
```

Returns

TCPIP_ARP_HANDLE

- On Success - Returns a valid handle
- On Failure - Null handle

Description

This function will register a notification handler with the ARP module.

Remarks

None.

Preconditions

The ARP module should have been initialized.

Parameters

Parameters	Description
hNet	Specifies interface to register on. Use hNet == 0 to register on all interfaces available.
handler	Handler to be called for event.
hParam	The hParam is passed by the client and will be used by the ARP when the notification is made. It is used for per-thread content or if more modules, for example, share the same handler and need a way to differentiate the callback.

Function

TCPIP_ARP_HANDLE TCPIP_ARP_HandlerRegister(TCPIP_NET_HANDLE hNet,
TCPIP_ARP_EVENT_HANDLER handler, const void* hParam)

TCPIP_ARP_IsResolved Function

Determines if an ARP request has been resolved yet.

File

arp.h

C

```
bool TCPIP_ARP_IsResolved(TCPIP_NET_HANDLE hNet, IPV4_ADDR* IPAddr, TCPIP_MAC_ADDR* MACAddr);
```

Description

This function checks if an ARP request has been resolved yet, and if so, stores the resolved MAC address in the pointer provided.

Remarks

None.

Preconditions

The ARP module should have been initialized.

Parameters

Parameters	Description
hNet	interface to use
IPAddr	The IP address to be resolved. This must match the IP address provided to the TCPIP_ARP_Resolve() function call.
MACAddr	A buffer to store the corresponding MAC address retrieved from the ARP query.

Function

bool TCPIP_ARP_IsResolved(TCPIP_NET_HANDLE hNet, IPV4_ADDR* IPAddr, TCPIP_MAC_ADDR* MACAddr)

TCPIP_ARP_Probe Function

Transmits an ARP probe to resolve an IP address.

File

arp.h

C

```
TCPIP_ARP_RESULT TCPIP_ARP_Probe(TCPIP_NET_HANDLE hNet, IPV4_ADDR* IPAddr, IPV4_ADDR* srcAddr,
TCPIP_ARP_OPERATION_TYPE opType);
```

Returns

- ARP_RES_ENTRY_SOLVED - if the required entry is already solved

- ARP_RES_ENTRY_QUEUED - if the required entry was already queued
- ARP_RES_ENTRY_NEW - if the operation succeeded and a new entry was added (and queued for resolving)
- ARP_RES_CACHE_FULL - if new entry could not be inserted, the cache was full
- ARP_RES_BAD_ADDRESS - bad address specified
- ARP_RES_NO_INTERFACE - no such interface

Description

This function transmits and ARP probe to determine the hardware address of a given IP address. The packet will use the type of operation and the source address specified as parameters.

Remarks

This function is a more advanced version of TCPIP_ARP_Resolve. It allows the caller to specify the operation type and the source address of the outgoing ARP packet. It also supports the ARP flags defined in TCPIP_ARP_OPERATION_TYPE.

No check is done for IPAddr to be valid.

To retrieve the ARP query result, call the TCPIP_ARP_IsResolved function.

Preconditions

The ARP module should have been initialized.

Parameters

Parameters	Description
hNet	interface to use
IPAddr	The IP address to be resolved. The address must be specified in network byte order (big endian).
srcAddr	The source address to be used in the ARP packet
opType	Operation code to be set in the outgoing ARP packet

Function

TCPIP_ARP_RESULT TCPIP_ARP_Probe(TCPIP_NET_HANDLE hNet, IPV4_ADDR* IPAddr,
IPV4_ADDR* srcAddr, TCPIP_ARP_OPERATION_TYPE opType)

TCPIP_ARP_Resolve Function

Transmits an ARP request to resolve an IP address.

File

arp.h

C

```
TCPIP_ARP_RESULT TCPIP_ARP_Resolve(TCPIP_NET_HANDLE hNet, IPV4_ADDR* IPAddr);
```

Returns

An element from the TCPIP_ARP_RESULT enumeration. ARP_RES_ENTRY_SOLVED - if the required entry is already solved ARP_RES_ENTRY_QUEUED - if the required entry was already queued ARP_RES_ENTRY_NEW - if the operation succeeded and a new entry was added (and queued for resolving) ARP_RES_CACHE_FULL - if new entry could not be inserted, the cache was full ARP_RES_BAD_ADDRESS - bad address specified ARP_RES_NO_INTERFACE - no such interface

Description

This function transmits and ARP request to determine the hardware address of a given IP address. Upon the address resolution it calls the registered handler (if available) with the supplied notification parameter (if != 0)

Remarks

To retrieve the ARP query result, call the TCPIP_ARP_IsResolved function.

Preconditions

The ARP module should have been initialized.

Parameters

Parameters	Description
hNet	interface to use

IPAddr	The IP address to be resolved. The address must be specified in network byte order (big endian).

Function

TCPIP_ARP_RESULT TCPIP_ARP_Resolve(TCPIP_NET_HANDLE hNet, IPV4_ADDR* IPAddr)

TCPIP_ARP_Task Function

Standard TCP/IP stack module task function.

File

arp.h

C

```
void TCPIP_ARP_Task();
```

Returns

None.

Description

Performs ARP module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The ARP module should have been initialized.

Function

void TCPIP_ARP_Task(void)

TCPIP_ARP_EntrySet Function

Adds an ARP cache entry for the specified interface.

File

arp.h

C

```
TCPIP_ARP_RESULT TCPIP_ARP_EntrySet(TCPIP_NET_HANDLE hNet, IPV4_ADDR* ipAdd, TCPIP_MAC_ADDR* hwAdd, bool perm);
```

Returns

- On Success - ARP_RES_OK/ARP_RES_ENTRY_EXIST
- On Failure - An Error for example, cache is full with permanent entries that cannot be purged or the permanent quota exceeded)

Description

This function will add an entry to the selected interface cache. The entry can be marked as as permanent (not subject to timeouts or updates from the network). If cache is full, an entry will be deleted to make room.

Remarks

None.

Preconditions

The ARP module should have been initialized.

Parameters

Parameters	Description
hNet	Interface to use
ipAdd	The IP address
hwAdd	The mapping MAC address for the supplied ipAdd

perm	if true, the entry will be marked as permanent

Function

TCPIP_ARP_RESULT TCPIP_ARP_EntrySet(TCPIP_NET_HANDLE hNet, IPV4_ADDR* ipAdd,
TCPIP_MAC_ADDR* hwAdd, bool perm)

b) Cache Manipulation Functions

TCPIP_ARP_CacheEntriesNoGet Function

Used to retrieve the number of entries for a specific interface.

File

arp.h

C

```
size_t TCPIP_ARP_CacheEntriesNoGet(TCPIP_NET_HANDLE hNet, TCPIP_ARP_ENTRY_TYPE type);
```

Returns

The number of entries of the specified type per interface.

Description

The function will return the number of entries of the specified type that are currently in the cache.

Remarks

None.

Preconditions

The ARP module should have been initialized.

Parameters

Parameters	Description
hNet	Interface to use
type	Type of ARP entry

Function

size_t TCPIP_ARP_CacheEntriesNoGet(TCPIP_NET_HANDLE hNet, TCPIP_ARP_ENTRY_TYPE type);

TCPIP_ARP_CacheThresholdSet Function

Sets the cache threshold for the specified interface in percent.

File

arp.h

C

```
TCPIP_ARP_RESULT TCPIP_ARP_CacheThresholdSet(TCPIP_NET_HANDLE hNet, int purgeThres, int purgeEntries);
```

Returns

- On Success - ARP_RES_OK
- On Failure - ARP_RES_NO_INTERFACE (if no such interface exists)

Description

This function sets the current value of the cache threshold for the selected interface. During the ARP operation, once the number of entries in the cache is greater than the purge threshold a number of purgeEntries (usually one) will be discarded

Remarks

None.

Preconditions

The ARP module should have been initialized.

Parameters

Parameters	Description
hNet	Interface handle to use
purgeThres	Threshold to start cache purging
purgeEntries	Number of entries to purge

Function

TCPIP_ARP_RESULT TCPIP_ARP_CacheThresholdSet(TCPIP_NET_HANDLE hNet,
int purgeThres, int purgeEntries);

TCPIP_ARP_EntryQuery Function

Queries an ARP cache entry using the index of the cache line.

File

arp.h

C

```
TCPIP_ARP_RESULT TCPIP_ARP_EntryQuery(TCPIP_NET_HANDLE hNet, size_t index, TCPIP_ARP_ENTRY_QUERY*
pArpQuery);
```

Returns

- On Success - ARP_RES_OK
- On Failure - ARP_RES_BAD_INDEX (if index is out of range) ARP_RES_NO_INTERFACE (if no such interface exists)

Description

This function can be used for displaying the cache contents.

Remarks

None.

Preconditions

The ARP module should have been initialized. The index has to be a valid one. For example, TCPIP_ARP_CacheEntriesNoGet populates the supplied TCPIP_ARP_ENTRY_QUERY query entry.

Parameters

Parameters	Description
hNet	Interface handle to use
index	Index to cache
pArpQuery	entry type, IP address, hardware address

Function

TCPIP_ARP_RESULT TCPIP_ARP_EntryQuery(TCPIP_NET_HANDLE hNet, size_t index,
TCPIP_ARP_ENTRY_QUERY* pArpQuery)

TCPIP_ARP_EntryRemoveAll Function

Removes all the mapping belonging to an interface.

File

arp.h

C

```
TCPIP_ARP_RESULT TCPIP_ARP_EntryRemoveAll(TCPIP_NET_HANDLE hNet);
```

Returns

TCPIP_ARP_RESULT

- On Success - ARP_RES_OK
- On Failure - ARP_RES_NO_INTERFACE (if no such interface exists)

Description

This function removes all existent mappings from the selected interface cache.

Remarks

None.

Preconditions

The ARP module should have been initialized.

Parameters

Parameters	Description
hNet	network interface handle

Function

TCPIP_ARP_RESULT TCPIP_ARP_EntryRemoveAll(TCPIP_NET_HANDLE hNet)

c) Data Types and Constants

TCPIP_ARP_ENTRY_QUERY Structure

ARP entry query.

File

arp.h

C

```
typedef struct {
  TCPIP_ARP_ENTRY_TYPE entryType;
  IPV4_ADDR entryIpAdd;
  TCPIP_MAC_ADDR entryHwAdd;
} TCPIP_ARP_ENTRY_QUERY;
```

Members

Members	Description
TCPIP_ARP_ENTRY_TYPE entryType;	what entry type
IPV4_ADDR entryIpAdd;	the entry IP address
TCPIP_MAC_ADDR entryHwAdd;	the entry hardware address

Description

Structure: TCPIP_ARP_ENTRY_QUERY

Data structure for an ARP query.

TCPIP_ARP_ENTRY_TYPE Enumeration

Type of ARP entry.

File

arp.h

C

```
typedef enum {
  ARP_ENTRY_TYPE_INVALID,
  ARP_ENTRY_TYPE_PERMANENT,
  ARP_ENTRY_TYPE_COMPLETE,
  ARP_ENTRY_TYPE_INCOMPLETE,
  ARP_ENTRY_TYPE_ANY,
  ARP_ENTRY_TYPE_TOTAL
} TCPIP_ARP_ENTRY_TYPE;
```

Members

Members	Description
ARP_ENTRY_TYPE_INVALID	empty entry
ARP_ENTRY_TYPE_PERMANENT	entry valid and permanent
ARP_ENTRY_TYPE_COMPLETE	entry valid
ARP_ENTRY_TYPE_INCOMPLETE	entry not resolved yet
ARP_ENTRY_TYPE_ANY	any busy entry (PERMANENT|COMPLETE|INCOMPLETE)
ARP_ENTRY_TYPE_TOTAL	total entries - the number of entries the cache can store

Description

Enumeration: TCPIP_ARP_ENTRY_TYPE

List of different ARP cache entries.

Remarks

None.

TCPIP_ARP_EVENT_HANDLER Type

Notification handler that can be called when a specific entry is resolved.

File

arp.h

C

```
typedef void (* TCPIP_ARP_EVENT_HANDLER)(TCPIP_NET_HANDLE hNet, const IPV4_ADDR* ipAdd, const
TCPIP_MAC_ADDR* MACAddr, TCPIP_ARP_EVENT_TYPE evType, const void* param);
```

Description

Type: TCPIP_ARP_EVENT_HANDLER

The format of a notification handler registered with the ARP module.

Remarks

The parameter member significance is module dependent. It can be an IP address, pointer to some other structure, etc. The handler is called when an event of some sort occurs for a particular IP address entry. If pNetIf == 0, the notification is called for events on any interface

TCPIP_ARP_EVENT_TYPE Enumeration

Events reported by ARP.

File

arp.h

C

```
typedef enum {
  ARP_EVENT_SOLVED = 1,
  ARP_EVENT_UPDATED = 2,
  ARP_EVENT_PERM_UPDATE = 3,
  ARP_EVENT_REMOVED_TMO = -1,
  ARP_EVENT_REMOVED_USER = -2,
  ARP_EVENT_REMOVED_EXPIRED = -3,
  ARP_EVENT_REMOVED_PURGED = -4
} TCPIP_ARP_EVENT_TYPE;
```

Members

Members	Description
ARP_EVENT_SOLVED = 1	a queued cache entry was solved;
ARP_EVENT_UPDATED = 2	an existent cache entry was updated
ARP_EVENT_PERM_UPDATE = 3	an update for an permanent entry was received however the permanent entry was not updated error events - entries removed from ARP cache
ARP_EVENT_REMOVED_TMO = -1	an entry could not be solved and a tmo occurred
ARP_EVENT_REMOVED_USER = -2	a queued cache entry was removed by ARP user

ARP_EVENT_REMOVED_EXPIRED = -3	a queued cache entry expired and was removed
ARP_EVENT_REMOVED_PURGED = -4	a queued cache entry was purged

Description

Enumeration: TCPIP_ARP_EVENT_TYPE

List of events reported by ARP.

Remarks

Possibly multiple events can be set, where it makes sense.

TCPIP_ARP_HANDLE Type

ARP handle.

File

arp.h

C

```
typedef const void* TCPIP_ARP_HANDLE;
```

Description

Type: TCPIP_ARP_HANDLE

A handle that a client needs to use when deregistering a notification handler.

Remarks

This handle can be used by the client after the event handler has been registered.

TCPIP_ARP_OPERATION_TYPE Enumeration

Type of ARP operation.

File

arp.h

C

```
typedef enum {
  ARP_OPERATION_REQ = 1,
  ARP_OPERATION_RESP = 2,
  ARP_OPERATION_MASK = 0x000f,
  ARP_OPERATION_CONFIGURE = 0x1000,
  ARP_OPERATION_GRATUITOUS = 0x2000,
  ARP_OPERATION_PROBE_ONLY = 0x4000
} TCPIP_ARP_OPERATION_TYPE;
```

Members

Members	Description
ARP_OPERATION_REQ = 1	ARP request
ARP_OPERATION_RESP = 2	ARP response
ARP_OPERATION_MASK = 0x000f	extract ARP operation
ARP_OPERATION_CONFIGURE = 0x1000	stack configuration ARP packet
ARP_OPERATION_GRATUITOUS = 0x2000	stack gratuitous ARP packet
ARP_OPERATION_PROBE_ONLY = 0x4000	an ARP probe is sent only once, the target address is not stored

Description

Enumeration: TCPIP_ARP_OPERATION_TYPE

Operation to be performed by an ARP probe.

Remarks

Used for low level functionality, TCPIP_ARP_Probe.

TCPIP_ARP_RESULT Enumeration

ARP results (success and failure codes).

File

arp.h

C

```
typedef enum {
  ARP_RES_OK = 0,
  ARP_RES_ENTRY_NEW,
  ARP_RES_ENTRY_SOLVED,
  ARP_RES_ENTRY_QUEUED,
  ARP_RES_ENTRY_EXIST,
  ARP_RES_PERM_QUOTA_EXCEED,
  ARP_RES_PROBE_OK,
  ARP_RES_NO_ENTRY = -1,
  ARP_RES_CACHE_FULL = -2,
  ARP_RES_TX_FAILED = -3,
  ARP_RES_BAD_INDEX = -4,
  ARP_RES_BAD_ADDRESS = -5,
  ARP_RES_NO_INTERFACE = -6,
  ARP_RES_BAD_TYPE = -7,
  ARP_RES_CONFIGURE_ERR = -8,
  ARP_RES_PROBE_FAILED = -9
} TCPIP_ARP_RESULT;
```

Members

Members	Description
ARP_RES_OK = 0	operation succeeded
ARP_RES_ENTRY_NEW	operation succeeded and a new entry was added
ARP_RES_ENTRY_SOLVED	the required entry is already solved
ARP_RES_ENTRY_QUEUED	the required entry was already queued
ARP_RES_ENTRY_EXIST	the required entry was already cached
ARP_RES_PERM_QUOTA_EXCEED	info: the quota of permanent entries was exceeded
ARP_RES_PROBE_OK	requested probe sent
ARP_RES_NO_ENTRY = -1	no such entry exists
ARP_RES_CACHE_FULL = -2	the cache is full and no entry could be removed to make room
ARP_RES_TX_FAILED = -3	failed to transmit an ARP message
ARP_RES_BAD_INDEX = -4	bad query index
ARP_RES_BAD_ADDRESS = -5	bad IP address specified
ARP_RES_NO_INTERFACE = -6	no such interface exists
ARP_RES_BAD_TYPE = -7	no such type is valid/exists
ARP_RES_CONFIGURE_ERR = -8	interface is configuring now, no ARP probes
ARP_RES_PROBE_FAILED = -9	requested probe failed

Description

Enumeration: TCPIP_ARP_RESULT

Various definitions for success and failure codes.

Remarks

None.

TCPIP_ARP_MODULE_CONFIG Structure

File

arp.h

C

```
typedef struct {
  size_t cacheEntries;
```

```
    bool deleteOld;
    int entrySolvedTmo;
    int entryPendingTmo;
    int entryRetryTmo;
    int permQuota;
    int purgeThres;
    int purgeQuanta;
    int retries;
    int gratProbeCount;
} TCPIP_ARP_MODULE_CONFIG;
```

Members

Members	Description
size_t cacheEntries;	cache entries for this interface
bool deleteOld;	delete old cache if still in place, else don't reinitialize it
int entrySolvedTmo;	solved entry removed after this tmo if not referenced - seconds
int entryPendingTmo;	timeout for a pending to be solved entry in the cache, in seconds
int entryRetryTmo;	timeout for resending an ARP request for a pending entry - seconds 1 sec < tmo < entryPendingTmo
int permQuota;	max percentage of permanent entries allowed in the cache -
int purgeThres;	purge threshold -
int purgeQuanta;	no of entries to delete once the threshold is reached
int retries;	no of retries for resolving an entry
int gratProbeCount;	no of retries done for a gratuitous ARP request

Description

This is type TCPIP_ARP_MODULE_CONFIG.

Files

Files

Name	Description
arp.h	Address Resolution Protocol (ARP) header file.
arp_config.h	ARP configuration file

Description

This section lists the source and header files used by the library.

arp.h

Address Resolution Protocol (ARP) header file.

Enumerations

	Name	Description
	TCPIP_ARP_ENTRY_TYPE	Type of ARP entry.
	TCPIP_ARP_EVENT_TYPE	Events reported by ARP.
	TCPIP_ARP_OPERATION_TYPE	Type of ARP operation.
	TCPIP_ARP_RESULT	ARP results (success and failure codes).

Functions

	Name	Description
	TCPIP_ARP_CacheEntriesNoGet	Used to retrieve the number of entries for a specific interface.
	TCPIP_ARP_CacheThresholdSet	Sets the cache threshold for the specified interface in percent.
	TCPIP_ARP_EntryGet	Gets the current mapping for an IP address.
	TCPIP_ARP_EntryQuery	Queries an ARP cache entry using the index of the cache line.
	TCPIP_ARP_EntryRemove	Removes the mapping of an address, even a permanent one
	TCPIP_ARP_EntryRemoveAll	Removes all the mapping belonging to an interface.
	TCPIP_ARP_EntryRemoveNet	Removes all the entries belonging to a network interface.
	TCPIP_ARP_EntrySet	Adds an ARP cache entry for the specified interface.

	TCPIP_ARP_HandlerDeRegister	Deregisters the event handler
	TCPIP_ARP_HandlerRegister	Register an ARP resolve handler.
	TCPIP_ARP_IsResolved	Determines if an ARP request has been resolved yet.
	TCPIP_ARP_Probe	Transmits an ARP probe to resolve an IP address.
	TCPIP_ARP_Resolve	Transmits an ARP request to resolve an IP address.
	TCPIP_ARP_Task	Standard TCP/IP stack module task function.

Structures

	Name	Description
	TCPIP_ARP_ENTRY_QUERY	ARP entry query.
	TCPIP_ARP_MODULE_CONFIG	This is type TCPIP_ARP_MODULE_CONFIG.

Types

	Name	Description
	TCPIP_ARP_EVENT_HANDLER	Notification handler that can be called when a specific entry is resolved.
	TCPIP_ARP_HANDLE	ARP handle.

Description

Address Resolution Protocol (ARP) Header file

This source file contains the ARP module API definitions.

File Name

arp.h

Company

Microchip Technology Inc.

arp_config.h

ARP configuration file

Macros

	Name	Description
	ARP_CACHE_DELETE_OLD	On initialization, delete the old cache if still in place Else don't re-initialize Default should be 1
	TCPIP_ARP_CACHE_ENTRIES	Number of entries in the cache. Default number of entries per interface.
	TCPIP_ARP_CACHE_ENTRY_RETRIES	Number of ARP requests generated for resolving an entry.
	TCPIP_ARP_CACHE_PENDING_ENTRY_TMO	Timeout for a cache entry pending to be solved, in seconds. The entry will be removed if the tmo elapsed and the entry has not been solved. A solved entry moves to the solved entries timeout.
	TCPIP_ARP_CACHE_PENDING_RETRY_TMO	Timeout for resending an ARP request for a pending entry. In order to prevent the ARP flooding the standard recommends it to be greater than 1 sec. It should be less than TCPIP_ARP_CACHE_PENDING_ENTRY_TMO
	TCPIP_ARP_CACHE_PERMANENT_QUOTA	Max percentage of permanent entries in the cache. Note that since permanent entries cannot be removed they tend to degrade the efficiency of the cache look up.
	TCPIP_ARP_CACHE_PURGE_QUANTA	The number of entries to delete, once the threshold is reached.
	TCPIP_ARP_CACHE_PURGE_THRESHOLD	Default purge threshold, percentage Once the number of resolved entries in the cache gets beyond the threshold some resolved entries will be purged.
	TCPIP_ARP_CACHE_SOLVED_ENTRY_TMO	Timeout for a solved entry in the cache, in seconds. The entry will be removed if the tmo elapsed and the entry has not been referenced again
	TCPIP_ARP_GRATUITOUS_PROBE_COUNT	Number of ARP requests generated when sending a gratuitous ARP probe. Default value should be 1.
	TCPIP_ARP_TASK_PROCESS_RATE	ARP task processing rate, in seconds. The ARP module will process a timer event with this rate for maintaining its own queues, processing timeouts, etc. Choose it so that the other ARP_CACHE_xxx_TMO are multiple of this The default value is 2 seconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

Berkeley Module

This section describes the TCP/IP Stack Library Berkeley Module.

Introduction

TCP/IP Stack Library Berkeley Module for Microchip Microcontrollers

This library provides the API of the Berkeley module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

The Berkeley Socket Distribution (BSD) APIs provide a BSD wrapper to the native Microchip TCP/IP Stack APIs. Using this interface, programmers familiar with BSD sockets can quickly develop applications using Microchip's TCP/IP Stack.

Using the Library

This topic describes the basic architecture of the Berkeley TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `berkeley_api.h`

The interface to the Berkeley TCP/IP Stack library is defined in the `berkeley_api.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the berkeley TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

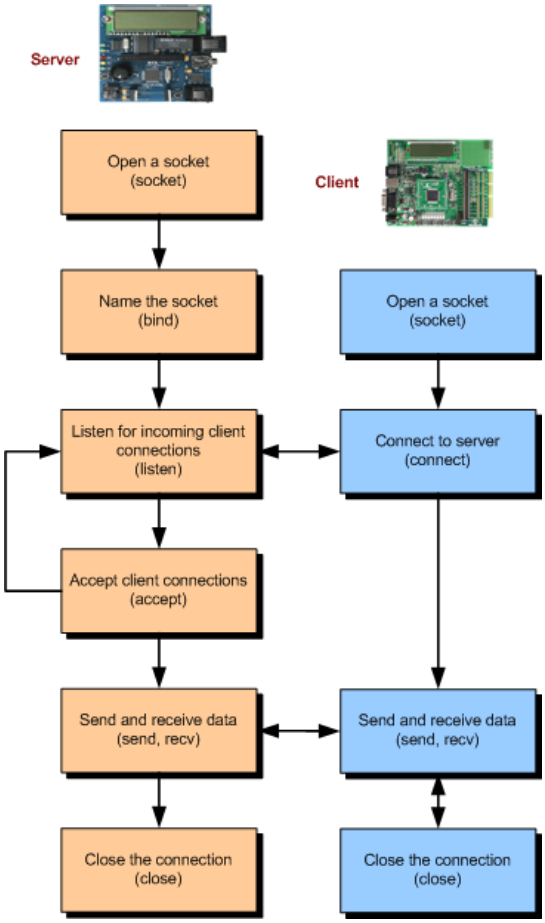
Abstraction Model

This library provides the API of the Berkeley TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

Berkeley Software Abstraction Block Diagram

The following illustration shows a typical interaction for a TCP server or client using the Berkeley socket APIs.



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Berkeley module.

Library Interface Section	Description
Functions	Routines for Configuring the Berkeley Socket API
Data Types and Constants	This section provides various definitions describing this API

Configuring the Library

Macros

	Name	Description
	MAX_BSD_SOCKETS	Berkeley API max number of sockets simultaneous supported

Description

The configuration of the Berkeley TCP/IP Stack is based on the file `tcpip_config.h`.

This header file contains the configuration selection for the Berkeley TCP/IP Stack. Based on the selections made, the Berkeley TCP/IP Stack may support the selected features. These configuration settings will apply to all instances of the Berkeley TCP/IP Stack.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

MAX_BSD_SOCKETS Macro

File

berkeley_api_config.h

C

```
#define MAX_BSD_SOCKETS (4)
```

Description

Berkeley API max number of sockets simultaneous supported

Building the Library

This section lists the files that are available in the Berkeley module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/berkeley_api.c`	Berkeley API implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The Berkeley module depends on the following modules:

- TCP/IP Stack Library
- UDP Module
- TCP Module

Library Interface

a) Functions

	Name	Description
	accept	This function accepts connection requests queued for a listening socket.
	bind	This function assigns a name to the socket descriptor.
	closesocket	The closesocket function closes an existing socket.
	connect	This function connects to the peer communications end point.
	gethostname	Returns the standard host name for the system.
	listen	The listen function sets the specified socket in a listen mode.
	recv	The recv() function is used to receive incoming data that has been queued for a socket.
	recvfrom	The recvfrom() function is used to receive incoming data that has been queued for a socket.
	send	The send function is used to send outgoing data on an already connected socket.
	sendto	This function used to send the data for both connection oriented and connection-less sockets.

	socket	This function creates a new Berkeley socket.
	getsockopt	Allows setting options to a socket like adjust RX/TX buffer size, etc
	setsockopt	Allows setting options to a socket like adjust RX/TX buffer size, etc
	gethostbyname	The gethostbyname function returns a structure of type hostent for the given host name.
	getsockname	Returns the current address to which the socket is bound.
	TCPIP_BSD_Socket	Returns the native socket number associated with the BSD socket.
	freeaddrinfo	Frees the memory allocated by getaddrinfo
	getaddrinfo	Does an address look up for the provided node name.

b) Data Types and Constants

	Name	Description
	AF_INET	Internet Address Family - IPv4, UDP, TCP, etc.
	INADDR_ANY	IP address for server binding.
	INVALID_TCP_PORT	Invalid TCP port
	IP_ADDR_ANY	IP Address for server binding
	IPPROTO_IP	Indicates IP pseudo-protocol.
	IPPROTO_TCP	Indicates TCP level options
	IPPROTO_UDP	Indicates UDP level options
	SOCK_DGRAM	Connectionless datagram socket. Use UDP for the Internet address family.
	SOCK_STREAM	Connection based byte streams. Use TCP for the Internet address family.
	SOCKET_CNXN_IN_PROGRESS	Socket connection state.
	SOCKET_DISCONNECTED	Socket disconnected
	SOCKET_ERROR	Socket error
	SOCKADDR	generic address structure for all address families
	SOCKADDR_IN	In the Internet address family
	SOCKET	Socket descriptor
	in_addr	in_addr structure
	sockaddr	generic address structure for all address families
	sockaddr_in	In the Internet address family
	addrinfo	This is record addrinfo.
	EAI_AGAIN	Temporary failure in name resolution.
	EAI_BADFLAGS	Invalid value for `ai_flags' field.
	EAI_FAIL	Non-recoverable failure in name res.
	EAI_FAMILY	ai_family' not supported.
	EAI_MEMORY	Memory allocation failure.
	EAI_NONAME	NAME or SERVICE is unknown.
	EAI_OVERFLOW	Argument buffer overflow.
	EAI_SERVICE	SERVICE not supported for `ai_socktype'.
	EAI_SOCKTYPE	ai_socktype' not supported.
	EAI_SYSTEM	System error returned in `errno'.
	ICMP6_FILTER	SEt the IPv6 Filtering options - Not yet supported
	IP_ADD_MEMBERSHIP	Join a multicast group - Not yet supported
	IP_DROP_MEMBERSHIP	Leave a multicast group - Not yet supported
	IP_MULTICAST_IF	Set the Interface that multicast packets should be sent on - Not yet supported
	IP_MULTICAST_LOOP	Specify a copy of multicast packets should be delivered to the sending host - Not yet supported
	IP_MULTICAST_TTL	Set the Time to Live option for multicast packets - Not yet supported
	IP_OPTIONS	IP Header Options - Not yet supported
	IP_TOS	Type of Service - Not yet supported
	IP_TTL	Time to Live - Not yet supported
	IPPROTO_ICMPV6	Indicates IPv6 ICMP Protocol Options
	IPPROTO_IPV6	Indicates IP v6 Header options
	IPV6_CHECKSUM	Sets the IPv6 Checksum options - Not yet supported
	IPV6_JOIN_GROUP	Join an IPv6 multicast group - Not yet supported
	IPV6_LEAVE_GROUP	Leave an IPv6 multicast group - Not yet supported

	IPV6_MULTICAST_HOPS	Set the hop limit for multicast IPv6 packets - Not yet supported
	IPV6_MULTICAST_IF	Set the Interface that multicast IPv6 packets should be sent on - Not yet supported
	IPV6_MULTICAST_LOOP	Specify a copy of multicast IPv6 packets should be delivered to the sending host - Not yet supported
	IPV6_UNICAST_HOPS	Set the hop limit for unicast IPv6 packets - Not yet supported
	IPV6_V6ONLY	Sets the socket to IPv6 only - Not yet supported
	SO_BROADCAST	Enables the Socket for sending broadcast data
	SO_DEBUG	Indicates if low level debut is active - Not yet supported
	SO_DONTROUTE	Bypass normal routing - Not yet supported
	SO_KEEPALIVE	Keep the connection alive by sending periodic transmissions - Not yet supported
	SO_LINGER	Indicates if the system should send any buffered data when a socket is closed
	SO_OOBINLINE	Indicates whether or not Out of Band Data should be received inline with normal data - Not yet supported
	SO_RCVBUF	Receive Buffer Size (TCP only)
	SO_RCVLOWAT	Receive Low Water mark - Not yet supported
	SO_RCVTIMEO	Set the Receive Timeout - Not yet supported
	SO_REUSEADDR	Indicates if the local socket can be reused immediately after close - Not yet supported
	SO_SNDBUF	Send Buffer Size
	SO_SNDLOWAT	Send Low Water mark - Not yet supported
	SO_SNDTIMEO	Set the Send Timeout - Not yet supported
	SOL_SOCKET	Indicates socket level options
	TCP_NODELAY	Indicates if TCP is to buffer packets - Not yet supported
	linger	This is record linger.
	hostent	This is record hostent.
	HOST_NOT_FOUND	Authoritative Answer host not found
	NO_DATA	Valid name, no data record of requested type
	NO_RECOVERY	Non recoverable errors,
	TRY_AGAIN	Non authoritative host not found or server fail
	in6_addr	This is record in6_addr.
	sockaddr_in6	In the Internet address family
	sockaddr_storage	This is record sockaddr_storage.
	SOCKADDR_IN6	This is type SOCKADDR_IN6.
	AF_INET6	Internet Address Family - IPv6
	__ss_aligntype	Structure large enough to hold any socket address (with the historical exception of AF_UNIX). 128 bytes reserved.
	_BERKELEY_API_HEADER_FILE	This is macro _BERKELEY_API_HEADER_FILE.
	_SS_PADSIZE	This is macro _SS_PADSIZE.
	_SS_SIZE	This is macro _SS_SIZE.
	BERKELEY_MODULE_CONFIG	Berkeley API module configuration structure

Description

This section describes the Application Programming Interface (API) functions of the Berkeley module.

Refer to each section for a detailed description.

a) Functions

accept Function

This function accepts connection requests queued for a listening socket.

File

berkeley_api.h

C

```
SOCKET accept(SOCKET s, struct sockaddr* addr, int* addrlen);
```

Returns

If the accept function succeeds, it returns a non-negative integer that is a descriptor for the accepted socket. Otherwise, the value SOCKET_ERROR is returned (and errno is set accordingly).

Description

The accept function is used to accept connection requests queued for a listening socket. If a connection request is pending, accept removes the request from the queue, and a new socket is created for the connection. The original listening socket remains open and continues to queue new connection requests. The socket must be a SOCK_STREAM type socket.

Remarks

None.

Preconditions

The listen function should be called.

Parameters

Parameters	Description
s	Socket descriptor returned from a previous call to socket. Must be bound to a local name and in listening mode.
addr	Optional pointer to a buffer that receives the address of the connecting entity.
addrlen	Optional pointer to an integer that contains the length of the address addr

Function

SOCKET accept(SOCKET s, struct sockaddr* addr, int* addrlen)

bind Function

This function assigns a name to the socket descriptor.

File

berkeley_api.h

C

```
int bind(SOCKET s, const struct sockaddr* name, int namelen);
```

Returns

If bind is successful, a value of 0 is returned. A return value of SOCKET_ERROR indicates an error (and errno is set accordingly).

Description

The bind function assigns a name to an unnamed socket. The name represents the local address of the communication endpoint. For sockets of type SOCK_STREAM, the name of the remote endpoint is assigned when a connect or accept function is executed.

Remarks

None.

Preconditions

The socket function should be called.

Parameters

Parameters	Description
s	Socket descriptor returned from a previous call to socket
name	pointer to the sockaddr structure containing the local address of the socket
namelen	length of the sockaddr structure

Function

int bind(SOCKET s, const struct sockaddr* name, int namelen)

closesocket Function

The closesocket function closes an existing socket.

File

berkeley_api.h

C

```
int closesocket(SOCKET s);
```

Returns

If closesocket is successful, a value of 0 is returned. A return value of SOCKET_ERROR (-1) indicates an error (and errno is set accordingly).

Description

The closesocket function closes an existing socket. This function releases the socket descriptor s. Any data buffered at the socket is discarded. If the socket s is no longer needed, closesocket() must be called in order to release all resources associated with s.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
s	Socket descriptor returned from a previous call to socket

Function

int closesocket(SOCKET s)

connect Function

This function connects to the peer communications end point.

File

berkeley_api.h

C

```
int connect(SOCKET s, struct sockaddr* name, int namelen);
```

Returns

If the connect() function succeeds, it returns 0. Otherwise, the value SOCKET_ERROR is returned to indicate an error condition (and errno is set accordingly). For stream based socket, if the connection is not established yet, connect returns SOCKET_ERROR and errno = EINPROGRESS.

Description

The connect function assigns the address of the peer communications endpoint. For stream sockets, connection is established between the endpoints. For datagram sockets, an address filter is established between the endpoints until changed with another connect() function.

Remarks

None.

Preconditions

The socket function should be called.

Parameters

Parameters	Description
s	Socket descriptor returned from a previous call to socket
name	Pointer to the sockaddr structure containing the peer address and port number
namelen	Length of the sockaddr structure

Function

int connect(SOCKET s, struct sockaddr* name, int namelen)

gethostname Function

Returns the standard host name for the system.

File

berkeley_api.h

C

```
int gethostname(char* name, int namelen);
```

Returns

Success will return a value of 0. If name is too short to hold the host name or any other error occurs, SOCKET_ERROR (-1) will be returned (and errno is set accordingly). On error, *name will be unmodified and no null terminator will be generated.

Description

This function returns the standard host name of the system which is calling this function. The returned name is null-terminated.

Remarks

The function returns the host name as set on the default network interface.

Preconditions

None.

Parameters

Parameters	Description
name	Pointer to a buffer that receives the local host name
namelen	Size of the name array

Function

int gethostname(char* name, int namelen)

listen Function

The listen function sets the specified socket in a listen mode.

File

berkeley_api.h

C

```
int listen(SOCKET s, int backlog);
```

Returns

Returns 0 on success; otherwise returns SOCKET_ERROR (and errno is set accordingly).

Description

This function sets the specified socket in a listen mode. Calling the listen function indicates that the application is ready to accept connection requests arriving at a socket of type SOCK_STREAM. The connection request is queued (if possible) until accepted with an accept function. The backlog parameter defines the maximum number of pending connections that may be queued.

Remarks

None.

Preconditions

bind() must have been called on the s socket first.

Parameters

Parameters	Description
s	Socket identifier returned from a prior socket() call.
backlog	Maximum number of connection requests that can be queued. Note that each backlog requires a TCP socket to be allocated.

Function

int listen(SOCKET s, int backlog)

recv Function

The recv() function is used to receive incoming data that has been queued for a socket.

File

berkeley_api.h

C

```
int recv(SOCKET s, char* buf, int len, int flags);
```

Returns

If the recv function is successful, the socket is valid and it has pending data:

- The supplied buffer is non NULL and has non zero length, the function will return the number of bytes copied to the application buffer.
- The supplied buffer is NULL or has zero length then no data will be copied and the function will return the number of bytes pending in the socket buffer.

A return value of SOCKET_ERROR (-1) indicates an error condition (and errno set accordingly). errno is set to EWOULDBLOCK if there is no data pending in the socket buffer.

A value of zero indicates socket has been shutdown by the peer.

Description

The recv() function is used to receive incoming data that has been queued for a socket. This function can be used with both datagram and stream socket. If the available data is too large to fit in the supplied application buffer buf, excess bytes are discarded in case of SOCK_DGRAM type sockets. For SOCK_STREAM types, the data is buffered internally so the application can retrieve all data by multiple calls of recvfrom.

Remarks

None.

Preconditions

The connect function should be called for TCP and UDP sockets. Server side, accept function should be called.

Parameters

Parameters	Description
s	Socket descriptor returned from a previous call to socket
buf	Application data receive buffer
len	Buffer length in bytes
flags	No significance in this implementation

Function

int recv(SOCKET s, char* buf, int len, int flags)

recvfrom Function

The recvfrom() function is used to receive incoming data that has been queued for a socket.

File

berkeley_api.h

C

```
int recvfrom(SOCKET s, char* buf, int len, int flags, struct sockaddr* from, int* fromlen);
```

Returns

If recvfrom is successful, the number of bytes copied to the application buffer buf is returned. A return value of SOCKET_ERROR (-1) indicates an error condition (and errno is set accordingly). A value of zero indicates socket has been shutdown by the peer.

Description

The recvfrom() function is used to receive incoming data that has been queued for a socket. This function can be used with both datagram and stream type sockets. If the available data is too large to fit in the supplied application buffer buf, excess bytes are discarded in case of SOCK_DGRAM type sockets. For SOCK_STREAM types, the data is buffered internally so the application can retrieve all data by multiple calls of

recvfrom.

Remarks

None.

Preconditions

The socket function should be called.

Parameters

Parameters	Description
s	Socket descriptor returned from a previous call to socket
buf	Application data receive buffer
len	Buffer length in bytes
flags	Message flags (currently this is not supported)
from	Pointer to the sockaddr structure that will be filled in with the destination address
fromlen	Size of buffer pointed by from

Function

int recvfrom(SOCKET s, char* buf, int len, int flags, struct sockaddr* from, int* fromlen)

send Function

The send function is used to send outgoing data on an already connected socket.

File

berkeley_api.h

C

```
int send(SOCKET s, const char* buf, int len, int flags);
```

Returns

On success, send returns number of bytes sent. Zero indicates no data send. In case of error it returns SOCKET_ERROR (and errno is set accordingly).

Description

The send function is used to send outgoing data on an already connected socket. This function is used to send a reliable, ordered stream of data bytes on a socket of type SOCK_STREAM but can also be used to send datagrams on a socket of type SOCK_DGRAM.

Remarks

None.

Preconditions

The connect function should be called for TCP and UDP sockets. Server side, accept function should be called.

Parameters

Parameters	Description
s	Socket descriptor returned from a previous call to socket
buf	Application data buffer containing data to transmit
len	Length of data in bytes
flags	Message flags (currently this field is not supported)

Function

int send(SOCKET s, const char* buf, int len, int flags)

sendto Function

This function used to send the data for both connection oriented and connection-less sockets.

File

berkeley_api.h

C

```
int sendto(SOCKET s, const char* buf, int len, int flags, const struct sockaddr* to, int tolen);
```

Returns

On success, sendto returns number of bytes sent. In case of error returns SOCKET_ERROR (and errno is set accordingly).

Description

The sendto function is used to send outgoing data on a socket. The destination address is given by to and tolen. Both Datagram and stream sockets are supported.

Remarks

None.

Preconditions

The socket function should be called.

Parameters

Parameters	Description
s	Socket descriptor returned from a previous call to socket.
buf	application data buffer containing data to transmit.
len	length of data in bytes.
flags	message flags. Currently this field is not supported.
to	Optional pointer to the sockaddr structure containing the destination address. If NULL, the currently bound remote port and IP address are used as the destination.
tolen	length of the sockaddr structure.

Function

int sendto(SOCKET s, const char* buf, int len, int flags, const struct sockaddr* to, int tolen)

socket Function

This function creates a new Berkeley socket.

File

berkeley_api.h

C

```
SOCKET socket(int af, int type, int protocol);
```

Returns

New socket descriptor. SOCKET_ERROR in case of error (and errno set accordingly).

Description

This function creates a new BSD socket for the Microchip TCP/IP stack. The return socket descriptor is used for the subsequent BSD operations.

Remarks

None.

Preconditions

BerkeleySocketInit function should be called.

Parameters

Parameters	Description
af	address family - AF_INET for IPv4, AF_INET6 for IPv6
type	socket type SOCK_DGRAM or SOCK_STREAM
protocol	IP protocol IPPROTO_UDP or IPPROTO_TCP

Function

SOCKET socket(int af, int type, int protocol)

getsockopt Function

Allows setting options to a socket like adjust RX/TX buffer size, etc

File

berkeley_api.h

C

```
int getsockopt(SOCKET s, uint32_t level, uint32_t option_name, uint8_t * option_value, uint32_t *
option_length);
```

Returns

- 0 - If successful
- -1 - If unsuccessful

Description

Various options can be set at the socket level. This function provides compatibility with BSD implementations.

Preconditions

None.

Parameters

Parameters	Description
s	Socket descriptor returned from a previous call to socket
level	On which level the operation is to be performed: • IPPROTO_IP - Applies to the IP protocol layer (not yet supported) • IPPROTO_TCP - Applies to the TCP protocol layer • SOL_SOCKET - Applies to the socket layer • IPPROTO_IPV6 - Applies to the IPv6 protocol layer (not yet supported) • IPPROTO_ICMPV6 - Applies to the ICMPv6 protocol layer (not yet supported)
option_name	The name of the option to be set: • IPPROTO_TCP • TCP_NODELAY - Specifies whether or not the stack should use the Nagle algorithm • SOL_SOCKET • SO_LINGER - Specifies what the stack should do with unsent data on close() • SO_RCVBUF - Specifies the size of the Receive Buffer (TCP only) • SO_SNDBUF - Specifies the size of the Transmit Buffer
option_value	For all values of option_name this is a pointer to the data, which in most cases is an integer. The only exception is SO_LINGER which points to a linger structure.
option_length	The size of the data pointed to by option_value

Function

int getsockopt(SOCKET s, uint32_t level, uint32_t option_name, uint8_t *option_value, uint32_t *option_length)

setsockopt Function

Allows setting options to a socket like adjust RX/TX buffer size, etc

File

berkeley_api.h

C

```
int setsockopt(SOCKET s, uint32_t level, uint32_t option_name, const uint8_t * option_value, uint32_t
option_length);
```

Returns

- 0 - If successful
- -1 - If unsuccessful

Description

Various options can be set at the socket level. This function provides compatibility with BSD implementations.

Preconditions

None.

Parameters

Parameters	Description
s	Socket descriptor returned from a previous call to socket
level	On which level the operation is to be performed: • IPPROTO_IP - Applies to the IP protocol layer (not yet supported) • IPPROTO_TCP - Applies to the TCP protocol layer • SOL_SOCKET - Applies to the socket layer • IPPROTO_IPV6 - Applies to the IPv6 protocol layer (not yet supported) • IPPROTO_ICMPV6 - Applies to the ICMPv6 protocol layer (not yet supported)
option_name	The name of the option to be set: • IPPROTO_TCP • TCP_NODELAY - Specifies whether or not the stack should use the Nagle algorithm • SOL_SOCKET • SO_LINGER - Specifies what the stack should do with unsent data on close() • SO_RCVBUF - Specifies the size of the Receive Buffer (TCP only) • SO_SNDBUF - Specifies the size of the Transmit Buffer
option_value	For all values of option_name this is a pointer to the data, which in most cases is an integer. The only exception is SO_LINGER which points to a linger structure.
option_length	The size of the data pointed to by option_value

Function

int setsockopt(SOCKET s, uint32_t level, uint32_t option_name, const uint8_t *option_value,
uint32_t option_length)

gethostbyname Function

The gethostbyname function returns a structure of type hostent for the given host name.

File

berkeley_api.h

C

```
struct hostent * gethostbyname(char * name);
```

Returns

The hostent structure on success, or NULL on error.

Remarks

This function supports IPv4 only. h_errno will be set to:

- TRY_AGAIN if the DNS query is current in progress,
- HOST_NOT_FOUND if the DNS query could not find a host name
- NO_RECOVERY if the DNS query had an unrecoverable error

Preconditions

None.

Parameters

Parameters	Description
name	The name of the host to be found

Function

struct hostent * gethostbyname(char *name)

getsockname Function

Returns the current address to which the socket is bound.

File

berkeley_api.h

C

```
int getsockname(SOCKET s, struct sockaddr * addr, int * addrlen);
```

Returns

- On success - 0 is returned and the data is updated accordingly.
- On error - -1 is returned and errno is set appropriately.

Description

The function returns the current address to which the socket is bound, in the buffer pointed to by addr.

Remarks

This function supports IPv4 connections only.

Preconditions

The socket function should be called.

Parameters

Parameters	Description
s	Socket descriptor returned from a previous call to socket
addr	address to store the current address to which the socket is bound
addrlen	on input it should point to the space (bytes) available in addr on output it points to the actual space required for storing the bound address

Function

int getsockname(SOCKET s, struct sockaddr *addr, int *addrlen);

TCPIP_BSD_Socket Function

Returns the native socket number associated with the BSD socket.

File

berkeley_api.h

C

```
int TCPIP_BSD_Socket(SOCKET s);
```

Returns

- On success - a socket number >= 0 is returned.
- On error - -1 is returned if no such socket exists and errno is set to EBADF.

Description

The function returns the native socket number associated with the BSD socket. Using this call the caller can switch to the native TCP/IP API.

Remarks

This function works for both TCP and UDP sockets.

The native UDP sockets are created after a call to bind (server sockets) or connect (client sockets). The native TCP sockets are created after a call to listen (server sockets) or connect (client sockets). Please note that calling the TCPIP_BSD_Socket before one of these calls will return an INVALID_SOCKET.

Preconditions

The socket function should be called.

Parameters

Parameters	Description
s	Socket descriptor returned from a previous call to socket

Function

int TCPIP_BSD_Socket(SOCKET s);

freeaddrinfo Function

Frees the memory allocated by getaddrinfo

File

berkeley_api.h

C

```
void freeaddrinfo(struct addrinfo * res);
```

Returns

None.

Description

Frees the memory allocated by getaddrinfo

Preconditions

getaddrinfo must have returned successfully.

Parameters

Parameters	Description
res	Memory allocated by getaddrinfo

Function

int freeaddrinfo(struct addrinfo *res);

getaddrinfo Function

Does an address look up for the provided node name.

File

berkeley_api.h

C

```
int getaddrinfo(const char * node, const char * service, const struct addrinfo * hints, struct addrinfo ** res);
```

Returns

On success, a 0 is returned.

- EAI_NONAME - When no name could be found
- EAI_FAIL - When a failure has occurred
- EAI_AGAIN - When the look-up is in progress. Call the function again later to check the results.

Description

This function deprecates gethostbyname. It handles both IPv4 and IPv6.

Preconditions

The MPLAB Harmony DNS client services must be active.

Parameters

Parameters	Description
node	The name of the server to look up.
service	Unused

hints	hints to the function. Currently only ai_family is used. Set to either 0, AF_INET or AF_INET6
res	Memory location of where the results are. Results must be freed with freeaddrinfo

Function

int getaddrinfo(const char *node, const char *service,
const struct addrinfo *hints,
struct addrinfo **res);

b) Data Types and Constants

AF_INET Macro

File

berkeley_api.h

C

```
#define AF_INET 2            // Internet Address Family - IPv4, UDP, TCP, etc.
```

Description

Internet Address Family - IPv4, UDP, TCP, etc.

INADDR_ANY Macro

File

berkeley_api.h

C

```
#define INADDR_ANY 0x01000000u    // IP address for server binding.
```

Description

IP address for server binding.

INVALID_TCP_PORT Macro

File

berkeley_api.h

C

```
#define INVALID_TCP_PORT (0L)  //Invalid TCP port
```

Description

Invalid TCP port

IP_ADDR_ANY Macro

File

berkeley_api.h

C

```
#define IP_ADDR_ANY 0x01000000u           // IP Address for server binding
```

Description

IP Address for server binding

IPPROTO_IP Macro

File

berkeley_api.h

C

```
#define IPPROTO_IP 0   // Indicates IP pseudo-protocol.
```

Description

Indicates IP pseudo-protocol.

IPPROTO_TCP Macro

File

berkeley_api.h

C

```
#define IPPROTO_TCP 6   // Indicates TCP level options
```

Description

Indicates TCP level options

IPPROTO_UDP Macro

File

berkeley_api.h

C

```
#define IPPROTO_UDP 17  // Indicates UDP level options
```

Description

Indicates UDP level options

SOCK_DGRAM Macro

File

berkeley_api.h

C

```
#define SOCK_DGRAM 110  //Connectionless datagram socket. Use UDP for the Internet address family.
```

Description

Connectionless datagram socket. Use UDP for the Internet address family.

SOCK_STREAM Macro

File

berkeley_api.h

C

```
#define SOCK_STREAM 100  //Connection based byte streams. Use TCP for the Internet address family.
```

Description

Connection based byte streams. Use TCP for the Internet address family.

SOCKET_CNXN_IN_PROGRESS Macro

File

berkeley_api.h

C

```
#define SOCKET_CNXN_IN_PROGRESS (-2) //Socket connection state.
```

Description

Socket connection state.

SOCKET_DISCONNECTED Macro

File

berkeley_api.h

C

```
#define SOCKET_DISCONNECTED (-3) //Socket disconnected
```

Description

Socket disconnected

SOCKET_ERROR Macro

File

berkeley_api.h

C

```
#define SOCKET_ERROR (-1) //Socket error
```

Description

Socket error

SOCKADDR Type

File

berkeley_api.h

C

```
typedef struct sockaddr SOCKADDR;
```

Description

generic address structure for all address families

SOCKADDR_IN Type

File

berkeley_api.h

C

```
typedef struct sockaddr_in SOCKADDR_IN;
```

Description

In the Internet address family

SOCKET Type

File

berkeley_api.h

C

```
typedef int16_t SOCKET;
```

Description

Socket descriptor

in_addr Structure

File

berkeley_api.h

C

```
struct in_addr {
  union {
    struct {
      uint8_t s_b1, s_b2, s_b3, s_b4;
    } S_un_b;
    struct {
      uint16_t s_w1, s_w2;
    } S_un_w;
    uint32_t S_addr;
  } S_un;
};
```

Members

Members	Description

union {
struct {
uint8_t s_b1, s_b2, s_b3, s_b4;
} S_un_b;
struct {
uint16_t s_w1, s_w2;
} S_un_w;
uint32_t S_addr;
} S_un;
	union of IP address

struct { uint8_t s_b1, s_b2, s_b3, s_b4; } S_un_b;	IP address in Byte
struct { uint16_t s_w1, s_w2; } S_un_w;	IP address in Word
uint32_t S_addr;	IP address

Description

in_addr structure

sockaddr Structure

File

berkeley_api.h

C

```
struct sockaddr {
  unsigned short sa_family;
  char sa_data[14];
};
```

Members

Members	Description
unsigned short sa_family;	address family
char sa_data[14];	up to 14 bytes of direct address

Description

generic address structure for all address families

sockaddr_in Structure

File

berkeley_api.h

C

```
struct sockaddr_in {
  short sin_family;
  uint16_t sin_port;
  struct in_addr sin_addr;
  char sin_zero[8];
};
```

Members

Members	Description
short sin_family;	Address family; must be AF_INET.
uint16_t sin_port;	Internet Protocol (IP) port.
struct in_addr sin_addr;	IP address in network byte order.
char sin_zero[8];	Padding to make structure the same size as SOCKADDR.

Description

In the Internet address family

addrinfo Structure

File

berkeley_api.h

C

```
struct addrinfo {
  int ai_flags;
  int ai_family;
  int ai_socktype;
  int ai_protocol;
  size_t ai_addrlen;
  struct sockaddr * ai_addr;
  char * ai_canonname;
  struct addrinfo * ai_next;
};
```

Description

This is record addrinfo.

EAI_AGAIN Macro

File

berkeley_api.h

C

```
#define EAI_AGAIN -3    /* Temporary failure in name resolution.  */
```

Description

Temporary failure in name resolution.

EAI_BADFLAGS Macro

File

berkeley_api.h

C

```
#define EAI_BADFLAGS -1    /* Invalid value for `ai_flags' field.  */
```

Description

Invalid value for `ai_flags' field.

EAI_FAIL Macro

File

berkeley_api.h

C

```
#define EAI_FAIL -4    /* Non-recoverable failure in name res.  */
```

Description

Non-recoverable failure in name res.

EAI_FAMILY Macro

File

berkeley_api.h

C

```
#define EAI_FAMILY -6    /* `ai_family' not supported.  */
```

Description

ai_family‘ not supported.

EAI_MEMORY Macro

File

berkeley_api.h

C

```
#define EAI_MEMORY -10   /* Memory allocation failure.  */
```

Description

Memory allocation failure.

EAI_NONAME Macro

File

berkeley_api.h

C

```
#define EAI_NONAME -2    /* NAME or SERVICE is unknown.  */
```

Description

NAME or SERVICE is unknown.

EAI_OVERFLOW Macro

File

berkeley_api.h

C

```
#define EAI_OVERFLOW -12   /* Argument buffer overflow.  */
```

Description

Argument buffer overflow.

EAI_SERVICE Macro

File

berkeley_api.h

C

```
#define EAI_SERVICE -8    /* SERVICE not supported for `ai_socktype'.  */
```

Description

SERVICE not supported for `ai_socktype'.

EAI_SOCKTYPE Macro

File

berkeley_api.h

C

```
#define EAI_SOCKTYPE -7    /* `ai_socktype' not supported.  */
```

Description

ai_socktype' not supported.

EAI_SYSTEM Macro

File

berkeley_api.h

C

```
#define EAI_SYSTEM -11   /* System error returned in `errno'.  */
```

Description

System error returned in `errno'.

ICMP6_FILTER Macro

File

berkeley_api.h

C

```
#define ICMP6_FILTER 1    //SEt the IPv6 Filtering options - Not yet supported
```

Description

SEt the IPv6 Filtering options - Not yet supported

IP_ADD_MEMBERSHIP Macro

File

berkeley_api.h

C

```
#define IP_ADD_MEMBERSHIP 35  //Join a multicast group - Not yet supported
```

Description

Join a multicast group - Not yet supported

IP_DROP_MEMBERSHIP Macro

File

berkeley_api.h

C

```
#define IP_DROP_MEMBERSHIP 36  // Leave a multicast group - Not yet supported
```

Description

Leave a multicast group - Not yet supported

IP_MULTICAST_IF Macro

File

berkeley_api.h

C

```
#define IP_MULTICAST_IF 32  //Set the Interface that multicast packets should be sent on  - Not yet
supported
```

Description

Set the Interface that multicast packets should be sent on - Not yet supported

IP_MULTICAST_LOOP Macro

File

berkeley_api.h

C

```
#define IP_MULTICAST_LOOP 34  //Specify a copy of multicast packets should be delivered to the sending host
- Not yet supported
```

Description

Specify a copy of multicast packets should be delivered to the sending host - Not yet supported

IP_MULTICAST_TTL Macro

File

berkeley_api.h

C

```
#define IP_MULTICAST_TTL 33  //Set the Time to Live option for multicast packets - Not yet supported
```

Description

Set the Time to Live option for multicast packets - Not yet supported

IP_OPTIONS Macro

File

berkeley_api.h

C

```
#define IP_OPTIONS 4   //IP Header Options - Not yet supported
```

Description

IP Header Options - Not yet supported

IP_TOS Macro

File

berkeley_api.h

C

```
#define IP_TOS 1   //Type of Service - Not yet supported
```

Description

Type of Service - Not yet supported

IP_TTL Macro

File

berkeley_api.h

C

```
#define IP_TTL 2   //Time to Live - Not yet supported
```

Description

Time to Live - Not yet supported

IPPROTO_ICMPV6 Macro

File

berkeley_api.h

C

```
#define IPPROTO_ICMPV6 58  // Indicates IPv6 ICMP Protocol Options
```

Description

Indicates IPv6 ICMP Protocol Options

IPPROTO_IPV6 Macro

File

berkeley_api.h

C

```
#define IPPROTO_IPV6 41  // Indicates IP v6 Header options
```

Description

Indicates IP v6 Header options

IPV6_CHECKSUM Macro

File

berkeley_api.h

C

```
#define IPV6_CHECKSUM 7   //Sets the IPv6 Checksum options - Not yet supported
```

Description

Sets the IPv6 Checksum options - Not yet supported

IPV6_JOIN_GROUP Macro

File

berkeley_api.h

C

```
#define IPV6_JOIN_GROUP 20  //Join an IPv6 multicast group - Not yet supported
```

Description

Join an IPv6 multicast group - Not yet supported

IPV6_LEAVE_GROUP Macro

File

berkeley_api.h

C

```
#define IPV6_LEAVE_GROUP 21  //Leave an IPv6 multicast group - Not yet supported
```

Description

Leave an IPv6 multicast group - Not yet supported

IPV6_MULTICAST_HOPS Macro

File

berkeley_api.h

C

```
#define IPV6_MULTICAST_HOPS 18  //Set the hop limit for multicast IPv6 packets - Not yet supported
```

Description

Set the hop limit for multicast IPv6 packets - Not yet supported

IPV6_MULTICAST_IF Macro

File

berkeley_api.h

C

```
#define IPV6_MULTICAST_IF 17  //Set the Interface that multicast IPv6 packets should be sent on  - Not yet
supported
```

Description

Set the Interface that multicast IPv6 packets should be sent on - Not yet supported

IPV6_MULTICAST_LOOP Macro

File

berkeley_api.h

C

```
#define IPV6_MULTICAST_LOOP 19  //Specify a copy of multicast IPv6 packets should be delivered to the
sending host - Not yet supported
```

Description

Specify a copy of multicast IPv6 packets should be delivered to the sending host - Not yet supported

IPV6_UNICAST_HOPS Macro

File

berkeley_api.h

C

```
#define IPV6_UNICAST_HOPS 16  //Set the hop limit for unicast IPv6 packets - Not yet supported
```

Description

Set the hop limit for unicast IPv6 packets - Not yet supported

IPV6_V6ONLY Macro

File

berkeley_api.h

C

```
#define IPV6_V6ONLY 26  //Sets the socket to IPv6 only - Not yet supported
```

Description

Sets the socket to IPv6 only - Not yet supported

SO_BROADCAST Macro

File

berkeley_api.h

C

```
#define SO_BROADCAST 6   //Enables the Socket for sending broadcast data
```

Description

Enables the Socket for sending broadcast data

SO_DEBUG Macro

File

berkeley_api.h

C

```
#define SO_DEBUG 1   //Indicates if low level debut is active - Not yet supported
```

Description

Indicates if low level debut is active - Not yet supported

SO_DONTROUTE Macro

File

berkeley_api.h

C

```
#define SO_DONTROUTE 5   //Bypass normal routing - Not yet supported
```

Description

Bypass normal routing - Not yet supported

SO_KEEPALIVE Macro

File

berkeley_api.h

C

```
#define SO_KEEPALIVE 9   //Keep the connection alive by sending periodic transmissions - Not yet supported
```

Description

Keep the connection alive by sending periodic transmissions - Not yet supported

SO_LINGER Macro

File

berkeley_api.h

C

```
#define SO_LINGER 13  //Indicates if the system should send any buffered data when a socket is closed
```

Description

Indicates if the system should send any buffered data when a socket is closed

SO_OOBINLINE Macro

File

berkeley_api.h

C

```
#define SO_OOBINLINE 10  //Indicates whether or not Out of Band Data should be received inline with normal
data - Not yet supported
```

Description

Indicates whether or not Out of Band Data should be received inline with normal data - Not yet supported

SO_RCVBUF Macro

File

berkeley_api.h

C

```
#define SO_RCVBUF 8   //Receive Buffer Size (TCP only)
```

Description

Receive Buffer Size (TCP only)

SO_RCVLOWAT Macro

File

berkeley_api.h

C

```
#define SO_RCVLOWAT 18  //Receive Low Water mark - Not yet supported
```

Description

Receive Low Water mark - Not yet supported

SO_RCVTIMEO Macro

File

berkeley_api.h

C

```
#define SO_RCVTIMEO 20  //Set the Receive Timeout - Not yet supported
```

Description

Set the Receive Timeout - Not yet supported

SO_REUSEADDR Macro

File

berkeley_api.h

C

```
#define SO_REUSEADDR 2   //Indicates if the local socket can be reused immediately after close - Not yet
supported
```

Description

Indicates if the local socket can be reused immediately after close - Not yet supported

SO_SNDBUF Macro

File

berkeley_api.h

C

```
#define SO_SNDBUF 7   //Send Buffer Size
```

Description

Send Buffer Size

SO_SNDLOWAT Macro

File

berkeley_api.h

C

```
#define SO_SNDLOWAT 19  //Send Low Water mark - Not yet supported
```

Description

Send Low Water mark - Not yet supported

SO_SNDTIMEO Macro

File

berkeley_api.h

C

```
#define SO_SNDTIMEO 21  //Set the Send Timeout - Not yet supported
```

Description

Set the Send Timeout - Not yet supported

SOL_SOCKET Macro

File

berkeley_api.h

C

```
#define SOL_SOCKET 1   // Indicates socket level options
```

Description

Indicates socket level options

TCP_NODELAY Macro

File

berkeley_api.h

C

```
#define TCP_NODELAY 1 //Indicates if TCP is to buffer packets - Not yet supported
```

Description

Indicates if TCP is to buffer packets - Not yet supported

linger Structure

File

berkeley_api.h

C

```
struct linger {
  int l_onoff;
  int l_linger;
};
```

Members

Members	Description
int l_onoff;	Determines if the option is set
int l_linger;	Time to wait before data is discarded

Description

This is record linger.

hostent Structure

File

berkeley_api.h

C

```
struct hostent {
  char * h_name;
  char ** h_alias;
  int h_addrtype;
  int h_length;
  char ** h_addr_list;
};
```

Members

Members	Description
char * h_name;	Points to a string containing the name of the host
char ** h_alias;	points to a null terminated list of pointers that point to the aliases of the host
int h_addrtype;	Contains the address type for the host, currently only AF_INET is supported
int h_length;	Contains the length of the h_addr_list
char ** h_addr_list;	Points to a NULL terminated list of pointers that point to the address of the host

Description

This is record hostent.

HOST_NOT_FOUND Macro

File

berkeley_api.h

C

```
#define HOST_NOT_FOUND 1    // Authoritative Answer host not found
```

Description

Authoritative Answer host not found

NO_DATA Macro

File

berkeley_api.h

C

```
#define NO_DATA 4    // Valid name, no data record of requested type
```

Description

Valid name, no data record of requested type

NO_RECOVERY Macro

File

berkeley_api.h

C

```
#define NO_RECOVERY 3    //Non recoverable errors,
```

Description

Non recoverable errors,

TRY_AGAIN Macro

File

berkeley_api.h

C

```
#define TRY_AGAIN 2    //Non authoritative host not found or server fail
```

Description

Non authoritative host not found or server fail

in6_addr Structure

File

berkeley_api.h

C

```
struct in6_addr {
  union {
    uint8_t u6_addr8[16];
    uint16_t u6_addr16[8];
    uint32_t u6_addr32[4];
  } in6_u;
};
```

Members

Members	Description
uint8_t u6_addr8[16];	IP address in Bytes
uint16_t u6_addr16[8];	IP address in 16 bit Words
uint32_t u6_addr32[4];	IP address in 32 bit Words

Description

This is record in6_addr.

sockaddr_in6 Structure

File

berkeley_api.h

C

```
struct sockaddr_in6 {
  short sin6_family;
  uint16_t sin6_port;
  uint32_t sin6_flowinfo;
  struct in6_addr sin6_addr;
  uint32_t sin6_scope_id;
};
```

Members

Members	Description
short sin6_family;	Address family; must be AF_INET.
uint16_t sin6_port;	Internet Protocol (IP) port.
uint32_t sin6_flowinfo;	IPv6 flow information
struct in6_addr sin6_addr;	IPv6 address in network byte order.
uint32_t sin6_scope_id;	IPv6 Scope Id

Description

In the Internet address family

sockaddr_storage Structure

File

berkeley_api.h

C

```
struct sockaddr_storage {
  short ss_family;
  __ss_aligntype __ss_align;
  char __ss_padding[_SS_PADSIZE];
};
```

Members

Members	Description
short ss_family;	Address family
__ss_aligntype __ss_align;	Force desired alignment.

Description

This is record sockaddr_storage.

SOCKADDR_IN6 Type

File

berkeley_api.h

C

```
typedef struct sockaddr_in6 SOCKADDR_IN6;
```

Description

This is type SOCKADDR_IN6.

AF_INET6 Macro

File

berkeley_api.h

C

```
#define AF_INET6 10          // Internet Address Family - IPv6
```

Description

Internet Address Family - IPv6

__ss_aligntype Macro

File

berkeley_api.h

C

```
#define __ss_aligntype __uint32_t
```

Description

Structure large enough to hold any socket address (with the historical exception of AF_UNIX). 128 bytes reserved.

_BERKELEY_API_HEADER_FILE Macro

File

berkeley_api.h

C

```
#define _BERKELEY_API_HEADER_FILE
```

Description

This is macro _BERKELEY_API_HEADER_FILE.

_SS_PADSIZE Macro

File

berkeley_api.h

C

```
#define _SS_PADSIZE (_SS_SIZE - (2 * sizeof (__ss_aligntype)))
```

Description

This is macro _SS_PADSIZE.

_SS_SIZE Macro

File

berkeley_api.h

C

```
#define _SS_SIZE 128
```

Description

This is macro _SS_SIZE.

BERKELEY_MODULE_CONFIG Structure

File

berkeley_api.h

C

```
typedef struct {
  uint8_t maxSockets;
} BERKELEY_MODULE_CONFIG;
```

Members

Members	Description
uint8_t maxSockets;	Maximum number of sockets supported

Description

Berkeley API module configuration structure

Files

Files

Name	Description
berkeley_api.h	The Berkeley Socket Distribution (BSD) APIs provide a BSD wrapper to the native Microchip TCP/IP Stack APIs.
berkeley_api_config.h	Berkeley Sockets API Client and Server

Description

This section lists the source and header files used by the library.

berkeley_api.h

The Berkeley Socket Distribution (BSD) APIs provide a BSD wrapper to the native Microchip TCP/IP Stack APIs.

Functions

	Name	Description
	accept	This function accepts connection requests queued for a listening socket.

	bind	This function assigns a name to the socket descriptor.
	closesocket	The closesocket function closes an existing socket.
	connect	This function connects to the peer communications end point.
	freeaddrinfo	Frees the memory allocated by getaddrinfo
	getaddrinfo	Does an address look up for the provided node name.
	gethostbyname	The gethostbyname function returns a structure of type hostent for the given host name.
	gethostname	Returns the standard host name for the system.
	getsockname	Returns the current address to which the socket is bound.
	getsockopt	Allows setting options to a socket like adjust RX/TX buffer size, etc
	listen	The listen function sets the specified socket in a listen mode.
	recv	The recv() function is used to receive incoming data that has been queued for a socket.
	recvfrom	The recvfrom() function is used to receive incoming data that has been queued for a socket.
	send	The send function is used to send outgoing data on an already connected socket.
	sendto	This function used to send the data for both connection oriented and connection-less sockets.
	setsockopt	Allows setting options to a socket like adjust RX/TX buffer size, etc
	socket	This function creates a new Berkeley socket.
	TCPIP_BSD_Socket	Returns the native socket number associated with the BSD socket.

Macros

	Name	Description
	__ss_aligntype	Structure large enough to hold any socket address (with the historical exception of AF_UNIX). 128 bytes reserved.
	_BERKELEY_API_HEADER_FILE	This is macro _BERKELEY_API_HEADER_FILE.
	_SS_PADSIZE	This is macro _SS_PADSIZE.
	_SS_SIZE	This is macro _SS_SIZE.
	AF_INET	Internet Address Family - IPv4, UDP, TCP, etc.
	AF_INET6	Internet Address Family - IPv6
	EAI_AGAIN	Temporary failure in name resolution.
	EAI_BADFLAGS	Invalid value for `ai_flags' field.
	EAI_FAIL	Non-recoverable failure in name res.
	EAI_FAMILY	ai_family' not supported.
	EAI_MEMORY	Memory allocation failure.
	EAI_NONAME	NAME or SERVICE is unknown.
	EAI_OVERFLOW	Argument buffer overflow.
	EAI_SERVICE	SERVICE not supported for `ai_socktype'.
	EAI_SOCKTYPE	ai_socktype' not supported.
	EAI_SYSTEM	System error returned in `errno'.
	HOST_NOT_FOUND	Authoritative Answer host not found
	ICMP6_FILTER	SEt the IPv6 Filtering options - Not yet supported
	INADDR_ANY	IP address for server binding.
	INVALID_TCP_PORT	Invalid TCP port
	IP_ADD_MEMBERSHIP	Join a multicast group - Not yet supported
	IP_ADDR_ANY	IP Address for server binding
	IP_DROP_MEMBERSHIP	Leave a multicast group - Not yet supported
	IP_MULTICAST_IF	Set the Interface that multicast packets should be sent on - Not yet supported
	IP_MULTICAST_LOOP	Specify a copy of multicast packets should be delivered to the sending host - Not yet supported
	IP_MULTICAST_TTL	Set the Time to Live option for multicast packets - Not yet supported
	IP_OPTIONS	IP Header Options - Not yet supported
	IP_TOS	Type of Service - Not yet supported
	IP_TTL	Time to Live - Not yet supported
	IPPROTO_ICMPV6	Indicates IPv6 ICMP Protocol Options
	IPPROTO_IP	Indicates IP pseudo-protocol.
	IPPROTO_IPV6	Indicates IP v6 Header options
	IPPROTO_TCP	Indicates TCP level options

	IPPROTO_UDP	Indicates UDP level options
	IPV6_CHECKSUM	Sets the IPv6 Checksum options - Not yet supported
	IPV6_JOIN_GROUP	Join an IPv6 multicast group - Not yet supported
	IPV6_LEAVE_GROUP	Leave an IPv6 multicast group - Not yet supported
	IPV6_MULTICAST_HOPS	Set the hop limit for multicast IPv6 packets - Not yet supported
	IPV6_MULTICAST_IF	Set the Interface that multicast IPv6 packets should be sent on - Not yet supported
	IPV6_MULTICAST_LOOP	Specify a copy of multicast IPv6 packets should be delivered to the sending host - Not yet supported
	IPV6_UNICAST_HOPS	Set the hop limit for unicast IPv6 packets - Not yet supported
	IPV6_V6ONLY	Sets the socket to IPv6 only - Not yet supported
	NO_DATA	Valid name, no data record of requested type
	NO_RECOVERY	Non recoverable errors,
	SO_BROADCAST	Enables the Socket for sending broadcast data
	SO_DEBUG	Indicates if low level debut is active - Not yet supported
	SO_DONTROUTE	Bypass normal routing - Not yet supported
	SO_KEEPALIVE	Keep the connection alive by sending periodic transmissions - Not yet supported
	SO_LINGER	Indicates if the system should send any buffered data when a socket is closed
	SO_OOBINLINE	Indicates whether or not Out of Band Data should be received inline with normal data - Not yet supported
	SO_RCVBUF	Receive Buffer Size (TCP only)
	SO_RCVLOWAT	Receive Low Water mark - Not yet supported
	SO_RCVTIMEO	Set the Receive Timeout - Not yet supported
	SO_REUSEADDR	Indicates if the local socket can be reused immediately after close - Not yet supported
	SO_SNDBUF	Send Buffer Size
	SO_SNDLOWAT	Send Low Water mark - Not yet supported
	SO_SNDTIMEO	Set the Send Timeout - Not yet supported
	SOCK_DGRAM	Connectionless datagram socket. Use UDP for the Internet address family.
	SOCK_STREAM	Connection based byte streams. Use TCP for the Internet address family.
	SOCKET_CNXN_IN_PROGRESS	Socket connection state.
	SOCKET_DISCONNECTED	Socket disconnected
	SOCKET_ERROR	Socket error
	SOL_SOCKET	Indicates socket level options
	TCP_NODELAY	Indicates if TCP is to buffer packets - Not yet supported
	TRY_AGAIN	Non authoritative host not found or server fail

Structures

	Name	Description
	addrinfo	This is record addrinfo.
	hostent	This is record hostent.
	in_addr	in_addr structure
	in6_addr	This is record in6_addr.
	linger	This is record linger.
	sockaddr	generic address structure for all address families
	sockaddr_in	In the Internet address family
	sockaddr_in6	In the Internet address family
	sockaddr_storage	This is record sockaddr_storage.
	BERKELEY_MODULE_CONFIG	Berkeley API module configuration structure

Types

	Name	Description
	SOCKADDR	generic address structure for all address families
	SOCKADDR_IN	In the Internet address family
	SOCKADDR_IN6	This is type SOCKADDR_IN6.
	SOCKET	Socket descriptor

Description

Berkeley Socket Distribution API Header File

The Berkeley Socket Distribution (BSD) APIs provide a BSD wrapper to the native Microchip TCP/IP Stack APIs. Using this interface, programmers familiar with BSD sockets can quickly develop applications using Microchip's TCP/IP Stack.

File Name

berkeley_api.h

Company

Microchip Technology Inc.

berkeley_api_config.h

Berkeley Sockets API Client and Server

Macros

	Name	Description
	MAX_BSD_SOCKETS	Berkeley API max number of sockets simultaneous supported

Description

Berkeley Sockets API Configuration file

This file contains the Berkeley API module configuration options

DHCP Module

This section describes the TCP/IP Stack Library DHCP module.

Introduction

TCP/IP Stack Library Dynamic Host Configuration Protocol (DHCP) Module for Microchip Microcontrollers

This library provides the API of the DHCP module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

The DHCP client module will allow your application to dynamically obtain an IP address and a subnet mask from a DHCP server on the same network. Additionally, the DHCP client will get other parameters, such as gateway and DNS addresses.

Using the Library

This topic describes the basic architecture of the DHCP TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `dhcp.h`

The interface to the DHCP TCP/IP Stack library is defined in the `dhcp.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the DHCP TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

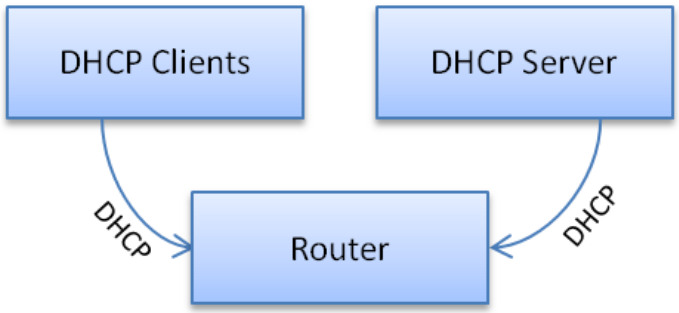
This library provides the API of the DHCP TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

This module provides software abstraction of the DHCP module existent in any TCP/IP Stack implementation. It removes the overhead of address resolution from all other modules in the stack.

DHCP Software Abstraction Block Diagram

Typical DCHP Usage



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the DHCP module.

Library Interface Section	Description
Configuration Functions	Routines for Configuring DHCP
Status Functions	Routines for Obtaining DHCP Status Information
Data Types and Constants	This section provides various definitions describing this API

How the Library Works

The Dynamic Host Configuration protocol (DHCP) is a standard networking protocol used to automatically allocate IP addresses for hosts in a network.

The DHCP server has a pool of IP addresses, which are leased for clients requesting them. The leases have a time-out after which the hosts need to renew the lease or acquire a new one.

The DHCP client module in the TCP/IP stack takes care of the communication with the DHCP server and renewing the lease when the time-out expires.

Configuring the Library

Macros

	Name	Description
	TCPIP_DHCP_BOOT_FILE_NAME_SIZE	size of the storage for the Boot file name should always be <= 128 default value is 128
	TCPIP_DHCP_STORE_BOOT_FILE_NAME	enable the usage of the Boot file name received from the DHCP server

Description

The configuration of the DHCP TCP/IP Stack is based on the file `system_config.h` (which may include a `dhcp_config.h` file).

This header file contains the configuration parameters for the DHCP TCP/IP Stack. Based on the selections made, the DHCP TCP/IP Stack will adjust its behavior.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_DHCP_BOOT_FILE_NAME_SIZE Macro

File

dhcp_config.h

C

```
#define TCPIP_DHCP_BOOT_FILE_NAME_SIZE 128
```

Description

size of the storage for the Boot file name should always be <= 128 default value is 128

TCPIP_DHCP_STORE_BOOT_FILE_NAME Macro

File

dhcp_config.h

C

```
#define TCPIP_DHCP_STORE_BOOT_FILE_NAME
```

Description

enable the usage of the Boot file name received from the DHCP server

Building the Library

This section lists the files that are available in the DHCP module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/dhcp.c`	DHCP implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The DHCP module depends on the following modules:

- TCP/IP Stack Library
- UDP Module

Library Interface

a) Configuration Functions

	Name	Description
	TCPIP_DHCP_Disable	Disables the DHCP Client for the specified interface.

	TCPIP_DHCP_Enable	Enables the DHCP client for the specified interface.
	TCPIP_DHCP_HandlerDeRegister	Deregisters a previously registered DHCP handler.
	TCPIP_DHCP_HandlerRegister	Registers a DHCP Handler.
	TCPIP_DHCP_HostNameCallbackRegister	Registers a DHCP host name callback with the DHCP client.
	TCPIP_DHCP_Renew	Renews the DHCP lease for the specified interface.
	TCPIP_DHCP_Request	Requests the supplied IPv4 address from a DHCP server.

b) Status Functions

	Name	Description
	TCPIP_DHCP_IsBound	Determines if the DHCP client has an IP address lease on the specified interface.
	TCPIP_DHCP_IsEnabled	Determines if the DHCP client is enabled on the specified interface.
	TCPIP_DHCP_IsServerDetected	Determines if the DHCP client on the specified interface has been able to contact a DHCP server.
	TCPIP_DHCP_IsActive	Determines if the DHCP client is currently active on the specified interface.

c) Data Types and Constants

	Name	Description
	TCPIP_DHCP_EVENT_HANDLER	DHCP event handler prototype.
	TCPIP_DHCP_EVENT_TYPE	DHCP Event Type
	TCPIP_DHCP_HANDLE	DHCP handle.
	TCPIP_DHCP_MODULE_CONFIG	DHCP Module Configuration run-time parameters.
	TCPIP_DHCP_INFO	Reports DHCP module information.
	TCPIP_DHCP_STATUS	Lists the current status of the DHCP module.
	TCPIP_DHCP_HOST_NAME_CALLBACK	DHCP Host name callback function.
	TCPIP_DHCP_HOST_NAME_SIZE	Maximum size of a host name to be advertised to the DHCP server

Description

This section describes the Application Programming Interface (API) functions of the DHCP module.

Refer to each section for a detailed description.

a) Configuration Functions

TCPIP_DHCP_Disable Function

Disables the DHCP Client for the specified interface.

File

dhcp.h

C

```
bool TCPIP_DHCP_Disable(TCPIP_NET_HANDLE hNet);
```

Returns

- true - if successful
- false - if unsuccessful

Description

This function disables the DHCP client for the specified interface. If it is already disabled, no action is taken.

Remarks

When the DHCP client is disabled and the interface continues using its old configuration, it is possible that the lease may expire and the DHCP server provide the IP address to another client. The application should not keep the old lease unless it is sure that there is no danger of conflict.

Preconditions

The DHCP module must be initialized.

Parameters

Parameters	Description
pNetIf	Interface to disable the DHCP client on.

Function

bool TCPIP_DHCP_Disable(TCPIP_NET_HANDLE hNet)

TCPIP_DHCP_Enable Function

Enables the DHCP client for the specified interface.

File

dhcp.h

C

```
bool TCPIP_DHCP_Enable(TCPIP_NET_HANDLE hNet);
```

Returns

- true - if successful
- false - if unsuccessful

Description

This function enables the DHCP client for the specified interface, if it is disabled. If it is already enabled, no action is taken.

Preconditions

The DHCP module must be initialized.

Parameters

Parameters	Description
hNet	Interface to enable the DHCP client on.

Function

void TCPIP_DHCP_Enable(TCPIP_NET_HANDLE hNet)

TCPIP_DHCP_HandlerDeRegister Function

Deregisters a previously registered DHCP handler.

File

dhcp.h

C

```
bool TCPIP_DHCP_HandlerDeRegister(TCPIP_DHCP_HANDLE hDhcp);
```

Returns

- true - if the call succeeds
- false - if no such handler is registered

Description

This function deregisters the DHCP event handler.

Preconditions

The DHCP module must be initialized.

Parameters

Parameters	Description
hDhcp	A handle returned by a previous call to TCPIP_DHCP_HandlerRegister.

Function

TCPIP_DHCP_HandlerDeRegister(TCPIP_DHCP_HANDLE hDhcp)

TCPIP_DHCP_HandlerRegister Function

Registers a DHCP Handler.

File

dhcp.h

C

```
TCPIP_DHCP_HANDLE TCPIP_DHCP_HandlerRegister(TCPIP_NET_HANDLE hNet, TCPIP_DHCP_EVENT_HANDLER handler, const void* hParam);
```

Returns

Returns a valid handle if the call succeeds, or a null handle if the call failed (out of memory, for example).

Description

This function registers a DHCP event handler. The DHCP module will call the registered handler when a DHCP event (TCPIP_DHCP_EVENT_TYPE) occurs.

Remarks

The handler has to be short and fast. It is meant for setting an event flag, not for lengthy processing!

The hParam is passed by the client and will be used by the DHCP when the notification is made. It is used for per-thread content or if more modules, for example, share the same handler and need a way to differentiate the callback.

Preconditions

The DHCP module must be initialized.

Parameters

Parameters	Description
hNet	Interface handle. Use hNet == 0 to register on all interfaces available.
handler	Handler to be called when a DHCP event occurs.
hParam	Parameter to be used in the handler call. This is user supplied and is not used by the DHCP module.

Function

TCPIP_DHCP_HandlerRegister(TCPIP_NET_HANDLE hNet, TCPIP_DHCP_EVENT_HANDLER handler,

const void* hParam)

TCPIP_DHCP_HostNameCallbackRegister Function

Registers a DHCP host name callback with the DHCP client.

File

dhcp.h

C

```
bool TCPIP_DHCP_HostNameCallbackRegister(TCPIP_NET_HANDLE hNet, TCPIP_DHCP_HOST_NAME_CALLBACK nameCallback, bool writeBack);
```

Returns

- true - if the call succeeds
- false - if error (no such interface, etc.)

Description

This function registers a DHCP host name callback function. The DHCP module will call the registered callback when a host name needs to be presented to the DHCP server.

Remarks

The nameCallback function has to be valid for the length of DHCP client communication with the server, i.e. when the reported status is bound or some error.

There is no corresponding deregister function. Simply call TCPIP_DHCP_HostNameCallbackRegister with the nameCallback set to 0.

If such a callback is not registered, then the NetBios name will be used for the DHCP host name.

The callback function has to return a character string that's compatible with the rules imposed for the host names:

- Host names may contain only alphanumeric characters, minus signs ("-"), and periods (".")
- They must begin with an alphabetic character and end with an alphanumeric character

To enforce these rules the extra processing is performed internally (on either user supplied host name or NetBios name):

- spaces, if present, will be stripped from the string
- illegal characters will be replaced by TCPIP_DHCP_HOST_REPLACE_CHAR character (default is lower case 'x')

If after processing the resulting string is null, the DHCP host name option is skipped.

The callback function has to return a character string that's at least 2 characters in size;

Preconditions

The DHCP module must be initialized.

Parameters

Parameters	Description
hNet	Interface handle. Use hNet == 0 to register on all interfaces available.
nameCallback	Callback to be called to get a DHCP host name
writeBack	if true, the resulting name will be written to the address returned by the nameCallback (it shouldn't be const!)

Function

bool TCPIP_DHCP_HostNameCallbackRegister(TCPIP_NET_HANDLE hNet,
TCPIP_DHCP_HOST_NAME_CALLBACK nameCallback, bool writeBack)

TCPIP_DHCP_Renew Function

Renews the DHCP lease for the specified interface.

File

dhcp.h

C

```
bool TCPIP_DHCP_Renew(TCPIP_NET_HANDLE hNet);
```

Returns

- true - if successful
- false - if unsuccessful

Description

This function attempts to contact the server and renew the DHCP lease for the specified interface. The interface should have the DHCP enabled and in bound state for this call to succeed.

Preconditions

The DHCP module must be initialized and enabled, and have a valid lease.

Parameters

Parameters	Description
hNet	Interface on which to renew the DHCP lease.

Function

void TCPIP_DHCP_Renew(TCPIP_NET_HANDLE hNet)

TCPIP_DHCP_Request Function

Requests the supplied IPv4 address from a DHCP server.

File

dhcp.h

C

```
bool TCPIP_DHCP_Request(TCPIP_NET_HANDLE hNet, IPV4_ADDR reqAddress);
```

Returns

- true - if successful
- false - if the supplied IP address is invalid or the DHCP client is in the middle of a transaction

Description

If the DHCP client is not enabled on that interface, this call will first try to enable it. If this succeeds or the DHCP client was already enabled, the following steps are taken: The DHCP client probes the DHCP server and requests the supplied IPv4 address as a valid lease for the specified interface. If the server acknowledges the request, then this is the new IPv4 address of the interface. If the DHCP server rejects the request, then the whole DHCP process is resumed starting with the DHCP Discovery phase.

Remarks

The requested IPv4 address should be a previous lease that was granted to the host. This call should be used when the host is restarting.

Preconditions

The DHCP module must be initialized and enabled, and have a valid lease.

Parameters

Parameters	Description
hNet	Interface to renew the DHCP lease on.

Function

void TCPIP_DHCP_Request(TCPIP_NET_HANDLE hNet, IPV4_ADDR reqAddress)

b) Status Functions

TCPIP_DHCP_IsBound Function

Determines if the DHCP client has an IP address lease on the specified interface.

File

dhcp.h

C

```
bool TCPIP_DHCP_IsBound(TCPIP_NET_HANDLE hNet);
```

Returns

- true - DHCP client has obtained an IP address lease (and likely other parameters) and these values are currently being used
- false - No IP address is currently leased

Description

This functin returns the status of the current IP address lease on the specified interface.

Preconditions

None.

Parameters

Parameters	Description
hNet	Interface to query

Function

bool TCPIP_DHCP_IsBound(TCPIP_NET_HANDLE hNet)

TCPIP_DHCP_IsEnabled Function

Determines if the DHCP client is enabled on the specified interface.

File

dhcp.h

C

```
bool TCPIP_DHCP_IsEnabled(TCPIP_NET_HANDLE hNet);
```

Returns

- true - if the DHCP client service is enabled on the specified interface
- false - if the DHCP client service is not enabled on the specified interface

Description

This function returns the current state of the DHCP client on the specified interface.

Preconditions

The DHCP module must be initialized.

Parameters

Parameters	Description
hNet	Interface to query.

Function

bool TCPIP_DHCP_IsEnabled(TCPIP_NET_HANDLE hNet)

TCPIP_DHCP_IsServerDetected Function

Determines if the DHCP client on the specified interface has been able to contact a DHCP server.

File

dhcp.h

C

```
bool TCPIP_DHCP_IsServerDetected(TCPIP_NET_HANDLE hNet);
```

Returns

- true - At least one DHCP server is attached to the specified network interface
- false - No DHCP servers are currently detected on the specified network interface

Description

This function determines if the DHCP client on the specified interface received any reply from a DHCP server.

Preconditions

The DHCP module must be initialized.

Parameters

Parameters	Description
hNet	Interface to query.

Function

bool TCPIP_DHCP_IsServerDetected(TCPIP_NET_HANDLE hNet)

TCPIP_DHCP_IsActive Function

Determines if the DHCP client is currently active on the specified interface.

File

dhcp.h

C

```
bool TCPIP_DHCP_IsActive(TCPIP_NET_HANDLE hNet);
```

Returns

- true - if the DHCP client service is currently active on the specified interface
- false - if the DHCP client service is not active on the specified interface

Description

This function returns the current state of the DHCP client on the specified interface.

Remarks

The DHCP client service could be enabled bot not active. For example when there was no DHCP server detected on the network.

Preconditions

The DHCP module must be initialized.

Parameters

Parameters	Description
hNet	Interface to query.

Function

bool TCPIP_DHCP_IsActive(TCPIP_NET_HANDLE hNet)

c) Data Types and Constants

TCPIP_DHCP_EVENT_HANDLER Type

DHCP event handler prototype.

File

dhcp.h

C

```
typedef void (* TCPIP_DHCP_EVENT_HANDLER)(TCPIP_NET_HANDLE hNet, TCPIP_DHCP_EVENT_TYPE evType, const void*
param);
```

Description

Type: TCPIP_DHCP_EVENT_HANDLER

Prototype of a DHCP event handler. Clients can register a handler with the DHCP service. Once an DHCP event occurs the DHCP service will called the registered handler. The handler has to be short and fast. It is meant for setting an event flag, *not* for lengthy processing!

TCPIP_DHCP_EVENT_TYPE Enumeration

DHCP Event Type

File

dhcp.h

C

```
typedef enum {
  DHCP_EVENT_NONE = 0,
  DHCP_EVENT_DISCOVER,
  DHCP_EVENT_REQUEST,
  DHCP_EVENT_ACK,
  DHCP_EVENT_ACK_INVALID,
  DHCP_EVENT_DECLINE,
  DHCP_EVENT_NACK,
  DHCP_EVENT_TIMEOUT,
  DHCP_EVENT_BOUND,
  DHCP_EVENT_REQUEST_RENEW,
  DHCP_EVENT_REQUEST_REBIND,
  DHCP_EVENT_CONN_LOST,
  DHCP_EVENT_CONN_ESTABLISHED,
  DHCP_EVENT_SERVICE_DISABLED
} TCPIP_DHCP_EVENT_TYPE;
```

Members

Members	Description
DHCP_EVENT_NONE = 0	DHCP no event

DHCP_EVENT_DISCOVER	DHCP discovery sent: cycle started
DHCP_EVENT_REQUEST	DHCP request sent
DHCP_EVENT_ACK	DHCP request acknowledge was received
DHCP_EVENT_ACK_INVALID	DHCP acknowledge received but discarded as invalid
DHCP_EVENT_DECLINE	DHCP lease declined
DHCP_EVENT_NACK	DHCP negative acknowledge was received
DHCP_EVENT_TIMEOUT	DHCP server timeout
DHCP_EVENT_BOUND	DHCP lease obtained
DHCP_EVENT_REQUEST_RENEW	lease request renew sent
DHCP_EVENT_REQUEST_REBIND	lease request rebind sent
DHCP_EVENT_CONN_LOST	connection to the DHCP server lost
DHCP_EVENT_CONN_ESTABLISHED	connection re-established
DHCP_EVENT_SERVICE_DISABLED	DHCP service disabled, reverted to the default IP address

Description

Enumeration: TCPIP_DHCP_EVENT_TYPE

None.

TCPIP_DHCP_HANDLE Type

DHCP handle.

File

dhcp.h

C

```
typedef const void* TCPIP_DHCP_HANDLE;
```

Description

Type: TCPIP_DHCP_HANDLE

A handle that a client can use after the event handler has been registered.

TCPIP_DHCP_MODULE_CONFIG Structure

DHCP Module Configuration run-time parameters.

File

dhcp.h

C

```
typedef struct {
  bool dhcpEnable;
  int dhcpTmo;
  int dhcpCliPort;
  int dhcpSrvPort;
} TCPIP_DHCP_MODULE_CONFIG;
```

Members

Members	Description
bool dhcpEnable;	DHCP client enable at module start-up
int dhcpTmo;	timeout to wait for DHCP lease, seconds
int dhcpCliPort;	client port for DHCP client transactions
int dhcpSrvPort;	remote server port for DHCP server messages

Description

DHCP Module Configuration

This structure contains the data that's passed to the DHCP module at the TCP/IP stack initialization.

TCPIP_DHCP_INFO Structure

Reports DHCP module information.

File

dhcp.h

C

```
typedef struct {
  TCPIP_DHCP_STATUS status;
  uint32_t dhcpTime;
  uint32_t leaseStartTime;
  uint32_t leaseDuration;
  uint32_t renewTime;
  uint32_t rebindTime;
  IPV4_ADDR dhcpAddress;
  IPV4_ADDR serverAddress;
  const char* bootFileName;
} TCPIP_DHCP_INFO;
```

Members

Members	Description
TCPIP_DHCP_STATUS status;	current status
uint32_t dhcpTime;	current DHCP time, seconds the following fields are significant only if a lease has been obtained and is currently valid i.e. status >= TCPIP_DHCP_BOUND
uint32_t leaseStartTime;	time when lease was requested
uint32_t leaseDuration;	lease duration as returned by the server, seconds
uint32_t renewTime;	the time for moving to renew state, seconds
uint32_t rebindTime;	the time for moving to rebind state, seconds
IPV4_ADDR dhcpAddress;	IPv4 address obtained by DHCP
IPV4_ADDR serverAddress;	IPv4 address of the server that granted the lease
const char* bootFileName;	pointer to the bootfile name that was returned by the server This will be 0 if TCPIP_DHCP_STORE_BOOT_FILE_NAME option is not enabled!

Description

Structure: TCPIP_DHCP_INFO

This data structure is used for reporting current info and status of the DHCP module. Used in getting info about the DHCP module.

TCPIP_DHCP_STATUS Enumeration

Lists the current status of the DHCP module.

File

dhcp.h

C

```
typedef enum {
  TCPIP_DHCP_IDLE = 0,
  TCPIP_DHCP_WAIT_LINK,
  TCPIP_DHCP_GET_SOCKET,
  TCPIP_DHCP_SEND_DISCOVERY,
  TCPIP_DHCP_GET_OFFER,
  TCPIP_DHCP_SEND_REQUEST,
  TCPIP_DHCP_GET_REQUEST_ACK,
  TCPIP_DHCP_WAIT_LEASE_CHECK,
  TCPIP_DHCP_WAIT_LEASE_RETRY,
  TCPIP_DHCP_BOUND,
  TCPIP_DHCP_BOUND_RENEW,
  TCPIP_DHCP_SEND_RENEW,
  TCPIP_DHCP_GET_RENEW_ACK,
  TCPIP_DHCP_SEND_REBIND,
  TCPIP_DHCP_GET_REBIND_ACK
} TCPIP_DHCP_STATUS;
```

Members

Members	Description
TCPIP_DHCP_IDLE = 0	idle/inactive state
TCPIP_DHCP_WAIT_LINK	waiting for an active connection
TCPIP_DHCP_GET_SOCKET	trying to obtain a socket
TCPIP_DHCP_SEND_DISCOVERY	sending a Discover message
TCPIP_DHCP_GET_OFFER	waiting for a DHCP Offer
TCPIP_DHCP_SEND_REQUEST	sending a REQUEST message (REQUESTING)
TCPIP_DHCP_GET_REQUEST_ACK	waiting for a Request ACK message
TCPIP_DHCP_WAIT_LEASE_CHECK	waiting for received lease verification
TCPIP_DHCP_WAIT_LEASE_RETRY	waiting for another attempt after the lease verification failed
TCPIP_DHCP_BOUND	bound
TCPIP_DHCP_BOUND_RENEW	a lease renew is initiated
TCPIP_DHCP_SEND_RENEW	sending a REQUEST message (RENEW state)
TCPIP_DHCP_GET_RENEW_ACK	waiting for ACK in RENEW state
TCPIP_DHCP_SEND_REBIND	sending REQUEST message (REBIND state)
TCPIP_DHCP_GET_REBIND_ACK	waiting for ACK in REBIND state

Description

Enumeration: TCPIP_DHCP_STATUS

This enumeration lists the current status of the DHCP module. Used in getting information about the DHCP state machine.

TCPIP_DHCP_HOST_NAME_CALLBACK Type

DHCP Host name callback function.

File

dhcp.h

C

```
typedef char* (* TCPIP_DHCP_HOST_NAME_CALLBACK)(TCPIP_NET_HANDLE hNet);
```

Description

Type: TCPIP_DHCP_HOST_NAME_CALLBACK

Prototype of a DHCP callback function that returns the host name to be presented to the server by the DHCP client.

This callback will be called by the DHCP client when communicating to the server and a host name is needed.

Remarks

There are certain restictions that apply to the host name strings. See the TCPIP_DHCP_HostNameCallbackRegister function.

TCPIP_DHCP_HOST_NAME_SIZE Macro

File

dhcp_config.h

C

```
#define TCPIP_DHCP_HOST_NAME_SIZE 20
```

Description

Maximum size of a host name to be advertised to the DHCP server

Files

Files

Name	Description

dhcp_config.h	DCHP configuration file

Description

This section lists the source and header files used by the library.

dhcp.h

Dynamic Host Configuration Protocol (DHCP) client API definitions.

Enumerations

	Name	Description
	TCPIP_DHCP_EVENT_TYPE	DHCP Event Type
	TCPIP_DHCP_STATUS	Lists the current status of the DHCP module.

Functions

	Name	Description
	TCPIP_DHCP_Disable	Disables the DHCP Client for the specified interface.
	TCPIP_DHCP_Enable	Enables the DHCP client for the specified interface.
	TCPIP_DHCP_HandlerDeRegister	Deregisters a previously registered DHCP handler.
	TCPIP_DHCP_HandlerRegister	Registers a DHCP Handler.
	TCPIP_DHCP_HostNameCallbackRegister	Registers a DHCP host name callback with the DHCP client.
	TCPIP_DHCP_InfoGet	Returns information about the DHCP client on the specified interface.
	TCPIP_DHCP_IsActive	Determines if the DHCP client is currently active on the specified interface.
	TCPIP_DHCP_IsBound	Determines if the DHCP client has an IP address lease on the specified interface.
	TCPIP_DHCP_IsEnabled	Determines if the DHCP client is enabled on the specified interface.
	TCPIP_DHCP_IsServerDetected	Determines if the DHCP client on the specified interface has been able to contact a DHCP server.
	TCPIP_DHCP_Renew	Renews the DHCP lease for the specified interface.
	TCPIP_DHCP_Request	Requests the supplied IPv4 address from a DHCP server.
	TCPIP_DHCP_RequestTimeoutSet	Sets the DHCP client request and base time-out values.
	TCPIP_DHCP_Task	Standard TCP/IP stack module task function.

Structures

	Name	Description
	TCPIP_DHCP_INFO	Reports DHCP module information.
	TCPIP_DHCP_MODULE_CONFIG	DHCP Module Configuration run-time parameters.

Types

	Name	Description
	TCPIP_DHCP_EVENT_HANDLER	DHCP event handler prototype.
	TCPIP_DHCP_HANDLE	DHCP handle.
	TCPIP_DHCP_HOST_NAME_CALLBACK	DHCP Host name callback function.

Description

Dynamic Host Configuration Protocol (DHCP) Client API Header File

Provides automatic IP address, subnet mask, gateway address, DNS server address, and other configuration parameters on DHCP enabled networks.

File Name

dhcp.h

Company

Microchip Technology Inc.

dhcp_config.h

DCHP configuration file

Macros

	Name	Description
	TCPIP_DHCP_BOOT_FILE_NAME_SIZE	size of the storage for the Boot file name should always be <= 128 default value is 128
	TCPIP_DHCP_CLIENT_ENABLED	Default value for the enable/disable the DHCP client at stack start-up.
	TCPIP_DHCP_HOST_NAME_SIZE	Maximum size of a host name to be advertised to the DHCP server
	TCPIP_DHCP_STORE_BOOT_FILE_NAME	enable the usage of the Boot file name received from the DHCP server
	TCPIP_DHCP_TASK_TICK_RATE	The DHCP task processing rate: number of milliseconds to generate an DHCP tick. Used by the DHCP state machine The default value is 200 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_DHCP_TIMEOUT	Defines how long to wait before a DHCP lease is acquired when the DHCP module is enabled, seconds

DHCP Server Module

This section describes the TCP/IP Stack Library DHCP Server module.

Introduction

TCP/IP Stack Library DHCP Server Module for Microchip Microcontrollers

This library provides the API of the DHCP Server module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

The DHCP Server module is used to assign the IP address to the DHCP client from the configured IP address database. When the server receives a request from a client, the DHCP server determines the network to which the DHCP client is connected, and then allocates an IP address that is appropriate for the client, and sends configuration information appropriate for that client. DHCP servers typically grant IP addresses to clients only for a limited interval. DHCP clients are responsible for renewing their IP address before that interval has expired, and must stop using the address once the interval has expired, if they have not been able to renew it.

Using the Library

This topic describes the basic architecture of the DHCP Server TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `dhcps.h`

The interface to the DHCP Server TCP/IP Stack library is defined in the `dhcps.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the DHCP Server TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

This library provides the API of the DHCP Server TCP/IP module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

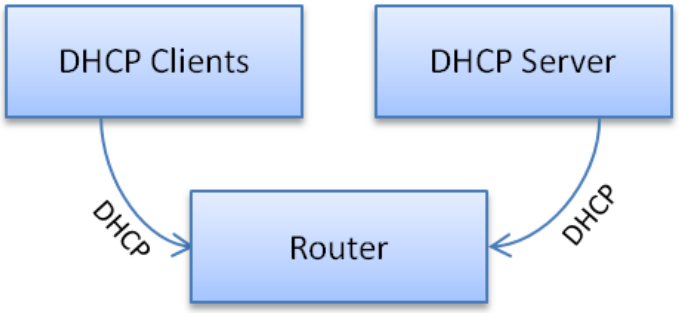
Description

DHCP Server Software Abstraction Block Diagram

This module provides software abstraction of the DHCP Server module existent in any TCP/IP Stack implementation. It removes the overhead of

address resolution from all other modules in the stack.

Typical DCHP Usage



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the DHCP Server module.

Library Interface Section	Description
Configuration Functions	Routines for Configuring DHCP server
Status Functions	Routines for Obtaining DHCP Status Information
Data Types and Constants	This section provides various definitions describing this API

How the Library Works

To use DHCP Server, include the files `dhcps.c`, `dhcp.c`, and `dhcp.h` in your project, and add or uncomment the definition "#define TCPIP_STACK_USE_DHCP_SERVER" to `tcpip_config.h`.

Configuring the Library

Macros

	Name	Description
	TCPIP_DHCPS_DEFAULT_IP_ADDRESS_RANGE_START	These below IPv4 DHCP server address details are default address and it is assigned to the network default network interface. for Other interfaces , tcpip_stack_init.c file should be use to configure DHCP_POOL_CONFIG[]. IPv4 Address range is starting from 100, because the from 1 to 100 is reserved. Reserved Address will be used for the gateway address. Start of IP address Range , network_config.h ipaddress and this start of IP address should be in same SUBNET RECOMENDED - network_config.h ipaddress should be 192.168.1.1 if DHCP server ip address range starts from 192.168.1.100.
	TCPIP_DHCPS_DEFAULT_SERVER_IP_ADDRESS	DHCP server Address per interface. DHCP server Address selection should be in the same subnet.
	TCPIP_DHCPS_DEFAULT_SERVER_NETMASK_ADDRESS	DHCP server subnet Address per interface.
	TCPIP_DHCPS_DEFAULT_SERVER_PRIMARY_DNS_ADDRESS	DHCP server DNS primary Address
	TCPIP_DHCPS_DEFAULT_SERVER_SECONDARY_DNS_ADDRESS	DHCP server DNS Secondary Address
	TCPIP_DHCPS_LEASE_DURATION	Timeout for a solved entry in the cache, in seconds the entry will be removed if the TMO elapsed and the entry has not been referenced again
	TCPIP_DHCPS_LEASE_ENTRIES_DEFAULT	The Maximum Number of entries in the lease table Default total number of entries for all the the interface
	TCPIP_DHCPS_LEASE_REMOVED_BEFORE_ACK	Timeout for a unsolved entry , in seconds and should be removed from the entry if there is no REQUEST after OFFER

	TCPIP_DHCPS_LEASE_SOLVED_ENTRY_TMO	Timeout for a solved entry in the cache, in seconds. The entry will be removed if the TMO lapsed and the entry has not been referenced again
	TCPIP_DHCPS_TASK_PROCESS_RATE	DHCPS task processing rate, in milliseconds. The DHCPS module will process a timer event with this rate for maintaining its own queues, processing timeouts, etc. Choose it so that the other TMO are multiple of this The default value is 200 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

Description

The configuration of the DHCP Server TCP/IP Stack is based on the file `dhcps_config.h`.

This header file contains the configuration selection for the DHCP Server TCP/IP Stack. Based on the selections made, the DHCP Server TCP/IP Stack may support the selected features. These configuration settings will apply to all instances of the DHCP Server TCP/IP Stack.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_DHCPS_DEFAULT_IP_ADDRESS_RANGE_START Macro

File

dhcps_config.h

C

```
#define TCPIP_DHCPS_DEFAULT_IP_ADDRESS_RANGE_START "192.168.1.100"
```

Description

These below IPv4 DHCP server address details are default address and it is assigned to the network default network interface. for Other interfaces , tcpip_stack_init.c file should be use to configure DHCP_POOL_CONFIG[]. IPv4 Address range is starting from 100, because the from 1 to 100 is reserved. Reserved Address will be used for the gateway address. Start of IP address Range , network_config.h ipaddress and this start of IP address should be in same SUBNET RECOMENDED - network_config.h ipaddress should be 192.168.1.1 if DHCP server ip address range starts from 192.168.1.100.

TCPIP_DHCPS_DEFAULT_SERVER_IP_ADDRESS Macro

File

dhcps_config.h

C

```
#define TCPIP_DHCPS_DEFAULT_SERVER_IP_ADDRESS "192.168.1.1"
```

Description

DHCP server Address per interface. DHCP server Address selection should be in the same subnet.

TCPIP_DHCPS_DEFAULT_SERVER_NETMASK_ADDRESS Macro

File

dhcps_config.h

C

```
#define TCPIP_DHCPS_DEFAULT_SERVER_NETMASK_ADDRESS "255.255.255.0"
```

Description

DHCP server subnet Address per interface.

TCPIP_DHCPS_DEFAULT_SERVER_PRIMARY_DNS_ADDRESS Macro

File

dhcps_config.h

C

```
#define TCPIP_DHCPS_DEFAULT_SERVER_PRIMARY_DNS_ADDRESS "192.168.1.1"
```

Description

DHCP server DNS primary Address

TCPIP_DHCPS_DEFAULT_SERVER_SECONDARY_DNS_ADDRESS Macro

File

dhcps_config.h

C

```
#define TCPIP_DHCPS_DEFAULT_SERVER_SECONDARY_DNS_ADDRESS "192.168.1.1"
```

Description

DHCP server DNS Secondary Address

TCPIP_DHCPS_LEASE_DURATION Macro

File

dhcps_config.h

C

```
#define TCPIP_DHCPS_LEASE_DURATION TCPIP_DHCPS_LEASE_SOLVED_ENTRY_TMO
```

Description

Timeout for a solved entry in the cache, in seconds the entry will be removed if the TMO elapsed and the entry has not been referenced again

TCPIP_DHCPS_LEASE_ENTRIES_DEFAULT Macro

File

dhcps_config.h

C

```
#define TCPIP_DHCPS_LEASE_ENTRIES_DEFAULT 15
```

Description

The Maximum Number of entries in the lease table Default total number of entries for all the the interface

TCPIP_DHCPS_LEASE_REMOVED_BEFORE_ACK Macro

File

dhcps_config.h

C

```
#define TCPIP_DHCPS_LEASE_REMOVED_BEFORE_ACK (5)
```

Description

Timeout for a unsolved entry , in seconds and should be removed from the entry if there is no REQUEST after OFFER

TCPIP_DHCPS_LEASE_SOLVED_ENTRY_TMO Macro

File

dhcps_config.h

C

```
#define TCPIP_DHCPS_LEASE_SOLVED_ENTRY_TMO (20 * 60)
```

Description

Timeout for a solved entry in the cache, in seconds. The entry will be removed if the TMO lapsed and the entry has not been referenced again

TCPIP_DHCPS_TASK_PROCESS_RATE Macro

File

dhcps_config.h

C

```
#define TCPIP_DHCPS_TASK_PROCESS_RATE (200)
```

Description

DHCPS task processing rate, in milliseconds. The DHCPS module will process a timer event with this rate for maintaining its own queues, processing timeouts, etc. Choose it so that the other TMO are multiple of this The default value is 200 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

Building the Library

This section lists the files that are available in the DHCP Server module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/dhcps.c`	DHCP Server implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The DHCP Server module depends on the following modules:

- TCP/IP Stack Library
- UDP Module

Library Interface

a) Configuration Functions

	Name	Description
	TCPIP_DHCPS_Disable	Disables the DHCP Server for the specified interface.

	TCPIP_DHCPS_Enable	Enables the DHCP Server for the specified interface.
	TCPIP_DHCPS_RemovePoolEntries	Removes all the entries or only used entries of a certain type belonging to a network interface.
	TCPIP_DHCPS_LeaseEntryRemove	Remove one entry from the DHCP server leased entry.
	TCPIP_DHCP_RequestTimeoutSet	Sets the DHCP client request and base time-out values.
	TCPIP_DHCP_Task	Standard TCP/IP stack module task function.
	TCPIP_DHCPS_Task	Standard TCP/IP stack module task function.

b) Status Functions

	Name	Description
	TCPIP_DHCPS_IsEnabled	Determines if the DHCP Server is enabled on the specified interface.
	TCPIP_DHCPS_GetPoolEntries	Get all the entries or only used entries of a certain type belonging to a network interface.
	TCPIP_DHCPS_LeaseEntryGet	Get the lease entry details as per TCPIP_DHCPS_LEASE_HANDLE and per interface.
	TCPIP_DHCP_InfoGet	Returns information about the DHCP client on the specified interface.

c) Data Types and Constants

	Name	Description
	TCPIP_DHCPS_LEASE_ENTRY	DHCP Server module runtime and initialization configuration data.
	TCPIP_DHCPS_LEASE_HANDLE	DHCP Server Lease Handle
	TCPIP_DHCPS_POOL_ENTRY_TYPE	DHCP server pool types are used to get and remove the leased IP address details.
	TCPIP_DHCPS_ADDRESS_CONFIG	DHCP server configuration and IP address range.
	TCPIP_DHCP_CLIENT_ENABLED	Default value for the enable/disable the DHCP client at stack start-up.
	TCPIP_DHCP_TASK_TICK_RATE	The DHCP task processing rate: number of milliseconds to generate an DHCP tick. Used by the DHCP state machine The default value is 200 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_DHCP_TIMEOUT	Defines how long to wait before a DHCP lease is acquired when the DHCP module is enabled, seconds
	TCPIP_DHCPS_MODULE_CONFIG	DHCP Server module runtime and initialization configuration data.

Description

This section describes the Application Programming Interface (API) functions of the DHCP Server module.

Refer to each section for a detailed description.

a) Configuration Functions

TCPIP_DHCPS_Disable Function

Disables the DHCP Server for the specified interface.

File

dhcps.h

C

```
bool TCPIP_DHCPS_Disable(TCPIP_NET_HANDLE hNet);
```

Returns

- true - If successful
- false - If unsuccessful

Description

This function disables the DHCP Server for the specified interface. If it is already disabled, no action is taken.

Remarks

When the interface continues using its old configuration, it is possible that the lease may take sometime to expire. And The communication will be there until it is not expired.Lease time is configured in dhcps_config.h.

Preconditions

The DHCP Server module must be initialized.

Parameters

Parameters	Description
hNet	Interface on which to disable the DHCP Server

Function

bool TCPIP_DHCPS_Disable(TCPIP_NET_HANDLE hNet)

TCPIP_DHCPS_Enable Function

Enables the DHCP Server for the specified interface.

File

dhcps.h

C

```
bool TCPIP_DHCPS_Enable(TCPIP_NET_HANDLE hNet);
```

Returns

- true - If successful
- false - If unsuccessful

Description

This function enables the DHCP Server for the specified interface, if it is disabled. If it is already enabled, nothing is done.

Preconditions

The DHCP Server module must be initialized.

Parameters

Parameters	Description
hNet	Interface on which to enable the DHCP Server

Function

void TCPIP_DHCPS_Enable(TCPIP_NET_HANDLE hNet)

TCPIP_DHCPS_RemovePoolEntries Function

Removes all the entries or only used entries of a certain type belonging to a network interface.

File

dhcps.h

C

```
bool TCPIP_DHCPS_RemovePoolEntries(TCPIP_NET_HANDLE netH, TCPIP_DHCPS_POOL_ENTRY_TYPE type);
```

Returns

- true - If successful
- false - If unsuccessful

Description

This function is used to remove the DHCP server entries from the pool as per TCPIP_DHCPS_POOL_ENTRY_TYPE.

Remarks

None.

Preconditions

the DHCP Server module should have been initialized.

Parameters

Parameters	Description
hNet	Interface handle to use

type	type of entries to remove: DHCP_SERVER_POOL_ENTRY_ALL, DHCP_SERVER_POOL_ENTRY_IN_USE

Function

bool TCPIP_DHCPS_RemovePoolEntries(TCPIP_NET_HANDLE netH, TCPIP_DHCPS_POOL_ENTRY_TYPE type);

TCPIP_DHCPS_LeaseEntryRemove Function

Remove one entry from the DHCP server leased entry.

File

dhcps.h

C

```
bool TCPIP_DHCPS_LeaseEntryRemove(TCPIP_NET_HANDLE netH, TCPIP_MAC_ADDR* hwAdd);
```

Returns

- true - If successful
- false - If unsuccessful

Description

This function is used to remove one entry from the leased HASH table with respect to the interface and the MAC address.

Remarks

This function is called from the command line to remove one entry and from the Wi-FI Driver module to remove a node that is disconnected from the AP.

Preconditions

The DHCP Server module should have been initialized.

Parameters

Parameters	Description
netH	Interface handle to use
hwAdd	MAC address that need to be removed from the HASH table

Function

bool TCPIP_DHCPS_LeaseEntryRemove(TCPIP_NET_HANDLE netH, TCPIP_MAC_ADDR* hwAdd)

TCPIP_DHCP_RequestTimeoutSet Function

Sets the DHCP client request and base time-out values.

File

dhcp.h

C

```
bool TCPIP_DHCP_RequestTimeoutSet(TCPIP_NET_HANDLE hNet, uint16_t initTmo, uint16_t dhcpBaseTmo);
```

Returns

- true - if successful
- false - if a wrong interface handle or time-out value was provided

Description

This function allows the run time adjustment of the DHCP time-out values. It specifies for how long the client has to wait for a valid DHCP server reply during the initialization process until acquisition of the host address is considered to have failed. It also sets the DHCP base timeout for DHCP transactions with the server. This is automatically incremented by the DHCP client using an exponential back-off algorithm. Recommended value is 2 <= dhcpBaseTmo <= 64 seconds.

Preconditions

The DHCP module must be initialized.

Parameters

Parameters	Description
hNet	Interface handle
initTmo	Initialization time-out to wait for a valid lease acquisition, in seconds
dhcpBaseTmo	DHCP time-out value for DHCP requests, in seconds

Function

bool TCPIP_DHCP_RequestTimeoutSet(TCPIP_NET_HANDLE hNet, uint16_t initTmo,
uint16_t dhcpBaseTmo)

TCPIP_DHCP_Task Function

Standard TCP/IP stack module task function.

File

dhcp.h

C

```
void TCPIP_DHCP_Task();
```

Returns

None.

Description

This function performs DHCP module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

DHCP module should have been initialized

Function

void TCPIP_DHCP_Task(void)

TCPIP_DHCPS_Task Function

Standard TCP/IP stack module task function.

File

dhcps.h

C

```
void TCPIP_DHCPS_Task();
```

Returns

None.

Description

This function performs DHCP Server module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The DHCP Server module should have been initialized.

Function

void TCPIP_DHCPS_Task(void)

b) Status Functions

TCPIP_DHCPS_IsEnabled Function

Determines if the DHCP Server is enabled on the specified interface.

File

dhcps.h

C

```
bool TCPIP_DHCPS_IsEnabled(TCPIP_NET_HANDLE hNet);
```

Returns

- true - If successful
- false - If unsuccessful

Description

This function returns the current state of the DHCP Server on the specified interface.

Preconditions

The DHCP Server module must be initialized.

Parameters

Parameters	Description
hNet	Interface to query

Function

bool TCPIP_DHCPS_IsEnabled(TCPIP_NET_HANDLE hNet)

TCPIP_DHCPS_GetPoolEntries Function

Get all the entries or only used entries of a certain type belonging to a network interface.

File

dhcps.h

C

```
int TCPIP_DHCPS_GetPoolEntries(TCPIP_NET_HANDLE netH, TCPIP_DHCPS_POOL_ENTRY_TYPE type);
```

Returns

- true - If successful
- false - If unsuccessful

Description

This function is used to get the DHCP server entries from the pool as per TCPIP_DHCPS_POOL_ENTRY_TYPE.

Remarks

None.

Preconditions

The DHCP server module should have been initialized.

Parameters

Parameters	Description
hNet	Interface handle to use
type	type of entries to remove: • DHCP_SERVER_POOL_ENTRY_ALL, • DHCP_SERVER_POOL_ENTRY_IN_USE

Function

int TCPIP_DHCPS_GetPoolEntries(TCPIP_NET_HANDLE netH, TCPIP_DHCPS_POOL_ENTRY_TYPE type);

TCPIP_DHCPS_LeaseEntryGet Function

Get the lease entry details as per TCPIP_DHCPS_LEASE_HANDLE and per interface.

File

dhcps.h

C

```
TCPIP_DHCPS_LEASE_HANDLE TCPIP_DHCPS_LeaseEntryGet(TCPIP_NET_HANDLE netH, TCPIP_DHCPS_LEASE_ENTRY*
pLeaseEntry, TCPIP_DHCPS_LEASE_HANDLE leaseHandle);
```

Returns

- non-zero TCPIP_DHCPS_LEASE_HANDLE - To be used in the subsequent calls
- 0 - If end of list or wrong interface, or DHCP server is not running on that interface

Description

This function returns a lease entry for the TCPIP_DHCPS_LEASE_HANDLE. if the lease entry is not present for that TCPIP_DHCPS_LEASE_HANDLE, then it will return the next valid lease entry.

Preconditions

The DHCP Server module must be initialized.

Parameters

Parameters	Description
netH	Lease entry for this Interface
pLeaseEntry	Client lease entry details
leaseHandle	Lease index

Function

TCPIP_DHCPS_LEASE_HANDLE TCPIP_DHCPS_LeaseEntryGet(TCPIP_NET_HANDLE netH,
TCPIP_DHCPS_LEASE_ENTRY* pLeaseEntry, TCPIP_DHCPS_LEASE_HANDLE leaseHandle);

TCPIP_DHCP_InfoGet Function

Returns information about the DHCP client on the specified interface.

File

dhcp.h

C

```
bool TCPIP_DHCP_InfoGet(TCPIP_NET_HANDLE hNet, TCPIP_DHCP_INFO* pDhcpInfo);
```

Returns

- true - if the interface is enabled and exists and the DHCP client service information filled in the supplied storage
- false - if the specified interface is not enabled, does not exist, or does not have a DHCP client

Description

This function returns the current state and lease info of the DHCP client on the specified interface.

Preconditions

The DHCP module must be initialized.

Parameters

Parameters	Description
hNet	Interface to query.
pDhcpInfo	storage to return the DHCP info

Function

bool TCPIP_DHCP_InfoGet(TCPIP_NET_HANDLE hNet, TCPIP_DHCP_INFO* pDhcpInfo);

c) Data Types and Constants

TCPIP_DHCPS_LEASE_ENTRY Structure

DHCP Server module runtime and initialization configuration data.

File

dhcps.h

C

```
typedef struct {
  TCPIP_MAC_ADDR hwAdd;
  IPV4_ADDR ipAddress;
  uint32_t leaseTime;
} TCPIP_DHCPS_LEASE_ENTRY;
```

Members

Members	Description
TCPIP_MAC_ADDR hwAdd;	Client MAC address
IPV4_ADDR ipAddress;	Leased IP address
uint32_t leaseTime;	Lease period

Description

Structure: TCPIP_DHCPS_MODULE_CONFIG

DHCP server configuration and initialization data. Configuration is part of tcpip_stack_init.c.

TCPIP_DHCPS_LEASE_HANDLE Type

DHCP Server Lease Handle

File

dhcps.h

C

```
typedef const void* TCPIP_DHCPS_LEASE_HANDLE;
```

Description

Type: TCPIP_DHCPS_LEASE_HANDLE

A handle that server is using to provide the index of a lease entry.

Remarks

This handle is used by command handler to get the Index of Lease entry.

TCPIP_DHCPS_POOL_ENTRY_TYPE Enumeration

DHCP server pool types are used to get and remove the leased IP address details.

File

dhcps.h

C

```
typedef enum {
  DHCP_SERVER_POOL_ENTRY_ALL,
  DHCP_SERVER_POOL_ENTRY_IN_USE
} TCPIP_DHCPS_POOL_ENTRY_TYPE;
```

Members

Members	Description
DHCP_SERVER_POOL_ENTRY_ALL	Get or Remove all the Leased address
DHCP_SERVER_POOL_ENTRY_IN_USE	Get or remove only Leased IP address

Description

Enumeration: TCPIP_DHCPS_POOL_ENTRY_TYPE

DHCP_SERVER_POOL_ENTRY_ALL - Get or Remove all the leased address which includes both solved and unsolved entries.
DHCP_SERVER_POOL_ENTRY_IN_USE - Get or Remove only solved leased IP address.

TCPIP_DHCPS_ADDRESS_CONFIG Structure

DHCP server configuration and IP address range.

File

dhcps.h

C

```
typedef struct {
  int interfaceIndex;
  char* serverIPAddress;
  char* startIPAddRange;
  char* ipMaskAddress;
  char* priDNS;
  char* secondDNS;
  bool poolEnabled;
} TCPIP_DHCPS_ADDRESS_CONFIG;
```

Members

Members	Description
int interfaceIndex;	Interface Index
char* serverIPAddress;	Server IP address
char* startIPAddRange;	Start IP address
char* ipMaskAddress;	Netmask
char* priDNS;	Primary DNS server Address
char* secondDNS;	Secondary DNS server Address
bool poolEnabled;	true if pool is valid , false if pool is invalid

Description

Structure: TCPIP_DHCPS_ADDRESS_CONFIG

DHCP server configuration and network initialization data. Configuration is part of tcpip_stack_init.c.

TCPIP_DHCP_CLIENT_ENABLED Macro

File

dhcp_config.h

C

```
#define TCPIP_DHCP_CLIENT_ENABLED 1
```

Description

Default value for the enable/disable the DHCP client at stack start-up.

Remarks

the interface initialization setting in TCPIP_NETWORK_CONFIG takes precedence!

TCPIP_DHCP_TASK_TICK_RATE Macro

File

dhcp_config.h

C

```
#define TCPIP_DHCP_TASK_TICK_RATE (200)
```

Description

The DHCP task processing rate: number of milliseconds to generate an DHCP tick. Used by the DHCP state machine The default value is 200 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

TCPIP_DHCP_TIMEOUT Macro

File

dhcp_config.h

C

```
#define TCPIP_DHCP_TIMEOUT (10)
```

Description

Defines how long to wait before a DHCP lease is acquired when the DHCP module is enabled, seconds

TCPIP_DHCPS_MODULE_CONFIG Structure

DHCP Server module runtime and initialization configuration data.

File

dhcps.h

C

```
typedef struct {
  bool enabled;
  bool deleteOldLease;
  size_t leaseEntries;
  uint32_t entrySolvedTmo;
  TCPIP_DHCPS_ADDRESS_CONFIG * dhcpServer;
} TCPIP_DHCPS_MODULE_CONFIG;
```

Members

Members	Description
bool enabled;	enable DHCP server
bool deleteOldLease;	delete old cache if still in place, specific DHCP parameters
size_t leaseEntries;	max number of lease entries
uint32_t entrySolvedTmo;	solved entry removed after this tmo in seconds
TCPIP_DHCPS_ADDRESS_CONFIG * dhcpServer;	DHCP server lease address configuration details uint32_t dhcpServerCnt; // Max DHCP server support

Description

Structure: TCPIP_DHCPS_MODULE_CONFIG

DHCP server configuration and initialization data . Configuration is part of tcpip_stack_init.c.

Files

Files

Name	Description
dhcps.h	Dynamic Host Configuration Protocol(DHCP) Server APIs.
dhcps_config.h	DHCPS configuration file

Description

This section lists the source and header files used by the library.

dhcps.h

Dynamic Host Configuration Protocol(DHCP) Server APIs.

Enumerations

	Name	Description
	TCPIP_DHCPS_POOL_ENTRY_TYPE	DHCP server pool types are used to get and remove the leased IP address details.

Functions

	Name	Description
	TCPIP_DHCPS_Disable	Disables the DHCP Server for the specified interface.
	TCPIP_DHCPS_Enable	Enables the DHCP Server for the specified interface.
	TCPIP_DHCPS_GetPoolEntries	Get all the entries or only used entries of a certain type belonging to a network interface.
	TCPIP_DHCPS_IsEnabled	Determines if the DHCP Server is enabled on the specified interface.
	TCPIP_DHCPS_LeaseEntryGet	Get the lease entry details as per TCPIP_DHCPS_LEASE_HANDLE and per interface.
	TCPIP_DHCPS_LeaseEntryRemove	Remove one entry from the DHCP server leased entry.
	TCPIP_DHCPS_RemovePoolEntries	Removes all the entries or only used entries of a certain type belonging to a network interface.
	TCPIP_DHCPS_Task	Standard TCP/IP stack module task function.

Structures

	Name	Description
	TCPIP_DHCPS_ADDRESS_CONFIG	DHCP server configuration and IP address range.
	TCPIP_DHCPS_LEASE_ENTRY	DHCP Server module runtime and initialization configuration data.
	TCPIP_DHCPS_MODULE_CONFIG	DHCP Server module runtime and initialization configuration data.

Types

	Name	Description
	TCPIP_DHCPS_LEASE_HANDLE	DHCP Server Lease Handle

Description

Dynamic Host Configuration Protocol (DHCP) Server API Header File

The DHCP server assigns a free IP address to a requesting client from the range defined in the dhcps_config.h file. Lease time per IP address is decided as per the TMO configuration which is defined in dhcps_config.h.

File Name

dhcps.h

DHCPv6 Module

This section describes the TCP/IP Stack Library DHCPv6 module.

Introduction

TCP/IP Stack Library IPv6 Dynamic Host Configuration Protocol (DHCPv6) Module for Microchip Microcontrollers

This library provides the API of the DHCPv6 module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

The DHCPv6 client module will allow your application to dynamically obtain an IPv6 address from a DHCPv6 server. Additionally, the DHCPv6 client will get other parameters, such as DNS servers and the domain search list.

Using the Library

This topic describes the basic architecture of the DHCPv6 TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `dhcpv6.h`

The interface to the DHCPv6 TCP/IP Stack library is defined in the `dhcpv6.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the DHCPv6 TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

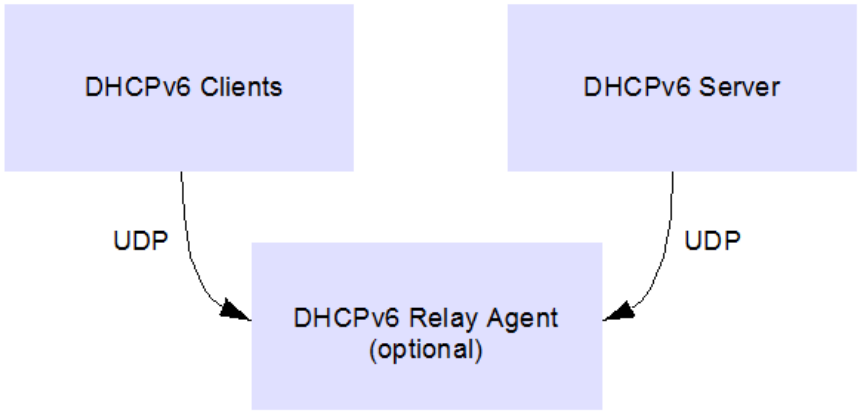
This library provides the API of the DHCPv6 TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

This module provides software abstraction of the DHCPv6 module existent in the TCP/IP Stack implementation. The DHCPv6 module works together with the IPv6 Stateless Address Auto-configuration protocol and provides stateful temporary/non-temporary (IATA, IANA) global addresses for the IPv6 host.

DHCPv6 Software Abstraction Block Diagram

Typical DCHPv6 Usage



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the DHCPv6 module.

Library Interface Section	Description
Configuration Functions	Routines for Configuring DHCPv6
Status Functions	Routines for Obtaining DHCPv6 Status Information
Data Types and Constants	This section provides various definitions describing this API

How the Library Works

The IPv6 Dynamic Host Configuration Protocol (DHCPv6) is a standard networking protocol used to automatically allocate IPv6 addresses for hosts in a network.

The DHCPv6 server has a pool of IP addresses, which are leased for clients requesting them. The leases have a limited lifetime after which the hosts need to renew the lease or acquire a new one.

The DHCPv6 client module in the TCP/IP stack takes care of the communication with the DHCPv6 server and renewing the lease when the lifetime expires.

Configuring the Library

Macros

	Name	Description
	TCPIP_DHCPV6_CLIENT_DUID_TYPE	Default DUID type to be used by the client
	TCPIP_DHCPV6_CLIENT_PORT	Clients listen for DHCP messages on UDP port:
	TCPIP_DHCPV6_DNS_SERVERS_NO	number of DNS servers to store from a DHCP server reply
	TCPIP_DHCPV6_DOMAIN_SEARCH_LIST_SIZE	space for the Domain Search List option - multiple of 16
	TCPIP_DHCPV6_FORCED_SERVER_PREFERENCE	preference value that forces the server selection 8 bit value!
	TCPIP_DHCPV6_IA_FREE_DESCRIPTORS_NO	maximum number of free IA descriptors per client
	TCPIP_DHCPV6_IA_SOLICIT_ADDRESS_PREF_LTIME	default lifetimes for the solicited addresses
	TCPIP_DHCPV6_IA_SOLICIT_ADDRESS_VALID_LTIME	This is macro TCPIP_DHCPV6_IA_SOLICIT_ADDRESS_VALID_LTIME.
	TCPIP_DHCPV6_IANA_DEFAULT_T1	default values for IANA T1, T2
	TCPIP_DHCPV6_IANA_DEFAULT_T2	This is macro TCPIP_DHCPV6_IANA_DEFAULT_T2.
	TCPIP_DHCPV6_IANA_DESCRIPTORS_NO	maximum number of IANA descriptors per client
	TCPIP_DHCPV6_IANA_SOLICIT_ADDRESSES_NO	default addresses for IANA in a solicit message
	TCPIP_DHCPV6_IANA_SOLICIT_DEFAULT_ADDRESS	default values for the IANA Solicit addresses irrelevant if TCPIP_DHCPV6_IANA_SOLICIT_ADDRESSES_NO == 0 should be a value for each TCPIP_DHCPV6_IANA_SOLICIT_ADDRESSES_NO
	TCPIP_DHCPV6_IANA_SOLICIT_T1	default values for IANA T1, T2 in a solicit message
	TCPIP_DHCPV6_IANA_SOLICIT_T2	This is macro TCPIP_DHCPV6_IANA_SOLICIT_T2.
	TCPIP_DHCPV6_IATA_DEFAULT_T1	default values for IATA T1, T2 If 0, the timeout will be infinite (0xffffffff)
	TCPIP_DHCPV6_IATA_DEFAULT_T2	This is macro TCPIP_DHCPV6_IATA_DEFAULT_T2.
	TCPIP_DHCPV6_IATA_DESCRIPTORS_NO	maximum number of IATA descriptors per client
	TCPIP_DHCPV6_IATA_SOLICIT_ADDRESSES_NO	default addresses for IATA in a solicit message
	TCPIP_DHCPV6_IATA_SOLICIT_DEFAULT_ADDRESS	default values for the IANA Solicit addresses irrelevant if TCPIP_DHCPV6_IATA_SOLICIT_ADDRESSES_NO == 0 should be a value for each TCPIP_DHCPV6_IATA_SOLICIT_ADDRESSES_NO
	TCPIP_DHCPV6_MESSAGE_BUFFER_SIZE	default value of the buffer to assemble messages, etc.
	TCPIP_DHCPV6_MESSAGE_BUFFERS	default number of buffers
	TCPIP_DHCPV6_MIN_UDP_TX_BUFFER_SIZE	minimum size of a UDP buffer
	TCPIP_DHCPV6_SERVER_PORT	Servers and relay agents listen for DHCP messages on UDP port:
	TCPIP_DHCPV6_SKIP_DAD_PROCESS	defining this symbol will skip the DAD processing for DHCPv6 generated addresses
	TCPIP_DHCPV6_STATUS_CODE_MESSAGE_LEN	number of character to reserve for a server status code associated message
	TCPIP_DHCPV6_TASK_TICK_RATE	The DHCPv6 task processing rate: number of milliseconds to generate an DHCPv6 tick. Used by the DHCPv6 state machine The default value is 100 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_STACK_USE_DHCPV6_CLIENT	This symbol enables the DHCPv6 client as being part of the build
	TCPIP_DHCPV6_USER_NOTIFICATION	allow DHCPV6 client user notification if enabled, the TCPIP_DHCPV6_HandlerRegister/TCPIP_DHCPV6_HandlerDeRegister functions exist and can be used

Description

The configuration of the DHCPv6 TCP/IP Stack is based on the file `system_config.h` (which may include a `dhcpv6_config.h` file).

This header file contains the configuration parameters for the DHCPv6 TCP/IP Stack. Based on the selections made, the DHCPv6 TCP/IP Stack will adjust its behavior.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_DHCPV6_CLIENT_DUID_TYPE Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_CLIENT_DUID_TYPE TCPIP_DHCPV6_DUID_TYPE_LL
```

Description

Default DUID type to be used by the client

TCPIP_DHCPV6_CLIENT_PORT Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_CLIENT_PORT 546
```

Description

Clients listen for DHCP messages on UDP port:

TCPIP_DHCPV6_DNS_SERVERS_NO Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_DNS_SERVERS_NO 2
```

Description

number of DNS servers to store from a DHCP server reply

TCPIP_DHCPV6_DOMAIN_SEARCH_LIST_SIZE Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_DOMAIN_SEARCH_LIST_SIZE 64
```

Description

space for the Domain Search List option - multiple of 16

TCPIP_DHCPV6_FORCED_SERVER_PREFERENCE Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_FORCED_SERVER_PREFERENCE 255
```

Description

preference value that forces the server selection 8 bit value!

TCPIP_DHCPV6_IA_FREE_DESCRIPTORS_NO Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_IA_FREE_DESCRIPTORS_NO 2
```

Description

maximum number of free IA descriptors per client

TCPIP_DHCPV6_IA_SOLICIT_ADDRESS_PREF_LTIME Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_IA_SOLICIT_ADDRESS_PREF_LTIME 0
```

Description

default lifetimes for the solicited addresses

TCPIP_DHCPV6_IA_SOLICIT_ADDRESS_VALID_LTIME Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_IA_SOLICIT_ADDRESS_VALID_LTIME 0
```

Description

This is macro TCPIP_DHCPV6_IA_SOLICIT_ADDRESS_VALID_LTIME.

TCPIP_DHCPV6_IANA_DEFAULT_T1 Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_IANA_DEFAULT_T1 0
```

Description

default values for IANA T1, T2

TCPIP_DHCPV6_IANA_DEFAULT_T2 Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_IANA_DEFAULT_T2 0
```

Description

This is macro TCPIP_DHCPV6_IANA_DEFAULT_T2.

TCPIP_DHCPV6_IANA_DESCRIPTORS_NO Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_IANA_DESCRIPTORS_NO 4
```

Description

maximum number of IANA descriptors per client

TCPIP_DHCPV6_IANA_SOLICIT_ADDRESSES_NO Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_IANA_SOLICIT_ADDRESSES_NO 0
```

Description

default addresses for IANA in a solicit message

TCPIP_DHCPV6_IANA_SOLICIT_DEFAULT_ADDRESS Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_IANA_SOLICIT_DEFAULT_ADDRESS "::0"
```

Description

default values for the IANA Solicit addresses irrelevant if TCPIP_DHCPV6_IANA_SOLICIT_ADDRESSES_NO == 0 should be a value for each TCPIP_DHCPV6_IANA_SOLICIT_ADDRESSES_NO

TCPIP_DHCPV6_IANA_SOLICIT_T1 Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_IANA_SOLICIT_T1 0
```

Description

default values for IANA T1, T2 in a solicit message

TCPIP_DHCPV6_IANA_SOLICIT_T2 Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_IANA_SOLICIT_T2 0
```

Description

This is macro TCPIP_DHCPV6_IANA_SOLICIT_T2.

TCPIP_DHCPV6_IATA_DEFAULT_T1 Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_IATA_DEFAULT_T1 0
```

Description

default values for IATA T1, T2 If 0, the timeout will be infinite (0xffffffff)

TCPIP_DHCPV6_IATA_DEFAULT_T2 Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_IATA_DEFAULT_T2 0
```

Description

This is macro TCPIP_DHCPV6_IATA_DEFAULT_T2.

TCPIP_DHCPV6_IATA_DESCRIPTORS_NO Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_IATA_DESCRIPTORS_NO 2
```

Description

maximum number of IATA descriptors per client

TCPIP_DHCPV6_IATA_SOLICIT_ADDRESSES_NO Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_IATA_SOLICIT_ADDRESSES_NO 0
```

Description

default addresses for IATA in a solicit message

TCPIP_DHCPV6_IATA_SOLICIT_DEFAULT_ADDRESS Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_IATA_SOLICIT_DEFAULT_ADDRESS 0
```

Description

default values for the IANA Solicit addresses irrelevant if TCPIP_DHCPV6_IATA_SOLICIT_ADDRESSES_NO == 0 should be a value for each TCPIP_DHCPV6_IATA_SOLICIT_ADDRESSES_NO

TCPIP_DHCPV6_MESSAGE_BUFFER_SIZE Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_MESSAGE_BUFFER_SIZE 512
```

Description

default value of the buffer to assemble messages, etc.

TCPIP_DHCPV6_MESSAGE_BUFFERS Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_MESSAGE_BUFFERS 8
```

Description

default number of buffers

TCPIP_DHCPV6_MIN_UDP_TX_BUFFER_SIZE Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_MIN_UDP_TX_BUFFER_SIZE 512
```

Description

minimum size of a UDP buffer

TCPIP_DHCPV6_SERVER_PORT Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_SERVER_PORT 547
```

Description

Servers and relay agents listen for DHCP messages on UDP port:

TCPIP_DHCPV6_SKIP_DAD_PROCESS Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_SKIP_DAD_PROCESS
```

Description

defining this symbol will skip the DAD processing for DHCPv6 generated addresses

TCPIP_DHCPV6_STATUS_CODE_MESSAGE_LEN Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_STATUS_CODE_MESSAGE_LEN 0
```

Description

number of character to reserve for a server status code associated message

TCPIP_DHCPV6_TASK_TICK_RATE Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_TASK_TICK_RATE (100)
```

Description

The DHCPv6 task processing rate: number of milliseconds to generate an DHCPv6 tick. Used by the DHCPv6 state machine The default value is 100 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

TCPIP_STACK_USE_DHCPV6_CLIENT Macro

File

dhcpv6_config.h

C

```
#define TCPIP_STACK_USE_DHCPV6_CLIENT
```

Description

This symbol enables the DHCPv6 client as being part of the build

TCPIP_DHCPV6_USER_NOTIFICATION Macro

File

dhcpv6_config.h

C

```
#define TCPIP_DHCPV6_USER_NOTIFICATION false
```

Description

allow DHCPV6 client user notification if enabled, the TCPIP_DHCPV6_HandlerRegister/TCPIP_DHCPV6_HandlerDeRegister functions exist and can be used

Building the Library

This section lists the files that are available in the DHCPv6 module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
/tcpip.h	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/dhcpv6.c	DHCPv6 implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The DHCPv6 module depends on the following modules:

- TCP/IP Stack Library
- UDP Module

Library Interface

a) Configuration Functions

	Name	Description
	TCPIP_DHCPV6_HandlerDeRegister	DHCPV6 event deregistration
	TCPIP_DHCPV6_HandlerRegister	DHCPV6 event registration
	TCPIP_DHCPV6_Task	Standard TCP/IP stack module task function.

b) Status Functions

	Name	Description
	TCPIP_DHCPV6_ClientInfoGet	client status reporting
	TCPIP_DHCPV6_IaInfoGet	IA status reporting

c) Data Types and Constants

	Name	Description
	TCPIP_DHCPV6_CLIENT_INFO	DHCPv6 client info
	TCPIP_DHCPV6_CLIENT_STATE	DHCPv6 Current Status
	TCPIP_DHCPV6_CONFIG_FLAGS	DHCPV6 start up flags
	TCPIP_DHCPV6_DUID_TYPE	types of DUID for DHCPv6
	TCPIP_DHCPV6_EVENT_HANDLER	DHCPv6 event handler prototype.
	TCPIP_DHCPV6_HANDLE	a DHCPV6 handle
	TCPIP_DHCPV6_IA_EVENT	IA event info
	TCPIP_DHCPV6_IA_INFO	DHCPv6 IA info
	TCPIP_DHCPV6_IA_STATE	IA run states
	TCPIP_DHCPV6_IA_SUBSTATE	IA run substates most IA run states that must send a message go through these substates
	TCPIP_DHCPV6_IA_TYPE	supported types of IA
	TCPIP_DHCPV6_MODULE_CONFIG	DHCPv6 module configuration
	TCPIP_DHCPV6_SERVER_STATUS_CODE	DHCPV6 server status code

Description

This section describes the Application Programming Interface (API) functions of the DHCPv6 module.

Refer to each section for a detailed description.

a) Configuration Functions

TCPIP_DHCPV6_HandlerDeRegister Function

File

dhcpv6.h

C

```
bool TCPIP_DHCPV6_HandlerDeRegister(TCPIP_DHCPV6_HANDLE hDhcp);
```

Description

DHCPV6 event deregistration

TCPIP_DHCPV6_HandlerRegister Function

File

dhcpv6.h

C

```
TCPIP_DHCPV6_HANDLE TCPIP_DHCPV6_HandlerRegister(TCPIP_NET_HANDLE hNet, TCPIP_DHCPV6_EVENT_HANDLER handler,
const void* hParam);
```

Description

DHCPV6 event registration

TCPIP_DHCPV6_Task Function

Standard TCP/IP stack module task function.

File

dhcpv6.h

C

```
void TCPIP_DHCPV6_Task();
```

Returns

None.

Description

This function performs DHCPv6 module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

DHCPv6 module should have been initialized

Function

void TCPIP_DHCPV6_Task(void)

b) Status Functions

TCPIP_DHCPV6_ClientInfoGet Function

File

dhcpv6.h

C

```
bool TCPIP_DHCPV6_ClientInfoGet(TCPIP_NET_HANDLE hNet, TCPIP_DHCPV6_CLIENT_INFO* pClientInfo);
```

Description

client status reporting

TCPIP_DHCPV6_IaInfoGet Function

File

dhcpv6.h

C

```
bool TCPIP_DHCPV6_IaInfoGet(TCPIP_NET_HANDLE hNet, int iaIx, TCPIP_DHCPV6_IA_INFO* pIaInfo);
```

Description

IA status reporting

c) Data Types and Constants

TCPIP_DHCPV6_CLIENT_INFO Structure

File

dhcpv6.h

C

```
typedef struct {
  TCPIP_DHCPV6_CLIENT_STATE clientState;
  int nIanas;
  int nIatas;
  int nFreeIas;
  uint32_t dhcpTime;
  TCPIP_DHCPV6_SERVER_STATUS_CODE lastStatusCode;
  void* statusBuff;
  size_t statusBuffSize;
  int nDnsServers;
  IPV6_ADDR* dnsBuff;
  size_t dnsBuffSize;
  int domainSearchListSize;
  void* domainBuff;
  size_t domainBuffSize;
} TCPIP_DHCPV6_CLIENT_INFO;
```

Members

Members	Description
TCPIP_DHCPV6_CLIENT_STATE clientState;	client state at the moment of the call
int nIanas;	number of IANA the client has
int nIatas;	number of IATA the client has
int nFreeIas;	number of free IAs the client has
uint32_t dhcpTime;	current DHCPV6 time; seconds
TCPIP_DHCPV6_SERVER_STATUS_CODE lastStatusCode;	last status code for the client
void* statusBuff;	buffer to copy the latest status message associated with the client
size_t statusBuffSize;	size of this buffer
int nDnsServers;	number of DNS servers
IPV6_ADDR* dnsBuff;	buffer to copy the DNS Servers obtained from the DHCPV6 server
size_t dnsBuffSize;	size of this buffer
int domainSearchListSize;	size of domainSearchList
void* domainBuff;	buffer to store the domain Search list obtained from the DHCPv6 server
size_t domainBuffSize;	size of this buffer

Description

DHCPv6 client info

TCPIP_DHCPV6_CLIENT_STATE Enumeration

DHCPv6 Current Status

File

dhcpv6.h

C

```
typedef enum {
  TCPIP_DHCPV6_CLIENT_STATE_INIT = 0,
  TCPIP_DHCPV6_CLIENT_STATE_IDLE,
  TCPIP_DHCPV6_CLIENT_STATE_RUN,
  TCPIP_DHCPV6_CLIENT_STATE_WAIT_LINK,
  TCPIP_DHCPV6_CLIENT_STATE_NUMBER
} TCPIP_DHCPV6_CLIENT_STATE;
```

Members

Members	Description
TCPIP_DHCPV6_CLIENT_STATE_INIT = 0	initialization state/unknown
TCPIP_DHCPV6_CLIENT_STATE_IDLE	idle/inactive state
TCPIP_DHCPV6_CLIENT_STATE_RUN	up and running in one of the run states
TCPIP_DHCPV6_CLIENT_STATE_WAIT_LINK	up and running, waiting for a connection
TCPIP_DHCPV6_CLIENT_STATE_NUMBER	number of states

Description

Enumeration: TCPIP_DHCPV6_CLIENT_STATE

This enumeration lists the current status of the DHCPv6 module. Used in getting info about the DHCPv6 state machine.

TCPIP_DHCPV6_CONFIG_FLAGS Enumeration

File

dhcpv6.h

C

```
typedef enum {
  TCPIP_DHCPV6_FLAG_NONE = 0,
  TCPIP_DHCPV6_FLAG_START_ENABLE = 0x01,
  TCPIP_DHCPV6_FLAG_DAD_DISABLE = 0x02,
  TCPIP_DHCPV6_FLAG_IA_IGNORE_RENEW_LTIME = 0x04,
  TCPIP_DHCPV6_FLAG_IA_IGNORE_REBIND_LTIME = 0x08,
  TCPIP_DHCPV6_FLAG_IA_NOTIFY_SUB_STATE = 0x80
} TCPIP_DHCPV6_CONFIG_FLAGS;
```

Members

Members	Description
TCPIP_DHCPV6_FLAG_START_ENABLE = 0x01	enable the DHCPv6 at stack start up
TCPIP_DHCPV6_FLAG_DAD_DISABLE = 0x02	disable the DAD processing for DHCP generated addresses Use only for testing or in special cases Default should be disabled
TCPIP_DHCPV6_FLAG_IA_IGNORE_RENEW_LTIME = 0x04	if enabled, the IA (and its associated address) renew process will be valid as dictated by t1/defaultIataT1 and its address preferred lifetime will be ignored If disabled, the IA and its address will attempt renew when the minimum of address preferred lifetime and t1/defaultIataT1 expired Default should be disabled
TCPIP_DHCPV6_FLAG_IA_IGNORE_REBIND_LTIME = 0x08	if enabled, the IA (and its associated address) rebind process will be valid as dictated by t2/defaultIataT2 and its address valid lifetime will be ignored If disabled, the IA and its address will attempt rebind when the minimum of address valid lifetime and t2/defaultIataT2 expired Default should be disabled

TCPIP_DHCPV6_FLAG_IA_NOTIFY_SUB_STATE = 0x80	if enabled, the IA notifications will be generated for IA substate changes too (finer grain) if disabled, notifications will be generated for IA state changes only Default should be disabled

Description

DHCPV6 start up flags

TCPIP_DHCPV6_DUID_TYPE Enumeration

File

dhcpv6.h

C

```
typedef enum {
  TCPIP_DHCPV6_DUID_TYPE_NONE = 0,
  TCPIP_DHCPV6_DUID_TYPE_LLT = 1,
  TCPIP_DHCPV6_DUID_TYPE_EN = 2,
  TCPIP_DHCPV6_DUID_TYPE_LL = 3
} TCPIP_DHCPV6_DUID_TYPE;
```

Members

Members	Description
TCPIP_DHCPV6_DUID_TYPE_NONE = 0	invalid
TCPIP_DHCPV6_DUID_TYPE_LLT = 1	LinkLayer + time
TCPIP_DHCPV6_DUID_TYPE_EN = 2	Enterprise Number
TCPIP_DHCPV6_DUID_TYPE_LL = 3	Link Layer Address

Description

types of DUID for DHCPv6

TCPIP_DHCPV6_EVENT_HANDLER Type

DHCPv6 event handler prototype.

File

dhcpv6.h

C

```
typedef void (* TCPIP_DHCPV6_EVENT_HANDLER)(TCPIP_NET_HANDLE hNet, TCPIP_DHCPV6_CLIENT_STATE clientState,
const TCPIP_DHCPV6_IA_EVENT* pDhcpIaEv, const void* param);
```

Description

DHCPv6 reported event structure:

Type: TCPIP_DHCPV6_EVENT_HANDLER

Prototype of a DHCP event handler. Clients can register a handler with the DHCP service. Once an DHCP event occurs the DHCP service will called the registered handler. The handler has to be short and fast. It is meant for setting an event flag, *not* for lengthy processing!

if pDhcpIaEvent == 0, no info is carried for a specific IA if pDhcpIaEvent != 0, the info carried by this pointer is not persistent and is valid only within the context of this event handler!

TCPIP_DHCPV6_HANDLE Type

File

dhcpv6.h

C

```
typedef const void* TCPIP_DHCPV6_HANDLE;
```

Description

a DHCPV6 handle

TCPIP_DHCPV6_IA_EVENT Union

File

dhcpv6.h

C

```
typedef union {
  uint32_t eventVal;
  struct {
    uint8_t iaType;
    uint8_t iaState;
    uint8_t iaSubState;
    uint8_t iaIndex;
  }
} TCPIP_DHCPV6_IA_EVENT;
```

Members

Members	Description
uint8_t iaType;	a TCPIP_DHCPV6_IA_TYPE value
uint8_t iaState;	a TCPIP_DHCPV6_IA_STATE value
uint8_t iaSubState;	a TCPIP_DHCPV6_IA_SUBSTATE value
uint8_t iaIndex;	index/ID of this IA for this client

Description

IA event info

TCPIP_DHCPV6_IA_INFO Structure

File

dhcpv6.h

C

```
typedef struct {
  TCPIP_DHCPV6_IA_TYPE iaType;
  TCPIP_DHCPV6_IA_STATE iaState;
  TCPIP_DHCPV6_IA_SUBSTATE iaSubState;
  int iaIndex;
  uint32_t iaId;
  uint32_t tAcquire;
  uint32_t t1;
  uint32_t t2;
  IPV6_ADDR ipv6Addr;
  uint32_t prefLTime;
  uint32_t validLTime;
  TCPIP_DHCPV6_SERVER_STATUS_CODE lastStatusCode;
  void* statusBuff;
  size_t statusBuffSize;
} TCPIP_DHCPV6_IA_INFO;
```

Members

Members	Description
TCPIP_DHCPV6_IA_TYPE iaType;	IA type
TCPIP_DHCPV6_IA_STATE iaState;	IA state
TCPIP_DHCPV6_IA_SUBSTATE iaSubState;	IA substate
int iaIndex;	index of this IA for this client
uint32_t iaId;	ID of this IA the following fields are meaningful only for iaState >= TCPIP_DHCPV6_IA_STATE_BOUND
uint32_t tAcquire;	time of which the address was acquired
uint32_t t1;	IANA only: extend lifetime contact server time
uint32_t t2;	IANA only: extend lifetime contact any server time
IPV6_ADDR ipv6Addr;	16 bytes IPV6 address associated with this IA
uint32_t prefLTime;	preferred life time for the IPv6 address; seconds

uint32_t validLTime;	valid life time for the IPv6 address; seconds
TCPIP_DHCPV6_SERVER_STATUS_CODE lastStatusCode;	last status code for this IA
void* statusBuff;	buffer to copy the latest status message associated with this IA
size_t statusBuffSize;	size of this buffer

Description

DHCPv6 IA info

TCPIP_DHCPV6_IA_STATE Enumeration

File

dhcpv6.h

C

```
typedef enum {
  TCPIP_DHCPV6_IA_STATE_SOLICIT,
  TCPIP_DHCPV6_IA_STATE_REQUEST,
  TCPIP_DHCPV6_IA_STATE_DAD,
  TCPIP_DHCPV6_IA_STATE_DECLINE,
  TCPIP_DHCPV6_IA_STATE_BOUND,
  TCPIP_DHCPV6_IA_STATE_RENEW,
  TCPIP_DHCPV6_IA_STATE_REBIND,
  TCPIP_DHCPV6_IA_STATE_CONFIRM,
  TCPIP_DHCPV6_IA_STATE_RELEASE,
  TCPIP_DHCPV6_IA_STATE_ERROR_TRANSIENT,
  TCPIP_DHCPV6_IA_STATE_ERROR_FATAL,
  TCPIP_DHCPV6_IA_STATE_NUMBER
} TCPIP_DHCPV6_IA_STATE;
```

Members

Members	Description
TCPIP_DHCPV6_IA_STATE_SOLICIT	solicitation
TCPIP_DHCPV6_IA_STATE_REQUEST	perform request
TCPIP_DHCPV6_IA_STATE_DAD	start the DAD state
TCPIP_DHCPV6_IA_STATE_DECLINE	decline the DAD addresses
TCPIP_DHCPV6_IA_STATE_BOUND	bound;
TCPIP_DHCPV6_IA_STATE_RENEW	renew address
TCPIP_DHCPV6_IA_STATE_REBIND	rebind address
TCPIP_DHCPV6_IA_STATE_CONFIRM	confirm address
TCPIP_DHCPV6_IA_STATE_RELEASE	release address
TCPIP_DHCPV6_IA_STATE_ERROR_TRANSIENT	an error occurred for which either user intervention is required
TCPIP_DHCPV6_IA_STATE_ERROR_FATAL	fatal error occurred; not properly configured options/buffers, etc;
TCPIP_DHCPV6_IA_STATE_NUMBER	number of run states

Description

IA run states

TCPIP_DHCPV6_IA_SUBSTATE Enumeration

File

dhcpv6.h

C

```
typedef enum {
  TCPIP_DHCPV6_IA_SUBSTATE_START,
  TCPIP_DHCPV6_IA_SUBSTATE_IDELAY,
  TCPIP_DHCPV6_IA_SUBSTATE_TRANSMIT,

  uint32_t solicitValidLTime;
  int nMsgBuffers;
  int msgBufferSize;
} TCPIP_DHCPV6_MODULE_CONFIG;
```

Members

Members	Description
TCPIP_DHCPV6_CONFIG_FLAGS configFlags;	DHCPv6 client configuration flags
uint16_t dhcpCliPort;	client port for DHCPv6 client transactions
uint16_t dhcpSrvPort;	remote server port for DHCPv6 server messages
uint16_t duidType;	TCPIP_DHCPV6_DUID_TYPE: type to use for the DHCPv6 clients
uint16_t nIanaDcpts;	number of IANAs per client; default should be 1
uint16_t nIataDcpts;	number of IATAs per client; default should be 0
uint16_t nFreeDcpts;	number of free IAs per client - they could be added at run time; default should be 0
uint32_t defaultIanaT1;	The default time at which the client contacts the server to extend the lifetimes of the assigned IA_NA addresses If the IANA t1 value received from the server is 0, then this value will be used to override A value of 0 means the t1 is infinite default value should be 0
uint32_t defaultIanaT2;	The default time at which the client contacts any available server to extend the lifetimes of the assigned IA_NA addresses If the IANA t2 value received from the server is 0, then this value will be used to override if !0 it should be > defaultIanaT1! Has to be > t1 A value of 0 means the t2 is infinite default value should be 0
uint32_t defaultIataT1;	The default time at which the client contacts the server to extend the lifetimes of the assigned IATA addresses If 0, the timeout will be infinite (0xffffffff)
uint32_t defaultIataT2;	The default time at which the client contacts any available server to extend the lifetimes of the assigned IA_TA addresses if !0 it should be > defaultIataT1! If 0, the timeout will be infinite (0xffffffff)
uint32_t ianaSolicitT1;	The default T1 time to solicit from the server default should be 0
uint32_t ianaSolicitT2;	The default T2 time to solicit from the server default should be 0
uint32_t solicitPrefLTime;	default addresses preferred lifetime to solicit from the server default should be 0
uint32_t solicitValidLTime;	default addresses valid lifetime to solicit from the server default should be 0
int nMsgBuffers;	number of message buffers to allocate for this client these buffers are used for the TX/RX operations Enough buffers need to be allocated for gathering server advertisements and being able to transmit messages default should be 4
int msgBufferSize;	size of the message buffers default is 512 bytes

TCPIP_DHCPV6_SERVER_STATUS_CODE Enumeration

File

dhcpv6.h

C

```
typedef enum {
  TCPIP_DHCPV6_SERVER_STAT_SUCCESS = 0,
  TCPIP_DHCPV6_SERVER_STAT_UNSPEC_FAIL = 1,
  TCPIP_DHCPV6_SERVER_STAT_NO_ADDRS_AVAIL = 2,
  TCPIP_DHCPV6_SERVER_STAT_NO_BINDING = 3,
  TCPIP_DHCPV6_SERVER_STAT_NOT_ON_LINK = 4,
  TCPIP_DHCPV6_SERVER_STAT_USE_MULTICAST = 5,
  TCPIP_DHCPV6_SERVER_STAT_MAX_CODE = 5,
  TCPIP_DHCPV6_SERVER_STAT_EXT_ERROR = -1
} TCPIP_DHCPV6_SERVER_STATUS_CODE;
```

Members

Members	Description
TCPIP_DHCPV6_SERVER_STAT_SUCCESS = 0	success
TCPIP_DHCPV6_SERVER_STAT_UNSPEC_FAIL = 1	Failure, reason unspecified; this status code is sent by either a client or a server to indicate a failure not explicitly specified in the RFC.
TCPIP_DHCPV6_SERVER_STAT_NO_ADDRS_AVAIL = 2	Server has no addresses available to assign to the IA(s).
TCPIP_DHCPV6_SERVER_STAT_NO_BINDING = 3	Client record (binding) unavailable.
TCPIP_DHCPV6_SERVER_STAT_NOT_ON_LINK = 4	The prefix for the address is not appropriate for the link to which the client is attached.

TCPIP_DHCPV6_SERVER_STAT_USE_MULTICAST = 5	Sent by a server to a client to force the client to send messages to the server using the All_DHCP_Relay_Agents_and_Servers address.
TCPIP_DHCPV6_SERVER_STAT_MAX_CODE = 5	maximum valid value
TCPIP_DHCPV6_SERVER_STAT_EXT_ERROR = -1	an error occurred, status code not found, etc.

Macros

	Name	Description
	TCPIP_DHCPV6_CLIENT_DUID_TYPE	Default DUID type to be used by the client
	TCPIP_DHCPV6_CLIENT_PORT	Clients listen for DHCP messages on UDP port:
	TCPIP_DHCPV6_DNS_SERVERS_NO	number of DNS servers to store from a DHCP server reply
	TCPIP_DHCPV6_DOMAIN_SEARCH_LIST_SIZE	space for the Domain Search List option - multiple of 16
	TCPIP_DHCPV6_FORCED_SERVER_PREFERENCE	preference value that forces the server selection 8 bit value!
	TCPIP_DHCPV6_IA_FREE_DESCRIPTORS_NO	maximum number of free IA descriptors per client
	TCPIP_DHCPV6_IA_SOLICIT_ADDRESS_PREF_LTIME	default lifetimes for the solicited addresses
	TCPIP_DHCPV6_IA_SOLICIT_ADDRESS_VALID_LTIME	This is macro TCPIP_DHCPV6_IA_SOLICIT_ADDRESS_VALID_LTIME.
	TCPIP_DHCPV6_IANA_DEFAULT_T1	default values for IANA T1, T2
	TCPIP_DHCPV6_IANA_DEFAULT_T2	This is macro TCPIP_DHCPV6_IANA_DEFAULT_T2.
	TCPIP_DHCPV6_IANA_DESCRIPTORS_NO	maximum number of IANA descriptors per client
	TCPIP_DHCPV6_IANA_SOLICIT_ADDRESSES_NO	default addresses for IANA in a solicit message
	TCPIP_DHCPV6_IANA_SOLICIT_DEFAULT_ADDRESS	default values for the IANA Solicit addresses irrelevant if TCPIP_DHCPV6_IANA_SOLICIT_ADDRESSES_NO == 0 should be a value for each TCPIP_DHCPV6_IANA_SOLICIT_ADDRESSES_NO
	TCPIP_DHCPV6_IANA_SOLICIT_T1	default values for IANA T1, T2 in a solicit message
	TCPIP_DHCPV6_IANA_SOLICIT_T2	This is macro TCPIP_DHCPV6_IANA_SOLICIT_T2.
	TCPIP_DHCPV6_IATA_DEFAULT_T1	default values for IATA T1, T2 If 0, the timeout will be infinite (0xffffffff)
	TCPIP_DHCPV6_IATA_DEFAULT_T2	This is macro TCPIP_DHCPV6_IATA_DEFAULT_T2.
	TCPIP_DHCPV6_IATA_DESCRIPTORS_NO	maximum number of IATA descriptors per client
	TCPIP_DHCPV6_IATA_SOLICIT_ADDRESSES_NO	default addresses for IATA in a solicit message
	TCPIP_DHCPV6_IATA_SOLICIT_DEFAULT_ADDRESS	default values for the IANA Solicit addresses irrelevant if TCPIP_DHCPV6_IATA_SOLICIT_ADDRESSES_NO == 0 should be a value for each TCPIP_DHCPV6_IATA_SOLICIT_ADDRESSES_NO
	TCPIP_DHCPV6_MESSAGE_BUFFER_SIZE	default value of the buffer to assemble messages, etc.
	TCPIP_DHCPV6_MESSAGE_BUFFERS	default number of buffers
	TCPIP_DHCPV6_MIN_UDP_TX_BUFFER_SIZE	minimum size of a UDP buffer
	TCPIP_DHCPV6_SERVER_PORT	Servers and relay agents listen for DHCP messages on UDP port:
	TCPIP_DHCPV6_SKIP_DAD_PROCESS	defining this symbol will skip the DAD processing for DHCPv6 generated addresses
	TCPIP_DHCPV6_STATUS_CODE_MESSAGE_LEN	number of character to reserve for a server status code associated message
	TCPIP_DHCPV6_TASK_TICK_RATE	The DHCPv6 task processing rate: number of milliseconds to generate an DHCPv6 tick. Used by the DHCPv6 state machine The default value is 100 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_DHCPV6_USER_NOTIFICATION	allow DHCPV6 client user notification if enabled, the TCPIP_DHCPV6_HandlerRegister/TCPIP_DHCPV6_HandlerDeRegister functions exist and can be used

	TCPIP_STACK_USE_DHCPV6_CLIENT	This symbol enables the DHCPv6 client as being part of the build

DNS Module

This section describes the TCP/IP Stack Library DNS module.

Introduction

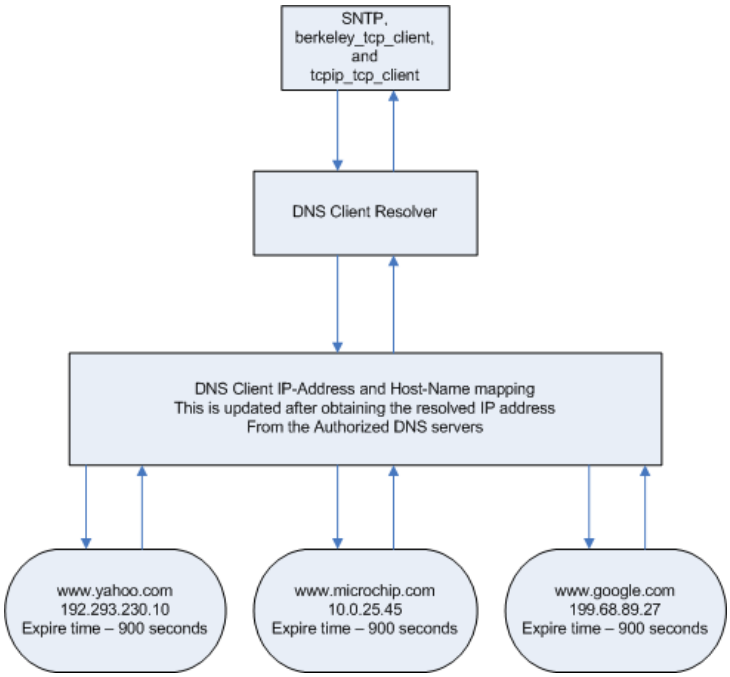
TCP/IP Stack Library Domain Name System (DNS) Module for Microchip Microcontrollers

This library provides the API of the DNS module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

The Domain Name Service associates host names (i.e., www.microchip.com) with IP addresses (i.e., 10.0.54.2). The DNS Client module provides DNS resolution capabilities to the stack. As illustrated in the figure, a typical resolution process is as follows:

- The DNS Client, also known as the DNS Resolver, will try to resolve the IP address from its local resources, which includes the Name to Address mappings in the local DNS cache. DNS clients are capable of caching the previous DNS query results and this module supports maximum cache entries as per the configuration parameter of DNS_CLIENT_CACHE_ENTRIES. Each cache entry is capable of storing the maximum number of IPv4 and IPv6 address, which is done per the configured parameters of DNS_CLIENT_CACHE_PER_IPV4_ADDRESS and DNS_CLIENT_CACHE_PER_IPV6_ADDRESS. The DNS resolver will use these available local resources and if it cannot find the IP Address as per DNS Record type, it will then query a DNS server that it knows for the IP Address.
- The DNS server will directly answer the query if it is the authoritative server for the particular domain (ex.: www.microchip.com); otherwise, it will check its local cache of the previous queries. If it cannot find the IP Address, it will then query the DNS servers on the Internet.
- Next, the DNS Server will query one of the root servers requesting a list of Authoritative servers for the .COM domain. The Root server will respond with the list of servers addresses hosting the .COM domain.
- The Authoritative DNS server will then respond with the IP Address or a list of IP Address (if more than one server hosts the website www.microchip.com) for www.microchip.com.
- The address that the DNS server returns back to the DNS client is then passed to the DNS application, which initially requested the IP Address information -- in this case, the TCP/IP client application.
- Finally, the Application then knows where to go to fetch the web site.



Using the Library

This topic describes the basic architecture of the DNS TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `dns.h`

The interface to the DNS TCP/IP Stack library is defined in the `dns.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the DNS TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

This library provides the API of the DNS TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

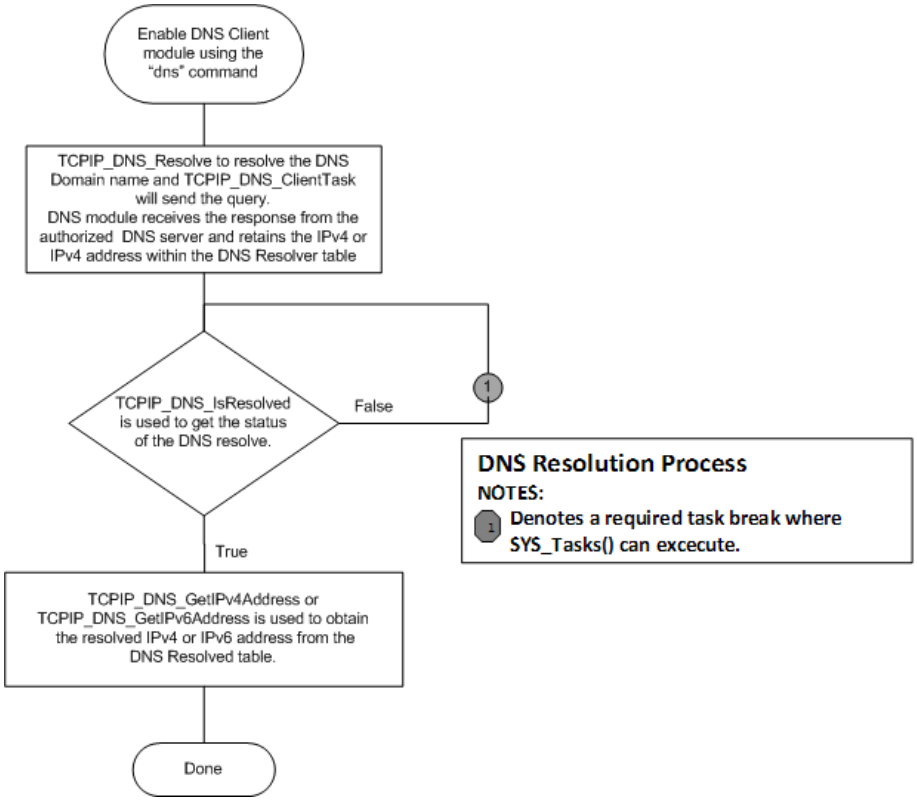
Description

DNS is part of the Application Layer. How the DNS Client works and how it is used is described in the following algorithm and figure.

1. By default, the DNS client is enabled and the DNS module can be enabled from the command prompt using the command "dns PIC32INT on". If the DNS Client module is enabled, a UDP socket will opened for port number 53 for the DNS client applications. The DNS client module can be disabled from the command prompt using "dns PIC32INT off".

   Note: For the Wi-Fi module, the interface name "PIC32INT" will be changed to "MRF24W".

2. Applications or demonstrations such as berkeley_tcp_client, berkeley_udp_client, tcpip_tcp_client, and tcpip_udp_client, use the TCPIP_DNS_Resolve function with Host name and Record type as arguments to resolve the domain host name. The DNS module supports the Record type of "A" and "AAAA". Record Type "A" is used for IPv4 and "AAAA" is used for an IPv6 address.
3. The resolved domain name and the mapped IPv4 or IPv6 address will be stored in a table with the expire time, which is calculated from the query response.
4. The number of the IPv4 and IPv6 address will be cached as per the DNS_CLIENT_CACHE_PER_IPV4_ADDRESS function and per the DNS_CLIENT_CACHE_PER_IPV6_ADDRESS function from the query response.
5. The TCPIP_DNS_IsResolved function will return DNS_RES_OK if the domain name resolve is successful.
6. The TCPIP_DNS_GetNumberOfIPAddresses function is used to obtain the number of the IPv4 or IPv6 address, which is present in the DNS Resolver table. The DNS Resolver table is a mapping table of the IP address, domain name, and the expire time.
7. The functions, TCPIP_DNS_GetIPv4Address and TCPIP_DNS_GetIPv6Address, are used to obtain the IPv4 or Ipv6 address from the resolved table as per the domain host name and index number. The index number should be less than DNS_CLIENT_CACHE_PER_IPV4_ADDRESS or DNS_CLIENT_CACHE_PER_IPV6_ADDRESS. The index number is the location of the resolved table, which will help to fetch the IPv4 or IPv6 address from the exact location. For example, if index == 0, TCPIP_DNS_GetIPv4Address or TCPIP_DNS_GetIPv6Address will return 0th location IPv4 or Ipv6 address if there is more than one IPv4 or IPv6 address.



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the DNS module.

Library Interface Section	Description
General Functions	This section provides general interface routines to DNS
Data Types and Constants	This section provides various definitions describing this API

Configuring the Library

Macros

	Name	Description
	TCPIP_DNS_CLIENT_CACHE_ENTRIES	Number of DNS resolver entries
	TCPIP_DNS_CLIENT_CACHE_ENTRY_TMO	DNS client cache entry time-out. If this symbol is zero then the entry time-out will be the one specified by the DNS server when the name was solved. Otherwise this value will be used as the cache entry time-out. Default should be 0.
	TCPIP_DNS_CLIENT_CACHE_PER_IPV4_ADDRESS	Maximum and default number of IPv4 answers to be considered while processing DNS response from server for a query.
	TCPIP_DNS_CLIENT_CACHE_PER_IPV6_ADDRESS	Maximum and default number of IPv6 answers to be considered while processing DNS response from server for a query.
	TCPIP_DNS_CLIENT_SERVER_TMO	When the DNS Client connected to the DNS Server this is the elapsed time after which an the communication is considered to have timed failed if there was no reply from the server In seconds
	TCPIP_DNS_CLIENT_TASK_PROCESS_RATE	DNS Client task processing rate, in milliseconds. The DNS Client module will process a timer event with this rate for processing its own state machine, etc. The default value is 200 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_DNS_CLIENT_CACHE_DEFAULT_TTL_VAL	Default TTL time for a solved entry in the cache This value will be used when the DNS server TTL value for an entry is 0

	TCPIP_DNS_CLIENT_CACHE_UNSOLVED_ENTRY_TMO	Time-out for the a unsolved name, in seconds. The name resolution will be aborted if the TMO elapsed and the name could not be solved Should be greater than TCPIP_DNS_CLIENT_LOOKUP_RETRY_TMO
	TCPIP_DNS_CLIENT_USER_NOTIFICATION	allow DNS client user notification if enabled, the TCPIP_DNS_HandlerRegister/TCPIP_DNS_HandlerDeRegister functions exist and can be used
	TCPIP_DNS_CLIENT_ADDRESS_TYPE	This parameter can be used to choose ithe type of IP connection for the DNS client: IPv4 or IPv6. Currently only IPv4 is supported and this parameter is not used. Reserved for future development
	TCPIP_DNS_CLIENT_LOOKUP_RETRY_TMO	Retry lookup for a unsolved entry in the cache, in seconds. If the TCPIP_DNS_CLIENT_LOOKUP_RETRY_TMO seconds elapsed and the name has not been solved then the name entry will be marked with server timeout and the resolution will be retried. Should be less than TCPIP_DNS_CLIENT_CACHE_UNSOLVED_ENTRY_TMO
	TCPIP_DNS_CLIENT_MAX_HOSTNAME_LEN	Max DNS host name size
	TCPIP_DNS_CLIENT_MAX_SELECT_INTERFACES	Max number of interfaces to take part in the DNS selection algorithm Should be always greater than 1: • the default interface should always be considered for DNS resolution Depending on how many active interfaces select those to be considered for DNS resolution

Description

The configuration of the DNS TCP/IP Stack is based on the file `tcpip_config.h`.

This header file contains the configuration selection for the DNS TCP/IP Stack. Based on the selections made, the DNS TCP/IP Stack may support the selected features. These configuration settings will apply to all instances of the DNS TCP/IP Stack.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_DNS_CLIENT_CACHE_ENTRIES Macro

File

dns_config.h

C

```
#define TCPIP_DNS_CLIENT_CACHE_ENTRIES 5
```

Description

Number of DNS resolver entries

TCPIP_DNS_CLIENT_CACHE_ENTRY_TMO Macro

File

dns_config.h

C

```
#define TCPIP_DNS_CLIENT_CACHE_ENTRY_TMO 0
```

Description

DNS client cache entry time-out. If this symbol is zero then the entry time-out will be the one specified by the DNS server when the name was solved. Otherwise this value will be used as the cache entry time-out. Default should be 0.

TCPIP_DNS_CLIENT_CACHE_PER_IPV4_ADDRESS Macro

File

dns_config.h

C

```
#define TCPIP_DNS_CLIENT_CACHE_PER_IPV4_ADDRESS 5
```

Description

Maximum and default number of IPv4 answers to be considered while processing DNS response from server for a query.

TCPIP_DNS_CLIENT_CACHE_PER_IPV6_ADDRESS Macro

File

dns_config.h

C

```
#define TCPIP_DNS_CLIENT_CACHE_PER_IPV6_ADDRESS 1
```

Description

Maximum and default number of IPv6 answers to be considered while processing DNS response from server for a query.

TCPIP_DNS_CLIENT_SERVER_TMO Macro

File

dns_config.h

C

```
#define TCPIP_DNS_CLIENT_SERVER_TMO (1*60)
```

Description

When the DNS Client connected to the DNS Server this is the elapsed time after which an the communication is considered to have timed failed if there was no reply from the server In seconds

TCPIP_DNS_CLIENT_TASK_PROCESS_RATE Macro

File

dns_config.h

C

```
#define TCPIP_DNS_CLIENT_TASK_PROCESS_RATE (200)
```

Description

DNS Client task processing rate, in milliseconds. The DNS Client module will process a timer event with this rate for processing its own state machine, etc. The default value is 200 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

TCPIP_DNS_CLIENT_CACHE_DEFAULT_TTL_VAL Macro

File

dns_config.h

C

```
#define TCPIP_DNS_CLIENT_CACHE_DEFAULT_TTL_VAL (20 * 60)
```

Description

Default TTL time for a solved entry in the cache This value will be used when the DNS server TTL value for an entry is 0

TCPIP_DNS_CLIENT_CACHE_UNSOLVED_ENTRY_TMO Macro

File

dns_config.h

C

```
#define TCPIP_DNS_CLIENT_CACHE_UNSOLVED_ENTRY_TMO (10)
```

Description

Time-out for the a unsolved name, in seconds. The name resolution will be aborted if the TMO elapsed and the name could not be solved Should be greater than TCPIP_DNS_CLIENT_LOOKUP_RETRY_TMO

TCPIP_DNS_CLIENT_USER_NOTIFICATION Macro

File

dns_config.h

C

```
#define TCPIP_DNS_CLIENT_USER_NOTIFICATION false
```

Description

allow DNS client user notification if enabled, the TCPIP_DNS_HandlerRegister/TCPIP_DNS_HandlerDeRegister functions exist and can be used

TCPIP_DNS_CLIENT_ADDRESS_TYPE Macro

File

dns_config.h

C

```
#define TCPIP_DNS_CLIENT_ADDRESS_TYPE IP_ADDRESS_TYPE_IPV4
```

Description

This parameter can be used to choose ithe type of IP connection for the DNS client: IPv4 or IPv6. Currently only IPv4 is supported and this parameter is not used. Reserved for future development

TCPIP_DNS_CLIENT_LOOKUP_RETRY_TMO Macro

File

dns_config.h

C

```
#define TCPIP_DNS_CLIENT_LOOKUP_RETRY_TMO (3)
```

Description

Retry lookup for a unsolved entry in the cache, in seconds. If the TCPIP_DNS_CLIENT_LOOKUP_RETRY_TMO seconds elapsed and the name has not been solved then the name entry will be marked with server timeout and the resolution will be retried. Should be less than TCPIP_DNS_CLIENT_CACHE_UNSOLVED_ENTRY_TMO

TCPIP_DNS_CLIENT_MAX_HOSTNAME_LEN Macro

File

dns_config.h

C

```
#define TCPIP_DNS_CLIENT_MAX_HOSTNAME_LEN 32
```

Description

Max DNS host name size

TCPIP_DNS_CLIENT_MAX_SELECT_INTERFACES Macro

File

dns_config.h

C

```
#define TCPIP_DNS_CLIENT_MAX_SELECT_INTERFACES 4
```

Description

Max number of interfaces to take part in the DNS selection algorithm Should be always greater than 1:

- the default interface should always be considered for DNS resolution

Depending on how many active interfaces select those to be considered for DNS resolution

Building the Library

This section lists the files that are available in the DNS module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/dns.c`	DNS implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The DNS module depends on the following modules:

- TCP/IP Stack Library
- UDP Module

Library Interface

a) General Functions

	Name	Description
	TCPIP_DNS_Enable	Enables the DNS Client for the specified interface.
	TCPIP_DNS_Disable	Disables the DNS Client for the specified interface.
	TCPIP_DNS_HandlerDeRegister	Deregisters a previously registered DNS client handler.
	TCPIP_DNS_HandlerRegister	Registers a DNS client Handler.
	TCPIP_DNS_IsEnabled	Determines if the DNS client is enabled on that specified interface.
	TCPIP_DNS_IsNameResolved	Determines if the DNS resolution is complete and provides the host IP address.
	TCPIP_DNS_RemoveAll	Removes all the cached entries from DNS resolver.
	TCPIP_DNS_RemoveEntry	Remove a hostname from the DNS Hash entry.
	TCPIP_DNS_ClientTask	Standard TCP/IP stack module task function.
	TCPIP_DNS_ClientInfoGet	Get the current DNS client parameters.
	TCPIP_DNS_EntryQuery	Queries a DNS Resolver specific entry.
	TCPIP_DNS_GetIPAddressesNumber	Get the count of resolved IPv4 and/or IPv6 address for a host name.

	TCPIP_DNS_GetIPv4Addresses	Get IPV4 addresses for a DNS resolved name.
	TCPIP_DNS_GetIPv6Addresses	Get IPV6 addresses for a DNS resolved name.
	TCPIP_DNS_Resolve	Begins resolution of an address.
	TCPIP_DNS_Send_Query	Forces resolution of an address.
	TCPIP_DNS_IsResolved	Determines if the DNS resolution is complete and provides the host IP address.

b) Data Types and Constants

	Name	Description
	TCPIP_DNS_EVENT_HANDLER	Notification handler that can be called when a specific entry is resolved and entry is timed out.
	TCPIP_DNS_EVENT_TYPE	This enumeration is used to notify DNS client applications.
	TCPIP_DNS_HANDLE	DNS client handle.
	TCPIP_DNS_RESULT	DNS client result codes.
	TCPIP_DNS_CLIENT_MODULE_CONFIG	Provides a place holder for DNS client configuration.
	TCPIP_DNS_CLIENT_INFO	General DNS client info.
	TCPIP_DNS_ENTRY_QUERY	DNS module query data for both IPv4 and IPv6 .
	TCPIP_DNS_ENABLE_FLAGS	Flags for enabling the DNS service on an interface.
	TCPIP_DNS_RESOLVE_TYPE	DNS query record type.

Description

This section describes the Application Programming Interface (API) functions of the DNS module.

Refer to each section for a detailed description.

a) General Functions

TCPIP_DNS_Enable Function

Enables the DNS Client for the specified interface.

File

dns.h

C

```
bool TCPIP_DNS_Enable(TCPIP_NET_HANDLE hNet, TCPIP_DNS_ENABLE_FLAGS flags);
```

Returns

- true - if successful
- false - if unsuccessful: the requested interface could not be selected for DNS name resolving.

Description

This function enables the DNS Client name resolution for the specified interface. The additional flags give better control on how the name resolution is performed.

Remarks

The interface selection for the name resolution tries to find a valid interface, i.e. an interface that is up and has a valid DNS server. The selection is done following these rules:

- if a strict interface is set, only that interface is used for name resolution
- else if there is a preferred interface, that one will be tried first
- else the default interface is used
- else any available interface will be used

Additionally, if a retry is attempted using the same selected interface, an alternate DNS server from that interface will be selected, if available.

Only one strict interface can exist at any time. Selecting a new strict interface will replace the old one.

Only one preferred interface can exist at any time. Selecting a new preferred interface will replace the old one.

The selected interface has to be up and running for the call to succeed

Preconditions

The DNS module must be initialized.

Parameters

Parameters	Description
hNet	Interface to enable the DNS Client on
flags	specify further attributes for this interface: act as a strict, preferred or default interface

Function

bool TCPIP_DNS_Enable(TCPIP_NET_HANDLE hNet, TCPIP_DNS_ENABLE_FLAGS flags)

TCPIP_DNS_Disable Function

Disables the DNS Client for the specified interface.

File

dns.h

C

```
bool TCPIP_DNS_Disable(TCPIP_NET_HANDLE hNet, bool clearCache);
```

Returns

- true - if successful
- false - if unsuccessful

Description

This function disables the DNS Client for the specified interface.

Remarks

When the DNS client is disabled on a requested interface the previously solved names will still be part of the cache and will expire when their timeout occurs. If the TTL for a name sent by the DNS server was ignored and another default/arbitrary value was used, then the entry will stay cached until that timeout occurs (i.e. timeout not specified by the DNS server). To avoid this, you can clear the cache by setting the clearCache parameter to true.

If the disabled interface matches the strict interface set by TCPIP_DNS_Enable this function will set the strict interface to 0.

If the disabled interface matches the preferred interface set by TCPIP_DNS_Enable this function will set the preferred interface to 0.

Preconditions

The DNS module must be initialized.

Parameters

Parameters	Description
hNet	Interface for which to disable the DNS Client.
clearCache	If true, all the existent name entries will be cleared from the cache

Function

bool TCPIP_DNS_Disable(TCPIP_NET_HANDLE hNet, bool clearCache)

TCPIP_DNS_HandlerDeRegister Function

Deregisters a previously registered DNS client handler.

File

dns.h

C

```
bool TCPIP_DNS_HandlerDeRegister(TCPIP_DNS_HANDLE hDns);
```

Returns

- true - if the call succeeds
- false - if no such handler is registered

Description

This function deregisters the DNS client event handler.

Preconditions

The DNS module must be initialized.

Parameters

Parameters	Description
hDns	A handle returned by a previous call to TCPIP_DNS_HandlerRegister.

Function

bool TCPIP_DNS_HandlerDeRegister(TCPIP_DNS_HANDLE hDns);

TCPIP_DNS_HandlerRegister Function

Registers a DNS client Handler.

File

dns.h

C

```
TCPIP_DNS_HANDLE TCPIP_DNS_HandlerRegister(TCPIP_NET_HANDLE hNet, TCPIP_DNS_EVENT_HANDLER handler, const void* hParam);
```

Returns

- Returns a valid handle if the call succeeds
- Returns null handle if the call failed (out of memory, for example)

Description

This function registers a DNS client event handler. The DNS client module will call the registered handler when a DNS client event (TCPIP_DNS_EVENT_TYPE) occurs.

Remarks

The handler has to be short and fast. It is meant for setting an event flag, *not* for lengthy processing!

Preconditions

The DNS module must be initialized.

Parameters

Parameters	Description
hNet	Interface handle. Use hNet == 0 to register on all interfaces available.
handler	Handler to be called when a DNS client event occurs.
hParam	Pointer to non-volatile ASCIIZ string to be used in the handler call. It is used as a domain/host name. If not NULL, a DNS notification will be delivered only for a name resolution that matches the hParam. If the hParam == 0, then the notification is triggered for any host name resolution.

Function

TCPIP_DNS_HANDLE

TCPIP_DNS_HandlerRegister(TCPIP_NET_HANDLE hNet, TCPIP_DNS_EVENT_HANDLER handler, const void* hParam);

TCPIP_DNS_IsEnabled Function

Determines if the DNS client is enabled on that specified interface.

File

dns.h

C

```
bool TCPIP_DNS_IsEnabled(TCPIP_NET_HANDLE hNet);
```

Returns

- true - if the DNS client service is enabled on the specified interface
- false - if the DNS client service is not enabled on the specified interface

Description

This function returns the current state of DNS Client on the specified interface.

Preconditions

The DNS module must be initialized.

Parameters

Parameters	Description
hNet	Interface to query.

Function

bool TCPIP_DNS_IsEnabled(CPIP_NET_HANDLE hNet)

TCPIP_DNS_IsNameResolved Function

Determines if the DNS resolution is complete and provides the host IP address.

File

dns.h

C

```
TCPIP_DNS_RESULT TCPIP_DNS_IsNameResolved(const char* hostName, IPV4_ADDR* hostIPv4, IPV6_ADDR* hostIPv6);
```

Description

Call this function to determine if the DNS name resolution has been completed. This function allows for retrieval of separate IPv4 and IPv6 addresses for a name.

Remarks

The function will set either an IPv6 or an IPv4 address to the hostIP address, depending on what's available.

Preconditions

TCPIP_DNS_Resolve has been called.

Parameters

Parameters	Description
hostName	A pointer to the null terminated string specifying the host for which to resolve an IP.
hostIPv4	A pointer to an IPV4_ADDR structure in which to store the resolved IPv4 address if resolution is complete. Could be NULL if not needed.
hostIPv6	A pointer to an IPV6_ADDR structure in which to store the resolved IPv6 address if resolution is complete. Could be NULL if not needed.

Function

TCPIP_DNS_RESULT TCPIP_DNS_IsNameResolved(const char* hostName, IPV4_ADDR* hostIPv4, IPV6_ADDR* hostIPv6);

TCPIP_DNS_RemoveAll Function

Removes all the cached entries from DNS resolver.

File

dns.h

C

```
TCPIP_DNS_RESULT TCPIP_DNS_RemoveAll();
```

Returns

- TCPIP_DNS_RES_OK - If successful
- TCPIP_DNS_RES_NO_SERVICE - DNS resolver non existent/uninitialized.

Description

This function is used to remove all the entries from the DNS cache. It removes both the solved and unresolved entries.

Remarks

None.

Preconditions

The DNS module must be initialized.

Function

TCPIP_DNS_RESULT TCPIP_DNS_RemoveAll(void)

TCPIP_DNS_RemoveEntry Function

Remove a hostname from the DNS Hash entry.

File

dns.h

C

```
TCPIP_DNS_RESULT TCPIP_DNS_RemoveEntry(const char * hostName);
```

Returns

- TCPIP_DNS_RES_OK - If name was successfully removed
- TCPIP_DNS_RES_INVALID_HOSTNAME - invalid name supplied
- TCPIP_DNS_RES_NO_SERVICE - DNS resolver non existent/uninitialized.
- TCPIP_DNS_RES_NO_NAME_ENTRY - no such name exists

Description

This function is used to remove an entry (host name) from the DNS cache.

Remarks

None.

Preconditions

The DNS module must be initialized.

Parameters

Parameters	Description
hostName	Domain name to be inserted.

Function

TCPIP_DNS_RESULT TCPIP_DNS_RemoveEntry(const char *hostName)

TCPIP_DNS_ClientTask Function

Standard TCP/IP stack module task function.

File

dns.h

C

```
void TCPIP_DNS_ClientTask();
```

Returns

None.

Description

This function performs DNS module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The DNS module should have been initialized.

Function

void TCPIP_DNS_ClientTask(void)

TCPIP_DNS_ClientInfoGet Function

Get the current DNS client parameters.

File

dns.h

C

```
TCPIP_DNS_RESULT TCPIP_DNS_ClientInfoGet(TCPIP_DNS_CLIENT_INFO* pClientInfo);
```

Returns

- TCPIP_DNS_RES_OK on success
- TCPIP_DNS_RES_NO_SERVICE - DNS resolver non existent/uninitialized.

Description

This function is used to get the current settings of the DNS client.

Remarks

None

Preconditions

The DNS client module must be initialized.

Parameters

Parameters	Description
pClientInfo	pointer to a TCPIP_DNS_CLIENT_INFO data structure to receive the DNS client information.

Function

TCPIP_DNS_RESULT TCPIP_DNS_ClientInfoGet(TCPIP_DNS_CLIENT_INFO* pClientInfo)

TCPIP_DNS_EntryQuery Function

Queries a DNS Resolver specific entry.

File

dns.h

C

```
TCPIP_DNS_RESULT TCPIP_DNS_EntryQuery(TCPIP_DNS_ENTRY_QUERY * pDnsQuery, int queryIndex);
```

Returns

- TCPIP_DNS_RES_OK - valid address for this index, successful

Errors:

- TCPIP_DNS_RES_NO_SERVICE - DNS resolver non existent/uninitialized.
- TCPIP_DNS_RES_INVALID_HOSTNAME - invalid string, len, pDnsQuery provided
- TCPIP_DNS_RES_EMPTY_IX_ENTRY - no name associated with this entry
- TCPIP_DNS_RES_NO_IX_ENTRY - invalid query index

Description

This function is used to query the DNS client for a specified entry. The entry to be queried is selected by its index.

Remarks

None

Preconditions

The DNS client module must be initialized.

Parameters

Parameters	Description
pDnsQuery	address to store the the query result
queryIndex	entry index to be selected; should start with 0

Function

TCPIP_DNS_RESULT TCPIP_DNS_EntryQuery(TCPIP_DNS_ENTRY_QUERY *pDnsQuery, int queryIndex);

TCPIP_DNS_GetIPAddressesNumber Function

Get the count of resolved IPv4 and/or IPv6 address for a host name.

File

dns.h

C

```
int TCPIP_DNS_GetIPAddressesNumber(const char* hostName, IP_ADDRESS_TYPE type);
```

Description

This function returns the total count of IPv4 and/or IPv6 addresses that exist for a resolved host name.

Remarks

None.

Preconditions

TCPIP_DNS_Resolve has been called.

Parameters

Parameters	Description
hostName	A pointer to the null terminated string specifying the host name
type	IP_ADDRESS_TYPE_IPV4/IP_ADDRESS_TYPE_IPV6/IP_ADDRESS_TYPE_ANY

Function

int TCPIP_DNS_GetIPAddressesNumber(const char* hostName, IP_ADDRESS_TYPE type)

TCPIP_DNS_GetIPv4Addresses Function

Get IPV4 addresses for a DNS resolved name.

File

dns.h

C

```
int TCPIP_DNS_GetIPv4Addresses(const char* hostName, int startIndex, IPV4_ADDR* pIPv4Addr, int
nIPv4Addresses);
```

Returns

> 0 - the number of addresses copied to the pIPv4Addr array 0 - if the host name was not found, invalid index, bad parameter, etc.

Description

This function will return IPv4 addresses for a host name if the DNS resolution has been completed.

Remarks

None.

Preconditions

TCPIP_DNS_Resolve has been called.

Parameters

Parameters	Description
hostName	A pointer to the null terminated string specifying the host name.
startIndex	starting index of the IP address to be returned when multiple addresses are available
The max number of addresses that can be stored for a host name is given by	TCPIP_DNS_CLIENT_MODULE_CONFIG::nIPv4Entries. The current number of valid entries for an address is given by TCPIP_DNS_GetIPAddressesNumber(). A valid index is [0, TCPIP_DNS_GetIPAddressesNumber(IP_ADDRESS_TYPE_IPV4));
pIPv4Addr	pointer to array of IPv4 addresses to store the host IPv4 addresses
nIPv4Addresses	number of IPv4 addresses in the pIPv4Addr array.

Function

int TCPIP_DNS_GetIPv4Addresses(const char* hostName, int startIndex, IPV4_ADDR* pIPv4Addr, int nIPv4Addresses);

TCPIP_DNS_GetIPv6Addresses Function

Get IPV6 addresses for a DNS resolved name.

File

dns.h

C

```
int TCPIP_DNS_GetIPv6Addresses(const char* hostName, int startIndex, IPV6_ADDR* pIPv6Addr, int
nIPv6Addresses);
```

Returns

> 0 - the number of addresses copied to the pIPv6Addr array 0 - if the host name was not found, invalid index, bad parameter, etc.

Description

This function will return IPv6 addresses for a host name if the DNS resolution has been completed.

Remarks

None.

Preconditions

TCPIP_DNS_Resolve has been called.

Parameters

Parameters	Description
hostName	A pointer to the null terminated string specifying the host name.
startIndex	starting index of the IP address to be returned when multiple addresses are available
The max number of addresses that can be stored for a host name is given by	TCPIP_DNS_CLIENT_MODULE_CONFIG::nIPv6Entries. The current number of valid entries for an address is given by TCPIP_DNS_GetIPAddressesNumber(). A valid index is [0, TCPIP_DNS_GetIPAddressesNumber(IP_ADDRESS_TYPE_IPV6));
pIPv6Addr	pointer to array of IPv6 addresses to store the host IPv6 addresses
nIPv6Addresses	number of IPv6 addresses in the pIPv6Addr array.

Function

int TCPIP_DNS_GetIPv6Addresses(const char* hostName, int startIndex, IPV6_ADDR* pIPv6Addr, int nIPv6Addresses);

TCPIP_DNS_Resolve Function

Begins resolution of an address.

File

dns.h

C

```
TCPIP_DNS_RESULT TCPIP_DNS_Resolve(const char* hostName, TCPIP_DNS_RESOLVE_TYPE type);
```

Returns

TCPIP_DNS_RES_OK - success, name is solved. TCPIP_DNS_RES_PENDING - operation is ongoing
TCPIP_DNS_RES_NAME_IS_IPADDRESS - name request is a IPv4 or IPv6 address

or an error code if an error occurred

Description

This function attempts to resolve a host name to an IP address. When called, it will attempt to send a DNS query to a DNS server for resolving the name. Call TCPIP_DNS_IsResolved to determine if name resolution is complete.

Remarks

To clear the cache use TCPIP_DNS_Disable(hNet, true);

Preconditions

DNS client module initialized.

Parameters

Parameters	Description
hostName	A pointer to the null terminated string specifying the host for which to resolve an IP.
type	a TCPIP_DNS_RESOLVE_TYPE value specifying the desired resolution

Function

TCPIP_DNS_RESULT TCPIP_DNS_Resolve(const char* hostName, TCPIP_DNS_RESOLVE_TYPE type)

TCPIP_DNS_Send_Query Function

Forces resolution of an address.

File

dns.h

C

```
TCPIP_DNS_RESULT TCPIP_DNS_Send_Query(const char* hostName, TCPIP_DNS_RESOLVE_TYPE type);
```

Returns

TCPIP_DNS_RES_OK - success, name is solved. TCPIP_DNS_RES_PENDING - operation is ongoing
TCPIP_DNS_RES_NAME_IS_IPADDRESS - name request is a IPv4 or IPv6 address

or an error code if an error occurred

Description

This function attempts to send a query packet for the supplied host name and DNS type.

Remarks

If the name is already part of the DNS resolution process (has been previously requested with TCPIP_DNS_Resolve or TCPIP_DNS_Send_Query) the function will force a new DNS query . If the name resolution is already solved and completed, this function will mark it as incomplete and a new response from the server will be requested.

If the name was not part of the DNS client resolution, then this function is equivalent to TCPIP_DNS_Resolve().

Preconditions

The DNS client module must be initialized.

Parameters

Parameters	Description
hostName	A pointer to the null terminated string specifying the host for which to resolve an IP.
type	a TCPIP_DNS_RESOLVE_TYPE value specifying the desired resolution

Function

TCPIP_DNS_RESULT TCPIP_DNS_Send_Query(const char* hostName, TCPIP_DNS_RESOLVE_TYPE type)

TCPIP_DNS_IsResolved Function

Determines if the DNS resolution is complete and provides the host IP address.

File

dns.h

C

```
TCPIP_DNS_RESULT TCPIP_DNS_IsResolved(const char* hostName, IP_MULTI_ADDRESS* hostIP, IP_ADDRESS_TYPE type);
```

Description

Call this function to determine if the DNS resolution of an address has been completed. If so, the resolved address will be provided in hostIP.

Remarks

The function will set either an IPv6 or an IPv4 address to the hostIP address, depending on what's available.

If type IP_ADDRESS_TYPE_ANY is specified the hostIP will be updated with the first available solved address: either IPv6 or IPv4!

Preconditions

TCPIP_DNS_Resolve has been called.

Parameters

Parameters	Description
hostName	A pointer to the null terminated string specifying the host for which to resolve an IP.
hostIP	A pointer to an IP_MULTI_ADDRESS structure in which to store the resolved IPv4/IPv6 address if resolution is complete. Could be NULL if not needed.
type	type of address needed: IP_ADDRESS_TYPE_IPV4/IP_ADDRESS_TYPE_IPV6/IP_ADDRESS_TYPE_ANY

Function

TCPIP_DNS_RESULT TCPIP_DNS_IsResolved(const char* hostName, IP_MULTI_ADDRESS* hostIP, IP_ADDRESS_TYPE type)

b) Data Types and Constants

TCPIP_DNS_EVENT_HANDLER Type

Notification handler that can be called when a specific entry is resolved and entry is timed out.

File

dns.h

C

```
typedef void (* TCPIP_DNS_EVENT_HANDLER)(TCPIP_NET_HANDLE hNet, TCPIP_DNS_EVENT_TYPE evType, const char*
name, const void* param);
```

Description

Type: TCPIP_DNS_EVENT_HANDLER

The format of a notification handler registered with the DNS module. Once an DNS event occurs the DNS service will be called for the registered handler.

Remarks

If pNetIf == 0, the notification is called for events on any interface.

Parameters

Parameters	Description
hNet	the interface on which the DNS event occurred
evType	the DNS reported event
name	the host name associated with the event
param	additional user parameter - see TCPIP_DNS_HandlerRegister

TCPIP_DNS_EVENT_TYPE Enumeration

This enumeration is used to notify DNS client applications.

File

dns.h

C

```
typedef enum {
  TCPIP_DNS_EVENT_NONE,
  TCPIP_DNS_EVENT_NAME_QUERY,
  TCPIP_DNS_EVENT_NAME_RESOLVED,
  TCPIP_DNS_EVENT_NAME_EXPIRED,
  TCPIP_DNS_EVENT_NAME_REMOVED,
  TCPIP_DNS_EVENT_NAME_ERROR,
  TCPIP_DNS_EVENT_SOCKET_ERROR,
  TCPIP_DNS_EVENT_NO_INTERFACE
} TCPIP_DNS_EVENT_TYPE;
```

Members

Members	Description
TCPIP_DNS_EVENT_NONE	DNS no event
TCPIP_DNS_EVENT_NAME_QUERY	DNS Query sent
TCPIP_DNS_EVENT_NAME_RESOLVED	DNS Name resolved
TCPIP_DNS_EVENT_NAME_EXPIRED	name entry expired
TCPIP_DNS_EVENT_NAME_REMOVED	name removed to make room for another entry
TCPIP_DNS_EVENT_NAME_ERROR	no such name reported by the DNS server
TCPIP_DNS_EVENT_SOCKET_ERROR	a DNS probe could not be sent, socket was busy, TX failed, etc.
TCPIP_DNS_EVENT_NO_INTERFACE	a DNS probe could not be sent, no DNS interface could be selected

Description

Enumeration: TCPIP_DNS_EVENT_TYPE

These events are used while notifying to the registered applications.

Remarks

None.

TCPIP_DNS_HANDLE Type

DNS client handle.

File

dns.h

C

```
typedef const void* TCPIP_DNS_HANDLE;
```

Description

Type: TCPIP_DNS_HANDLE

A handle that a application needs to use when deregistering a notification handler.

Remarks

This handle can be used by the application after the event handler has been registered.

TCPIP_DNS_RESULT Enumeration

DNS client result codes.

File

dns.h

C

```
typedef enum {
  TCPIP_DNS_RES_OK = 0,
  TCPIP_DNS_RES_PENDING,
  TCPIP_DNS_RES_NAME_IS_IPADDRESS,
  TCPIP_DNS_RES_NO_NAME_ENTRY = -1,
  TCPIP_DNS_RES_NO_IP_ENTRY = -2,
  TCPIP_DNS_RES_NO_IX_ENTRY = -3,
  TCPIP_DNS_RES_EMPTY_IX_ENTRY = -4,
  TCPIP_DNS_RES_SERVER_TMO = -5,
  TCPIP_DNS_RES_NO_SERVICE = -6,
  TCPIP_DNS_RES_NO_INTERFACE = -7,
  TCPIP_DNS_RES_CACHE_FULL = -8,
  TCPIP_DNS_RES_INVALID_HOSTNAME = -9,
  TCPIP_DNS_RES_SOCKET_ERROR = -10
} TCPIP_DNS_RESULT;
```

Members

Members	Description
TCPIP_DNS_RES_OK = 0	operation succeeded
TCPIP_DNS_RES_PENDING	operation is ongoing
TCPIP_DNS_RES_NAME_IS_IPADDRESS	DNS request is a IPv4 or IPv6 address
TCPIP_DNS_RES_NO_NAME_ENTRY = -1	no such name exists
TCPIP_DNS_RES_NO_IP_ENTRY = -2	no such IP type exists
TCPIP_DNS_RES_NO_IX_ENTRY = -3	no such index exists
TCPIP_DNS_RES_EMPTY_IX_ENTRY = -4	no entry associated to this index exists
TCPIP_DNS_RES_SERVER_TMO = -5	DNS server response tmo
TCPIP_DNS_RES_NO_SERVICE = -6	DNS service not implemented or uninitialized
TCPIP_DNS_RES_NO_INTERFACE = -7	no interface for DNS traffic available
TCPIP_DNS_RES_CACHE_FULL = -8	the cache is full and no entry could be added
TCPIP_DNS_RES_INVALID_HOSTNAME = -9	Invalid hostname
TCPIP_DNS_RES_SOCKET_ERROR = -10	DNS UDP socket error: not ready, TX error, etc.

Description

Enumeration: TCPIP_DNS_RESULT

DNS Client operations results.

Remarks

None.

TCPIP_DNS_CLIENT_MODULE_CONFIG Structure

Provides a place holder for DNS client configuration.

File

dns.h

C

```
typedef struct {
  bool deleteOldLease;
  int cacheEntries;
  uint32_t entrySolvedTmo;
  int nIPv4Entries;
  IP_ADDRESS_TYPE ipAddressType;
  int nIPv6Entries;
} TCPIP_DNS_CLIENT_MODULE_CONFIG;
```

Members

Members	Description
bool deleteOldLease;	Delete old cache if still in place, specific DNS parameters
int cacheEntries;	Max number of cache entries
uint32_t entrySolvedTmo;	Solved entry removed after this tmo if not referenced - seconds

int nIPv4Entries;	Number of IPv4 entries per DNS name and Default value is 1.
IP_ADDRESS_TYPE ipAddressType;	IP protocol type to use for connecting to the DNS server: IPv4 or IPv6 Currently only IPv4 is supported and this parameter is not used Reserved for future improvements
int nIPv6Entries;	Number of IPv6 address per DNS Name Default value is 1 and is used only when IPv6 is enabled

Description

Structure: TCPIP_DNS_CLIENT_MODULE_CONFIG

DNS module runtime configuration and initialization parameters.

Remarks

None.

TCPIP_DNS_CLIENT_INFO Structure

General DNS client info.

File

dns.h

C

```
typedef struct {
  TCPIP_NET_HANDLE strictNet;
  TCPIP_NET_HANDLE prefNet;
  uint32_t dnsTime;
  uint16_t pendingEntries;
  uint16_t currentEntries;
  uint16_t totalEntries;
} TCPIP_DNS_CLIENT_INFO;
```

Members

Members	Description
TCPIP_NET_HANDLE strictNet;	current strict DNS interface
TCPIP_NET_HANDLE prefNet;	current preferred DNS interface
uint32_t dnsTime;	current DNS time, seconds
uint16_t pendingEntries;	number of entries that need to be solved
uint16_t currentEntries;	number of solved and unslolved name entries
uint16_t totalEntries;	total number of supported name entries

Description

Structure: TCPIP_DNS_CLIENT_INFO

DNS module data structure used for getting information about the module settings.

Remarks

None.

TCPIP_DNS_ENTRY_QUERY Structure

DNS module query data for both IPv4 and IPv6 .

File

dns.h

C

```
typedef struct {
  char* hostName;
  int nameLen;
  IPV4_ADDR * ipv4Entry;
  int nIPv4Entries;
  IPV6_ADDR * ipv6Entry;
  int nIPv6Entries;
  TCPIP_DNS_RESULT status;
  uint32_t ttlTime;
```

```
  TCPIP_NET_HANDLE hNet;
  int serverIx;
  int nIPv4ValidEntries;
  int nIPv6ValidEntries;
} TCPIP_DNS_ENTRY_QUERY;
```

Members

Members	Description
char* hostName;	Pointer to a name to receive the host name for that particular entry
int nameLen;	hostName buffer size
IPV4_ADDR * ipv4Entry;	array of IPv4 entries/addresses to be populated
int nIPv4Entries;	number of entries in the ipv4Entry[] array;
IPV6_ADDR * ipv6Entry;	array of IPv6 entries/addresses to be populated
int nIPv6Entries;	number of entries in the ipv6Entry[] array;
TCPIP_DNS_RESULT status;	current status for this name: • TCPIP_DNS_RES_OK: name is resolved • TCPIP_DNS_RES_PENDING: name is pending • TCPIP_DNS_RES_SERVER_TMO: server timeout
uint32_t ttlTime;	time to live for a solved DNS entry
TCPIP_NET_HANDLE hNet;	interface the name was obtained or on which the query is currently ongoing
int serverIx;	index of the server used on that interface
int nIPv4ValidEntries;	number of valid entries written to the ipv4Entry
int nIPv6ValidEntries;	number of valid entries written to the ipv6Entry

Description

Structure: TCPIP_DNS_ENTRY_QUERY

DNS module uses this structure to return information about a resolved IPv4 and IPv6 address.

Remarks

None.

TCPIP_DNS_ENABLE_FLAGS Enumeration

Flags for enabling the DNS service on an interface.

File

dns.h

C

```
typedef enum {
  TCPIP_DNS_ENABLE_DEFAULT = 0,
  TCPIP_DNS_ENABLE_STRICT,
  TCPIP_DNS_ENABLE_PREFERRED
} TCPIP_DNS_ENABLE_FLAGS;
```

Members

Members	Description
TCPIP_DNS_ENABLE_DEFAULT = 0	the interface is capable of performing DNS name resolution
TCPIP_DNS_ENABLE_STRICT	only this interface will be used for DNS name resolution
TCPIP_DNS_ENABLE_PREFERRED	prefer this interface when doing DNS name resolution

Description

Enumeration: TCPIP_DNS_ENABLE_FLAGS

This enumeration lists the TCPIP_DNS_ENABLE_FLAGS argument for TCPIP_DNS_Enable.

Remarks

See the TCPIP_DNS_Enable description for details

TCPIP_DNS_RESOLVE_TYPE Enumeration

DNS query record type.

File

dns.h

C

```
typedef enum {
  TCPIP_DNS_TYPE_A = 1,
  TCPIP_DNS_TYPE_MX = 15,
  TCPIP_DNS_TYPE_AAAA = 28u,
  TCPIP_DNS_TYPE_ANY = 0xff
} TCPIP_DNS_RESOLVE_TYPE;
```

Members

Members	Description
TCPIP_DNS_TYPE_A = 1	Indicates an A (standard address) record.
TCPIP_DNS_TYPE_MX = 15	Indicates an MX (mail exchanger) record.
TCPIP_DNS_TYPE_AAAA = 28u	Indicates a quad-A (IPv6 address) address record.

Description

Enumeration: TCPIP_DNS_RESOLVE_TYPE

This enumeration lists the RecordType argument for TCPIP_DNS_Resolve. The stack supports DNS_TYPE_A and DNS_TYPE_AAAA.

Remarks

None.

Files

Files

Name	Description
dns.h	DNS definitions and interface file.
dns_config.h	DNS configuration file

Description

This section lists the source and header files used by the library.

dns.h

DNS definitions and interface file.

Enumerations

	Name	Description
	TCPIP_DNS_ENABLE_FLAGS	Flags for enabling the DNS service on an interface.
	TCPIP_DNS_EVENT_TYPE	This enumeration is used to notify DNS client applications.
	TCPIP_DNS_RESOLVE_TYPE	DNS query record type.
	TCPIP_DNS_RESULT	DNS client result codes.

Functions

	Name	Description
	TCPIP_DNS_ClientInfoGet	Get the current DNS client parameters.
	TCPIP_DNS_ClientTask	Standard TCP/IP stack module task function.
	TCPIP_DNS_Disable	Disables the DNS Client for the specified interface.
	TCPIP_DNS_Enable	Enables the DNS Client for the specified interface.
	TCPIP_DNS_EntryQuery	Queries a DNS Resolver specific entry.
	TCPIP_DNS_GetIPAddressesNumber	Get the count of resolved IPv4 and/or IPv6 address for a host name.
	TCPIP_DNS_GetIPv4Addresses	Get IPV4 addresses for a DNS resolved name.

	TCPIP_DNS_GetIPv6Addresses	Get IPV6 addresses for a DNS resolved name.
	TCPIP_DNS_HandlerDeRegister	Deregisters a previously registered DNS client handler.
	TCPIP_DNS_HandlerRegister	Registers a DNS client Handler.
	TCPIP_DNS_IsEnabled	Determines if the DNS client is enabled on that specified interface.
	TCPIP_DNS_IsNameResolved	Determines if the DNS resolution is complete and provides the host IP address.
	TCPIP_DNS_IsResolved	Determines if the DNS resolution is complete and provides the host IP address.
	TCPIP_DNS_RemoveAll	Removes all the cached entries from DNS resolver.
	TCPIP_DNS_RemoveEntry	Remove a hostname from the DNS Hash entry.
	TCPIP_DNS_Resolve	Begins resolution of an address.
	TCPIP_DNS_Send_Query	Forces resolution of an address.

Structures

	Name	Description
	TCPIP_DNS_CLIENT_INFO	General DNS client info.
	TCPIP_DNS_CLIENT_MODULE_CONFIG	Provides a place holder for DNS client configuration.
	TCPIP_DNS_ENTRY_QUERY	DNS module query data for both IPv4 and IPv6 .

Types

	Name	Description
	TCPIP_DNS_EVENT_HANDLER	Notification handler that can be called when a specific entry is resolved and entry is timed out.
	TCPIP_DNS_HANDLE	DNS client handle.

Description

Domain Name System (DNS) Client API Header file

This source file contains the DNS client module API.

File Name

dns.h

Company

Microchip Technology Inc.

dns_config.h

DNS configuration file

Macros

	Name	Description
	TCPIP_DNS_CLIENT_ADDRESS_TYPE	This parameter can be used to choose ithe type of IP connection for the DNS client: IPv4 or IPv6. Currently only IPv4 is supported and this parameter is not used. Reserved for future development
	TCPIP_DNS_CLIENT_CACHE_DEFAULT_TTL_VAL	Default TTL time for a solved entry in the cache This value will be used when the DNS server TTL value for an entry is 0
	TCPIP_DNS_CLIENT_CACHE_ENTRIES	Number of DNS resolver entries
	TCPIP_DNS_CLIENT_CACHE_ENTRY_TMO	DNS client cache entry time-out. If this symbol is zero then the entry time-out will be the one specified by the DNS server when the name was solved. Otherwise this value will be used as the cache entry time-out. Default should be 0.
	TCPIP_DNS_CLIENT_CACHE_PER_IPV4_ADDRESS	Maximum and default number of IPv4 answers to be considered while processing DNS response from server for a query.
	TCPIP_DNS_CLIENT_CACHE_PER_IPV6_ADDRESS	Maximum and default number of IPv6 answers to be considered while processing DNS response from server for a query.
	TCPIP_DNS_CLIENT_CACHE_UNSOLVED_ENTRY_TMO	Time-out for the a unsolved name, in seconds. The name resolution will be aborted if the TMO elapsed and the name could not be solved Should be greater than TCPIP_DNS_CLIENT_LOOKUP_RETRY_TMO

	TCPIP_DNS_CLIENT_LOOKUP_RETRY_TMO	Retry lookup for a unsolved entry in the cache, in seconds. If the TCPIP_DNS_CLIENT_LOOKUP_RETRY_TMO seconds elapsed and the name has not been solved then the name entry will be marked with server timeout and the resolution will be retried. Should be less than TCPIP_DNS_CLIENT_CACHE_UNSOLVED_ENTRY_TMO
	TCPIP_DNS_CLIENT_MAX_HOSTNAME_LEN	Max DNS host name size
	TCPIP_DNS_CLIENT_MAX_SELECT_INTERFACES	Max number of interfaces to take part in the DNS selection algorithm Should be always greater than 1: • the default interface should always be considered for DNS resolution Depending on how many active interfaces select those to be considered for DNS resolution
	TCPIP_DNS_CLIENT_SERVER_TMO	When the DNS Client connected to the DNS Server this is the elapsed time after which an the communication is considered to have timed failed if there was no reply from the server In seconds
	TCPIP_DNS_CLIENT_TASK_PROCESS_RATE	DNS Client task processing rate, in milliseconds. The DNS Client module will process a timer event with this rate for processing its own state machine, etc. The default value is 200 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_DNS_CLIENT_USER_NOTIFICATION	allow DNS client user notification if enabled, the TCPIP_DNS_HandlerRegister/TCPIP_DNS_HandlerDeRegister functions exist and can be used

DNS Server Module

This section describes the TCP/IP Stack Library DNS Server module.

Introduction

TCP/IP Stack Library Domain Name System Server (DNSS) Module for Microchip Microcontrollers

This library provides the API of the DNS Server module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

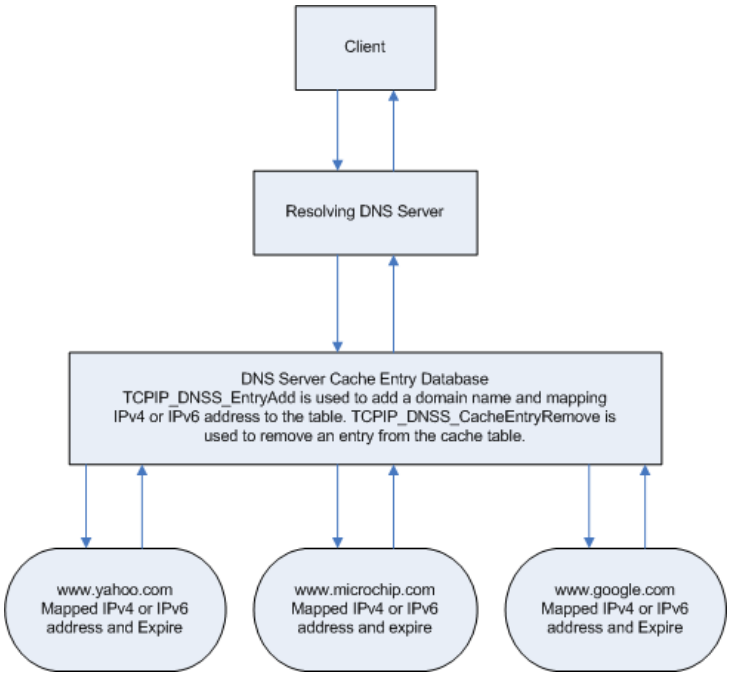
A step-by-step analysis of the DNS Server is as follows:

1. DNS server can be enabled or disabled by using the dnss command (it is not interface based).
2. The client initiates a query to find the Domain Name Server. The client sends the query to the DNS Server of the TCP/IP stack.
3. The DNS Server of the TCP/IP Stack first checks the Boolean value of replyBoardAddr of DNSS_MODULE_CONFIG. If this is true, the DNS server will send an answer with its own board address as the DNS server address to the requested Client. If it is false, it then checks its own cache, whether or not it already knows the answer. But, as the answer is not present, it generates NO response for the client query.

- Cache entry is updated by adding a entry to it using command handler
- Cache entry is the table of Name , IPv4/IPv6 address. and expire time
- The dnsserv command is used to add, delete and display the DNS server details
- Users can add either one IPv4 or IPv6 address at a time
- Maximum Name and IPv4/IPv6 address combination is determined from the IPv4EntriesPerDNSName and IPv6EntriesPerDNSName of DNSS_MODULE_CONFIG

4. Authoritative Name servers and Addition Name servers are not processed.
5. The TCP/IP DNS Server stores the answer in its cache for future use and answers to the client by sending the IP address of the Domain Name Server, which is added by the user using command dnsserv.
6. The client may store the answer to the DNS query in it's own cache for future use. Then, the client communicates directly with the Domain

Name server using the IP address.



Using the Library

This topic describes the basic architecture of the DNSS TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `dnss.h`

The interface to the DNS TCP/IP Stack library is defined in the `dnss.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the DNS TCP/IP Stack library should include `tcpip.h`.

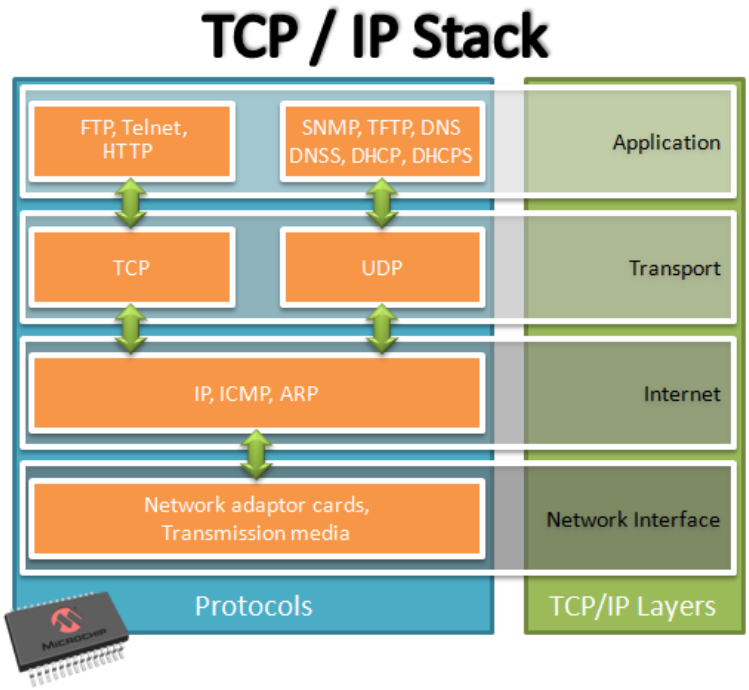
Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

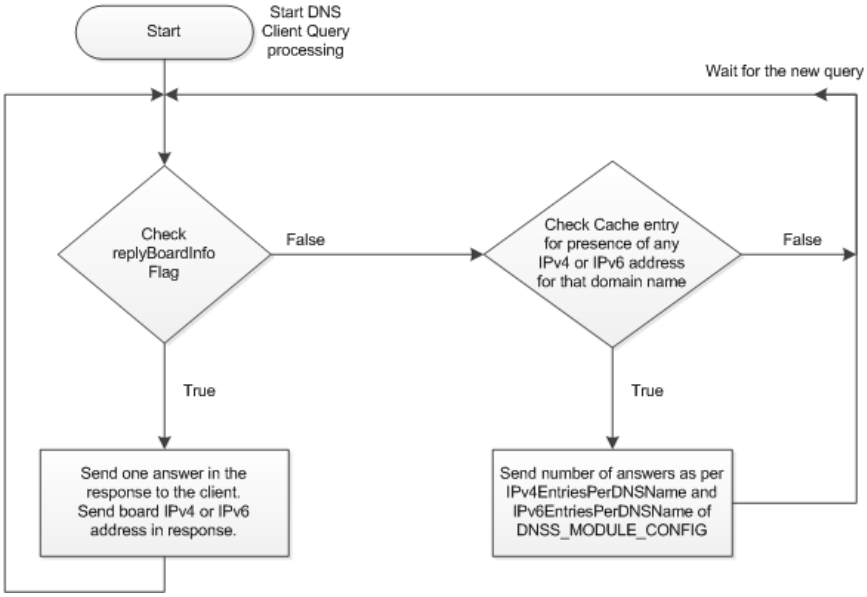
This library provides the API of the DNSS TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

DNSS is part of the Application Layer, as illustrated in the following figure.



DNSS resolution operations follow a simple state machine, as indicated in the following diagram.



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the DNSS module.

Library Interface Section	Description
General Functions	This section provides general interface routines to DNS
Data Types and Constants	This section provides various definitions describing this API

Configuring the Library

Macros

	Name	Description
	TCPIP_DNSS_CACHE_MAX_SERVER_ENTRIES	Maximum DNS server Cache entries. It is the sum of TCPIP_DNSS_CACHE_PER_IPV4_ADDRESS and TCPIP_DNSS_CACHE_PER_IPV6_ADDRESS.
	TCPIP_DNSS_CACHE_PER_IPV4_ADDRESS	Maximum and default number of IPv4 entries will be allowed to be configured from command prompt. and these many entries will be allowed to be sent in response for the DNS query with record type TCPIP_DNS_TYPE_A.
	TCPIP_DNSS_CACHE_PER_IPV6_ADDRESS	Maximum and default number of IPv6 entries will be allowed to be configured from command prompt. and these many entries will be allowed to be sent in response for the DNS query with record type TCPIP_DNS_TYPE_AAAA.
	TCPIP_DNSS_HOST_NAME_LEN	Default DNS host name length
	TCPIP_DNSS_REPLY_BOARD_ADDR	Reply DNS info with Board info only if the requested DNS host name is not present if TCPIP_DNSS_REPLY_BOARD_ADDR != 1 , then return no such name This is used for a boolean variable . the value should be 0 or 1
	TCPIP_DNSS_TASK_PROCESS_RATE	DNS Server time out task processing rate, in milliseconds. The DNS Server module will process a timer event with this rate for processing its own state machine, etc. The default value is 33 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_DNSS_TTL_TIME	Default TTL time for a IP address is 10 minutes

Description

The configuration of the DNSS TCP/IP Stack is based on the file `tcpip_config.h`.

This header file contains the configuration selection for the DNSS TCP/IP Stack. Based on the selections made, the DNSS TCP/IP Stack may support the selected features. These configuration settings will apply to all instances of the DNSS TCP/IP Stack.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_DNSS_CACHE_MAX_SERVER_ENTRIES Macro

File

dnss_config.h

C

```
#define TCPIP_DNSS_CACHE_MAX_SERVER_ENTRIES
(TCPIP_DNSS_CACHE_PER_IPV4_ADDRESS+TCPIP_DNSS_CACHE_PER_IPV6_ADDRESS)
```

Description

Maximum DNS server Cache entries. It is the sum of TCPIP_DNSS_CACHE_PER_IPV4_ADDRESS and TCPIP_DNSS_CACHE_PER_IPV6_ADDRESS.

TCPIP_DNSS_CACHE_PER_IPV4_ADDRESS Macro

File

dnss_config.h

C

```
#define TCPIP_DNSS_CACHE_PER_IPV4_ADDRESS 2
```

Description

Maximum and default number of IPv4 entries will be allowed to be configured from command prompt. and these many entries will be allowed to be sent in response for the DNS query with record type TCPIP_DNS_TYPE_A.

TCPIP_DNSS_CACHE_PER_IPV6_ADDRESS Macro

File

dnss_config.h

C

```
#define TCPIP_DNSS_CACHE_PER_IPV6_ADDRESS 1
```

Description

Maximum and default number of IPv6 entries will be allowed to be configured from command prompt. and these many entries will be allowed to be sent in response for the DNS query with record type TCPIP_DNS_TYPE_AAAA.

TCPIP_DNSS_HOST_NAME_LEN Macro

File

dnss_config.h

C

```
#define TCPIP_DNSS_HOST_NAME_LEN 64u
```

Description

Default DNS host name length

TCPIP_DNSS_REPLY_BOARD_ADDR Macro

File

dnss_config.h

C

```
#define TCPIP_DNSS_REPLY_BOARD_ADDR 1
```

Description

Reply DNS info with Board info only if the requested DNS host name is not present if TCPIP_DNSS_REPLY_BOARD_ADDR != 1 , then return no such name This is used for a boolean variable . the value should be 0 or 1

TCPIP_DNSS_TASK_PROCESS_RATE Macro

File

dnss_config.h

C

```
#define TCPIP_DNSS_TASK_PROCESS_RATE (33)
```

Description

DNS Server time out task processing rate, in milliseconds. The DNS Server module will process a timer event with this rate for processing its own state machine, etc. The default value is 33 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

TCPIP_DNSS_TTL_TIME Macro

File

dnss_config.h

C

```
#define TCPIP_DNSS_TTL_TIME (10*60)
```

Description

Default TTL time for a IP address is 10 minutes

Building the Library

This section lists the files that are available in the DNS Server module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/dnss.c`	DNS Server implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The DNS Server module depends on the following modules:

- TCP/IP Stack Library
- UDP Module

Library Interface

a) General Functions

	Name	Description
	TCPIP_DNSS_AddressCntGet	Get DNS Server IPv4 or IPv4 Address count details for the Input value of Index
	TCPIP_DNSS_CacheEntryRemove	Remove DNS server cache entry by Hostname and IP Type and IP(v4 or v6) address
	TCPIP_DNSS_Disable	Disables the DNS Server for the specified interface.
	TCPIP_DNSS_Enable	Enables the DNS server for the specified interface.
	TCPIP_DNSS_EntryAdd	Add a IPv4 or IPv6 entry to the DNS server table.
	TCPIP_DNSS_IsEnabled	Determines if the DNS Server is enabled on the specified interface.
	TCPIP_DNSS_EntryGet	Get DNS server IP address details from resolver pool entry.
	TCPIP_DNSS_Task	Standard TCP/IP stack module task function.

b) Data Types and Constants

	Name	Description
	TCPIP_DNSS_MODULE_CONFIG	Provides a place holder for DNS server configuration.
	TCPIP_DNSS_RESULT	DNS result codes

Description

This section describes the Application Programming Interface (API) functions of the DNSS module.

Refer to each section for a detailed description.

a) General Functions

TCPIP_DNSS_AddressCntGet Function

Get DNS Server IPv4 or IPv4 Address count details for the Input value of Index

File

dnss.h

C

```
TCPIP_DNSS_RESULT TCPIP_DNSS_AddressCntGet(int index, uint8_t * hostName, uint8_t * ipCount);
```

Returns

TCPIP_DNSS_RESULT

Description

This function is used to get the number of IPv4 and IPv6 address entry details from hash entry table. Here input parameter is index value. Output will be the hostname and IP address count. IP address count is the summation of both IPv4 and IPv6 address.

Remarks

None.

Preconditions

DNSServerInit should be called.

Parameters

Parameters	Description
hostName	Get DNS host name
ipCount	Get the number of IPv4 or IPv6 Server address
index	Server count details per index value

Function

TCPIP_DNSS_RESULT TCPIP_DNSS_AddressCntGet(uint8_t * hostName,uint8_t * ipCount,int index)

TCPIP_DNSS_CacheEntryRemove Function

Remove DNS server cache entry by Hostname and IP Type and IP(v4 or v6) address

File

dnss.h

C

```
TCPIP_DNSS_RESULT TCPIP_DNSS_CacheEntryRemove(const char* name, IP_ADDRESS_TYPE type, IP_MULTI_ADDRESS*
pAdd);
```

Returns

- DNSS_RES_OK - If entry remove is successful
- DNSS_RES_NO_ENTRY - No such entry is present
- DNSS_RES_MEMORY_FAIL - No Memory is present for IPv4 or IPv6 address type

Description

This function is used for command prompt dnsDelSrv and to delete a entry IPv4 or IPv6 from hostName. Every time this is used to delete either one IPv4 or IPv6 address with respect to the DNS hostname, there will be an expire time for a Host entry.

Preconditions

The DNS server must be initialized.

Parameters

Parameters	Description
name	Hostname
type	IP_ADDRESS_TYPE_IPV4 or IP_ADDRESS_TYPE_IPV6
pAdd	v4 or v6 address

Function

TCPIP_DNSS_RESULT TCPIP_DNSS_CacheEntryRemove(const char* name, IP_ADDRESS_TYPE type,
IP_MULTI_ADDRESS* pAdd)

TCPIP_DNSS_Disable Function

Disables the DNS Server for the specified interface.

File

dnss.h

C

```
bool TCPIP_DNSS_Disable(TCPIP_NET_HANDLE hNet);
```

Returns

- true - if successful
- false - if unsuccessful

Description

This function disables the DNS Server for the specified interface. If it is already disabled, no action is taken.

Remarks

none

Preconditions

The DNS server must be initialized.

Parameters

Parameters	Description
hNet	Interface on which to disable the DNS Server.

Function

bool TCPIP_DNSS_Disable(TCPIP_NET_HANDLE hNet)

TCPIP_DNSS_Enable Function

Enables the DNS server for the specified interface.

File

dnss.h

C

```
bool TCPIP_DNSS_Enable(TCPIP_NET_HANDLE hNet);
```

Returns

- true - if successful
- false - if unsuccessful

Description

This function enables the DNS Server for the specified interface, if it is disabled. If it is already enabled, nothing is done.

Preconditions

The DNS server must be initialized.

Parameters

Parameters	Description
hNet	Interface to enable the DNS Server on.

Function

bool TCPIP_DNSS_Enable(TCPIP_NET_HANDLE hNet)

TCPIP_DNSS_EntryAdd Function

Add a IPv4 or IPv6 entry to the DNS server table.

File

dnss.h

C

```
TCPIP_DNSS_RESULT TCPIP_DNSS_EntryAdd(const char* name, IP_ADDRESS_TYPE type, IP_MULTI_ADDRESS* pAdd,
uint32_t validStartTime);
```

Returns

- DNSS_RES_OK - If entry remove is successful
- DNSS_RES_NO_ENTRY - If Hostname is NULL value and Invalid IP type
- DNSS_RES_MEMORY_FAIL - No Memory is present for IPv4 or IPv6 address type
- DNSS_RES_CACHE_FULL - If there is no space for the new entry

Description

This function is used to add a IPv4 or IPv6 entry. Every time this is used to add either one IPv4 or IPv6 address with respect to the DNS hostname, there will be an expire time for a Host entry.

Remarks

None.

Preconditions

DNS Server Initialized.

Parameters

Parameters	Description
name	Hostname
type	IP_ADDRESS_TYPE_IPV4 or IP_ADDRESS_TYPE_IPV6
pAdd	IPv4 or IPv6 address
validStartTime	Time-out value for the entry

Function

TCPIP_DNSS_RESULT TCPIP_DNSS_EntryAdd(const char* name, IP_ADDRESS_TYPE type,
IP_MULTI_ADDRESS* pAdd,uint32_t validStartTime);

TCPIP_DNSS_IsEnabled Function

Determines if the DNS Server is enabled on the specified interface.

File

dnss.h

C

```
bool TCPIP_DNSS_IsEnabled(TCPIP_NET_HANDLE hNet);
```

Returns

- true - if the DNS Server is enabled on the specified interface
- false - if the DNS Server is not enabled on the specified interface

Description

This function returns the current state of the DNS Server on the specified interface.

Preconditions

The DNS server must be initialized.

Parameters

Parameters	Description
hNet	Interface to query.

Function

bool TCPIP_DNSS_IsEnabled(TCPIP_NET_HANDLE hNet)

TCPIP_DNSS_EntryGet Function

Get DNS server IP address details from resolver pool entry.

File

dnss.h

C

```
TCPIP_DNSS_RESULT TCPIP_DNSS_EntryGet(uint8_t * hostName, IP_ADDRESS_TYPE type, int index,
IP_MULTI_ADDRESS* pGetAdd, uint32_t * ttltime);
```

Returns

TCPIP_DNSS_RESULT

Description

This function is used to get the DNS server IPv4 or IPv6 address from resolver pool entry as per hostname and IP type and from the index value. This IP type can be a IPv4 and IPv6 type. This is used for DNS record type.

Remarks

None.

Preconditions

DNSServerInit should be called.

Parameters

Parameters	Description
hostName	DNS host name
type	DNS IP type (it will be ipv4 or ipv6 type and it is mapped to DNS record type) this can be used for DNS record type
index	get the next entry after this index value
pGetAdd	get the zero th IPv4 or IPv6 address
ttltime	timeout value

Function

TCPIP_DNSS_RESULT TCPIP_DNSS_EntryGet(uint8_t * hostName,IP_ADDRESS_TYPE type,
int index, IP_MULTI_ADDRESS* pGetAdd,uint32_t *ttltime);

TCPIP_DNSS_Task Function

Standard TCP/IP stack module task function.

File

dnss.h

C

```
void TCPIP_DNSS_Task();
```

Returns

None.

Description

This function performs DNSS module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The DNSS module should have been initialized.

Function

void TCPIP_DNSS_Task(void)

b) Data Types and Constants

TCPIP_DNSS_MODULE_CONFIG Structure

Provides a place holder for DNS server configuration.

File

dnss.h

C

```
typedef struct {
  bool deleteOldLease;
  bool replyBoardAddr;
  size_t IPv4EntriesPerDNSName;
  size_t IPv6EntriesPerDNSName;
} TCPIP_DNSS_MODULE_CONFIG;
```

Members

Members	Description
bool deleteOldLease;	Delete old cache if still in place,
bool replyBoardAddr;	Reply with board address specific DNS server parameters
size_t IPv4EntriesPerDNSName;	Number of IPv4 entries per DNS name. Default value is 1.
size_t IPv6EntriesPerDNSName;	Number of IPv6 address per DNS Name. Default value is 1 Used only when IPv6 is enabled

Description

Structure: TCPIP_DNSS_MODULE_CONFIG

DNS Server run-time configuration and initialization parameter.

Remarks

None.

TCPIP_DNSS_RESULT Enumeration

DNS result codes

File

dnss.h

C

```
typedef enum {
  DNSS_RES_OK = 0,
  DNSS_RES_NO_SERVICE = -1,
  DNSS_RES_CACHE_FULL = -2,
  DNSS_RES_NO_ENTRY = -3,
  DNSS_RES_NO_IPADDRESS = -4,
  DNSS_RES_MEMORY_FAIL = -5,
```

```
  DNSS_RES_DUPLICATE_ENTRY = -6
} TCPIP_DNSS_RESULT;
```

Members

Members	Description
DNSS_RES_OK = 0	operation succeeded
DNSS_RES_NO_SERVICE = -1	DNS service not implemented or uninitialized
DNSS_RES_CACHE_FULL = -2	the cache is full and no entry could be added
DNSS_RES_NO_ENTRY = -3	DNSS no such name
DNSS_RES_NO_IPADDRESS = -4	No such IP address
DNSS_RES_MEMORY_FAIL = -5	out of memory failure
DNSS_RES_DUPLICATE_ENTRY = -6	duplicate entry was found

Description

Enumeration: TCPIP_DNSS_RESULT

DNS Server operations results.

Remarks

None.

Files

Files

Name	Description

Dynamic DNS Module

This section describes the TCP/IP Stack Library Dynamic DNS (DDNS) module.

Introduction

TCP/IP Stack Library Dynamic Domain Name System (DDNS) Module for Microchip Microcontrollers

This library provides the API of the DDNS module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

The Dynamic DNS Client module provides a method for updating a dynamic IP address to a public DDNS service. These services can be used to provide DNS hostname mapping to devices that behind routers, firewalls, and/or on networks that dynamically assign IP addresses.

Note that this only solves one of the two problems for communicating to devices on local subnets from the Internet. While Dynamic DNS can help to locate the device, the router or firewall it sits behind must still properly forward the incoming connection request. This generally requires port forwarding to be configured for the router behind which the device is located.

The Dynamic DNS client supports the popular interface used by No-IP (noip.com) and DNS-O-Matic (dnsomatic.com).

Important! The dynamic DNS services stipulate that updates should be made no more frequently than 10 minutes, and only when the IP address has changed. Updates made more often than that are considered abusive, and may eventually cause your account to be disabled. Production devices that get rebooted frequently may need to store the last known IP in non-volatile memory. You also should not enable this module while testing the rest of your application.

Using the Library

This topic describes the basic architecture of the DDNS TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `ddns.h`

The interface to the DDNS TCP/IP Stack library is defined in the `ddns.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the DDNS TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

This library provides the API of the DDNS TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

DDNS Software Abstraction Block Diagram

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Dynamic DNS module.

Library Interface Section	Description
Functions	Routines for Configuring DDNS
Data Types and Constants	This section provides various definitions describing this API

Configuring the Library

Macros

	Name	Description
	TCPIP_DDNS_CHECKIP_SERVER	Default CheckIP server for determining current IP address
	TCPIP_DDNS_TASK_TICK_RATE	dynDNS task rate, ms The default value is hundreds of milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

Description

The configuration of the DDNS TCP/IP Stack Library is based on the file `tcpip_config.h`.

This header file contains the configuration selection for the DDNS TCP/IP Stack Library. Based on the selections made, the DDNS TCP/IP Stack Library may support the selected features. These configuration settings will apply to all instances of the DDNS TCP/IP Stack Library.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_DDNS_CHECKIP_SERVER Macro

File

ddns_config.h

C

```
#define TCPIP_DDNS_CHECKIP_SERVER (const uint8_t*)"checkip.dyndns.com"
```

Description

Default CheckIP server for determining current IP address

TCPIP_DDNS_TASK_TICK_RATE Macro

File

ddns_config.h

C

```
#define TCPIP_DDNS_TASK_TICK_RATE 777
```

Description

dynDNS task rate, ms The default value is hundreds of milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

Building the Library

This section lists the files that are available in the Dynamic DNS module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/ddns.c`	Dynamic DNS Server implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The Dynamic DNS module depends on the following modules:

- TCP/IP Stack Library
- DNS Module
- TCP Module

Library Interface

a) Functions

	Name	Description
	TCPIP_DDNS_LastIPGet	Returns the status of the most recent update.
	TCPIP_DDNS_LastStatusGet	Returns the last known external IP address of the device.
	TCPIP_DDNS_ServiceSet	Selects a preconfigured Dynamic DNS service.
	TCPIP_DDNS_UpdateForce	Forces an immediate DDNS update.
	TCPIP_DDNS_Task	Standard TCP/IP stack module task function.

b) Data Types and Constants

	Name	Description
	DDNS_MODULE_CONFIG	This is type DDNS_MODULE_CONFIG.
	DDNS_POINTERS	Configuration parameters for the Dynamic DNS Client
	DDNS_SERVICES	Dynamic DNS Services. Must support the DynDNS API (Auxlang) and correspond to ddnsServiceHosts and ddnsServicePorts in DynDNS.c.
	DDNS_STATUS	Status message for DynDNS client. GOOD and NOCHG are okay, but ABUSE through 911 are fatal. UNCHANGED through INVALID are locally defined.

Description

This section describes the Application Programming Interface (API) functions of the Dynamic DNS module.

Refer to each section for a detailed description.

a) Functions

TCPIP_DDNS_LastIPGet Function

Returns the status of the most recent update.

File

ddns.h

C

```
IPV4_ADDR TCPIP_DDNS_LastIPGet();
```

Returns

DDNS_STATUS indicating the status code for the most recent update.

Description

This function returns the status of the most recent update. See the DDNS_STATUS enumeration for possible codes.

Preconditions

None.

Function

DDNS_STATUS TCPIP_DDNS_LastStatusGet(void)

TCPIP_DDNS_LastStatusGet Function

Returns the last known external IP address of the device.

File

ddns.h

C

```
DDNS_STATUS TCPIP_DDNS_LastStatusGet();
```

Returns

The last known external IP address of the device.

Description

This function returns the last known external IP address of the device.

Preconditions

None.

Function

IPV4_ADDR TCPIP_DDNS_LastIPGet(void)

TCPIP_DDNS_ServiceSet Function

Selects a preconfigured Dynamic DNS service.

File

ddns.h

C

```
void TCPIP_DDNS_ServiceSet(DDNS_SERVICES svc);
```

Returns

None.

Description

This function selects a Dynamic DNS service based on parameters configured in ddnsServiceHosts and ddnsServicePorts. These arrays must match the DDNS_SERVICES enumeration.

Preconditions

None.

Parameters

Parameters	Description
svc	one of the DDNS_SERVICES elements to indicate the selected service

Function

void TCPIP_DDNS_ServiceSet(DDNS_SERVICES svc)

TCPIP_DDNS_UpdateForce Function

Forces an immediate DDNS update.

File

ddns.h

C

```
void TCPIP_DDNS_UpdateForce();
```

Returns

None.

Description

This function forces the DDNS Client to execute a full update immediately. Any error message is cleared, and the update will be executed whether the IP address has changed or not. Call this function every time the DDNSClient parameters have been modified.

Preconditions

TCPIP_DDNS_Initialize must have been called.

Function

void TCPIP_DDNS_UpdateForce(void)

TCPIP_DDNS_Task Function

Standard TCP/IP stack module task function.

File

ddns.h

C

```
void TCPIP_DDNS_Task();
```

Returns

None.

Description

Performs DDNS module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

DDNS module should have been initialized

Function

void TCPIP_DDNS_Task(void)

b) Data Types and Constants

DDNS_MODULE_CONFIG Structure

File

ddns.h

C

```
typedef struct {
} DDNS_MODULE_CONFIG;
```

Description

This is type DDNS_MODULE_CONFIG.

DDNS_POINTERS Structure

Configuration parameters for the Dynamic DNS Client

File

ddns.h

C

```
typedef struct {
  union {
    uint8_t * szRAM;
    const uint8_t * szROM;
  } CheckIPServer;
  uint16_t CheckIPPort;
  union {
    uint8_t * szRAM;
    const uint8_t * szROM;
  } UpdateServer;
  uint16_t UpdatePort;
  union {
    uint8_t * szRAM;
    const uint8_t * szROM;
  } Username;
```

```
  union {
    uint8_t * szRAM;
    const uint8_t * szROM;
  } Password;
  union {
    uint8_t * szRAM;
    const uint8_t * szROM;
  } Host;
  struct {
    unsigned char CheckIPServer : 1;
    unsigned char UpdateServer : 1;
    unsigned char Username : 1;
    unsigned char Password : 1;
    unsigned char Host : 1;
  } ROMPointers;
} DDNS_POINTERS;
```

Description

This structure of pointers configures the Dynamic DNS Client. Initially, all pointers will be null and the client will be disabled. Set `DDNSClient.[field name].szRAM` to use a string stored in RAM, or `DDNSClient.[field name].szROM` to use a string stored in const. Where, `[field name]`, is one of the following parameters.

If a const string is specified, `DDNSClient.ROMPointers.[field name]` must also be set to 1 to indicate that this field should be retrieved from const instead of RAM.

Parameters

Parameters	Description
CheckIPServer	The server used to determine the external IP address
CheckIPPort	Port on the above server to connect to
UpdateServer	The server where updates should be posted
UpdatePort	Port on the above server to connect to
Username	The user name for the dynamic DNS server
Password	The password to supply when making updates
Host	The host name you wish to update
ROMPointers	Indicates which parameters to read from const instead of RAM.

DDNS_SERVICES Enumeration

File

ddns.h

C

```
typedef enum {
  DYNDNS_ORG = 0u,
  NO_IP_COM,
  DNSOMATIC_COM
} DDNS_SERVICES;
```

Members

Members	Description
DYNDNS_ORG = 0u	www.dyndns.org
NO_IP_COM	www.no-ip.com
DNSOMATIC_COM	www.dnsomatic.com

Description

Dynamic DNS Services. Must support the DynDNS API (Auxlang) and correspond to ddnsServiceHosts and ddnsServicePorts in DynDNS.c.

DDNS_STATUS Enumeration

File

ddns.h

C

```
typedef enum {
  DDNS_STATUS_GOOD = 0u,
  DDNS_STATUS_NOCHG,
  DDNS_STATUS_ABUSE,
  DDNS_STATUS_BADSYS,
  DDNS_STATUS_BADAGENT,
  DDNS_STATUS_BADAUTH,
  DDNS_STATUS_NOT_DONATOR,
  DDNS_STATUS_NOT_FQDN,
  DDNS_STATUS_NOHOST,
  DDNS_STATUS_NOT_YOURS,
  DDNS_STATUS_NUMHOST,
  DDNS_STATUS_DNSERR,
  DDNS_STATUS_911,
  DDNS_STATUS_UPDATE_ERROR,
  DDNS_STATUS_UNCHANGED,
  DDNS_STATUS_CHECKIP_ERROR,
  DDNS_STATUS_DNS_ERROR,
  DDNS_STATUS_SKT_ERROR,
  DDNS_STATUS_INVALID,
  DDNS_STATUS_UNKNOWN
} DDNS_STATUS;
```

Members

Members	Description
DDNS_STATUS_GOOD = 0u	Update successful, hostname is now updated
DDNS_STATUS_NOCHG	Update changed no setting and is considered abusive. Additional 'nochg' updates will cause hostname to be blocked.
DDNS_STATUS_ABUSE	The hostname specified is blocked for update abuse.
DDNS_STATUS_BADSYS	System parameter not valid. Should be dyndns, statdns or custom.
DDNS_STATUS_BADAGENT	The user agent was blocked or not sent.
DDNS_STATUS_BADAUTH	The username and password pair do not match a real user.
DDNS_STATUS_NOT_DONATOR	An option available only to credited users (such as offline URL) was specified, but the user is not a credited user. If multiple hosts were specified, only a single !donator will be returned.
DDNS_STATUS_NOT_FQDN	The hostname specified is not a fully-qualified domain name (not in the form hostname.dyndns.org or domain.com).
DDNS_STATUS_NOHOST	The hostname specified does not exist in this user account (or is not in the service specified in the system parameter).
DDNS_STATUS_NOT_YOURS	The hostname specified does not belong to this user account.
DDNS_STATUS_NUMHOST	Too many hosts specified in an update.
DDNS_STATUS_DNSERR	Unspecified DNS error encountered by the DDNS service.
DDNS_STATUS_911	There is a problem or scheduled maintenance with the DDNS service.
DDNS_STATUS_UPDATE_ERROR	Error communicating with Update service.
DDNS_STATUS_UNCHANGED	The IP Check indicated that no update was necessary.
DDNS_STATUS_CHECKIP_ERROR	Error communicating with CheckIP service.
DDNS_STATUS_DNS_ERROR	DNS error resolving the CheckIP service.
DDNS_STATUS_SKT_ERROR	TCP socket opening error
DDNS_STATUS_INVALID	DDNS Client data is not valid.
DDNS_STATUS_UNKNOWN	DDNS client has not yet been executed with this configuration.

Description

Status message for DynDNS client. GOOD and NOCHG are okay, but ABUSE through 911 are fatal. UNCHANGED through INVALID are locally defined.

Files

Files

Name	Description
ddns.h	The Dynamic DNS Client module provides a method for updating a dynamic IP address to a public DDNS service.
ddns_config.h	Dynamic DNS configuration file

Description

FTP Module

This section describes the TCP/IP Stack Library FTP module.

Introduction

TCP/IP Stack Library File Transfer Protocol (FTP) Module for Microchip Microcontrollers

This library provides the API of the FTP module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

An embedded File Transfer Protocol (FTP) server is an excellent addition to any network-enabled device. FTP server capability facilitates the uploading of files to, and downloading of files from, an embedded device. Almost all computers have, at the very least, a command line FTP client that will allow a user to connect to an embedded FTP server.

Using the Library

This topic describes the basic architecture of the FTP TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `ftp.h`

The interface to the FTP TCP/IP Stack library is defined in the `ftp.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the FTP TCP/IP Stack library should include `tcpip.h`.

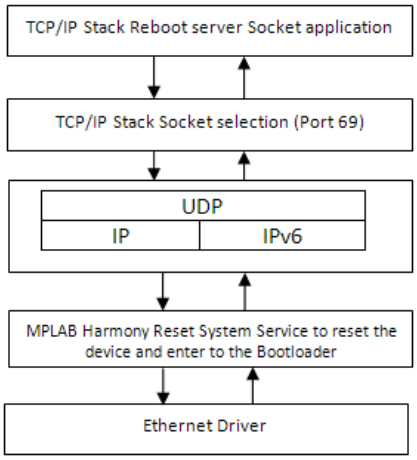
Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

This library provides the API of the FTP TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

FTP Server Dependencies



Since the FTP server requires the use of the TCP/IP stack and a file system, which can be a MPFS or MDD, it also inherits the program memory and RAM requirements of those as well.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the FTP module.

Library Interface Section	Description
General Functions	This section provides a routine that performs FTP module tasks in the TCP/IP stack.
Data Types and Constants	This section provides various definitions describing this API

Configuring the Library

Macros

	Name	Description
	TCPIP_FTP_DATA_SKT_RX_BUFF_SIZE	Define the size of the RX buffer for the FTP Data socket Use 0 for default TCP RX buffer size. The default recommended value for high throughput is > 2MSS (3 KB). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput.
	TCPIP_FTP_DATA_SKT_TX_BUFF_SIZE	Define the size of the TX buffer for the FTP Data socket Use 0 for default TCP TX buffer size. The default recommended value for high throughput is > 2MSS (3 KB). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput.
	TCPIP_FTP_MAX_CONNECTIONS	Maximum number of FTP connections allowed
	TCPIP_FTP_PASSWD_LEN	Specifies the max length of FTP login password
	TCPIP_FTP_PUT_ENABLED	Comment this line out to disable MPFS
	TCPIP_FTP_USER_NAME_LEN	Specifies the max length for user name
	TCPIP_FTPS_TASK_TICK_RATE	The FTP server task rate, milliseconds The default value is 33 milliseconds. The lower the rate (higher the frequency) the higher the FTP server priority and higher transfer rates could be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_FTP_TIMEOUT	FTP timeout, seconds

Description

The configuration of the FTP TCP/IP Stack is based on the file `tcpip_config.h`.

This header file contains the configuration selection for the FTP TCP/IP Stack. Based on the selections made, the FTP TCP/IP Stack may support the selected features. These configuration settings will apply to all instances of the FTP TCP/IP Stack.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_FTP_DATA_SKT_RX_BUFF_SIZE Macro

File

ftp_config.h

C

```
#define TCPIP_FTP_DATA_SKT_RX_BUFF_SIZE 0
```

Description

Define the size of the RX buffer for the FTP Data socket Use 0 for default TCP RX buffer size. The default recommended value for high throughput is > 2MSS (3 KB). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput.

TCPIP_FTP_DATA_SKT_TX_BUFF_SIZE Macro

File

ftp_config.h

C

```
#define TCPIP_FTP_DATA_SKT_TX_BUFF_SIZE 0
```

Description

Define the size of the TX buffer for the FTP Data socket Use 0 for default TCP TX buffer size. The default recommended value for high throughput is > 2MSS (3 KB). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput.

TCPIP_FTP_MAX_CONNECTIONS Macro

File

ftp_config.h

C

```
#define TCPIP_FTP_MAX_CONNECTIONS (1)
```

Description

Maximum number of FTP connections allowed

TCPIP_FTP_PASSWD_LEN Macro

File

ftp_config.h

C

```
#define TCPIP_FTP_PASSWD_LEN (10)
```

Description

Specifies the max length of FTP login password

TCPIP_FTP_PUT_ENABLED Macro

File

ftp_config.h

C

```
#define TCPIP_FTP_PUT_ENABLED
```

Description

Comment this line out to disable MPFS

TCPIP_FTP_USER_NAME_LEN Macro

File

ftp_config.h

C

```
#define TCPIP_FTP_USER_NAME_LEN (10)
```

Description

Specifies the max length for user name

TCPIP_FTPS_TASK_TICK_RATE Macro

File

ftp_config.h

C

```
#define TCPIP_FTPS_TASK_TICK_RATE 33
```

Description

The FTP server task rate, milliseconds The default value is 33 milliseconds. The lower the rate (higher the frequency) the higher the FTP server priority and higher transfer rates could be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

TCPIP_FTP_TIMEOUT Macro

File

ftp_config.h

C

```
#define TCPIP_FTP_TIMEOUT (1200ul)
```

Description

FTP timeout, seconds

Building the Library

This section lists the files that are available in the FTP module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/ftp.c`	FTP implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The FTP module depends on the following modules:

- TCP/IP Stack Library
- TCP Module
- File System Service Library

Library Interface

a) General Functions

	Name	Description
	TCPIP_FTP_ServerTask	Standard TCP/IP stack module task function.

b) Data Types and Constants

	Name	Description
	TCPIP_FTP_MODULE_CONFIG	FTP Sever module runtime and initialization configuration data.

Description

This section describes the Application Programming Interface (API) functions of the FTP module.

Refer to each section for a detailed description.

a) General Functions

TCPIP_FTP_ServerTask Function

Standard TCP/IP stack module task function.

File

ftp.h

C

```
void TCPIP_FTP_ServerTask();
```

Returns

None.

Description

This function performs FTP module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The FTP module should have been initialized.

Function

void TCPIP_FTP_ServerTask(void)

b) Data Types and Constants

TCPIP_FTP_MODULE_CONFIG Structure

FTP Sever module runtime and initialization configuration data.

File

ftp.h

C

```
typedef struct {
  uint16_t nConnections;
  uint16_t dataSktTxBuffSize;
  uint16_t dataSktRxBuffSize;
  char * userName;
  char * password;
} TCPIP_FTP_MODULE_CONFIG;
```

Members

Members	Description
uint16_t nConnections;	number of simultaneous FTP connections allowed
uint16_t dataSktTxBuffSize;	size of Data socket TX buffer for the associated socket; leave 0 for default
uint16_t dataSktRxBuffSize;	size of Data Socket RX buffer for the associated socket; leave 0 for default
char * userName;	FTP login User name. Size should not exceed more than TCPIP_FTP_USER_NAME_LEN
char * password;	FTP login password. Size should not exceed more than TCPIP_FTP_PASSWD_LEN

Description

Structure: TCPIP_FTP_MODULE_CONFIG

FTP server configuration and initialization data . Configuration is part of tcpip_stack_init.c.

Files

HTTP Module

This section describes the TCP/IP Stack Library HTTP module.

Introduction

TCP/IP Stack Library Hypertext Transfer Protocol (HTTP) Module for Microchip Microcontrollers

This library provides the API of the HTTP module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

The HTTP Web Server module allows a development board to act as a Web server. This facilitates an easy method to view status information and control applications using any standard Web browser.

Using the Library

This topic describes the basic architecture of the HTTP TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `http.h`

The interface to the HTTP TCP/IP Stack library is defined in the `http.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the HTTP TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

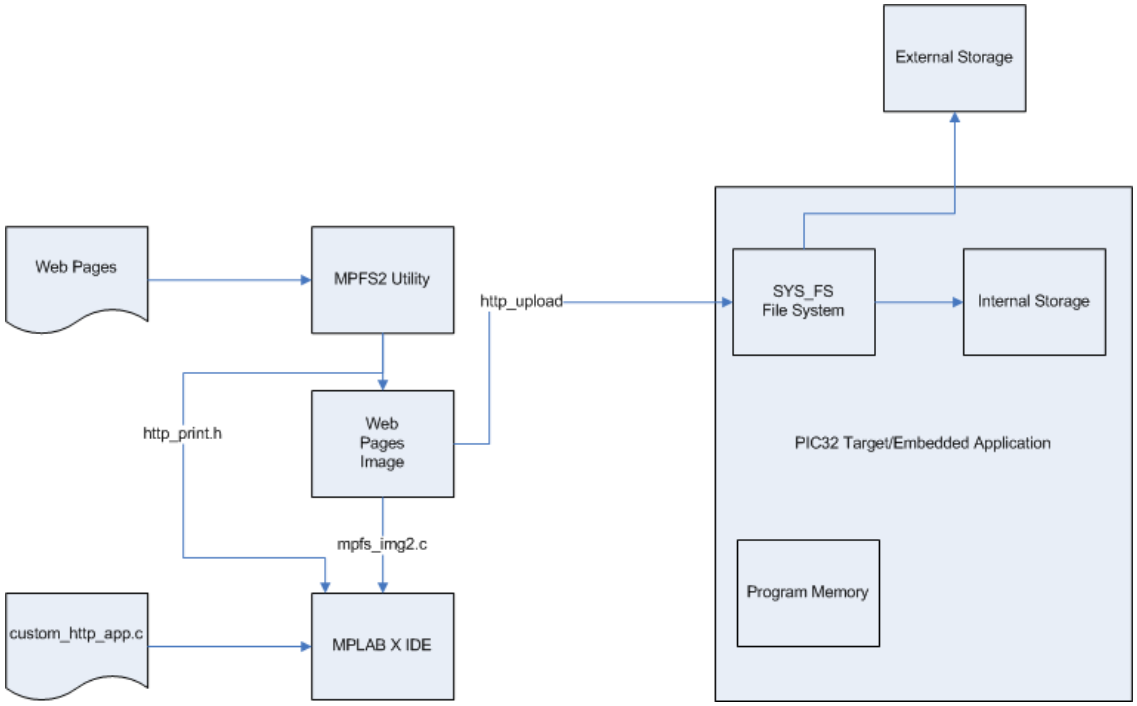
Abstraction Model

This library provides the API of the HTTP TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

HTTP Software Abstraction Block Diagram

Three main components are necessary to understand how the HTTP web server works: the web pages, the MPFS2 Utility, and the source files `custom_http_app.c` and `http_print.h`. An overview of the entire process is shown in the following diagram.



Web Pages

This includes all the HTML and associated images, CSS style sheets, and JavaScript files necessary to display the website. A sample application including all these components is located in the `web_pages2` folder.

MPFS2 Utility

This program, supplied by Microchip, packages the web pages into a format that can be efficiently stored in either external non-volatile storage, or internal Flash program memory. This program also indexes dynamic variables found in the web pages and updates `http_print.h` with these indices. The MPFS2 Utility generates a SYS_FS compatible file image that can be directly uploaded on the PIC32 development board or stored in the Flash program memory as a source file image to be included in the project.

When dynamic variables are added or removed from your application, the MPFS2 Utility will update `http_print.h`. When this happens, the project must be recompiled in the MPLAB X IDE to ensure that all the new variable indices get added into the application.

custom_http_app.c

This file implements the Web application. It describes the output for dynamic variables (via TCPIP_HTTP_Print_varname callbacks), parses data submitted through forms (in TCPIP_HTTP_GetExecute and TCPIP_HTTP_PostExecutePost) and validates authorization credentials (in TCPIP_HTTP_FileAuthenticate and TCPIP_HTTP_UserAuthenticate).

The functionality of these callbacks is described within the demonstration application's web pages, and is also documented within the `custom_http_app.c` example that is distributed with the stack.

http_print.h

This file is generated automatically by the MPFS2 Utility. It indexes all of the dynamic variables and provides the "glue" between the variables located in the Web pages and their associated TCPIP_HTTP_Print_varname callback functions defined in `custom_http_app.c`. This file does not require modification by the programmer.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the HTTP module.

Library Interface Section	Description
Functions	Routines for Configuring the HTTP module
Data Types and Constants	This section provides various definitions describing this API

HTTP Features

The HTTP Web Server module has many capabilities. The following topics will introduce these features and provide examples.

Dynamic Variables

One of the most basic needs is to provide status information back to the user of your Web application. The HTTP server provides for this using dynamic variable substitution callbacks. These commands in your HTML code will alert the server to execute a callback function at that point, which the developer creates to write data into the web page. Dynamic Variables should be considered the output of your application.

Description

Basic Use

To create a dynamic variable, simply enclose the name of the variable inside a pair of tilde (~) characters within the web pages' HTML source code. (ex: ~myVariable~) When you run the MPFS2 Utility to generate the web pages, it will automatically index these variables in `http_print.h`. This index will instruct your application to invoke the function TCPIP_HTTP_Print_myVariable when this string is encountered.

Here is an example of using a dynamic variable to insert the build date of your application into the web pages:

```
<div class="examplebox code">~builddate~</div>
The associated callback will print the value into the web page:
void TCPIP_HTTP_Print_builddate(HTTP_CONN_HANDLE connHandle)
{
    TCP_SOCKET sktHTTP = TCPIP_HTTP_CurrentConnectionSocketGet(connHandle);
    TCPIP_TCP_StringPut(sktHTTP, (const void*)__DATE__" "__TIME__);
}
```

Passing Parameters

You can also pass parameters to dynamic variables by placing numeric values inside of parenthesis after the variable name.

For example, ~led(2)~ will print the value of the second LED. The numeric values are passed as 16 bit values to your callback function. You can pass as many parameters as you wish to these functions, and if your C code has constants defined, those will be parsed as well. (ex: ~pair(3,TRUE)~).

The following code inserts the value of the push buttons into the web page, all using the same callback function:

```
<div class="examplebox code">btn(3)~ btn(2)~ btn(1)~ btn(0)~</div>
This associated callback will print the value of the requested button to the web page:
void TCPIP_HTTP_Print_btn(HTTP_CONN_HANDLE connHandle, uint16_t num)
{
    // Determine which button
    switch(num)
    {
        case 0:
            num = BUTTON0_IO;
            break;
        case 1:
            num = BUTTON1_IO;
            break;
        case 2:
            num = BUTTON2_IO;
            break;
        default:
            num = 0;
    }

    // Print the output
    TCPIP_TCP_StringPut(TCPIP_HTTP_CurrentConnectionSocketGet(connHandle), (num ? "up" : "down"));
}
```

Longer Outputs

The HTTP protocol operates in a fixed memory buffer for transmission, so not all data can be sent at once. Care must be taken inside of your callback function to avoid overrunning this buffer.

The callback functions must check how much space is available, write up to that many bytes, and then return. The callback will be invoked again when more space is free.

Note: For increased throughput performance, it is recommended that the callback should always try to write as much data as possible in each call.

To manage the output state, callbacks should make use of the callbackPos variable that is maintained by the Web server for each individual connection. This 32-bit value can be manipulated with the TCPIP_HTTP_CurrentConnectionCallbackPosGet and TCPIP_HTTP_CurrentConnectionCallbackPosSet functions.

The callbackPos is set to zero when a callback is first invoked. If a callback is only writing part of its output, it should set this field to a non-zero

value to indicate that it should be called again when more space is available. This value will be available to the callback during the next call, which allows the function to resume output where it left off. A common use is to store the number of bytes written, or remaining to be written, in this field. Once the callback is finished writing its output, it must set callbackPos back to zero to indicate completion.

The following code outputs the value of the build date of the application into the web pages:

```
<div class="examplebox code">~builddate~</div>

void TCPIP_HTTP_Print_builddate(HTTP_CONN_HANDLE connHandle)
{
    TCP_SOCKET sktHTTP;
    sktHTTP = TCPIP_HTTP_CurrentConnectionSocketGet(connHandle);

    TCPIP_HTTP_CurrentConnectionCallbackPosSet(connHandle, 0x01);
    if(TCPIP_TCP_PutIsReady(sktHTTP) < strlen((const char*)__DATE__" "__TIME__))
        return;

    TCPIP_HTTP_CurrentConnectionCallbackPosSet(connHandle, 0x00);
    TCPIP_TCP_StringPut(sktHTTP, (const void*)__DATE__" "__TIME__);
}
```

The initial call to TCPIP_TCP_PutIsReady determines how many bytes can be written to the buffer right now. When there is not enough buffer space for performing the output operation the function sets the current value of the callbackPos and returns. Once the output operation is performed the callbackPos is cleared to '0'.

Including Files

Often it is useful to include the entire contents of another file in your output. Most web pages have at least some portion that does not change, such as the header, menu of links, and footer. These sections can be abstracted out into separate files which makes them easier to manage and conserves storage space.

To include the entire contents of another file, use a dynamic variable that starts with "inc:", such as ~inc:header.inc~.

This sequence will cause the file header.inc to be read from the file system and inserted at this location.

The following example indicates how to include a standard menu bar section into every page:

```
<div id="menu">~inc:menu.inc~</div>
```

At this time, dynamic variables are not recursive, so any variables located inside files included in this manner are not parsed.

Form Processing

Many applications need to accept data from a user. A common solution is to present a form to the user in a Web page, and then have the device process the values submitted via this form. Web forms are usually submitted using one of two methods (GET and POST), and the HTTP Web server supports both.

Description

The GET Method

The GET method appends the data to the end of the URI. This data follows the question mark (?) in the browser's address bar. (ex: http://mchpboard/form.htm?led1=0&led2=1&led3=0) Data sent via GET is automatically decoded and stored in the current connection data buffer. Since it is to be stored in memory, this data is limited to the size of the connection data buffer which by default is 100 bytes (configurable by HTTP_MAX_DATA_LEN build time symbol or by the run time data passes at the HTTP module initialization).

It is generally easier to process data received in this manner.

The callback function TCPIP_HTTP_GetExecute is implemented by the application developer to process this data and perform any necessary actions. The function TCPIP_HTTP_ArgGet provides an easy method to retrieve submitted values for processing.

See the custom _http_app.c for an example of TCPIP_HTTP_GetExecute implementation.

The POST Method

The POST method transmits data after all the request headers have been sent. This data is not visible in the browser's address bar, and can only be seen with a packet capture tool. It does however use the same URL encoding method.

The HTTP server does not perform any preparsing of this data. All POST data is left in the TCP buffer, so the custom application will need to access the TCP buffer directly to retrieve and decode it. The functions TCPIP_HTTP_PostNameRead and TCPIP_HTTP_PostValueRead have been provided to assist with these requirements. However, these functions can only be used when at least entire variables are expected to fit in the TCP buffer at once. Most POST processing functions will be implemented as state machines to use these functions. There is a status variable per each connection that stores the current state accessible with TCPIP_HTTP_CurrentConnectionPostSmGet and TCPIP_HTTP_CurrentConnectionPostSmSet functions. This state machine variable is reset to zero with each new request. Functions should generally implement a state to read a variable name, and another to read an expected value. Additional states may be helpful depending on the application.

The following example form accepts an e-mail address, a subject, and a message body. Since this data will likely total over the size of the internal connection data buffer, it should be submitted via POST.

```
<form method="post" action="/email.htm">
```

```
To: <input type="text" name="to" maxlength="50" /><br />
Subject: <input type="text" name="subject" maxlength="50" /><br />
Message:<br />
<textarea name="msg" rows="6"></textarea><br />
<input type="submit" value="Send Message" /></div>
</form>
```

Suppose a user enters the following data into this form:

To: joe@picsaregood.com

Subject: Sent by a PIC

Message: I sent this message using my development board!

The TCPIP_HTTP_PostExecute function will be called with the following data still in the TCP buffer:

to=joe%40picsaregood.com&subject=Sent+by+a+PIC&msg=I+sent+this+message+using+my+development+board%21

To use the e-mail module, the application needs to read in the address and the subject, store those in RAM, and then send the message. However, since the message is not guaranteed to fit in RAM all at once, it must be read as space is available and passed to the e-mail module. A state machine, coupled with the TCPIP_HTTP_PostNameRead and

TCPIP_HTTP_PostValueRead functions can simplify this greatly.

See the TCPIP_HTTP_PostExecute and HTTPPostEmail functions in the supplied custom_http_app.c for a complete implementation of this example.

Authentication

The HTTP protocol provides a method for servers to request a user name and password from a client before granting access to a page. The HTTP server supports this authentication mechanism, allowing developers to require valid credentials for access to some or all pages.

Description

Authentication functionality is supported by two user-provided callback functions. The first, TCPIP_HTTP_FileAuthenticate, determines if the requested page requires valid credentials to proceed. The second, TCPIP_HTTP_UserAuthenticate, checks the user name and password against an accepted list and determines whether to grant or deny access. The connection stores the current authorization setting which can be manipulated by using the TCPIP_HTTP_CurrentConnectionIsAuthorizedGet and TCPIP_HTTP_CurrentConnectionIsAuthorizedSet functions.

Requiring Authentication

When a request is first made, the function TCPIP_HTTP_FileAuthenticate is called to determine if that page needs password protection. This function returns a value to instruct the HTTP server how to proceed. The most significant bit indicates whether or not access is granted. That is, values 0x80 and higher allow access unconditionally, while values 0x79 and lower will require a user name and password at a later point. The value returned is stored in the connection data so that it can be accessed by future callback functions.

The following example is the simplest case, in which all files require a password for access:

```
uint8_t TCPIP_HTTP_FileAuthenticate(HTTP_CONN_HANDLE connHandle, uint8_t* cFile)
{
return 0;
}
In some cases, only certain files will need to be protected. The second example requires a password for any
file located in the /treasure folder:
uint8_t TCPIP_HTTP_FileAuthenticate(HTTP_CONN_HANDLE connHandle, uint8_t* cFile)
{
    // Compare to "/treasure" folder. Don't use strcmp here, because
    // cFile has additional path info such as "/treasure/gold.htm"
    if(memcmp(cFile, (const void*)"treasure", 8) == 0)
    {   // Authentication will be needed later
        return 0;
    }

    // No authentication required
    return 0x80;
}
```

More complex uses could require an administrative user to access the `/admin` folder, while any authenticated user can access the rest of the site. This requires the TCPIP_HTTP_FileAuthenticate to return different authentication values for a different file.

Validating Credentials

The TCPIP_HTTP_UserAuthenticate function determines if the supplied user name and password are valid to access the specific resource. Again, the most significant bit indicates whether or not access is granted. The value returned is also stored in the connection internal data and it can be accessed by future callback functions.

The following example is the simplest case, in which one user/password pair is accepted for all pages:

```
uint8_t TCPIP_HTTP_UserAuthenticate(HTTP_CONN_HANDLE connHandle, uint8_t* cUser, uint8_t* cPass)
```

```
{
    if(!strcmp((char*)cUser, (const char*)"AliBaba") &&
    !strcmp((char*)cPass, (const char*)"Open Sesame!") )
    {
        return 0x80;
    }

    return 0;
}
```

More complex uses are certainly feasible. Many applications may choose to store the user names and passwords in protected files so that they may be updated by a privileged user. In some cases, you may have multiple users with various levels of access. The application may wish to return various values above 0x80 in TCPIP_HTTP_UserAuthenticate so that later callback functions can determine which user logged in.

Cookies

By design, HTTP is a session-less and state-less protocol; every connection is an independent session with no relation to another.

Description

Cookies were added to the protocol description to solve this problem. This feature allows a web server to store small bits of text in a user's browser. These values will be returned to the server with every request, allowing the server to associate session variables with a request. Cookies are typically used for more advanced authentication systems.

Best practice is generally to store the bulk of the data on the server, and store only a unique identifier with the browser. This cuts down on data overhead and ensures that the user cannot modify the values stored with the session. However, logic must be implemented in the server to expire old sessions and allocate memory for new ones. If sensitive data is being stored, it is also important that the identifier be random enough so as to prevent stealing or spoofing another user's cookies.

Retrieving Cookies

In the HTTP server, cookies are retrieved automatically. They are stored in the connection internal data buffer just as any other GET form argument or URL parameter would be. The proper place to parse these values is therefore in the TCPIP_HTTP_GetExecute callback using the TCPIP_HTTP_ArgGet.

This model consumes some of the limited space available for URL parameters. Ensure that cookies do not consume more space than is available (as defined by HTTP_MAX_DATA_LEN) and that they will fit after any data that may be submitted via a GET form. If enough space is not available, the cookies will be truncated.

Setting Cookies

Cookies can be set in TCPIP_HTTP_GetExecute or TCPIP_HTTP_PostExecute. To set a cookie, store the name/value pairs in the connection internal buffer data as a series of null-terminated strings. Then, call TCPIP_HTTP_CurrentConnectionHasArgsSet with a parameter equal to the number of name/value pairs to be set. For example, the following code sets a cookie indicating a user's preference for a type of cookie:

```
void TCPIP_HTTP_GetExecute(void)
{
...
// Set a cookie
uint8_t* connData = TCPIP_HTTP_CurrentConnectionDataBufferGet(connHandle);
uint16_t httpBuffSize  = TCPIP_HTTP_CurrentConnectionDataBufferSizeGet(connHandle);
if(strlen(“flavor”) + strlen(“oatmeal raisin) + 2 <= httpBuffSize)
{
  strcpy((char*)connData, "flavor");
  strcpy((char*)connData + strlen("flavor") + 1, "oatmeal raisin");
  TCPIP_HTTP_CurrentConnectionHasArgsSet(connHandle, 1);
}

...
}
```

After this, all future requests from this browser will include the parameter "flavor" in the connection data along with the associated value of "oatmeal raisin".

Compression

All modern web browsers can receive files encoded with GZIP compression. For static files (those without dynamic variables), this can decrease the amount of data transmitted by as much as 60%.

Description

The MPFS2 Utility will automatically determine which files can benefit from GZIP compression, and will store the compressed file in the MPFS2 image when possible. This generally includes all JavaScript and CSS files. (Images are typically already compressed, so the MPFS2 Utility will generally decide it is better to store them uncompressed.) This HTTP server will then seamlessly return this compressed file to the browser. Less

non-volatile storage space will be required for storing the pages image, and faster transfers back to the client will result. No special configuration is required for this feature.

To prevent certain extensions from being compressed, use the Advanced Settings dialog in the MPFS2 Utility.

Configuring the Library

Macros

	Name	Description
	TCPIP_STACK_USE_BASE64_DECODE	Authentication requires Base64 decoding Enable basic authentication support
	TCPIP_HTTP_CACHE_LEN	Max lifetime (sec) of static responses as string
	TCPIP_HTTP_CONFIG_FLAGS	Define the HTTP module configuration flags Use 0 for default See HTTP_MODULE_FLAGS definition for possible values
	TCPIP_HTTP_DEFAULT_FILE	Indicate what HTTP file to serve when no specific one is requested
	TCPIP_HTTP_DEFAULT_LEN	For buffer overrun protection. Set to longest length of above two strings.
	TCPIP_HTTP_MAX_CONNECTIONS	Maximum numbers of simultaneous supported HTTP connections.
	TCPIP_HTTP_MAX_DATA_LEN	Define the maximum data length for reading cookie and GET/POST arguments (bytes)
	TCPIP_HTTP_MAX_HEADER_LEN	Set to length of longest string above
	TCPIP_HTTP_MIN_CALLBACK_FREE	Define the minimum number of bytes free in the TX FIFO before executing callbacks
	TCPIP_HTTP_SKT_RX_BUFF_SIZE	Define the size of the RX buffer for the HTTP socket Use 0 for default TCP socket value The default recommended value for high throughput is > 2MSS (3 KB). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput.
	TCPIP_HTTP_SKT_TX_BUFF_SIZE	Define the size of the TX buffer for the HTTP socket Use 0 for default TCP socket value The default recommended value for high throughput is > 2MSS (3 KB). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput.
	TCPIP_HTTP_TIMEOUT	Max time (sec) to await more data before timing out and disconnecting the socket
	TCPIP_HTTP_USE_AUTHENTICATION	Enable basic authentication support
	TCPIP_HTTP_USE_COOKIES	Enable cookie support
	TCPIP_HTTP_USE_POST	Define which HTTP modules to use If not using a specific module, comment it to save resources Enable POST support
	TCPIP_HTTPS_DEFAULT_FILE	Indicate what HTTPS file to serve when no specific one is requested
	TCPIP_HTTP_FILE_UPLOAD_ENABLE	Configure MPFS over HTTP updating Comment this line to disable updating via HTTP
	TCPIP_HTTP_FILE_UPLOAD_NAME	This is macro TCPIP_HTTP_FILE_UPLOAD_NAME.
	TCPIP_HTTP_TASK_RATE	The HTTP task rate, ms The default value is 33 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_HTTP_NO_AUTH_WITHOUT_SSL	Uncomment to require secure connection before requesting a password

Description

The configuration of the HTTP TCP/IP Stack is based on the file `tcpip_config.h` (which may include `http_config.h`).

This header file contains the configuration selection for the HTTP TCP/IP Stack. Based on the selections made, the HTTP TCP/IP Stack may support the selected features.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_STACK_USE_BASE64_DECODE Macro

File

http_config.h

C

```
#define TCPIP_STACK_USE_BASE64_DECODE
```

Description

Authentication requires Base64 decoding Enable basic authentication support

TCPIP_HTTP_CACHE_LEN Macro

File

http_config.h

C

```
#define TCPIP_HTTP_CACHE_LEN ("600")
```

Description

Max lifetime (sec) of static responses as string

TCPIP_HTTP_CONFIG_FLAGS Macro

File

http_config.h

C

```
#define TCPIP_HTTP_CONFIG_FLAGS 0
```

Description

Define the HTTP module configuration flags Use 0 for default See HTTP_MODULE_FLAGS definition for possible values

TCPIP_HTTP_DEFAULT_FILE Macro

File

http_config.h

C

```
#define TCPIP_HTTP_DEFAULT_FILE "index.htm"
```

Description

Indicate what HTTP file to serve when no specific one is requested

TCPIP_HTTP_DEFAULT_LEN Macro

File

http_config.h

C

```
#define TCPIP_HTTP_DEFAULT_LEN (10u)
```

Description

For buffer overrun protection. Set to longest length of above two strings.

TCPIP_HTTP_MAX_CONNECTIONS Macro

File

http_config.h

C

```
#define TCPIP_HTTP_MAX_CONNECTIONS (4)
```

Description

Maximum numbers of simultaneous supported HTTP connections.

TCPIP_HTTP_MAX_DATA_LEN Macro

File

http_config.h

C

```
#define TCPIP_HTTP_MAX_DATA_LEN (100u)
```

Description

Define the maximum data length for reading cookie and GET/POST arguments (bytes)

TCPIP_HTTP_MAX_HEADER_LEN Macro

File

http_config.h

C

```
#define TCPIP_HTTP_MAX_HEADER_LEN (15u)
```

Description

Set to length of longest string above

TCPIP_HTTP_MIN_CALLBACK_FREE Macro

File

http_config.h

C

```
#define TCPIP_HTTP_MIN_CALLBACK_FREE (16u)
```

Description

Define the minimum number of bytes free in the TX FIFO before executing callbacks

TCPIP_HTTP_SKT_RX_BUFF_SIZE Macro

File

http_config.h

C

```
#define TCPIP_HTTP_SKT_RX_BUFF_SIZE 0
```

Description

Define the size of the RX buffer for the HTTP socket Use 0 for default TCP socket value The default recommended value for high throughput is > 2MSS (3 KB). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput.

TCPIP_HTTP_SKT_TX_BUFF_SIZE Macro

File

http_config.h

C

```
#define TCPIP_HTTP_SKT_TX_BUFF_SIZE 0
```

Description

Define the size of the TX buffer for the HTTP socket Use 0 for default TCP socket value The default recommended value for high throughput is > 2MSS (3 KB). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput.

TCPIP_HTTP_TIMEOUT Macro

File

http_config.h

C

```
#define TCPIP_HTTP_TIMEOUT (45u)
```

Description

Max time (sec) to await more data before timing out and disconnecting the socket

TCPIP_HTTP_USE_AUTHENTICATION Macro

File

http_config.h

C

```
#define TCPIP_HTTP_USE_AUTHENTICATION
```

Description

Enable basic authentication support

TCPIP_HTTP_USE_COOKIES Macro

File

http_config.h

C

```
#define TCPIP_HTTP_USE_COOKIES
```

Description

Enable cookie support

TCPIP_HTTP_USE_POST Macro

File

http_config.h

C

```
#define TCPIP_HTTP_USE_POST
```

Description

Define which HTTP modules to use If not using a specific module, comment it to save resources Enable POST support

TCPIP_HTTPS_DEFAULT_FILE Macro

File

http_config.h

C

```
#define TCPIP_HTTPS_DEFAULT_FILE "index.htm"
```

Description

Indicate what HTTPS file to serve when no specific one is requested

TCPIP_HTTP_FILE_UPLOAD_ENABLE Macro

File

http_config.h

C

```
#define TCPIP_HTTP_FILE_UPLOAD_ENABLE
```

Description

Configure MPFS over HTTP updating Comment this line to disable updating via HTTP

TCPIP_HTTP_FILE_UPLOAD_NAME Macro

File

http_config.h

C

```
#define TCPIP_HTTP_FILE_UPLOAD_NAME "mpfsupload"
```

Description

This is macro TCPIP_HTTP_FILE_UPLOAD_NAME.

TCPIP_HTTP_TASK_RATE Macro

File

http_config.h

C

```
#define TCPIP_HTTP_TASK_RATE 33
```

Description

The HTTP task rate, ms The default value is 33 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

TCPIP_HTTP_NO_AUTH_WITHOUT_SSL Macro

File

http_config.h

C

```
#define TCPIP_HTTP_NO_AUTH_WITHOUT_SSL
```

Description

Uncomment to require secure connection before requesting a password

Building the Library

This section lists the files that are available in the HTTP module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/http.c	HTTP Server implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The HTTP module depends on the following modules:

- TCP/IP Stack Library
- TCP Module
- File System Service Library

Library Interface

a) Functions

	Name	Description
	TCPIP_HTTP_ArgGet	Locates a form field value in a given data array.
	TCPIP_HTTP_CurrentConnectionByteCountDec	Decrements the connection byte count.
	TCPIP_HTTP_CurrentConnectionByteCountGet	Returns how many bytes have been read so far
	TCPIP_HTTP_CurrentConnectionByteCountSet	Sets how many bytes have been read so far.
	TCPIP_HTTP_CurrentConnectionCallbackPosGet	Returns the callback position indicator.
	TCPIP_HTTP_CurrentConnectionCallbackPosSet	Sets the callback position indicator.
	TCPIP_HTTP_CurrentConnectionHasArgsGet	Checks whether there are get or cookie arguments.
	TCPIP_HTTP_CurrentConnectionHasArgsSet	Sets whether there are get or cookie arguments.
	TCPIP_HTTP_CurrentConnectionPostSmSet	Set the POST state machine state.
	TCPIP_HTTP_CurrentConnectionStatusGet	Gets HTTP status.
	TCPIP_HTTP_FileAuthenticate	Determines if a given file name requires authentication
	TCPIP_HTTP_GetExecute	Processes GET form field variables and cookies.
	TCPIP_HTTP_PostExecute	Processes POST form variables and data.
	TCPIP_HTTP_Print_varname	Inserts dynamic content into a web page
	TCPIP_HTTP_UserAuthenticate	Performs validation on a specific user name and password.
	TCPIP_HTTP_CurrentConnectionDataBufferGet	Returns pointer to connection general purpose data buffer.
	TCPIP_HTTP_CurrentConnectionFileGet	Get handle to current connection's file.
	TCPIP_HTTP_CurrentConnectionIsAuthorizedGet	Gets the authorized state for the current connection.
	TCPIP_HTTP_CurrentConnectionIsAuthorizedSet	Sets the authorized state for the current connection.
	TCPIP_HTTP_CurrentConnectionPostSmGet	Get the POST state machine state.
	TCPIP_HTTP_CurrentConnectionSocketGet	Get the socket for the current connection.
	TCPIP_HTTP_CurrentConnectionStatusSet	Sets HTTP status.
	TCPIP_HTTP_CurrentConnectionUserDataGet	Gets the user data parameter for the current connection.
	TCPIP_HTTP_CurrentConnectionUserDataSet	Sets the user data parameter for the current connection.
	TCPIP_HTTP_FileInclude	Writes a file byte-for-byte to the currently loaded TCP socket.
	TCPIP_HTTP_PostNameRead	Reads a name from a URL encoded string in the TCP buffer.
	TCPIP_HTTP_PostValueRead	Reads a value from a URL encoded string in the TCP buffer.
	TCPIP_HTTP_URLDecode	Parses a string from URL encoding to plain-text.
	TCPIP_HTTP_PostReadPair	Reads a name and value pair from a URL encoded string in the TCP buffer.

	TCPIP_HTTP_Task	Standard TCP/IP stack module task function.
	TCPIP_HTTP_ActiveConnectionCountGet	Gets the number of active connections.
	TCPIP_HTTP_CurrentConnectionHandleGet	Gets the connection handle of a HTTP connection.
	TCPIP_HTTP_CurrentConnectionIndexGet	Gets the index of the HTTP connection.

b) Data Types and Constants

	Name	Description
	HTTP_CONN_HANDLE	HTTP connection identifier, handle of a HTTP connection
	HTTP_FILE_TYPE	File type definitions
	HTTP_IO_RESULT	Result states for execution callbacks
	HTTP_MODULE_FLAGS	HTTP module configuration flags Multiple flags can be OR-ed
	HTTP_READ_STATUS	Result states for TCPIP_HTTP_PostNameRead, TCPIP_HTTP_PostValueRead and TCPIP_HTTP_PostReadPair
	HTTP_STATUS	Supported Commands and Server Response Codes
	TCPIP_HTTP_MODULE_CONFIG	HTTP module dynamic configuration data

Description

This section describes the Application Programming Interface (API) functions of the HTTP module.

Refer to each section for a detailed description.

a) Functions

TCPIP_HTTP_ArgGet Function

Locates a form field value in a given data array.

File

http.h

C

```
const uint8_t* TCPIP_HTTP_ArgGet(const uint8_t* cData, const uint8_t* cArg);
```

Returns

A pointer to the argument value, or NULL if not found.

Description

This function searches through a data array to find the value associated with a given argument. It can be used to find form field values in data received over GET or POST.

The end of data is assumed to be reached when a null name parameter is encountered. This requires the string to have an even number of null-terminated strings, followed by an additional null terminator.

Remarks

None.

Preconditions

The data array has a valid series of null terminated name/value pairs.

Example

```
  void TCPIP_HTTP_Print_cookiename(HTTP_CONN_HANDLE connHandle)
  {
      const uint8_t *ptr;
      TCP_SOCKET sktHTTP;

      ptr = TCPIP_HTTP_ArgGet(TCPIP_HTTP_CurrentConnectionDataBufferGet(connHandle), (const
uint8_t*)"name");
      sktHTTP = TCPIP_HTTP_CurrentConnectionSocketGet(connHandle);
      if(ptr)
          TCPIP_TCP_StringPut(sktHTTP, ptr);
      else
          TCPIP_TCP_StringPut(sktHTTP, (const uint8_t*)"not set");
```

```
}
```

Parameters

Parameters	Description
cData	the buffer to search
cArg	the name of the argument to find

Function

const uint8_t* TCPIP_HTTP_ArgGet(const uint8_t* cData, const uint8_t* cArg)

TCPIP_HTTP_CurrentConnectionByteCountDec Function

Decrements the connection byte count.

File

http.h

C

```
void TCPIP_HTTP_CurrentConnectionByteCountDec(HTTP_CONN_HANDLE connHandle, uint32_t byteCount);
```

Returns

None.

Description

This function decrements the current value of the counter showing the number of bytes read from the connection so far.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle
byteCount	byte count reduction

Function

void TCPIP_HTTP_CurrentConnectionByteCountDec(HTTP_CONN_HANDLE connHandle, uint32_t byteCount)

TCPIP_HTTP_CurrentConnectionByteCountGet Function

Returns how many bytes have been read so far

File

http.h

C

```
uint32_t TCPIP_HTTP_CurrentConnectionByteCountGet(HTTP_CONN_HANDLE connHandle);
```

Returns

Current connection byte count, how many bytes have been read so far.

Description

This function returns the current value of the counter showing the number of bytes read from the connection so far.

Remarks

None.

Preconditions

None.

Example

```
switch(TCPIP_HTTP_CurrentConnectionPostSmGet(connHandle))
{
    case SM_CFG_SNMP_READ_NAME:
        // If all parameters have been read, end
        if(TCPIP_HTTP_CurrentConnectionByteCountGet(connHandle) == 0u)
        {
            return HTTP_IO_DONE;
        }
     .
     .
     .
}
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

uint32_t TCPIP_HTTP_CurrentConnectionByteCountGet(HTTP_CONN_HANDLE connHandle)

TCPIP_HTTP_CurrentConnectionByteCountSet Function

Sets how many bytes have been read so far.

File

http.h

C

```
void TCPIP_HTTP_CurrentConnectionByteCountSet(HTTP_CONN_HANDLE connHandle, uint32_t byteCount);
```

Returns

None.

Description

This function sets the current value of the counter showing the number of bytes read from the connection so far.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle
byteCount	byte count to be set

Function

void TCPIP_HTTP_CurrentConnectionByteCountSet(HTTP_CONN_HANDLE connHandle, uint32_t byteCount)

TCPIP_HTTP_CurrentConnectionCallbackPosGet Function

Returns the callback position indicator.

File

http.h

C

```
uint32_t TCPIP_HTTP_CurrentConnectionCallbackPosGet(HTTP_CONN_HANDLE connHandle);
```

Returns

Callback position indicator for connection defined by connHandle.

Description

This function will return the current value of the callback position indicator for the HTTP connection identified by connHandle. The callback position indicator is used in the processing of the HTTP dynamic variables.

Remarks

None.

Preconditions

None.

Example

```
  uint32_t callbackPos;
  callbackPos = TCPIP_HTTP_CurrentConnectionCallbackPosGet(connHandle);
  if(callbackPos == 0x00u)
      callbackPos = (uint32_t)DDNSClient.Host.szRAM;
  callbackPos = (uint32_t)TCPIP_TCP_StringPut(TCPIP_HTTP_CurrentConnectionSocketGet(connHandle),
(uint8_t*)callbackPos);
  if(*(uint8_t*)callbackPos == '0')
      callbackPos = 0x00;
  TCPIP_HTTP_CurrentConnectionCallbackPosSet(connHandle, callbackPos);
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

uint32_t TCPIP_HTTP_CurrentConnectionCallbackPosGet(HTTP_CONN_HANDLE connHandle)

TCPIP_HTTP_CurrentConnectionCallbackPosSet Function

Sets the callback position indicator.

File

http.h

C

```
void TCPIP_HTTP_CurrentConnectionCallbackPosSet(HTTP_CONN_HANDLE connHandle, uint32_t callbackPos);
```

Returns

None.

Description

This function will set the current value of the callback position indicator for the HTTP connection identified by connHandle. The callback position indicator is used in the processing of the HTTP dynamic variables. When set to a value != 0, it indicates to the HTTP server that the application has more pending processing that needs to be done.

Remarks

None.

Preconditions

None.

Example

```
  void TCPIP_HTTP_Print_builddate(HTTP_CONN_HANDLE connHandle)
  {
      TCP_SOCKET sktHTTP;
      sktHTTP = TCPIP_HTTP_CurrentConnectionSocketGet(connHandle);

      TCPIP_HTTP_CurrentConnectionCallbackPosSet(connHandle, 0x01);
      if(TCPIP_TCP_PutIsReady(sktHTTP) < strlen((const char*)__DATE__" "__TIME__))
```

```
        { // Don't have room to output build date and time
            return;
        }
        TCPIP_HTTP_CurrentConnectionCallbackPosSet(connHandle, 0x00);
        TCPIP_TCP_StringPut(sktHTTP, (const void*)__DATE__" "__TIME__);
    }
```

Parameters

Parameters	Description
connHandle	HTTP connection handle
callbackPos	new connection callback position value

Function

void TCPIP_HTTP_CurrentConnectionCallbackPosSet(HTTP_CONN_HANDLE connHandle, uint32_t callbackPos)

TCPIP_HTTP_CurrentConnectionHasArgsGet Function

Checks whether there are get or cookie arguments.

File

http.h

C

```
uint8_t TCPIP_HTTP_CurrentConnectionHasArgsGet(HTTP_CONN_HANDLE connHandle);
```

Returns

The current value of the connection hasArgs.

Description

The function will get the value of the "cookies or get arguments" that are present.

Remarks

None.

Preconditions

None.

Example

```
uint8_t hasArgs = TCPIP_HTTP_CurrentConnectionHasArgsGet(connHandle);
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

uint8_t TCPIP_HTTP_CurrentConnectionHasArgsGet(HTTP_CONN_HANDLE connHandle)

TCPIP_HTTP_CurrentConnectionHasArgsSet Function

Sets whether there are get or cookie arguments.

File

http.h

C

```
void TCPIP_HTTP_CurrentConnectionHasArgsSet(HTTP_CONN_HANDLE connHandle, uint8_t args);
```

Returns

None.

Description

The function sets the value of the "cookies or get arguments" that are present.

Remarks

None.

Preconditions

None.

Example

```
else if(!memcmp(filename, "cookies.htm", 11))
{
    TCPIP_HTTP_CurrentConnectionHasArgsSet(connHandle, true);
}
```

Parameters

Parameters	Description
connHandle	HTTP connection handle
args	boolean if there are arguments or not

Function

void TCPIP_HTTP_CurrentConnectionHasArgsSet(HTTP_CONN_HANDLE connHandle, uint8_t args)

TCPIP_HTTP_CurrentConnectionPostSmSet Function

Set the POST state machine state.

File

http.h

C

```
void TCPIP_HTTP_CurrentConnectionPostSmSet(HTTP_CONN_HANDLE connHandle, uint16_t state);
```

Returns

None.

Description

This function sets the POST state machine state for the connection defined by connHandle. This state is maintained by the HTTP connection and can be used by the user of the HTTP to maintain its own POST state machine. The values of the POST state machine have significance only for the user of the HTTP connection.

Remarks

None.

Preconditions

None.

Example

```
uint8_t* httpDataBuff;
#define SM_POST_LCD_READ_NAME   1
#define SM_POST_LCD_READ_VALUE  2

switch(TCPIP_HTTP_CurrentConnectionPostSmGet(connHandle))
{
    // Find the name
    case SM_POST_LCD_READ_NAME:

        // Read a name
        if(TCPIP_HTTP_PostNameRead(connHandle, httpDataBuff, HTTP_MAX_DATA_LEN) == HTTP_READ_INCOMPLETE)
            return HTTP_IO_NEED_DATA;

        TCPIP_HTTP_CurrentConnectionPostSmSet(connHandle, SM_POST_LCD_READ_VALUE);
        // No break...continue reading value

    // Found the value, so store the LCD and return
    case SM_POST_LCD_READ_VALUE:
```

```
        .
        .
        .
    }
```

Parameters

Parameters	Description
connHandle	HTTP connection handle
state	16 bit integer state for POST state machine

Function

void TCPIP_HTTP_CurrentConnectionPostSmSet(HTTP_CONN_HANDLE connHandle, uint16_t state)

TCPIP_HTTP_CurrentConnectionStatusGet Function

Gets HTTP status.

File

http.h

C

```
HTTP_STATUS TCPIP_HTTP_CurrentConnectionStatusGet(HTTP_CONN_HANDLE connHandle);
```

Returns

A HTTP_STATUS value.

Description

This function returns the current HTTP status of the selected HTTP connection.

Remarks

None.

Preconditions

None.

Example

```
HTTP_STATUS currStat =  TCPIP_HTTP_CurrentConnectionStatusGet(connHandle);
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

HTTP_STATUS TCPIP_HTTP_CurrentConnectionStatusGet(HTTP_CONN_HANDLE connHandle);

TCPIP_HTTP_FileAuthenticate Function

Determines if a given file name requires authentication

File

http.h

C

```
uint8_t TCPIP_HTTP_FileAuthenticate(HTTP_CONN_HANDLE connHandle, uint8_t* cFile);
```

Returns

- <= 0x79 - valid authentication is required
- >= 0x80 - access is granted for this connection

Description

This function is implemented by the application developer. Its function is to determine if a file being requested requires authentication to view. The user name and password, if supplied, will arrive later with the request headers, and will be processed at that time.

Return values 0x80 - 0xff indicate that authentication is not required, while values from 0x00 to 0x79 indicate that a user name and password are required before proceeding. While most applications will only use a single value to grant access and another to require authorization, the range allows multiple "realms" or sets of pages to be protected, with different credential requirements for each.

The return value of this function is saved for the current connection and can be read using TCPIP_HTTP_CurrentConnectionIsAuthorizedGet(). It will be available to future callbacks, including TCPIP_HTTP_UserAuthenticate and any of the TCPIP_HTTP_GetExecute, TCPIP_HTTP_PostExecute, or TCPIP_HTTP_Print_varname callbacks.

Remarks

This function may NOT write to the TCP buffer.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle
cFile	the name of the file being requested

Function

uint8_t TCPIP_HTTP_FileAuthenticate(HTTP_CONN_HANDLE connHandle, uint8_t* cFile)

TCPIP_HTTP_GetExecute Function

Processes GET form field variables and cookies.

File

http.h

C

```
HTTP_IO_RESULT TCPIP_HTTP_GetExecute(HTTP_CONN_HANDLE connHandle);
```

Returns

- HTTP_IO_DONE - application is done processing
- HTTP_IO_NEED_DATA - this value may not be returned because more data will not become available
- HTTP_IO_WAITING - the application is waiting for an asynchronous process to complete, and this function should be called again later

Description

This function is implemented by the application developer. Its purpose is to parse the data received from URL parameters (GET method forms) and cookies and perform any application-specific tasks in response to these inputs. Any required authentication has already been validated.

When this function is called, the connection data buffer (see TCPIP_HTTP_CurrentConnectionDataBufferGet()) contains sequential name/value pairs of strings representing the data received. In this format, TCPIP_HTTP_ArgGet can be used to search for specific variables in the input. If data buffer space associated with this connection is required, connection data buffer may be overwritten here once the application is done with the values. Any data placed there will be available to future callbacks for this connection, including TCPIP_HTTP_PostExecute and any TCPIP_HTTP_Print_varname dynamic substitutions.

This function may also issue redirections by setting the connection data buffer to the destination file name or URL, and the connection httpStatus (TCPIP_HTTP_CurrentConnectionStatusSet()) to HTTP_REDIRECT.

Finally, this function may set cookies. Set connection data buffer to a series of name/value string pairs (in the same format in which parameters arrive) and then set the connection hasArgs (TCPIP_HTTP_CurrentConnectionHasArgsSet()) equal to the number of cookie name/value pairs. The cookies will be transmitted to the browser, and any future requests will have those values available in the connection data buffer.

Remarks

This function is only called if variables are received via URL parameters or Cookie arguments. This function may NOT write to the TCP buffer.

This function may service multiple HTTP requests simultaneously. Exercise caution when using global or static variables inside this routine. Use the connection callbackPos (TCPIP_HTTP_CurrentConnectionCallbackPosGet()) or the connection data buffer for storage associated with individual requests.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

HTTP_IO_RESULT TCPIP_HTTP_GetExecute(HTTP_CONN_HANDLE connHandle)

TCPIP_HTTP_PostExecute Function

Processes POST form variables and data.

File

http.h

C

```
HTTP_IO_RESULT TCPIP_HTTP_PostExecute(HTTP_CONN_HANDLE connHandle);
```

Returns

- HTTP_IO_DONE - application is done processing
- HTTP_IO_NEED_DATA - more data is needed to continue, and this function should be called again later
- HTTP_IO_WAITING - the application is waiting for an asynchronous process to complete, and this function should be called again later

Description

This function is implemented by the application developer. Its purpose is to parse the data received from POST forms and perform any application-specific tasks in response to these inputs. Any required authentication has already been validated before this function is called.

When this function is called, POST data will be waiting in the TCP buffer. The connection byteCount (see TCPIP_HTTP_CurrentConnectionByteCountGet will indicate the number of bytes remaining to be received before the browser request is complete.

Since data is still in the TCP buffer, the application must call TCPIP_TCP_ArrayGet in order to retrieve bytes. When this is done, connection byteCount MUST be updated to reflect how many bytes now remain. The functions TCPIP_TCP_ArrayFind and TCPIP_TCP_Find may be helpful to locate data in the TCP buffer.

In general, data submitted from web forms via POST is URL encoded. The TCPIP_HTTP_URLDecode function can be used to decode this information back to a standard string if required. If data buffer space associated with this connection is required, the connection data buffer (see TCPIP_HTTP_CurrentConnectionDataBufferGet()) may be overwritten here once the application is done with the values. Any data placed there will be available to future callbacks for this connection, including TCPIP_HTTP_PostExecute and any TCPIP_HTTP_Print_varname dynamic substitutions.

Whenever a POST form is processed it is recommended to issue a redirect back to the browser, either to a status page or to the same form page that was posted. This prevents accidental duplicate submissions (by clicking refresh or back/forward) and avoids browser warnings about "resubmitting form data". Redirects may be issued to the browser by setting the connection data buffer to the destination file or URL, and the connection httpStatus (TCPIP_HTTP_CurrentConnectionStatusSet()) to HTTP_REDIRECT.

Finally, this function may set cookies. Set the connection data buffer to a series of name/value string pairs (in the same format in which parameters arrive), and then set the connection hasArgs (TCPIP_HTTP_CurrentConnectionHasArgsSet) equal to the number of cookie name/value pairs. The cookies will be transmitted to the browser, and any future requests will have those values available in the connection data buffer.

Remarks

This function is only called when the request method is POST, and is only used when HTTP_USE_POST is defined. This method may NOT write to the TCP buffer.

This function may service multiple HTTP requests simultaneously. Exercise caution when using global or static variables inside this routine. Use the connection callbackPos (TCPIP_HTTP_CurrentConnectionCallbackPosGet) or connection data buffer for storage associated with individual requests.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

HTTP_IO_RESULT TCPIP_HTTP_PostExecute(HTTP_CONN_HANDLE connHandle)

TCPIP_HTTP_Print_varname Function

Inserts dynamic content into a web page

File

http.h

C

```
void TCPIP_HTTP_Print_varname(HTTP_CONN_HANDLE connHandle, uint16_t wParam1, uint16_t wParam2, ...);
```

Returns

None.

Description

Functions in this style are implemented by the application developer. These functions generate dynamic content to be inserted into web pages and other files returned by the HTTP server.

Functions of this type are called when a dynamic variable is located in a web page. (i.e., ~varname~) The name between the tilde '~' characters is appended to the base function name. In this example, the callback would be named TCPIP_HTTP_Print_varname.

The function prototype is located in your project's http_print.h, which is automatically generated by the mpfs2.jar utility. The prototype will have uint16_t parameters included for each parameter passed in the dynamic variable. For example, the variable "~myArray(2,6)~" will generate the prototype "void TCPIP_HTTP_Print_varname(uint16_t, uint16_t);".

When called, this function should write its output directly to the TCP socket using any combination of TCPIP_TCP_PutIsReady, TCPIP_TCP_Put, TCPIP_TCP_ArrayPut, TCPIP_TCP_StringPut, TCPIP_TCP_ArrayPut, and TCPIP_TCP_StringPut.

Before calling, the HTTP server guarantees that at least HTTP_MIN_CALLBACK_FREE bytes (defaults to 16 bytes) are free in the output buffer. If the function is writing less than this amount, it should simply write the data to the socket and return.

In situations where a function needs to write more this amount, it must manage its output state using the connection callbackPos (TCPIP_HTTP_CurrentConnectionCallbackPosGet/TCPIP_HTTP_CurrentConnectionCallbackPosSet). This value will be set to zero before the function is called. If the function is managing its output state, it must set this to a non-zero value before returning. Typically this is used to track how many bytes have been written, or how many remain to be written. If the connection callbackPos is non-zero, the function will be called again when more buffer space is available. Once the callback completes, set this value back to zero to resume normal servicing of the request.

Remarks

This function may service multiple HTTP requests simultaneously, especially when managing its output state. Exercise caution when using global or static variables inside this routine. Use the connection callbackPos or the connection data buffer for storage associated with individual requests.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle
wParam1	first parameter passed in the dynamic variable (if any)
wParam2	second parameter passed in the dynamic variable (if any)
...	additional parameters as necessary

Function

void TCPIP_HTTP_Print_varname(HTTP_CONN_HANDLE connHandle)

void TCPIP_HTTP_Print_varname(HTTP_CONN_HANDLE connHandle, uint16_t wParam1)

void TCPIP_HTTP_Print_varname(HTTP_CONN_HANDLE connHandle, uint16_t wParam1,

uint16_t wParam2, ...)

TCPIP_HTTP_UserAuthenticate Function

Performs validation on a specific user name and password.

File

http.h

C

```
uint8_t TCPIP_HTTP_UserAuthenticate(HTTP_CONN_HANDLE connHandle, uint8_t* cUser, uint8_t* cPass);
```

Returns

- <= 0x79 - the credentials were rejected
- >= 0x80 - access is granted for this connection

Description

This function is implemented by the application developer. Its function is to determine if the user name and password supplied by the client are acceptable for this resource. This callback function can thus to determine if only specific user names or passwords will be accepted for this resource.

Return values 0x80 - 0xff indicate that the credentials were accepted, while values from 0x00 to 0x79 indicate that authorization failed. While most applications will only use a single value to grant access, flexibility is provided to store multiple values in order to indicate which user (or user's group) logged in.

The value returned by this function is stored in the corresponding connection data and will be available with TCPIP_HTTP_CurrentConnectionIsAuthorizedGet in any of the TCPIP_HTTP_GetExecute, TCPIP_HTTP_PostExecute, or TCPIP_HTTP_Print_varname callbacks.

Remarks

This function is only called when an Authorization header is encountered.

This function may NOT write to the TCP buffer.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle
cUser	the user name supplied by the client
cPass	the password supplied by the client

Function

uint8_t TCPIP_HTTP_UserAuthenticate(HTTP_CONN_HANDLE connHandle, uint8_t* cUser, uint8_t* cPass)

TCPIP_HTTP_CurrentConnectionDataBufferGet Function

Returns pointer to connection general purpose data buffer.

File

http.h

C

```
uint8_t* TCPIP_HTTP_CurrentConnectionDataBufferGet(HTTP_CONN_HANDLE connHandle);
```

Returns

Pointer to the connection's general purpose data buffer.

Description

This function returns a pointer to the HTTP connection internal data buffer. This gives access to the application to the data that's stored in the HTTP connection buffer.

Remarks

None.

Preconditions

None.

Example

```
    void TCPIP_HTTP_Print_cookiename(HTTP_CONN_HANDLE connHandle)
    {
        const uint8_t *ptr;
        TCP_SOCKET sktHTTP;

        ptr = TCPIP_HTTP_ArgGet(TCPIP_HTTP_CurrentConnectionDataBufferGet(connHandle), (const
uint8_t*)"name");
        sktHTTP = TCPIP_HTTP_CurrentConnectionSocketGet(connHandle);
        if(ptr)
            TCPIP_TCP_StringPut(sktHTTP, ptr);
        else
```

```
        TCPIP_TCP_StringPut(sktHTTP, (const uint8_t*)"not set");
}
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

uint8_t* TCPIP_HTTP_CurrentConnectionDataBufferGet(HTTP_CONN_HANDLE connHandle)

TCPIP_HTTP_CurrentConnectionFileGet Function

Get handle to current connection's file.

File

http.h

C

```
SYS_FS_HANDLE TCPIP_HTTP_CurrentConnectionFileGet(HTTP_CONN_HANDLE connHandle);
```

Returns

Handle to File System file belonging to the connection defined by connHandle

Description

This function returns the handle of the current HTTP connection file.

Remarks

None.

Preconditions

None.

Example

```
uint8_t myBuff[20];

// Get the file handle and read from that file
SYS_FS_FileRead(myBuff, sizeof(myBuff), TCPIP_HTTP_CurrentConnectionFileGet(connHandle));
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

FILE_HANDLE TCPIP_HTTP_CurrentConnectionFileGet(HTTP_CONN_HANDLE connHandle)

TCPIP_HTTP_CurrentConnectionIsAuthorizedGet Function

Gets the authorized state for the current connection.

File

http.h

C

```
uint8_t TCPIP_HTTP_CurrentConnectionIsAuthorizedGet(HTTP_CONN_HANDLE connHandle);
```

Returns

A uint8_t representing the authorization status.

Description

This function returns the authorization status for the current HTTP connection. This is one of the values returned by the TCPIP_HTTP_FileAuthenticate() function.

Remarks

None.

Preconditions

None.

Example

```
uint8_t isAuth;

isAuth = TCPIP_HTTP_CurrentConnectionIsAuthorizedGet(connHandle);
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

uint8_t TCPIP_HTTP_CurrentConnectionIsAuthorizedGet(HTTP_CONN_HANDLE connHandle)

TCPIP_HTTP_CurrentConnectionIsAuthorizedSet Function

Sets the authorized state for the current connection.

File

http.h

C

```
void TCPIP_HTTP_CurrentConnectionIsAuthorizedSet(HTTP_CONN_HANDLE connHandle, uint8_t auth);
```

Returns

None.

Description

This function sets the authorization status for the current HTTP connection. This has to be one of the values in the set returned by the TCPIP_HTTP_FileAuthenticate() function.

Remarks

None.

Preconditions

None.

Example

```
uint8_t auth = 0x80;

TCPIP_HTTP_CurrentConnectionIsAuthorizedSet(connHandle, auth);
```

Parameters

Parameters	Description
connHandle	HTTP connection handle
auth	new authorization state

Function

void TCPIP_HTTP_CurrentConnectionIsAuthorizedSet(HTTP_CONN_HANDLE connHandle, uint8_t auth)

TCPIP_HTTP_CurrentConnectionPostSmGet Function

Get the POST state machine state.

File

http.h

C

```
uint16_t TCPIP_HTTP_CurrentConnectionPostSmGet(HTTP_CONN_HANDLE connHandle);
```

Returns

16-bit integer POST state machine state.

Description

This function returns the POST state machine state for the connection defined by connHandle. This state is maintained by the HTTP connection and can be used by the user of the HTTP to maintain its own POST state machine. The values of the POST state machine have significance only for the user of the HTTP connection.

Remarks

None.

Preconditions

None.

Example

```
#define SM_POST_LCD_READ_NAME   1
#define SM_POST_LCD_READ_VALUE  2

switch(TCPIP_HTTP_CurrentConnectionPostSmGet(connHandle))
{
    // Find the name
    case SM_POST_LCD_READ_NAME:
      .
      .
      .
    // Found the value, so store the LCD and return
    case SM_POST_LCD_READ_VALUE:
      .
      .
      .
}
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

uint16_t TCPIP_HTTP_CurrentConnectionPostSmGet(HTTP_CONN_HANDLE connHandle)

TCPIP_HTTP_CurrentConnectionSocketGet Function

Get the socket for the current connection.

File

http.h

C

```
TCP_SOCKET TCPIP_HTTP_CurrentConnectionSocketGet(HTTP_CONN_HANDLE connHandle);
```

Returns

TCP_SOCKET for the connection defined by connHandle.

Description

The function returns the TCP socket of the specified HTTP connection. The user gets access to the connection socket which it can use for sending/reading data.

Remarks

None.

Preconditions

None.

Example

```
uint32_t byteCount;
TCP_SOCKET sktHTTP;

byteCount = TCPIP_HTTP_CurrentConnectionByteCountGet(connHandle);
sktHTTP = TCPIP_HTTP_CurrentConnectionSocketGet(connHandle);
if(byteCount > TCPIP_TCP_GetIsReady(sktHTTP) + TCPIP_TCP_FifoRxFreeGet(sktHTTP))
{   // Configuration Failure
    TCPIP_HTTP_CurrentConnectionStatusSet(connHandle, HTTP_REDIRECT);
    return HTTP_IO_DONE;
}
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

TCP_SOCKET TCPIP_HTTP_CurrentConnectionSocketGet(HTTP_CONN_HANDLE connHandle)

TCPIP_HTTP_CurrentConnectionStatusSet Function

Sets HTTP status.

File

http.h

C

```
void TCPIP_HTTP_CurrentConnectionStatusSet(HTTP_CONN_HANDLE connHandle, HTTP_STATUS stat);
```

Returns

None.

Description

Allows write access to the HTTP status of the selected HTTP connection.

Remarks

None.

Preconditions

None.

Example

```
byteCount = TCPIP_HTTP_CurrentConnectionByteCountGet(connHandle);
sktHTTP = TCPIP_HTTP_CurrentConnectionSocketGet(connHandle);
if(byteCount > TCPIP_TCP_GetIsReady(sktHTTP) + TCPIP_TCP_FifoRxFreeGet(sktHTTP))
{   // Configuration Failure
    // 302 Redirect will be returned
    TCPIP_HTTP_CurrentConnectionStatusSet(connHandle, HTTP_REDIRECT);
}
```

Parameters

Parameters	Description
connHandle	HTTP connection handle
stat	new HTTP_STATUS enumeration value.

Function

void TCPIP_HTTP_CurrentConnectionStatusSet(HTTP_CONN_HANDLE connHandle, HTTP_STATUS stat)

TCPIP_HTTP_CurrentConnectionUserDataGet Function

Gets the user data parameter for the current connection.

File

http.h

C

```
const void* TCPIP_HTTP_CurrentConnectionUserDataGet(HTTP_CONN_HANDLE connHandle);
```

Returns

User data that's stored as part of the connection.

Description

This function returns the user data value for the current HTTP connection. This data belongs to the user and is not used in any way by the HTTP server module. It can be set by the user with TCPIP_HTTP_CurrentConnectionUserDataSet().

Remarks

None.

Preconditions

None.

Example

```
uint32_t myConnData;

myConnData = (uint32_t)TCPIP_HTTP_CurrentConnectionUserDataGet(connHandle);
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

const void* TCPIP_HTTP_CurrentConnectionUserDataGet(HTTP_CONN_HANDLE connHandle)

TCPIP_HTTP_CurrentConnectionUserDataSet Function

Sets the user data parameter for the current connection.

File

http.h

C

```
void TCPIP_HTTP_CurrentConnectionUserDataSet(HTTP_CONN_HANDLE connHandle, const void* uData);
```

Returns

None.

Description

This function will set the user data value for the current HTTP connection. This data belongs to the user and is not used in any way by the HTTP server module. It is available to the user by calling TCPIP_HTTP_CurrentConnectionUserDataGet.

Remarks

None.

Preconditions

None.

Example

```
uint32_t myConnData;
```

```
TCPIP_HTTP_CurrentConnectionUserDataSet(connHandle, (const void*)myConnData);
```

Parameters

Parameters	Description
connHandle	HTTP connection handle
uData	user supplied data

Function

void TCPIP_HTTP_CurrentConnectionUserDataSet(HTTP_CONN_HANDLE connHandle, const void* uData)

TCPIP_HTTP_FileInclude Function

Writes a file byte-for-byte to the currently loaded TCP socket.

File

http.h

C

```
void TCPIP_HTTP_FileInclude(HTTP_CONN_HANDLE connHandle, const uint8_t* cFile);
```

Returns

None.

Description

This function allows an entire file to be included as a dynamic variable, providing a basic templating system for HTML web pages. This reduces unneeded duplication of visual elements such as headers, menus, etc.

When pHttpCon->callbackPos is 0, the file is opened and as many bytes as possible are written. The current position is then saved to pHttpCon->callbackPos and the file is closed. On subsequent calls, reading begins at the saved location and continues. Once the end of the input file is reached, pHttpCon->callbackPos is set back to 0 to indicate completion.

Remarks

Users should not call this function directly, but should instead add dynamic variables in the form of `~inc:filename.ext~` in their HTML code to include (for example) the file "filename.ext" at that specified location. The mpfs2.jar utility will handle the rest.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle
cFile	the name of the file to be sent

Function

void TCPIP_HTTP_FileInclude(HTTP_CONN_HANDLE connHandle, const uint8_t* cFile)

TCPIP_HTTP_PostNameRead Function

Reads a name from a URL encoded string in the TCP buffer.

File

http.h

C

```
HTTP_READ_STATUS TCPIP_HTTP_PostNameRead(HTTP_CONN_HANDLE connHandle, uint8_t* cData, uint16_t wLen);
```

Returns

- HTTP_READ_OK - name was successfully read
- HTTP_READ_TRUNCTATED - entire name could not fit in the buffer, so the value was truncated and data has been lost
- HTTP_READ_INCOMPLETE - entire name was not yet in the buffer, so call this function again later to retrieve

Description

This function reads a name from a URL encoded string in the TCP buffer. This function is meant to be called from an TCPIP_HTTP_PostExecute callback to facilitate easier parsing of incoming data. This function also prevents buffer overflows by forcing the programmer to indicate how many bytes are expected. At least two extra bytes are needed in cData over the maximum length of data expected to be read.

This function will read until the next '=' character, which indicates the end of a name parameter. It assumes that the front of the buffer is the beginning of the name parameter to be read.

This function properly updates pHttpCon->byteCount by decrementing it by the number of bytes read. It also removes the delimiting '=' from the buffer.

Remarks

None.

Preconditions

The front of the TCP buffer is the beginning of a name parameter, and the rest of the TCP buffer contains a URL-encoded string with a name parameter terminated by a '=' character.

Parameters

Parameters	Description
connHandle	HTTP connection handle
cData	where to store the name once it is read
wLen	how many bytes can be written to cData

Function

HTTP_READ_STATUS TCPIP_HTTP_PostNameRead(HTTP_CONN_HANDLE connHandle, uint8_t* cData, uint16_t wLen)

TCPIP_HTTP_PostValueRead Function

Reads a value from a URL encoded string in the TCP buffer.

File

http.h

C

```
HTTP_READ_STATUS TCPIP_HTTP_PostValueRead(HTTP_CONN_HANDLE connHandle, uint8_t* cData, uint16_t wLen);
```

Returns

- HTTP_READ_OK - value was successfully read
- HTTP_READ_TRUNCTATED - entire value could not fit in the buffer, so the value was truncated and data has been lost
- HTTP_READ_INCOMPLETE - entire value was not yet in the buffer, so call this function again later to retrieve

Description

This function reads a value from a URL encoded string in the TCP buffer. This function is meant to be called from an TCPIP_HTTP_PostExecute callback to facilitate easier parsing of incoming data. This function also prevents buffer overflows by forcing the programmer to indicate how many bytes are expected. At least 2 extra bytes are needed in cData above the maximum length of data expected to be read.

This function will read until the next '&' character, which indicates the end of a value parameter. It assumes that the front of the buffer is the beginning of the value parameter to be read. If pHttpCon->byteCount indicates that all expected bytes are in the buffer, it assumes that all remaining data is the value and acts accordingly.

This function properly updates pHttpCon->byteCount by decrementing it by the number of bytes read. The terminating '&' character is also removed from the buffer.

Remarks

None.

Preconditions

The front of the TCP buffer is the beginning of a name parameter, and the rest of the TCP buffer contains a URL-encoded string with a name parameter terminated by a '=' character.

Parameters

Parameters	Description
connHandle	HTTP connection handle

cData	where to store the value once it is read
wLen	how many bytes can be written to cData

Function

HTTP_READ_STATUS TCPIP_HTTP_PostValueRead(HTTP_CONN_HANDLE connHandle, uint8_t* cData, uint16_t wLen)

TCPIP_HTTP_URLDecode Function

Parses a string from URL encoding to plain-text.

File

http.h

C

```
uint8_t* TCPIP_HTTP_URLDecode(uint8_t* cData);
```

Returns

A pointer to the last null terminator in data, which is also the first free byte for new data.

Description

This function parses a string from URL encoding to plain-text. The following conversions are made: '=' to '0', '&' to '0', '+' to ' ', and "%xx" to a single hex byte.

After completion, the data has been decoded and a null terminator signifies the end of a name or value. A second null terminator (or a null name parameter) indicates the end of all the data.

Remarks

This function is called by the stack to parse GET arguments and cookie data. User applications can use this function to decode POST data, but first need to verify that the string is null-terminated.

Preconditions

The data parameter is null terminated and has at least one extra byte free.

Parameters

Parameters	Description
cData	The string which is to be decoded in place.

Function

uint8_t* TCPIP_HTTP_URLDecode(uint8_t* cData)

TCPIP_HTTP_PostReadPair Macro

Reads a name and value pair from a URL encoded string in the TCP buffer.

File

http.h

C

```
#define TCPIP_HTTP_PostReadPair(connHandle, cData, wLen) TCPIP_HTTP_PostValueRead(connHandle, cData, wLen)
```

Returns

- HTTP_READ_OK - name and value were successfully read
- HTTP_READ_TRUNCTATED - entire name and value could not fit in the buffer, so input was truncated and data has been lost
- HTTP_READ_INCOMPLETE - entire name and value was not yet in the buffer, so call this function again later to retrieve

Description

Reads a name and value pair from a URL encoded string in the TCP buffer. This function is meant to be called from an TCPIP_HTTP_PostExecute callback to facilitate easier parsing of incoming data. This function also prevents buffer overflows by forcing the programmer to indicate how many bytes are expected. At least 2 extra bytes are needed in cData over the maximum length of data expected to be read.

This function will read until the next '&' character, which indicates the end of a value parameter. It assumes that the front of the buffer is the beginning of the name parameter to be read.

This function properly updates the connection byteCount (see TCPIP_HTTP_CurrentConnectionByteCountGet()) by decrementing it by the number of bytes read. It also removes the delimiting '&' from the buffer.

Once complete, two strings will exist in the cData buffer. The first is the parameter name that was read, while the second is the associated value.

Remarks

This function is aliased to TCPIP_HTTP_PostValueRead, since they effectively perform the same task. The name is provided only for completeness.

Preconditions

The front of the TCP buffer is the beginning of a name parameter, and the rest of the TCP buffer contains a URL-encoded string with a name parameter terminated by a '=' character and a value parameter terminated by a '&'.

Parameters

Parameters	Description
connHandle	HTTP connection handle
cData	where to store the name and value strings once they are read
wLen	how many bytes can be written to cData

Function

HTTP_READ_STATUS TCPIP_HTTP_PostReadPair(HTTP_CONN_HANDLE connHandle, uint8_t* cData, uint16_t wLen)

TCPIP_HTTP_Task Function

Standard TCP/IP stack module task function.

File

http.h

C

```
void TCPIP_HTTP_Task();
```

Returns

None.

Description

This function performs HTTP module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The HTTP module should have been initialized.

Function

void TCPIP_HTTP_Task(void)

TCPIP_HTTP_ActiveConnectionCountGet Function

Gets the number of active connections.

File

http.h

C

```
int TCPIP_HTTP_ActiveConnectionCountGet(int* pOpenCount);
```

Returns

The number of active and total connections.

Description

This function will return the number of active and total HTTP connections at the current time.

Remarks

The value returned by this function is informational only. The number of active connections changes dynamically.

Preconditions

None.

Example

```
int nConns;

nConns = TCPIP_HTTP_ActiveConnectionCountGet(0);
```

Parameters

Parameters	Description
pOpenCount	address to store the number of total opened connections Could be NULL if not needed.

Function

int TCPIP_HTTP_ActiveConnectionCountGet(int* pOpenCount);

TCPIP_HTTP_CurrentConnectionHandleGet Function

Gets the connection handle of a HTTP connection.

File

http.h

C

```
HTTP_CONN_HANDLE TCPIP_HTTP_CurrentConnectionHandleGet(int connIx);
```

Returns

A valid connection handle if the connection index is valid 0 if there is no such connection

Description

This function will return the connection handle of the requested HTTP connection index.

Remarks

None

Preconditions

None.

Example

```
HTTP_CONN_HANDLE connHandle;

connHandle = TCPIP_HTTP_CurrentConnectionHandleGet(0);
```

Parameters

Parameters	Description
connIx	the HTTP connection ix.

Function

HTTP_CONN_HANDLE TCPIP_HTTP_CurrentConnectionHandleGet(int connIx);

TCPIP_HTTP_CurrentConnectionIndexGet Function

Gets the index of the HTTP connection.

File

http.h

C

```
int TCPIP_HTTP_CurrentConnectionIndexGet(HTTP_CONN_HANDLE connHandle);
```

Returns

The connection index.

Description

This function will return the index of the requested HTTP connection.

Remarks

None

Preconditions

None.

Example

```
int connIx;

connIx = TCPIP_HTTP_CurrentConnectionIndexGet(connHandle);
```

Parameters

Parameters	Description
connHandle	the HTTP connection handle.

Function

int TCPIP_HTTP_CurrentConnectionIndexGet(HTTP_CONN_HANDLE connHandle);

b) Data Types and Constants

HTTP_CONN_HANDLE Type

File

http.h

C

```
typedef const void* HTTP_CONN_HANDLE;
```

Description

HTTP connection identifier, handle of a HTTP connection

HTTP_FILE_TYPE Enumeration

File

http.h

C

```
typedef enum {
  HTTP_TXT = 0u,
  HTTP_HTM,
  HTTP_HTML,
  HTTP_CGI,
  HTTP_XML,
  HTTP_CSS,
  HTTP_GIF,
  HTTP_PNG,
  HTTP_JPG,
  HTTP_JS,
  HTTP_JAVA,
  HTTP_WAV,
  HTTP_UNKNOWN
} HTTP_FILE_TYPE;
```

Members

Members	Description
HTTP_TXT = 0u	File is a text document
HTTP_HTM	File is HTML (extension .htm)
HTTP_HTML	File is HTML (extension .html)
HTTP_CGI	File is HTML (extension .cgi)
HTTP_XML	File is XML (extension .xml)
HTTP_CSS	File is stylesheet (extension .css)
HTTP_GIF	File is GIF image (extension .gif)
HTTP_PNG	File is PNG image (extension .png)
HTTP_JPG	File is JPG image (extension .jpg)
HTTP_JS	File is java script (extension .js)
HTTP_JAVA	File is java (extension .class)
HTTP_WAV	File is audio (extension .wav)
HTTP_UNKNOWN	File type is unknown

Description

File type definitions

HTTP_IO_RESULT Enumeration

File

http.h

C

```
typedef enum {
  HTTP_IO_DONE = 0u,
  HTTP_IO_NEED_DATA,
  HTTP_IO_WAITING
} HTTP_IO_RESULT;
```

Members

Members	Description
HTTP_IO_DONE = 0u	Finished with procedure
HTTP_IO_NEED_DATA	More data needed to continue, call again later
HTTP_IO_WAITING	Waiting for asynchronous process to complete, call again later

Description

Result states for execution callbacks

HTTP_MODULE_FLAGS Enumeration

File

http.h

C

```
typedef enum {
  HTTP_MODULE_FLAG_DEFAULT = 0x00,
  HTTP_MODULE_FLAG_ADJUST_SKT_FIFOS = 0x01,
  HTTP_MODULE_FLAG_NO_DELAY = 0x02
} HTTP_MODULE_FLAGS;
```

Members

Members	Description
HTTP_MODULE_FLAG_DEFAULT = 0x00	Default flags value
HTTP_MODULE_FLAG_ADJUST_SKT_FIFOS = 0x01	Adjust corresponding socket FIFO at run time. Improves throughput when the socket buffers are small.
HTTP_MODULE_FLAG_NO_DELAY = 0x02	Create the HTTP sockets with NO-DELAY option. It will flush data as soon as possible.

Description

HTTP module configuration flags Multiple flags can be OR-ed

HTTP_READ_STATUS Enumeration

File

http.h

C

```
typedef enum {
  HTTP_READ_OK = 0u,
  HTTP_READ_TRUNCATED,
  HTTP_READ_INCOMPLETE
} HTTP_READ_STATUS;
```

Members

Members	Description
HTTP_READ_OK = 0u	Read was successful
HTTP_READ_TRUNCATED	Buffer overflow prevented by truncating value
HTTP_READ_INCOMPLETE	Entire object is not yet in the buffer. Try again later.

Description

Result states for TCPIP_HTTP_PostNameRead, TCPIP_HTTP_PostValueRead and TCPIP_HTTP_PostReadPair

HTTP_STATUS Enumeration

File

http.h

C

```
typedef enum {
  HTTP_GET = 0u,
  HTTP_POST,
  HTTP_BAD_REQUEST,
  HTTP_UNAUTHORIZED,
  HTTP_NOT_FOUND,
  HTTP_OVERFLOW,
  HTTP_INTERNAL_SERVER_ERROR,
  HTTP_NOT_IMPLEMENTED,
  HTTP_REDIRECT,
  HTTP_SSL_REQUIRED,
  HTTP_MPFS_FORM,
  HTTP_MPFS_UP,
  HTTP_MPFS_OK,
  HTTP_MPFS_WAIT,
  HTTP_MPFS_ERROR
} HTTP_STATUS;
```

Members

Members	Description
HTTP_GET = 0u	GET command is being processed
HTTP_POST	POST command is being processed
HTTP_BAD_REQUEST	400 Bad Request will be returned
HTTP_UNAUTHORIZED	401 Unauthorized will be returned
HTTP_NOT_FOUND	404 Not Found will be returned
HTTP_OVERFLOW	414 Request-URI Too Long will be returned
HTTP_INTERNAL_SERVER_ERROR	500 Internal Server Error will be returned
HTTP_NOT_IMPLEMENTED	501 Not Implemented (not a GET or POST command)
HTTP_REDIRECT	302 Redirect will be returned
HTTP_SSL_REQUIRED	403 Forbidden is returned, indicating SSL is required
HTTP_MPFS_FORM	Show the MPFS Upload form

HTTP_MPFS_UP	An MPFS Upload is being processed
HTTP_MPFS_OK	An MPFS Upload was successful
HTTP_MPFS_WAIT	An MPFS Upload waiting for the write operation to complete
HTTP_MPFS_ERROR	An MPFS Upload was not a valid image

Description

Supported Commands and Server Response Codes

TCPIP_HTTP_MODULE_CONFIG Structure

File

http.h

C

```
typedef struct {
  uint16_t nConnections;
  uint16_t nTlsConnections;
  uint16_t dataLen;
  uint16_t sktTxBuffSize;
  uint16_t sktRxBuffSize;
  uint16_t tlsSktTxBuffSize;
  uint16_t tlsSktRxBuffSize;
  uint16_t configFlags;
} TCPIP_HTTP_MODULE_CONFIG;
```

Members

Members	Description
uint16_t nConnections;	number of simultaneous HTTP connections allowed
uint16_t nTlsConnections;	Not used in the current implementation; Number of simultaneous HTTPS connections allowed
uint16_t dataLen;	size of the data buffer for reading cookie and GET/POST arguments (bytes)
uint16_t sktTxBuffSize;	size of TX buffer for the associated socket; leave 0 for default
uint16_t sktRxBuffSize;	size of RX buffer for the associated socket; leave 0 for default
uint16_t tlsSktTxBuffSize;	Not used in the current implementation; Size of TLS TX buffer for the associated socket; leave 0 for default (min 512 bytes)
uint16_t tlsSktRxBuffSize;	Not used in the current implementation; Size of TLS RX buffer for the associated socket; leave 0 for default (min 512 bytes)
uint16_t configFlags;	a HTTP_MODULE_FLAGS value.

Description

HTTP module dynamic configuration data

Files

Files

Name	Description
http.h	The HTTP web server module together with a file system (SYS_FS) allow the board to act as a web server.
http_config.h	HTTP configuration file

Description

This section lists the source and header files used by the library.

http.h

The HTTP web server module together with a file system (SYS_FS) allow the board to act as a web server.

Enumerations

	Name	Description
	HTTP_FILE_TYPE	File type definitions

	HTTP_IO_RESULT	Result states for execution callbacks
	HTTP_MODULE_FLAGS	HTTP module configuration flags Multiple flags can be OR-ed
	HTTP_READ_STATUS	Result states for TCPIP_HTTP_PostNameRead, TCPIP_HTTP_PostValueRead and TCPIP_HTTP_PostReadPair
	HTTP_STATUS	Supported Commands and Server Response Codes

Functions

	Name	Description
	TCPIP_HTTP_ActiveConnectionCountGet	Gets the number of active connections.
	TCPIP_HTTP_ArgGet	Locates a form field value in a given data array.
	TCPIP_HTTP_CurrentConnectionByteCountDec	Decrements the connection byte count.
	TCPIP_HTTP_CurrentConnectionByteCountGet	Returns how many bytes have been read so far
	TCPIP_HTTP_CurrentConnectionByteCountSet	Sets how many bytes have been read so far.
	TCPIP_HTTP_CurrentConnectionCallbackPosGet	Returns the callback position indicator.
	TCPIP_HTTP_CurrentConnectionCallbackPosSet	Sets the callback position indicator.
	TCPIP_HTTP_CurrentConnectionDataBufferGet	Returns pointer to connection general purpose data buffer.
	TCPIP_HTTP_CurrentConnectionFileGet	Get handle to current connection's file.
	TCPIP_HTTP_CurrentConnectionHandleGet	Gets the connection handle of a HTTP connection.
	TCPIP_HTTP_CurrentConnectionHasArgsGet	Checks whether there are get or cookie arguments.
	TCPIP_HTTP_CurrentConnectionHasArgsSet	Sets whether there are get or cookie arguments.
	TCPIP_HTTP_CurrentConnectionIndexGet	Gets the index of the HTTP connection.
	TCPIP_HTTP_CurrentConnectionIsAuthorizedGet	Gets the authorized state for the current connection.
	TCPIP_HTTP_CurrentConnectionIsAuthorizedSet	Sets the authorized state for the current connection.
	TCPIP_HTTP_CurrentConnectionPostSmGet	Get the POST state machine state.
	TCPIP_HTTP_CurrentConnectionPostSmSet	Set the POST state machine state.
	TCPIP_HTTP_CurrentConnectionSocketGet	Get the socket for the current connection.
	TCPIP_HTTP_CurrentConnectionStatusGet	Gets HTTP status.
	TCPIP_HTTP_CurrentConnectionStatusSet	Sets HTTP status.
	TCPIP_HTTP_CurrentConnectionUserDataGet	Gets the user data parameter for the current connection.
	TCPIP_HTTP_CurrentConnectionUserDataSet	Sets the user data parameter for the current connection.
	TCPIP_HTTP_FileAuthenticate	Determines if a given file name requires authentication
	TCPIP_HTTP_FileInclude	Writes a file byte-for-byte to the currently loaded TCP socket.
	TCPIP_HTTP_GetExecute	Processes GET form field variables and cookies.
	TCPIP_HTTP_PostExecute	Processes POST form variables and data.
	TCPIP_HTTP_PostNameRead	Reads a name from a URL encoded string in the TCP buffer.
	TCPIP_HTTP_PostValueRead	Reads a value from a URL encoded string in the TCP buffer.
	TCPIP_HTTP_Print_varname	Inserts dynamic content into a web page
	TCPIP_HTTP_Task	Standard TCP/IP stack module task function.
	TCPIP_HTTP_URLDecode	Parses a string from URL encoding to plain-text.
	TCPIP_HTTP_UserAuthenticate	Performs validation on a specific user name and password.

Macros

	Name	Description
	TCPIP_HTTP_PostReadPair	Reads a name and value pair from a URL encoded string in the TCP buffer.

Structures

	Name	Description
	TCPIP_HTTP_MODULE_CONFIG	HTTP module dynamic configuration data

Types

	Name	Description
	HTTP_CONN_HANDLE	HTTP connection identifier, handle of a HTTP connection

Description

HTTP Headers for Microchip TCP/IP Stack

The HTTP module runs a web server within the TCP/IP stack. This facilitates an easy method to view status information and control applications

using any standard web browser.

File Name

http.h

Company

Microchip Technology Inc.

http_config.h

HTTP configuration file

Macros

	Name	Description
	TCPIP_HTTP_CACHE_LEN	Max lifetime (sec) of static responses as string
	TCPIP_HTTP_CONFIG_FLAGS	Define the HTTP module configuration flags Use 0 for default See HTTP_MODULE_FLAGS definition for possible values
	TCPIP_HTTP_DEFAULT_FILE	Indicate what HTTP file to serve when no specific one is requested
	TCPIP_HTTP_DEFAULT_LEN	For buffer overrun protection. Set to longest length of above two strings.
	TCPIP_HTTP_FILE_UPLOAD_ENABLE	Configure MPFS over HTTP updating Comment this line to disable updating via HTTP
	TCPIP_HTTP_FILE_UPLOAD_NAME	This is macro TCPIP_HTTP_FILE_UPLOAD_NAME.
	TCPIP_HTTP_MAX_CONNECTIONS	Maximum numbers of simultaneous supported HTTP connections.
	TCPIP_HTTP_MAX_DATA_LEN	Define the maximum data length for reading cookie and GET/POST arguments (bytes)
	TCPIP_HTTP_MAX_HEADER_LEN	Set to length of longest string above
	TCPIP_HTTP_MIN_CALLBACK_FREE	Define the minimum number of bytes free in the TX FIFO before executing callbacks
	TCPIP_HTTP_NO_AUTH_WITHOUT_SSL	Uncomment to require secure connection before requesting a password
	TCPIP_HTTP_SKT_RX_BUFF_SIZE	Define the size of the RX buffer for the HTTP socket Use 0 for default TCP socket value The default recommended value for high throughput is > 2MSS (3 KB). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput.
	TCPIP_HTTP_SKT_TX_BUFF_SIZE	Define the size of the TX buffer for the HTTP socket Use 0 for default TCP socket value The default recommended value for high throughput is > 2MSS (3 KB). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput.
	TCPIP_HTTP_TASK_RATE	The HTTP task rate, ms The default value is 33 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_HTTP_TIMEOUT	Max time (sec) to await more data before timing out and disconnecting the socket
	TCPIP_HTTP_USE_AUTHENTICATION	Enable basic authentication support
	TCPIP_HTTP_USE_COOKIES	Enable cookie support
	TCPIP_HTTP_USE_POST	Define which HTTP modules to use If not using a specific module, comment it to save resources Enable POST support
	TCPIP_HTTPS_DEFAULT_FILE	Indicate what HTTPS file to serve when no specific one is requested
	TCPIP_STACK_USE_BASE64_DECODE	Authentication requires Base64 decoding Enable basic authentication support

HTTP Net Module

This section describes the TCP/IP Stack Library HTTP Net Module.

Introduction

TCP/IP Stack Library Hypertext Transfer Protocol (HTTP) Net Module for Microchip Microcontrollers

This library provides the API of the HTTP Net Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

The HTTP Net Web Server module allows a development board to act as a Web server. This facilitates an easy method to view status information and control applications using any standard Web browser. It uses the Networking Presentation Layer to integrate with an external encryption services provider (usually wolfSSL) allowing for secure connections.

Using the Library

This topic describes the basic architecture of the HTTP Net TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `http_net.h`

The interface to the HTTP Net TCP/IP Stack library is defined in the `http_net.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the HTTP Net TCP/IP Stack library should include `tcpip.h`.

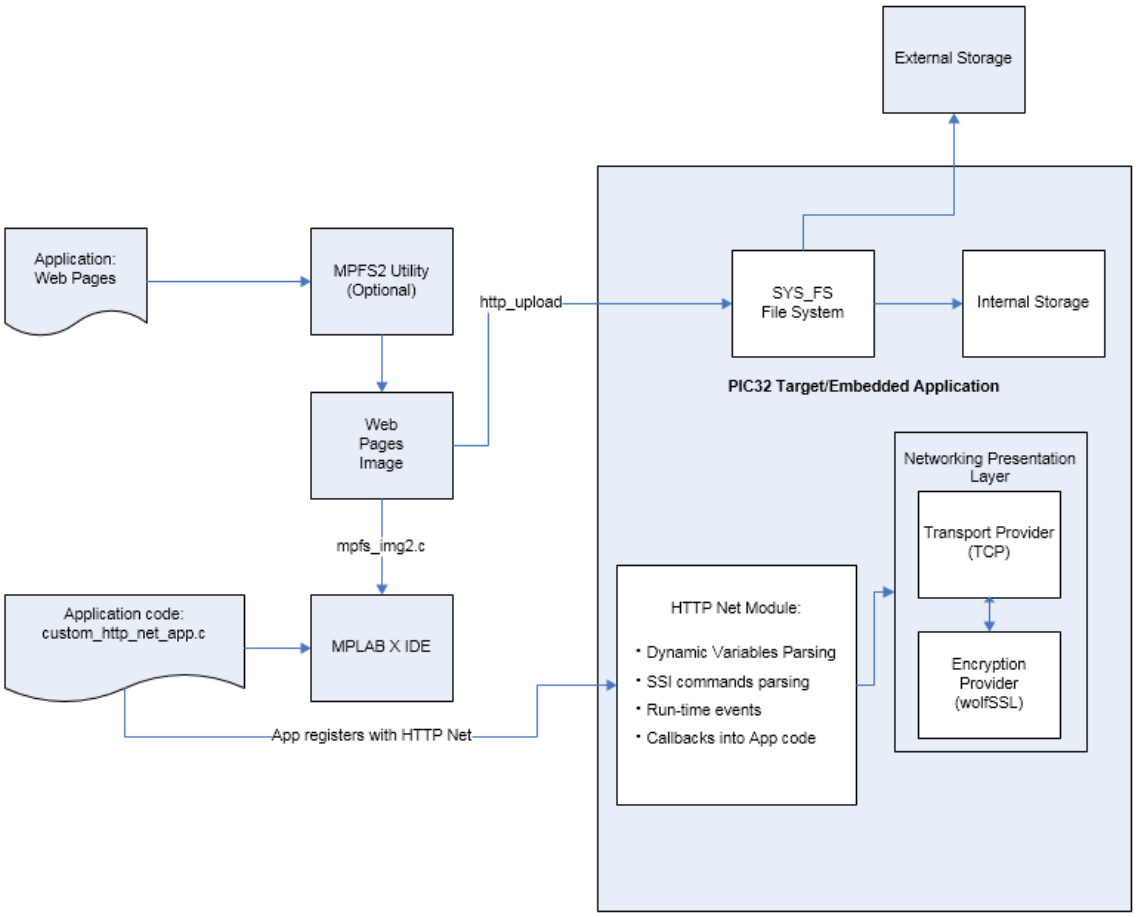
Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

This library provides the API of the HTTP Net TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

HTTP Net Software Abstraction Block Diagram



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the HTTP Net module.

Library Interface Section	Description
Functions	This section provides functions for configuring the HTTP Net module.
Data Types and Constants	This section provides various definitions describing this API.

HTTP Net Features

Lists the features of the HTTP Net module.

Description

The HTTP Net module is a HTTP server module that works using the Networking Presentation Layer of the MPLAB Harmony framework. This allows it to support both encrypted and plain text connections.

Some of the key features of the HTTP Net module include:

- The updated module implements HTTP 1.1 persistent connections by default, using the “Transfer-Encoding: chunked” HTTP header. It can be configured to operate with closing the connections like the previous HTTP server.
- The application has to dynamically register its HTTP processing functions with the HTTP Net server using the TCPIP_HTTP_NET_UserHandlerRegister call. The HTTP Net server no longer relies on well known function names.
- The HTTP Net server supports either secure or plain text connections, but not both simultaneously. The specification of a secure or non-secure connection can be easily done by:
- Selecting the server listening port: 80 or 443
- Using the module configuration flags
- The HTTP Net module reports run-time events that could be caught by the user application using the “eventReport” registered function that carries a TCPIP_HTTP_NET_EVENT_TYPE enumerated type

Dynamic Variables Processing

Describes dynamic variable processing.

Description

Parsing of the dynamic variables is done at run-time. The web pages could be changed at run-time, without the need for rebuilding the HTTP Net server. This allows the TCP/IP Stack to run as a library and only the application code to be changed accordingly. The application is required to register a “dynamicPrint” with the HTTP Net server. This function will be called at run-time to process the dynamic variables.

The supported syntax is `~var_name(param1, param2, …)~`. When parsing a string like this within a web page, the HTTP Net server will invoke the “dynamicPrint” function using a TCPIP_HTTP_DYN_VAR_DCPT data structure that specifies the dynamic variable name, its number and type of parameters as well as each parameter value.

For example, the variable `~myVariable(2,6)~` will generate the “dynamicPrint” call with the following parameters:

- `varDcpt.dynName = "myVariable";`
- `varDcpt.nArgs = 2;`
- `varDcpt.dynArgs->argType = TCPIP_HTTP_DYN_ARG_TYPE_INT32;`
- `varDcpt.dynArgs->argInt32 = 2;`
- `(varDcpt.dynArgs + 1)->argType = TCPIP_HTTP_DYN_ARG_TYPE_INT32;`
- `(varDcpt.dynArgs + 1)->argInt32 = 6;`

String and int32_t variable types are currently supported.

The application needs to return a TCPIP_HTTP_DYN_PRINT_RES result specifying if it’s done with processing or it needs to be called again.

Applications no longer have direct access to the underlying transport socket for a HTTP connection. All of the data write operations need to go through the required API function: TCPIP_HTTP_NET_DynamicWrite. This function actually just attaches the data to be written to the connection, using data descriptors. The actual output occurs only when all data is gathered and the data size is known.

Buffers used in a TCPIP_HTTP_NET_DynamicWrite need to be persistent until the moment when the output is generated. RAM buffers are supported by using a “dynamicAck” (TCPIP_HTTP_NET_DynAcknowledge) type function. Once the output operation is completed the HTTP Net module will call back into the application indicating that the corresponding buffer is no longer used and can be freed/reused.

In situations where the dynamic variable print function needs to perform additional write operations, or simply needs to be called again, it must a special result code: TCPIP_HTTP_DYN_PRINT_RES_PROCESS_AGAIN/TCPIP_HTTP_DYN_PRINT_RES_AGAIN. Typically this is used when outputting large amounts of data that cannot fit into one single buffer write operation or when the data is not available all at once.

Include Files Processing

Provides information on include file processing.

Description

The HTTP Net module dynamically parses the web pages and the file inclusion is done by the module itself, completely transparent for the application.

File Processing

Provides information on file processing.

Description

File processing consists of the following:

- An included file can include other files that have dynamic variables
- Application can include a file as part of its dynamic variable processing using the TCPIP_HTTP_NET_ConnectionFileInclude()API. That file can include other files.
- The only limit to the depth of inclusion is the memory resources and the TCPIP_HTTP_NET_MODULE_CONFIG:: maxRecurseLevel setting. A TCPIP_HTTP_NET_EVENT_DEPTH_ERROR event will be generated if the maximum depth is exceeded at run-time.

SSI Processing

Provides information on SSI processing.

Description

At run-time, the HTTP Net server processes a subset of the Server Side Includes (SSI) commands. SSI is a portable way to add small amounts of dynamic content on web pages in a standard way that is supported by most HTTP servers. Currently the `#include`, `#set` and `#echo` commands are supported. Other commands will be eventually added. This allows a better compatibility with other existing HTTP servers and is targeted at the removal of proprietary extensions.

Whenever executing an SSI command within a web page, the HTTP Net server will notify the application by using the registered SSI callback: `ssiNotify`. This callback contains a TCPIP_HTTP_SSI_NOTIFY_DCPT pointer to a structure describing the SSI context needed for processing:

- File name the SSI command belongs to
- The SSI command line
- Number of SSI attributes and their values, etc.

The application can do any modifications it chooses to and returns a value instructing the HTTP Net server if the processing of the command is necessary or not.

SSI include Command

The SSI Include command allows the dynamic inclusion of a file. The supported syntax is:

`<!--#include virtual="file_name" -->` or `<!--#include file="file_name" -->`.

Currently the arguments for both “virtual” and “file” commands are passed unaltered to the SYS_FS, so they behave identically. However it is recommended that the original SSI significance for these keywords should be maintained:

- Use “virtual” for specifying a URL relative to the document being server
- Use “file” for a file path, relative to the current directory (it cannot be an absolute path)

The `~inc:file_name~` keyword is maintained for backward compatibility. However the SSI include command should be preferred.

SSI set Command

The SSI `set` command allows to dynamically set a SSI variable value. The supported syntax is:

`<!--#set var="v_name" value="v_value" -->`.

String or integer variables are supported. Variable reference is also supported: `<!--#set var="n_name" value="$otherVar" -->`. This command will create or update the variable `n_name` to have the value of the variable `otherVar`, if it exists.

A new SSI variable will be created if a variable having the name `v_name` does not exist. If the variable `v_name` already exists, it will have its value updated as the result of this command.

An existing variable can be deleted using the empty value set command:

`<!--#set var="v_name" value="" -->`.

SSI echo Command

The SSI `echo` command allows the dynamic print of a SSI variable. The supported syntax is:

`<!--#echo var="v_name" -->`.

If the application `ssiNotify` exists, the HTTP Net server will call it and the application may choose to change the current value dynamically. If `ssiNotify` returns false, the HTTP Net server will display the current value of the variable `v_name` as part of the current page.

The SSI API can be used to evaluate or change the current value of the SSI variables:

- TCPIP_HTTP_NET_SSIVariableGet
- TCPIP_HTTP_NET_SSIVariableSet
- TCPIP_HTTP_NET_SSIVariableDelete

The maximum number of SSI variables is under the control of the application by using the configuration parameter: TCPIP_HTTP_NET_SSI_VARIABLES_NUMBER.

mpfs2.jar Utility

Provides information on the option mpfs2 utility.

Description

Dynamic Variable Processing

The HTTP Net server does not use the `DynRecord.bin` and `FileRcrd.bin` files for processing the dynamic variables. The parsing and processing of dynamic variables is done at run-time. Therefore, the mpfs2.jar utility is no longer necessary, other than to generate a `mpfs_img2.c` image file for the NVM MPFS image.

Application Custom Support Files

The application custom support files generated with MHC have new names: `custom_http_net_app.c` and `http_net_print.c`. However, the `http_net_print.c` file is not generated by the mpfs2 utility and is maintained only for easy comparison between HTTP and HTTP Net application processing. The `custom_http_net_app.c` file is entirely generated using a MHC template file and it is not dynamically updated in any way by the mpfs2 utility.

Generated File Name

Currently the name of the generated file for MPFS image is maintained unchanged: `mpfs_img2.c`.

MPFS Image Generation for Internal NVM Storage

The mpfs2 utility can still be used to generate the MPFS image for internal NVM storage. It can also be useful because it parses the web pages and comes out with the `http_print.c` file that contains the list of TCPIP_HTTP_Print functions. This can be helpful in gathering info about the dynamic variables that are contained within the web pages.

Note: For demonstration applications that use SSI, the file inclusion is now done in a standard way using HTML (i.e., `.htm`) files. Therefore, when generating the image, `*.htm` must be added to *Advanced Settings* > *Do Not Compress*.

Configuring the Library

Macros

	Name	Description
	TCPIP_HTTP_NET_CACHE_LEN	Max lifetime (sec) of static responses as string
	TCPIP_HTTP_NET_CONFIG_FLAGS	Define the HTTP module configuration flags Use 0 for default See HTTP_MODULE_FLAGS definition for possible values
	TCPIP_HTTP_NET_COOKIE_BUFFER_SIZE	Size of the buffer used for sending the cookies to the client. Should be able to accommodate the longest cookie response. Otherwise the cookies will be truncated.
	TCPIP_HTTP_NET_DEFAULT_FILE	Indicate what HTTP file to serve when no specific one is requested
	TCPIP_HTTP_NET_DYNVAR_ARG_MAX_NUMBER	maximum number of arguments for a dynamic variable
	TCPIP_HTTP_NET_DYNVAR_DESCRIPTORS_NUMBER	how many buffers descriptors for dynamic variable processing they are independent of the HTTP connection number all the HTTP connections use from the dynamic descriptors pool
	TCPIP_HTTP_NET_DYNVAR_MAX_LEN	maximum size for a complete dynamic variable: name + args must be <= TCPIP_HTTP_NET_FILE_PROCESS_BUFFER_SIZE! If it is much larger than needed then inefficiency occurs when reading data from the file and then discarding it because a much larger than needed data buffer was read
	TCPIP_HTTP_NET_FILE_UPLOAD_ENABLE	Configure MPFS over HTTP updating Comment this line to disable updating via HTTP
	TCPIP_HTTP_NET_FILE_UPLOAD_NAME	This is macro TCPIP_HTTP_NET_FILE_UPLOAD_NAME.

	TCPIP_HTTP_NET_FIND_PEEK_BUFF_SIZE	Size of the peek buffer to perform searches into. If the underlying transport layer supports offset peak operation with a offset, value could be smaller (80 characters, for example); otherwise, a one time peek is required and the buffer should be larger - 512 bytes recommended.
	TCPIP_HTTP_NET_MAX_CONNECTIONS	Maximum numbers of simultaneous supported HTTP connections.
	TCPIP_HTTP_NET_MAX_DATA_LEN	Define the maximum data length for reading cookie and GET/POST arguments (bytes)
	TCPIP_HTTP_NET_MAX_HEADER_LEN	The length of longest header string that can be parsed
	TCPIP_HTTP_NET_MAX_RECURSE_LEVEL	The maximum depth of recursive calls for serving a web page: • no dynvars files: 1 • file including a file: 2 • if the include file includes another file: +1 • if a dyn variable: +1 Default value is 3;
	TCPIP_HTTP_NET_RESPONSE_BUFFER_SIZE	Size of the buffer used for sending the response messages to the client. Should be able to accommodate the longest server response: Default setting should be 300 bytes
	TCPIP_HTTP_NET_SKT_RX_BUFF_SIZE	Define the size of the RX buffer for the HTTP socket Use 0 for default TCP socket value The default recommended value for high throughput is > 2MSS (3 KB). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput.
	TCPIP_HTTP_NET_SKT_TX_BUFF_SIZE	Define the size of the TX buffer for the HTTP socket Use 0 for default TCP socket value The default recommended value for high throughput is > 2MSS (3 KB). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput.
	TCPIP_HTTP_NET_TASK_RATE	The HTTP task rate, ms The default value is 33 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_HTTP_NET_TIMEOUT	Max time (sec) to await more data before timing out and disconnecting the socket
	TCPIP_HTTP_NET_USE_AUTHENTICATION	Enable basic authentication support
	TCPIP_HTTP_NET_USE_COOKIES	Enable cookie support
	TCPIP_HTTP_NET_USE_POST	Define which HTTP modules to use If not using a specific module, comment it to save resources Enable POST support
	TCPIP_HTTP_NET_CHUNK_RETRIES	retry limit for allocating a chunk from the pool If more retries are not successful the operation will be aborted
	TCPIP_HTTP_NET_CHUNKS_NUMBER	number of chunks that are created It depends on the TCPIP_HTTP_NET_MAX_RECURSE_LEVEL and on the number of connections Maximum number should be TCPIP_HTTP_NET_MAX_CONNECTIONS * TCPIP_HTTP_NET_MAX_RECURSE_LEVEL i.e. TCPIP_HTTP_NET_MODULE_CONFIG::nConnections * TCPIP_HTTP_NET_MODULE_CONFIG::nChunks All the chunks are in a pool and are used by all connections
	TCPIP_HTTP_NET_DYNVAR_PROCESS	This symbol enables the processing of dynamic variables Make it evaluate to false (0) if dynamic variables are not needed All the following symbols referring to dynamic variables are relevant only when TCPIP_HTTP_NET_DYNVAR_PROCESS != 0
	TCPIP_HTTP_NET_DYNVAR_PROCESS_RETRIES	retry limit for a dynamic variable processing ths puts a limit on the number of times a dynamic variable "dynamicPrint" function can return TCPIP_HTTP_DYN_PRINT_RES_AGAIN/TCPIP_HTTP_DYN_PRINT_RES_PROCESS_AGAIN and avoids having the HTTP code locked up forever. If more retries are attempted the processing will be considered done and dynamicPrint function will not be called again
	TCPIP_HTTP_NET_FILE_PROCESS_BUFFER_RETRIES	Retry limit for allocating a file buffer from the pool. If more retries are not successful the operation will be aborted.

	TCPIP_HTTP_NET_FILE_PROCESS_BUFFER_SIZE	Size of the buffer used for processing HTML, dynamic variable and binary files. For dynamic variable files it should be able to accommodate the longest HTML line size, including CRLF!
	TCPIP_HTTP_NET_FILE_PROCESS_BUFFERS_NUMBER	Number of file buffers to be created; These buffers are used to store data while file processing is done They are organized in a pool Each file being processed needs a file buffer and tries to get it from the pool If a buffer is not available, the HTTP conenction will wait for one to become available. Once the file is done the file buffer is released and could be used by a different file The number depends on the number of files that are processed in parallel To avoid deadlock the number should be >= than the number of... more
	TCPIP_HTTP_NET_FILENAME_MAX_LEN	maximum size of a HTTP file name with the path removed from the file name one extra char added for the string terminator
	TCPIP_HTTP_NET_SSI_ATTRIBUTES_MAX_NUMBER	maximum number of attributes for a SSI command most SSI commands take just one attribute/value pair per line but multiple attribute/value pairs on the same line are allowed where it makes sense
	TCPIP_HTTP_NET_SSI_CMD_MAX_LEN	maximum size for a SSI command line: command + attribute/value pairs must be <= TCPIP_HTTP_NET_FILE_PROCESS_BUFFER_SIZE! If it is much larger than needed then inefficiency occurs when reading data from the file and then discarding it because a much larger than needed data buffer was read
	TCPIP_HTTP_NET_SSI_ECHO_NOT_FOUND_MESSAGE	message to echo when echoing a not found variable
	TCPIP_HTTP_NET_SSI_PROCESS	This symbol enables the processing of SSI commands Make it evaluate to false (0) if SSI commands are not needed All the following symbols referring to SSI commands are relevant only when TCPIP_HTTP_NET_SSI_PROCESS != 0
	TCPIP_HTTP_NET_SSI_STATIC_ATTTRIB_NUMBER	number of static attributes associated to a SSI command if the command has more attributes than this number the excess will be allocated dynamically
	TCPIP_HTTP_NET_SSI_VARIABLE_NAME_MAX_LENGTH	maximum length of a SSI variable name any excess characters will be truncated Note that this can result in multiple variables being represented as one SSI variable
	TCPIP_HTTP_NET_SSI_VARIABLE_STRING_MAX_LENGTH	maximum size of a SSI string variable value any excess characters will be truncated Note that the variable value requires SSI storage that's allocated dynamically Also, this value determines the size of an automatic (stack) buffer when the variable is echoed. If this value is large, make sure you have enough stack space.
	TCPIP_HTTP_NET_SSI_VARIABLES_NUMBER	maximum number of SSI variables that can be created at run time These variables are stored in an internal hash. For max. efficiency this number should be a prime.

Description

The configuration of the HTTP Net TCP/IP Stack is based on the file `tcpip_config.h` (which may include `http_net_config.h`).

This header file contains the configuration selection for the HTTP Net TCP/IP Stack. Based on the selections made, the HTTP Net TCP/IP Stack may support the selected features.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_HTTP_NET_CACHE_LEN Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_CACHE_LEN ("600")
```

Description

Max lifetime (sec) of static responses as string

TCPIP_HTTP_NET_CONFIG_FLAGS Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_CONFIG_FLAGS 0
```

Description

Define the HTTP module configuration flags Use 0 for default See HTTP_MODULE_FLAGS definition for possible values

TCPIP_HTTP_NET_COOKIE_BUFFER_SIZE Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_COOKIE_BUFFER_SIZE 200
```

Description

Size of the buffer used for sending the cookies to the client. Should be able to accommodate the longest cookie response. Otherwise the cookies will be truncated.

TCPIP_HTTP_NET_DEFAULT_FILE Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_DEFAULT_FILE "index.htm"
```

Description

Indicate what HTTP file to serve when no specific one is requested

TCPIP_HTTP_NET_DYNVAR_ARG_MAX_NUMBER Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_DYNVAR_ARG_MAX_NUMBER 10
```

Description

maximum number of arguments for a dynamic variable

TCPIP_HTTP_NET_DYNVAR_DESCRIPTORS_NUMBER Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_DYNVAR_DESCRIPTORS_NUMBER 10
```

Description

how many buffers descriptors for dynamic variable processing they are independent of the HTTP connection number all the HTTP connections use from the dynamic descriptors pool

TCPIP_HTTP_NET_DYNVAR_MAX_LEN Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_DYNVAR_MAX_LEN 50
```

Description

maximum size for a complete dynamic variable: name + args must be <= TCPIP_HTTP_NET_FILE_PROCESS_BUFFER_SIZE! If it is much larger than needed then inefficiency occurs when reading data from the file and then discarding it because a much larger than needed data buffer was read

TCPIP_HTTP_NET_FILE_UPLOAD_ENABLE Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_FILE_UPLOAD_ENABLE
```

Description

Configure MPFS over HTTP updating Comment this line to disable updating via HTTP

TCPIP_HTTP_NET_FILE_UPLOAD_NAME Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_FILE_UPLOAD_NAME "mpfsupload"
```

Description

This is macro TCPIP_HTTP_NET_FILE_UPLOAD_NAME.

TCPIP_HTTP_NET_FIND_PEEK_BUFF_SIZE Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_FIND_PEEK_BUFF_SIZE 512
```

Description

Size of the peek buffer to perform searches into. If the underlying transport layer supports offset peak operation with a offset, value could be smaller (80 characters, for example); otherwise, a one time peek is required and the buffer should be larger - 512 bytes recommended.

Remarks

if upload is enabled (TCPIP_HTTP_NET_FILE_UPLOAD_ENABLE) then it is recommended for the peek buffer size to match the size of the socket RX buffer: TCPIP_HTTP_NET_SKT_RX_BUFF_SIZE Note that this is an automatic buffer (created on the stack) and enough stack space should be provided for the application.

TCPIP_HTTP_NET_MAX_CONNECTIONS Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_MAX_CONNECTIONS (4)
```

Description

Maximum numbers of simultaneous supported HTTP connections.

TCPIP_HTTP_NET_MAX_DATA_LEN Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_MAX_DATA_LEN (100u)
```

Description

Define the maximum data length for reading cookie and GET/POST arguments (bytes)

TCPIP_HTTP_NET_MAX_HEADER_LEN Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_MAX_HEADER_LEN (15u)
```

Description

The length of longest header string that can be parsed

TCPIP_HTTP_NET_MAX_RECURSE_LEVEL Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_MAX_RECURSE_LEVEL 3
```

Description

The maximum depth of recursive calls for serving a web page:

- no dynvars files: 1
- file including a file: 2
- if the include file includes another file: +1
- if a dyn variable: +1

Default value is 3;

TCPIP_HTTP_NET_RESPONSE_BUFFER_SIZE Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_RESPONSE_BUFFER_SIZE 300
```

Description

Size of the buffer used for sending the response messages to the client. Should be able to accommodate the longest server response: Default setting should be 300 bytes

TCPIP_HTTP_NET_SKT_RX_BUFF_SIZE Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_SKT_RX_BUFF_SIZE 2048
```

Description

Define the size of the RX buffer for the HTTP socket Use 0 for default TCP socket value The default recommended value for high throughput is > 2MSS (3 KB). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput.

TCPIP_HTTP_NET_SKT_TX_BUFF_SIZE Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_SKT_TX_BUFF_SIZE 2048
```

Description

Define the size of the TX buffer for the HTTP socket Use 0 for default TCP socket value The default recommended value for high throughput is > 2MSS (3 KB). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput.

TCPIP_HTTP_NET_TASK_RATE Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_TASK_RATE 33
```

Description

The HTTP task rate, ms The default value is 33 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

TCPIP_HTTP_NET_TIMEOUT Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_TIMEOUT (45u)
```

Description

Max time (sec) to await more data before timing out and disconnecting the socket

TCPIP_HTTP_NET_USE_AUTHENTICATION Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_USE_AUTHENTICATION
```

Description

Enable basic authentication support

TCPIP_HTTP_NET_USE_COOKIES Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_USE_COOKIES
```

Description

Enable cookie support

TCPIP_HTTP_NET_USE_POST Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_USE_POST
```

Description

Define which HTTP modules to use If not using a specific module, comment it to save resources Enable POST support

TCPIP_HTTP_NET_CHUNK_RETRIES Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_CHUNK_RETRIES 10
```

Description

retry limit for allocating a chunk from the pool If more retries are not successful the operation will be aborted

TCPIP_HTTP_NET_CHUNKS_NUMBER Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_CHUNKS_NUMBER 10
```

Description

number of chunks that are created It depends on the TCPIP_HTTP_NET_MAX_RECURSE_LEVEL and on the number of connections Maximum number should be TCPIP_HTTP_NET_MAX_CONNECTIONS * TCPIP_HTTP_NET_MAX_RECURSE_LEVEL i.e. TCPIP_HTTP_NET_MODULE_CONFIG::nConnections * TCPIP_HTTP_NET_MODULE_CONFIG::nChunks All the chunks are in a pool and are used by all connections

TCPIP_HTTP_NET_DYNVAR_PROCESS Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_DYNVAR_PROCESS 1
```

Description

This symbol enables the processing of dynamic variables Make it evaluate to false (0) if dynamic variables are not needed All the following symbols referring to dynamic variables are relevant only when TCPIP_HTTP_NET_DYNVAR_PROCESS != 0

TCPIP_HTTP_NET_DYNVAR_PROCESS_RETRIES Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_DYNVAR_PROCESS_RETRIES 10
```

Description

retry limit for a dynamic variable processing ths puts a limit on the number of times a dynamic variable "dynamicPrint" function can return TCPIP_HTTP_DYN_PRINT_RES_AGAIN/TCPIP_HTTP_DYN_PRINT_RES_PROCESS_AGAIN and avoids having the HTTP code locked up forever. If more retries are attempted the processing will be considered done and dynamicPrint function will not be called again

TCPIP_HTTP_NET_FILE_PROCESS_BUFFER_RETRIES Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_FILE_PROCESS_BUFFER_RETRIES 10
```

Description

Retry limit for allocating a file buffer from the pool. If more retries are not successful the operation will be aborted.

TCPIP_HTTP_NET_FILE_PROCESS_BUFFER_SIZE Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_FILE_PROCESS_BUFFER_SIZE 512
```

Description

Size of the buffer used for processing HTML, dynamic variable and binary files. For dynamic variable files it should be able to accommodate the longest HTML line size, including CRLF!

TCPIP_HTTP_NET_FILE_PROCESS_BUFFERS_NUMBER Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_FILE_PROCESS_BUFFERS_NUMBER 4
```

Description

Number of file buffers to be created; These buffers are used to store data while file processing is done They are organized in a pool Each file being processed needs a file buffer and tries to get it from the pool If a buffer is not available, the HTTP conenction will wait for one to become available. Once the file is done the file buffer is released and could be used by a different file The number depends on the number of files that are processed in parallel To avoid deadlock the number should be >= than the number of maximum files that can be open simultaneously: i.e. for file1 ->include file2 -> include file3 you'll need >= 3 file process buffers

TCPIP_HTTP_NET_FILENAME_MAX_LEN Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_FILENAME_MAX_LEN 25
```

Description

maximum size of a HTTP file name with the path removed from the file name one extra char added for the string terminator

TCPIP_HTTP_NET_SSI_ATTRIBUTES_MAX_NUMBER Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_SSI_ATTRIBUTES_MAX_NUMBER 4
```

Description

maximum number of attributes for a SSI command most SSI commands take just one attribute/value pair per line but multiple attribute/value pairs on the same line are allowed where it makes sense

TCPIP_HTTP_NET_SSI_CMD_MAX_LEN Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_SSI_CMD_MAX_LEN 100
```

Description

maximum size for a SSI command line: command + attribute/value pairs must be <= TCPIP_HTTP_NET_FILE_PROCESS_BUFFER_SIZE! If it is much larger than needed then inefficiency occurs when reading data from the file and then discarding it because a much larger than needed data buffer was read

TCPIP_HTTP_NET_SSI_ECHO_NOT_FOUND_MESSAGE Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_SSI_ECHO_NOT_FOUND_MESSAGE "SSI Echo - Not Found: "
```

Description

message to echo when echoing a not found variable

TCPIP_HTTP_NET_SSI_PROCESS Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_SSI_PROCESS 1
```

Description

This symbol enables the processing of SSI commands Make it evaluate to false (0) if SSI commands are not needed All the following symbols referring to SSI commands are relevant only when TCPIP_HTTP_NET_SSI_PROCESS != 0

TCPIP_HTTP_NET_SSI_STATIC_ATTTRIB_NUMBER Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_SSI_STATIC_ATTTRIB_NUMBER 2
```

Description

number of static attributes associated to a SSI command if the command has more attributes than this number the excess will be allocated dynamically

TCPIP_HTTP_NET_SSI_VARIABLE_NAME_MAX_LENGTH Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_SSI_VARIABLE_NAME_MAX_LENGTH 10
```

Description

maximum length of a SSI variable name any excess characters will be truncated Note that this can result in multiple variables being represented as one SSI variable

TCPIP_HTTP_NET_SSI_VARIABLE_STRING_MAX_LENGTH Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_SSI_VARIABLE_STRING_MAX_LENGTH 10
```

Description

maximum size of a SSI string variable value any excess characters will be truncated Note that the variable value requires SSI storage that's allocated dynamically Also, this value determines the size of an automatic (stack) buffer when the variable is echoed. If this value is large, make sure you have enough stack space.

TCPIP_HTTP_NET_SSI_VARIABLES_NUMBER Macro

File

http_net_config.h

C

```
#define TCPIP_HTTP_NET_SSI_VARIABLES_NUMBER 13
```

Description

maximum number of SSI variables that can be created at run time These variables are stored in an internal hash. For max. efficiency this number should be a prime.

Building the Library

This section lists the files that are available in the HTTP Net TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
/tcpip.h	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/http_net.c	HTTP Server implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The HTTP Net module depends on the following modules:

- TCP/IP Stack Library
- TCP Module
- File System Service Library

Library Interface

a) Functions

	Name	Description
	TCPIP_HTTP_NET_ActiveConnectionCountGet	Gets the number of active (and inactive) connections.
	TCPIP_HTTP_NET_ConnectionByteCountDec	Decrements the connection byte count.
	TCPIP_HTTP_NET_ArgGet	Locates a form field value in a given data array.
	TCPIP_HTTP_NET_ConnectionByteCountSet	Sets how many bytes have been read so far.
	TCPIP_HTTP_NET_ConnectionByteCountGet	Returns how many bytes have been read so far.
	TCPIP_HTTP_NET_ConnectionCallbackPosSet	Sets the callback position indicator.
	TCPIP_HTTP_NET_ConnectionCallbackPosGet	Returns the callback position indicator.
	TCPIP_HTTP_NET_ConnectionDataBufferGet	Returns pointer to connection general purpose data buffer.
	TCPIP_HTTP_NET_ConnectionDiscard	Discards any pending data in the connection RX buffer.
	TCPIP_HTTP_NET_ConnectionFileAuthenticate	Determines if a given file name requires authentication
	TCPIP_HTTP_NET_ConnectionFileGet	Get handle to current connection's file.
	TCPIP_HTTP_NET_ConnectionFileInclude	Writes a file to the HTTP connection.
	TCPIP_HTTP_NET_ConnectionHasArgsGet	Checks whether there are get or cookie arguments.
	TCPIP_HTTP_NET_ConnectionFlush	Immediately transmits all connection pending TX data.
	TCPIP_HTTP_NET_ConnectionIsAuthorizedGet	Gets the authorized state for the current connection.
	TCPIP_HTTP_NET_ConnectionGetExecute	Processes GET form field variables and cookies.
	TCPIP_HTTP_NET_ConnectionPostNameRead	Reads a name from a URL encoded string in the network transport buffer.
	TCPIP_HTTP_NET_ConnectionHasArgsSet	Sets whether there are get or cookie arguments.
	TCPIP_HTTP_NET_ConnectionPostSmGet	Get the POST state machine state.
	TCPIP_HTTP_NET_ConnectionIsAuthorizedSet	Sets the authorized state for the current connection.
	TCPIP_HTTP_NET_ConnectionPostValueRead	Reads a value from a URL encoded string in the network transport buffer.
	TCPIP_HTTP_NET_ConnectionNetHandle	Returns the network handle of the current connection.
	TCPIP_HTTP_NET_ConnectionSocketGet	Get the socket for the current connection.
	TCPIP_HTTP_NET_ConnectionPeek	Reads a specified number of data bytes from the connection RX buffer without removing them from the buffer.
	TCPIP_HTTP_NET_ConnectionStatusGet	Gets HTTP status.
	TCPIP_HTTP_NET_ConnectionPostExecute	Processes POST form variables and data.

	TCPIP_HTTP_NET_ConnectionUserDataGet	Gets the user data parameter for the current connection.
	TCPIP_HTTP_NET_ConnectionPostSmSet	Set the POST state machine state.
	TCPIP_HTTP_NET_ConnectionRead	Reads an array of data bytes from a connection's RX buffer.
	TCPIP_HTTP_NET_ConnectionReadBufferSize	Returns the size of the connection RX buffer.
	TCPIP_HTTP_NET_ConnectionReadIsReady	Determines how many bytes can be read from the connection RX buffer.
	TCPIP_HTTP_NET_ConnectionStatusSet	Sets HTTP status.
	TCPIP_HTTP_NET_ConnectionStringFind	Helper to find a string of characters in an incoming connection buffer.
	TCPIP_HTTP_NET_ConnectionUserAuthenticate	Performs validation on a specific user name and password.
	TCPIP_HTTP_NET_ConnectionUserDataSet	Sets the user data parameter for the current connection.
	TCPIP_HTTP_NET_DynAcknowledge	Dynamic variable acknowledge function
	TCPIP_HTTP_NET_DynamicWrite	Writes a data buffer to the current connection
	TCPIP_HTTP_NET_DynamicWriteString	Helper for writing a string within a dynamic variable context.
	TCPIP_HTTP_NET_DynPrint	Inserts dynamic content into a web page
	TCPIP_HTTP_NET_EventReport	Reports an event that occurred in the processing of a HTTP web page
	TCPIP_HTTP_NET_Task	Standard TCP/IP stack module task function.
	TCPIP_HTTP_NET_URLDecode	Parses a string from URL encoding to plain text.
	TCPIP_HTTP_NET_UserHandlerDeregister	Deregisters a previously registered HTTP user handler.
	TCPIP_HTTP_NET_UserHandlerRegister	Registers a user callback structure with the HTTP server
	TCPIP_HTTP_NET_ConnectionDataBufferSizeGet	Returns the size of the connection general purpose data buffer.
	TCPIP_HTTP_NET_ConnectionDynamicDescriptors	Returns the number of dynamic variable descriptors
	TCPIP_HTTP_NET_SSINotification	Reports an SSI processing event that occurs in the processing of a HTTP web page
	TCPIP_HTTP_NET_SSIVariableDelete	Function to delete an SSI variable.
	TCPIP_HTTP_NET_SSIVariableGet	Function to get access to an existing SSI variable.
	TCPIP_HTTP_NET_SSIVariableGetByIndex	Function to get access to an existing SSI variable.
	TCPIP_HTTP_NET_SSIVariableSet	Function to set an SSI variable.
	TCPIP_HTTP_NET_SSIVariablesNumberGet	Function to get the number of the current SSI variables.
	TCPIP_HTTP_NET_ConnectionHandleGet	Gets the connection handle of a HTTP connection.
	TCPIP_HTTP_NET_ConnectionIndexGet	Gets the index of the HTTP connection.

b) Data Types and Constants

	Name	Description
	_tag_TCPIP_HTTP_NET_USER_CALLBACK	HTTP user implemented callback data structure.
	TCPIP_HTTP_DYN_ARG_DCPT	HTTP dynamic argument descriptor.
	TCPIP_HTTP_DYN_ARG_TYPE	HTTP supported dynamic variables argument types.
	TCPIP_HTTP_DYN_PRINT_RES	Dynamic print result when a dynamic variable print callback function returns;
	TCPIP_HTTP_DYN_VAR_DCPT	HTTP dynamic variable descriptor.
	TCPIP_HTTP_DYN_VAR_FLAGS	HTTP supported dynamic variables flags.
	TCPIP_HTTP_NET_CONN_HANDLE	HTTP connection identifier, handle of a HTTP connection
	TCPIP_HTTP_NET_EVENT_TYPE	HTTP reported run-time events.
	TCPIP_HTTP_NET_IO_RESULT	Result states for execution callbacks
	TCPIP_HTTP_NET_MODULE_CONFIG	HTTP module dynamic configuration data
	TCPIP_HTTP_NET_MODULE_FLAGS	HTTP module configuration flags Multiple flags can be OR-ed
	TCPIP_HTTP_NET_READ_STATUS	Result states for TCPIP_HTTP_NET_ConnectionPostNameRead, TCPIP_HTTP_NET_ConnectionPostValueRead and TCPIP_HTTP_NET_ConnectionPostReadPair
	TCPIP_HTTP_NET_STATUS	Supported Commands and Server Response Codes
	TCPIP_HTTP_NET_USER_CALLBACK	HTTP user implemented callback data structure.
	TCPIP_HTTP_NET_USER_HANDLE	HTTP user handle.
	TCPIP_HTTP_NET_ConnectionPostReadPair	Reads a name and value pair from a URL encoded string in the network transport buffer.
	TCPIP_HTTP_SSI_ATTR_DCPT	HTTP SSI attribute descriptor.
	TCPIP_HTTP_SSI_NOTIFY_DCPT	HTTP SSI notification descriptor.

Description

This section describes the Application Programming Interface (API) functions of the HTTP Net module.

Refer to each section for a detailed description.

a) Functions

TCPIP_HTTP_NET_ActiveConnectionCountGet Function

Gets the number of active (and inactive) connections.

File

http_net.h

C

```
int TCPIP_HTTP_NET_ActiveConnectionCountGet(int* pOpenCount);
```

Returns

The number of active/total connections.

Description

This function will return the number of active and total opened HTTP connections at the current time.

Remarks

The value returned by this function is informational only. The number of active connections changes dynamically.

Preconditions

None.

Example

```
int nConns;

nConns = TCPIP_HTTP_NET_ActiveConnectionCountGet(0);
```

Parameters

Parameters	Description
pOpenCount	address to store the number of total HTTP opened connections Could be NULL if not needed

Function

int TCPIP_HTTP_NET_ActiveConnectionCountGet(int* pOpenCount);

TCPIP_HTTP_NET_ConnectionByteCountDec Function

Decrements the connection byte count.

File

http_net.h

C

```
void TCPIP_HTTP_NET_ConnectionByteCountDec(TCPIP_HTTP_NET_CONN_HANDLE connHandle, uint32_t byteCount);
```

Returns

None.

Description

This function decrements the current value of the counter showing the number of bytes read from the connection so far.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle
byteCount	byte count reduction

Function

void TCPIP_HTTP_NET_ConnectionByteCountDec(TCPIP_HTTP_NET_CONN_HANDLE connHandle,
uint32_t byteCount)

TCPIP_HTTP_NET_ArgGet Function

Locates a form field value in a given data array.

File

http_net.h

C

```
const uint8_t* TCPIP_HTTP_NET_ArgGet(const uint8_t* cData, const uint8_t* cArg);
```

Returns

A pointer to the argument value, or NULL if not found.

Description

This function searches through a data array to find the value associated with a given argument. It can be used to find form field values in data received over GET or POST.

The end of data is assumed to be reached when a null name parameter is encountered. This requires the string to have an even number of null-terminated strings, followed by an additional null terminator.

Remarks

None.

Preconditions

The data array has a valid series of null terminated name/value pairs.

Example

```
TCPIP_HTTP_NET_DynPrint(TCPIP_HTTP_NET_CONN_HANDLE connHandle, const TCPIP_HTTP_DYN_VAR_DCPT*
                        varDcpt, const TCPIP_HTTP_NET_USER_CALLBACK* pCBack)
{
    const uint8_t *ptr;

    ptr = TCPIP_HTTP_NET_ArgGet(TCPIP_HTTP_NET_ConnectionDataBufferGet(connHandle),
                                (const uint8_t*)"name");
    if(ptr == 0)
    {
        ptr = "not set";
    }
    else
    {
        strncpy(myBuffer, ptr, sizeof(myBuffer));
        ptr = myBuffer;
    }

    TCPIP_HTTP_NET_DynamicWrite(varDcpt, ptr, strlen(ptr), false);

}
```

Parameters

Parameters	Description
cData	the buffer to search
cArg	the name of the argument to find

Function

const uint8_t* TCPIP_HTTP_NET_ArgGet(const uint8_t* cData, const uint8_t* cArg)

TCPIP_HTTP_NET_ConnectionByteCountSet Function

Sets how many bytes have been read so far.

File

http_net.h

C

```
void TCPIP_HTTP_NET_ConnectionByteCountSet(TCPIP_HTTP_NET_CONN_HANDLE connHandle, uint32_t byteCount);
```

Returns

None.

Description

This function sets the current value of the counter showing the number of bytes read from the connection so far.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle
byteCount	byte count to be set

Function

void TCPIP_HTTP_NET_ConnectionByteCountSet(TCPIP_HTTP_NET_CONN_HANDLE connHandle,
uint32_t byteCount)

TCPIP_HTTP_NET_ConnectionByteCountGet Function

Returns how many bytes have been read so far.

File

http_net.h

C

```
uint32_t TCPIP_HTTP_NET_ConnectionByteCountGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

Current connection byte count, how many bytes have been read so far.

Description

This function returns the current value of the counter showing the number of bytes read from the connection so far.

Remarks

None.

Preconditions

None.

Example

```
switch(TCPIP_HTTP_NET_ConnectionPostSmGet(connHandle))
{
    case SM_CFG_SNMP_READ_NAME:
        // If all parameters have been read, end
```

```
            if(TCPIP_HTTP_NET_ConnectionByteCountGet(connHandle) == 0u)
            {
                return TCPIP_HTTP_NET_IO_RES_DONE;
            }
        .
        .
        .
    }
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

uint32_t TCPIP_HTTP_NET_ConnectionByteCountGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle)

TCPIP_HTTP_NET_ConnectionCallbackPosSet Function

Sets the callback position indicator.

File

http_net.h

C

```
void TCPIP_HTTP_NET_ConnectionCallbackPosSet(TCPIP_HTTP_NET_CONN_HANDLE connHandle, uint32_t callbackPos);
```

Returns

None.

Description

This function will set the current value of the callback position indicator for the HTTP connection identified by connHandle. The callback position indicator is used in the processing of the HTTP dynamic variables. When set to a value != 0, it indicates to the HTTP server that the application has more pending processing that needs to be done.

Remarks

None.

Preconditions

None.

Example

Parameters

Parameters	Description
connHandle	HTTP connection handle
callbackPos	new connection callback position value

Function

void TCPIP_HTTP_NET_ConnectionCallbackPosSet(TCPIP_HTTP_NET_CONN_HANDLE connHandle,
uint32_t callbackPos)

TCPIP_HTTP_NET_ConnectionCallbackPosGet Function

Returns the callback position indicator.

File

http_net.h

C

```
uint32_t TCPIP_HTTP_NET_ConnectionCallbackPosGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

Callback position indicator for connection defined by connHandle.

Description

This function will return the current value of the callback position indicator for the HTTP connection identified by connHandle. The callback position indicator is used in the processing of the HTTP dynamic variables.

Remarks

None.

Preconditions

None.

Example

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

uint32_t TCPIP_HTTP_NET_ConnectionCallbackPosGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle)

TCPIP_HTTP_NET_ConnectionDataBufferGet Function

Returns pointer to connection general purpose data buffer.

File

http_net.h

C

```
uint8_t* TCPIP_HTTP_NET_ConnectionDataBufferGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

Pointer to the connection's general purpose data buffer.

Description

This function returns a pointer to the HTTP connection internal data buffer. This gives access to the application to the data that's stored in the HTTP connection buffer.

Remarks

None.

Preconditions

None.

Example

```
TCPIP_HTTP_NET_DynPrint(TCPIP_HTTP_NET_CONN_HANDLE connHandle,
   const TCPIP_HTTP_DYN_VAR_DCPT* varDcpt,
   const TCPIP_HTTP_NET_USER_CALLBACK* pCBack)
{
    const uint8_t *ptr;

    ptr = TCPIP_HTTP_NET_ArgGet(TCPIP_HTTP_NET_ConnectionDataBufferGet
                               (connHandle), (const uint8_t*)"name");
    if(ptr == 0)
    {
        ptr = "not set";
    }
    else
    {
        strncpy(myBuffer, ptr, sizeof(myBuffer));
        ptr = myBuffer;
    }
```

```
        TCPIP_HTTP_NET_DynamicWrite(varDcpt, ptr, strlen(ptr), false);
    }
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

uint8_t* TCPIP_HTTP_NET_ConnectionDataBufferGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle)

TCPIP_HTTP_NET_ConnectionDiscard Function

Discards any pending data in the connection RX buffer.

File

http_net.h

C

```
uint16_t TCPIP_HTTP_NET_ConnectionDiscard(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

The number of bytes that have been discarded from the RX buffer.

Description

This function discards data from the connection RX buffer.

Preconditions

connHandle - a valid HTTP connection.

Parameters

Parameters	Description
connHandle	connection handle

Function

uint16_t TCPIP_HTTP_NET_ConnectionDiscard(TCPIP_HTTP_NET_CONN_HANDLE connHandle);

TCPIP_HTTP_NET_ConnectionFileAuthenticate Function

Determines if a given file name requires authentication

File

http_net.h

C

```
uint8_t TCPIP_HTTP_NET_ConnectionFileAuthenticate(TCPIP_HTTP_NET_CONN_HANDLE connHandle, const char* cFile,
const TCPIP_HTTP_NET_USER_CALLBACK* pCBack);
```

Returns

- <= 0x79 - valid authentication is required
- >= 0x80 - access is granted for this connection

Description

This function is implemented by the application developer. Its function is to determine if a file being requested requires authentication to view. The user name and password, if supplied, will arrive later with the request headers, and will be processed at that time.

Return values 0x80 - 0xff indicate that authentication is not required, while values from 0x00 to 0x79 indicate that a user name and password are required before proceeding. While most applications will only use a single value to grant access and another to require authorization, the range allows multiple "realms" or sets of pages to be protected, with different credential requirements for each.

The return value of this function is saved for the current connection and can be read using TCPIP_HTTP_NET_ConnectionIsAuthorizedGet. It will be available to future callbacks, including TCPIP_HTTP_NET_ConnectionUserAuthenticate and any of the TCPIP_HTTP_NET_ConnectionGetExecute, TCPIP_HTTP_NET_ConnectionPostExecute, or TCPIP_HTTP_NET_Print_varname callbacks.

Remarks

This function may NOT write to the network transport buffer.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle
cFile	the name of the file being requested
pCBack	user TCPIP_HTTP_NET_USER_CALLBACK pointer

Function

uint8_t TCPIP_HTTP_NET_ConnectionFileAuthenticate
(TCPIP_HTTP_NET_CONN_HANDLE connHandle,
const char* cFile, const TCPIP_HTTP_NET_USER_CALLBACK* pCBack)

TCPIP_HTTP_NET_ConnectionFileGet Function

Get handle to current connection's file.

File

http_net.h

C

```
SYS_FS_HANDLE TCPIP_HTTP_NET_ConnectionFileGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

Handle to File System file belonging to the connection defined by connHandle

Description

This function returns the handle of the current HTTP connection file.

Remarks

None.

Preconditions

None.

Example

```
uint8_t myBuff[20];

// Get the file handle and read from that file
SYS_FS_FileRead(myBuff, sizeof(myBuff), TCPIP_HTTP_NET_ConnectionFileGet(connHandle));
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

FILE_HANDLE TCPIP_HTTP_NET_ConnectionFileGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle)

TCPIP_HTTP_NET_ConnectionFileInclude Function

Writes a file to the HTTP connection.

File

http_net.h

C

```
bool TCPIP_HTTP_NET_ConnectionFileInclude(HTTP_CONN_HANDLE connHandle, const char* fileName);
```

Returns

true if the call succeeded, false if the file could not be opened

Description

This function allows an entire file to be included as part of a dynamic variable processing. This reduces unneeded duplication of visual elements such as headers, menus, etc.

It is not meant for the processing of dynamic variables that include files by using the "inc" keyword (see the Remarks section below).

Remarks

Should be called from within a dynamic variable processing function context. The function allows to insert a file, as part of the dynamic variable processing.

The included file can contain dynamic variables. However there's a limit for recursive calls (see TCPIP_HTTP_NET_MAX_RECURSE_LEVEL).

The file is just added to the processing queue. Returning true does not mean that the whole file has been already sent to the connection.

If the function returns true but an error occurs during the file processing an event will be reported using the TCPIP_HTTP_NET_EventReport callback.

If the function returns false an event will be reported using the TCPIP_HTTP_NET_EventReport callback with additional info.

Please note that the processing of HTTP dynamic keywords in the HTML code such as `~inc:filename.ext~` is processed internally by the HTTP module! For such a dynamic variable, control is not passed to the user.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle
fileName	the name of the file to be included

Function

bool TCPIP_HTTP_NET_ConnectionFileInclude(HTTP_CONN_HANDLE connHandle,

const char* fileName)

TCPIP_HTTP_NET_ConnectionHasArgsGet Function

Checks whether there are get or cookie arguments.

File

http_net.h

C

```
uint8_t TCPIP_HTTP_NET_ConnectionHasArgsGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

The current value of the connection hasArgs.

Description

The function will get the value of the "cookies or get arguments" that are present.

Remarks

None.

Preconditions

None.

Example

```
uint8_t hasArgs = TCPIP_HTTP_NET_ConnectionHasArgsGet(connHandle);
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

uint8_t TCPIP_HTTP_NET_ConnectionHasArgsGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle)

TCPIP_HTTP_NET_ConnectionFlush Function

Immediately transmits all connection pending TX data.

File

http_net.h

C

```
uint16_t TCPIP_HTTP_NET_ConnectionFlush(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

- number of flushed bytes
- 0 if no flushed bytes or some error

Description

This function calls the transport layer's flush function

Preconditions

connHandle - a valid HTTP connection.

Parameters

Parameters	Description
connHandle	connection handle

Function

uint16_t TCPIP_HTTP_NET_ConnectionFlush(TCPIP_HTTP_NET_CONN_HANDLE connHandle);

TCPIP_HTTP_NET_ConnectionIsAuthorizedGet Function

Gets the authorized state for the current connection.

File

http_net.h

C

```
uint8_t TCPIP_HTTP_NET_ConnectionIsAuthorizedGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

A uint8_t representing the authorization status.

Description

This function returns the authorization status for the current HTTP connection. This is one of the values returned by the TCPIP_HTTP_NET_ConnectionFileAuthenticate function.

Remarks

None.

Preconditions

None.

Example

```
uint8_t isAuth;
```

```
isAuth = TCPIP_HTTP_NET_ConnectionIsAuthorizedGet(connHandle);
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

uint8_t TCPIP_HTTP_NET_ConnectionIsAuthorizedGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle)

TCPIP_HTTP_NET_ConnectionGetExecute Function

Processes GET form field variables and cookies.

File

http_net.h

C

```
TCPIP_HTTP_NET_IO_RESULT TCPIP_HTTP_NET_ConnectionGetExecute(TCPIP_HTTP_NET_CONN_HANDLE connHandle, const
TCPIP_HTTP_NET_USER_CALLBACK* pCBack);
```

Returns

- TCPIP_HTTP_NET_IO_RES_DONE - application is done processing
- TCPIP_HTTP_NET_IO_RES_NEED_DATA - this value may not be returned because more data will not become available
- TCPIP_HTTP_NET_IO_RES_WAITING - the application is waiting for an asynchronous process to complete, and this function should be called again later

Description

This function is implemented by the application developer. Its purpose is to parse the data received from URL parameters (GET method forms) and cookies and perform any application-specific tasks in response to these inputs. Any required authentication has already been validated.

When this function is called, the connection data buffer (see TCPIP_HTTP_NET_ConnectionDataBufferGet) contains sequential name/value pairs of strings representing the data received. In this format, TCPIP_HTTP_NET_ArgGet can be used to search for specific variables in the input. If data buffer space associated with this connection is required, connection data buffer may be overwritten here once the application is done with the values. Any data placed there will be available to future callbacks for this connection, including TCPIP_HTTP_NET_ConnectionPostExecute and any TCPIP_HTTP_NET_Print_varname dynamic substitutions.

This function may also issue redirections by setting the connection data buffer to the destination file name or URL, and the connection httpStatus (TCPIP_HTTP_NET_ConnectionStatusSet()) to TCPIP_HTTP_NET_STAT_REDIRECT.

Finally, this function may set cookies. Set connection data buffer to a series of name/value string pairs (in the same format in which parameters arrive) and then set the connection hasArgs (TCPIP_HTTP_NET_ConnectionHasArgsSet) equal to the number of cookie name/value pairs. The cookies will be transmitted to the browser, and any future requests will have those values available in the connection data buffer.

Remarks

This function is only called if variables are received via URL parameters or Cookie arguments.

This function may NOT write to the network transport buffer.

This function may service multiple HTTP requests simultaneously. Exercise caution when using global or static variables inside this routine. Use the connection callbackPos (TCPIP_HTTP_NET_ConnectionCallbackPosGet) or the connection data buffer for storage associated with individual requests.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle
pCBack	user TCPIP_HTTP_NET_USER_CALLBACK pointer

Function

TCPIP_HTTP_NET_IO_RESULT TCPIP_HTTP_NET_ConnectionGetExecute

(TCPIP_HTTP_NET_CONN_HANDLE connHandle,

const TCPIP_HTTP_NET_USER_CALLBACK* pCBack)

TCPIP_HTTP_NET_ConnectionPostNameRead Function

Reads a name from a URL encoded string in the network transport buffer.

File

http_net.h

C

```
TCPIP_HTTP_NET_READ_STATUS TCPIP_HTTP_NET_ConnectionPostNameRead(TCPIP_HTTP_NET_CONN_HANDLE connHandle,
uint8_t* cData, uint16_t wLen);
```

Returns

- TCPIP_HTTP_NET_READ_OK - name was successfully read
- TCPIP_HTTP_NET_READ_TRUNCTATED - entire name could not fit in the buffer, so the value was truncated and data has been lost
- TCPIP_HTTP_NET_READ_INCOMPLETE - entire name was not yet in the buffer, so call this function again later to retrieve

Description

This function reads a name from a URL encoded string in the network transport buffer. This function is meant to be called from an TCPIP_HTTP_NET_ConnectionPostExecute callback to facilitate easier parsing of incoming data. This function also prevents buffer overflows by forcing the programmer to indicate how many bytes are expected. At least two extra bytes are needed in cData over the maximum length of data expected to be read.

This function will read until the next '=' character, which indicates the end of a name parameter. It assumes that the front of the buffer is the beginning of the name parameter to be read.

This function properly updates pHttpCon->byteCount by decrementing it by the number of bytes read. It also removes the delimiting '=' from the buffer.

Remarks

None.

Preconditions

The front of the network transport buffer is the beginning of a name parameter, and the rest of the network transport buffer contains a URL-encoded string with a name parameter terminated by a '=' character.

Parameters

Parameters	Description
connHandle	HTTP connection handle
cData	where to store the name once it is read
wLen	how many bytes can be written to cData

Function

TCPIP_HTTP_NET_READ_STATUS TCPIP_HTTP_NET_ConnectionPostNameRead (TCPIP_HTTP_NET_CONN_HANDLE connHandle, uint8_t* cData, uint16_t wLen)

TCPIP_HTTP_NET_ConnectionHasArgsSet Function

Sets whether there are get or cookie arguments.

File

http_net.h

C

```
void TCPIP_HTTP_NET_ConnectionHasArgsSet(TCPIP_HTTP_NET_CONN_HANDLE connHandle, uint8_t args);
```

Returns

None.

Description

The function sets the value of the "cookies or get arguments" that are present.

Remarks

None.

Preconditions

None.

Example

```
else if(!memcmp(filename, "cookies.htm", 11))
{
    TCPIP_HTTP_NET_ConnectionHasArgsSet(connHandle, true);
}
```

Parameters

Parameters	Description
connHandle	HTTP connection handle
args	boolean if there are arguments or not

Function

void TCPIP_HTTP_NET_ConnectionHasArgsSet(TCPIP_HTTP_NET_CONN_HANDLE connHandle, uint8_t args)

TCPIP_HTTP_NET_ConnectionPostSmGet Function

Get the POST state machine state.

File

http_net.h

C

```
uint16_t TCPIP_HTTP_NET_ConnectionPostSmGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

16-bit integer POST state machine state.

Description

This function returns the POST state machine state for the connection defined by connHandle. This state is maintained by the HTTP connection and can be used by the user of the HTTP to maintain its own POST state machine. The values of the POST state machine have significance only for the user of the HTTP connection.

Remarks

None.

Preconditions

None.

Example

```
#define SM_POST_LCD_READ_NAME   1
#define SM_POST_LCD_READ_VALUE  2

switch(TCPIP_HTTP_NET_ConnectionPostSmGet(connHandle))
{
    // Find the name
    case SM_POST_LCD_READ_NAME:
      .
      .
      .
    // Found the value, so store the LCD and return
    case SM_POST_LCD_READ_VALUE:
      .
      .
      .
}
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

uint16_t TCPIP_HTTP_NET_ConnectionPostSmGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle)

TCPIP_HTTP_NET_ConnectionIsAuthorizedSet Function

Sets the authorized state for the current connection.

File

http_net.h

C

```
void TCPIP_HTTP_NET_ConnectionIsAuthorizedSet(TCPIP_HTTP_NET_CONN_HANDLE connHandle, uint8_t auth);
```

Returns

None.

Description

This function sets the authorization status for the current HTTP connection. This has to be one of the values in the set returned by the TCPIP_HTTP_NET_ConnectionFileAuthenticate function.

Remarks

None.

Preconditions

None.

Example

```
uint8_t auth = 0x80;

TCPIP_HTTP_NET_ConnectionIsAuthorizedSet(connHandle, auth);
```

Parameters

Parameters	Description
connHandle	HTTP connection handle
auth	new authorization state

Function

void TCPIP_HTTP_NET_ConnectionIsAuthorizedSet(TCPIP_HTTP_NET_CONN_HANDLE connHandle, uint8_t auth)

TCPIP_HTTP_NET_ConnectionPostValueRead Function

Reads a value from a URL encoded string in the network transport buffer.

File

http_net.h

C

```
TCPIP_HTTP_NET_READ_STATUS TCPIP_HTTP_NET_ConnectionPostValueRead(TCPIP_HTTP_NET_CONN_HANDLE connHandle,
uint8_t* cData, uint16_t wLen);
```

Returns

- TCPIP_HTTP_NET_READ_OK - value was successfully read
- TCPIP_HTTP_NET_READ_TRUNCTATED - entire value could not fit in the buffer, so the value was truncated and data has been lost
- TCPIP_HTTP_NET_READ_INCOMPLETE - entire value was not yet in the buffer, so call this function again later to retrieve

Description

This function reads a value from a URL encoded string in the network transport buffer. This function is meant to be called from an TCPIP_HTTP_NET_ConnectionPostExecute callback to facilitate easier parsing of incoming data. This function also prevents buffer overflows by forcing the programmer to indicate how many bytes are expected. At least two extra bytes are needed in cData above the maximum length of data expected to be read.

This function will read until the next '&' character, which indicates the end of a value parameter. It assumes that the front of the buffer is the beginning of the value parameter to be read. If pHttpCon->byteCount indicates that all expected bytes are in the buffer, it assumes that all remaining data is the value and acts accordingly.

This function properly updates pHttpCon->byteCount by decrementing it by the number of bytes read. The terminating '&' character is also removed from the buffer.

Remarks

None.

Preconditions

The front of the network transport buffer is the beginning of a name parameter, and the rest of the network transport buffer contains a URL-encoded string with a name parameter terminated by a '=' character.

Parameters

Parameters	Description
connHandle	HTTP connection handle
cData	where to store the value once it is read
wLen	how many bytes can be written to cData

Function

TCPIP_HTTP_NET_READ_STATUS TCPIP_HTTP_NET_ConnectionPostValueRead (TCPIP_HTTP_NET_CONN_HANDLE connHandle, uint8_t* cData, uint16_t wLen)

TCPIP_HTTP_NET_ConnectionNetHandle Function

Returns the network handle of the current connection.

File

http_net.h

C

```
TCPIP_NET_HANDLE TCPIP_HTTP_NET_ConnectionNetHandle(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

The connection network handle.

Description

This function returns the network handle over which the current HTTP connection communicates.

Preconditions

connHandle - a valid HTTP connection.

Parameters

Parameters	Description
connHandle	connection handle

Function

TCPIP_NET_HANDLE TCPIP_HTTP_NET_ConnectionNetHandle(TCPIP_HTTP_NET_CONN_HANDLE connHandle);

TCPIP_HTTP_NET_ConnectionSocketGet Function

Get the socket for the current connection.

File

http_net.h

C

```
NET_PRES_SKT_HANDLE_T TCPIP_HTTP_NET_ConnectionSocketGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

NET_PRES_SKT_HANDLE_T for the connection defined by connHandle.

Description

The function returns the network transport socket of the specified HTTP connection. The user gets access to the connection socket which it can use for debugging or directly sending/reading data.

Remarks

This function gives direct access to the underlying transport socket. It is meant for test/advanced usage only. The regular connection functions should be used for manipulation of the connection data. Using the socket directly for data manipulation will disrupt the HTTP server functionality.

Preconditions

None.

Example

```
uint32_t byteCount;
int sktRxSize;

byteCount = TCPIP_HTTP_NET_ConnectionByteCountGet(connHandle);
sktRxSize = TCPIP_HTTP_NET_ConnectionReadBufferSize(connHandle);

if(byteCount > sktRxSize)
{   // Configuration Failure
    TCPIP_HTTP_NET_ConnectionStatusSet(connHandle, TCPIP_HTTP_NET_STAT_REDIRECT);
    return TCPIP_HTTP_NET_IO_RES_DONE;
}
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

NET_PRES_SKT_HANDLE_T TCPIP_HTTP_NET_ConnectionSocketGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle)

TCPIP_HTTP_NET_ConnectionPeek Function

Reads a specified number of data bytes from the connection RX buffer without removing them from the buffer.

File

http_net.h

C

```
uint16_t TCPIP_HTTP_NET_ConnectionPeek(TCPIP_HTTP_NET_CONN_HANDLE connHandle, void * buffer, uint16_t size);
```

Description

The function allows peeking into the connection buffer. The data will still be available for a next read operation.

Remarks

None

Preconditions

connHandle - a valid HTTP connection.

Parameters

Parameters	Description
connHandle	connection handle
buffer	Destination to write the peeked data bytes
size	Length of bytes to peek from the connection RX buffer

Function

uint16_t TCPIP_HTTP_NET_ConnectionPeek(TCPIP_HTTP_NET_CONN_HANDLE connHandle,

void * buffer, uint16_t size);

TCPIP_HTTP_NET_ConnectionStatusGet Function

Gets HTTP status.

File

http_net.h

C

```
TCPIP_HTTP_NET_STATUS TCPIP_HTTP_NET_ConnectionStatusGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

A TCPIP_HTTP_NET_STATUS value.

Description

This function returns the current HTTP status of the selected HTTP connection.

Remarks

None.

Preconditions

None.

Example

```
TCPIP_HTTP_NET_STATUS currStat =  TCPIP_HTTP_NET_ConnectionStatusGet(connHandle);
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

TCPIP_HTTP_NET_STATUS TCPIP_HTTP_NET_ConnectionStatusGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle);

TCPIP_HTTP_NET_ConnectionPostExecute Function

Processes POST form variables and data.

File

http_net.h

C

```
TCPIP_HTTP_NET_IO_RESULT TCPIP_HTTP_NET_ConnectionPostExecute(TCPIP_HTTP_NET_CONN_HANDLE connHandle, const
TCPIP_HTTP_NET_USER_CALLBACK* pCBack);
```

Returns

- TCPIP_HTTP_NET_IO_RES_DONE - application is done processing
- TCPIP_HTTP_NET_IO_RES_NEED_DATA - more data is needed to continue, and this function should be called again later
- TCPIP_HTTP_NET_IO_RES_WAITING - the application is waiting for an asynchronous process to complete, and this function should be called again later

Description

This function is implemented by the application developer. Its purpose is to parse the data received from POST forms and perform any application-specific tasks in response to these inputs. Any required authentication has already been validated before this function is called.

When this function is called, POST data will be waiting in the network transport buffer. The connection byteCount (see TCPIP_HTTP_NET_ConnectionByteCountGet will indicate the number of bytes remaining to be received before the browser request is complete.

Since data is still in the network transport buffer, the application must call TCPIP_HTTP_NET_ConnectionRead in order to retrieve bytes. When this is done, connection byteCount MUST be updated to reflect how many bytes now remain.

In general, data submitted from web forms via POST is URL encoded. The TCPIP_HTTP_NET_URLDecode function can be used to decode this information back to a standard string if required. If data buffer space associated with this connection is required, the connection data buffer (see TCPIP_HTTP_NET_ConnectionDataBufferGet) may be overwritten here once the application is done with the values. Any data placed there will be available to future callbacks for this connection, including TCPIP_HTTP_NET_ConnectionPostExecute and any TCPIP_HTTP_NET_Print_varname dynamic substitutions.

Whenever a POST form is processed it is recommended to issue a redirect back to the browser, either to a status page or to the same form page that was posted. This prevents accidental duplicate submissions (by clicking refresh or back/forward) and avoids browser warnings about "resubmitting form data". Redirects may be issued to the browser by setting the connection data buffer to the destination file or URL, and the connection httpStatus (TCPIP_HTTP_NET_ConnectionStatusSet) to TCPIP_HTTP_NET_STAT_REDIRECT.

Finally, this function may set cookies. Set the connection data buffer to a series of name/value string pairs (in the same format in which parameters arrive), and then set the connection hasArgs (TCPIP_HTTP_NET_ConnectionHasArgsSet) equal to the number of cookie name/value pairs. The cookies will be transmitted to the browser, and any future requests will have those values available in the connection data buffer.

Remarks

This function is only called when the request method is POST, and is only used when TCPIP_HTTP_NET_USE_POST is defined.

This method may NOT write to the network transport buffer.

This function may service multiple HTTP requests simultaneously. Exercise caution when using global or static variables inside this routine. Use the connection callbackPos (TCPIP_HTTP_NET_ConnectionCallbackPosGet) or connection data buffer for storage associated with individual requests.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle
pCBack	user TCPIP_HTTP_NET_USER_CALLBACK pointer

Function

TCPIP_HTTP_NET_IO_RESULT TCPIP_HTTP_NET_ConnectionPostExecute
(
TCPIP_HTTP_NET_CONN_HANDLE connHandle,
const
TCPIP_HTTP_NET_USER_CALLBACK* pCBack)

TCPIP_HTTP_NET_ConnectionUserDataGet Function

Gets the user data parameter for the current connection.

File

http_net.h

C

```
const void* TCPIP_HTTP_NET_ConnectionUserDataGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

User data that's stored as part of the connection.

Description

This function returns the user data value for the current HTTP connection. This data belongs to the user and is not used in any way by the HTTP server module. It can be set by the user with TCPIP_HTTP_NET_ConnectionUserDataSet.

Remarks

None.

Preconditions

None.

Example

```
uint32_t myConnData;

myConnData = (uint32_t)TCPIP_HTTP_NET_ConnectionUserDataGet(connHandle);
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

const void* TCPIP_HTTP_NET_ConnectionUserDataGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle)

TCPIP_HTTP_NET_ConnectionPostSmSet Function

Set the POST state machine state.

File

http_net.h

C

```
void TCPIP_HTTP_NET_ConnectionPostSmSet(TCPIP_HTTP_NET_CONN_HANDLE connHandle, uint16_t state);
```

Returns

None.

Description

This function sets the POST state machine state for the connection defined by connHandle. This state is maintained by the HTTP connection and can be used by the user of the HTTP to maintain its own POST state machine. The values of the POST state machine have significance only for the user of the HTTP connection.

Remarks

None.

Preconditions

None.

Example

```
uint8_t* httpDataBuff;
#define SM_POST_LCD_READ_NAME   1
#define SM_POST_LCD_READ_VALUE  2

switch(TCPIP_HTTP_NET_ConnectionPostSmGet(connHandle))
{
    // Find the name
    case SM_POST_LCD_READ_NAME:

        // Read a name
        if(TCPIP_HTTP_NET_ConnectionPostNameRead(connHandle, httpDataBuff,
           TCPIP_HTTP_NET_MAX_DATA_LEN) == TCPIP_HTTP_NET_READ_INCOMPLETE)
            return TCPIP_HTTP_NET_IO_RES_NEED_DATA;

        TCPIP_HTTP_NET_ConnectionPostSmSet(connHandle, SM_POST_LCD_READ_VALUE);
        // No break...continue reading value

    // Found the value, so store the LCD and return
    case SM_POST_LCD_READ_VALUE:
      .
      .
      .
}
```

Parameters

Parameters	Description
connHandle	HTTP connection handle
state	16 bit integer state for POST state machine

Function

void TCPIP_HTTP_NET_ConnectionPostSmSet(TCPIP_HTTP_NET_CONN_HANDLE connHandle,
uint16_t state)

TCPIP_HTTP_NET_ConnectionRead Function

Reads an array of data bytes from a connection's RX buffer.

File

http_net.h

C

```
uint16_t TCPIP_HTTP_NET_ConnectionRead(TCPIP_HTTP_NET_CONN_HANDLE connHandle, void * buffer, uint16_t size);
```

Returns

The number of bytes read from the socket. If less than len, the connection RX buffer became empty or the underlying socket is not connected.

Description

This function reads an array of data bytes from the connection RX buffer. The data is removed from the FIFO in the process.

Remarks

If the supplied buffer is null, the data is simply discarded.

Preconditions

connHandle - a valid HTTP connection.

Parameters

Parameters	Description
connHandle	connection handle
buffer	The pointer to the array to store data that was read
size	The number of bytes to be read.

Function

uint16_t TCPIP_HTTP_NET_ConnectionRead(TCPIP_HTTP_NET_CONN_HANDLE connHandle,
void * buffer, uint16_t size);

TCPIP_HTTP_NET_ConnectionReadBufferSize Function

Returns the size of the connection RX buffer.

File

http_net.h

C

```
uint16_t TCPIP_HTTP_NET_ConnectionReadBufferSize(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

The size of the connection RX buffer.

Description

This function discards data from the connection RX buffer.

Preconditions

connHandle - a valid HTTP connection.

Parameters

Parameters	Description
connHandle	connection handle

Function

uint16_t TCPIP_HTTP_NET_ConnectionReadBufferSize(TCPIP_HTTP_NET_CONN_HANDLE connHandle);

TCPIP_HTTP_NET_ConnectionReadIsReady Function

Determines how many bytes can be read from the connection RX buffer.

File

http_net.h

C

```
uint16_t TCPIP_HTTP_NET_ConnectionReadIsReady(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

The number of bytes available to be read from the connection RX buffer.

Description

This function determines how many bytes can be read from the connection RX buffer.

Remarks

When using an encrypted connection the number of available unencrypted bytes may turn out to be different than what this function returns.

Preconditions

connHandle - a valid HTTP connection.

Parameters

Parameters	Description
connHandle	connection handle

Function

uint16_t TCPIP_HTTP_NET_ConnectionReadIsReady(TCPIP_HTTP_NET_CONN_HANDLE connHandle);

TCPIP_HTTP_NET_ConnectionStatusSet Function

Sets HTTP status.

File

http_net.h

C

```
void TCPIP_HTTP_NET_ConnectionStatusSet(TCPIP_HTTP_NET_CONN_HANDLE connHandle, TCPIP_HTTP_NET_STATUS stat);
```

Returns

None.

Description

Allows write access to the HTTP status of the selected HTTP connection.

Remarks

None.

Preconditions

None.

Example

```
byteCount = TCPIP_HTTP_NET_ConnectionByteCountGet(connHandle);
int sktRxSize;

sktRxSize = TCPIP_HTTP_NET_ConnectionReadBufferSize(connHandle);

if(byteCount > sktRxSize)
{   // Configuration Failure
    // 302 Redirect will be returned
    TCPIP_HTTP_NET_ConnectionStatusSet(connHandle, TCPIP_HTTP_NET_STAT_REDIRECT);
}
```

Parameters

Parameters	Description
connHandle	HTTP connection handle
stat	new TCPIP_HTTP_NET_STATUS enumeration value.

Function

void TCPIP_HTTP_NET_ConnectionStatusSet(TCPIP_HTTP_NET_CONN_HANDLE connHandle,
TCPIP_HTTP_NET_STATUS stat)

TCPIP_HTTP_NET_ConnectionStringFind Function

Helper to find a string of characters in an incoming connection buffer.

File

http_net.h

C

```
uint16_t TCPIP_HTTP_NET_ConnectionStringFind(TCPIP_HTTP_NET_CONN_HANDLE connHandle, const char* str,
uint16_t startOffs, uint16_t searchLen);
```

Returns

- If string was found - a zero-indexed position in the RX buffer of the string occurrence
- 0xFFFF - Search array not found

Description

This function searches for an ASCIIZ string in the RX buffer of the connection. It does the search by performing a peek operation in the RX buffer, (i.e., the RX data in the buffer is not consumed and it is available for further read operations). It works for both encrypted and unencrypted connections.

Remarks

Note that the search will fail if there's more data in the TCP socket than could be read at once.

Preconditions

connHandle - a valid HTTP connection.

Parameters

Parameters	Description
connHandle	HTTP connection handle
str	0 terminated ASCII string to search for
startOffs	offset in the RX buffer to start the search from
searchLen	if !0 it is the length of buffer to search into (starting from startOffs); if 0, the whole buffer is searched

Function

uint16_t TCPIP_HTTP_NET_ConnectionStringFind(TCPIP_HTTP_NET_CONN_HANDLE connHandle,

const char* str, uint16_t startOffs, uint16_t searchLen);

TCPIP_HTTP_NET_ConnectionUserAuthenticate Function

Performs validation on a specific user name and password.

File

http_net.h

C

```
uint8_t TCPIP_HTTP_NET_ConnectionUserAuthenticate(TCPIP_HTTP_NET_CONN_HANDLE connHandle, const char* cUser,
const char* cPass, const TCPIP_HTTP_NET_USER_CALLBACK* pCBack);
```

Returns

- <= 0x79 - the credentials were rejected
- >= 0x80 - access is granted for this connection

Description

This function is implemented by the application developer. Its function is to determine if the user name and password supplied by the client are acceptable for this resource. This callback function can thus to determine if only specific user names or passwords will be accepted for this resource.

Return values 0x80 - 0xff indicate that the credentials were accepted, while values from 0x00 to 0x79 indicate that authorization failed. While most applications will only use a single value to grant access, flexibility is provided to store multiple values in order to indicate which user (or user's group) logged in.

The value returned by this function is stored in the corresponding connection data and will be available with TCPIP_HTTP_NET_ConnectionIsAuthorizedGet in any of the TCPIP_HTTP_NET_ConnectionGetExecute, TCPIP_HTTP_NET_ConnectionPostExecute, or TCPIP_HTTP_NET_Print_varname callbacks.

Remarks

This function is only called when an Authorization header is encountered.

This function may NOT write to the network transport buffer.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle
cUser	the user name supplied by the client
cPass	the password supplied by the client
pCBack	user TCPIP_HTTP_NET_USER_CALLBACK pointer

Function

uint8_t TCPIP_HTTP_NET_ConnectionUserAuthenticate(TCPIP_HTTP_NET_CONN_HANDLE

connHandle, const char* cUser, const char* cPass,

const TCPIP_HTTP_NET_USER_CALLBACK* pCBack)

TCPIP_HTTP_NET_ConnectionUserDataSet Function

Sets the user data parameter for the current connection.

File

http_net.h

C

```
void TCPIP_HTTP_NET_ConnectionUserDataSet(TCPIP_HTTP_NET_CONN_HANDLE connHandle, const void* uData);
```

Returns

None.

Description

This function will set the user data value for the current HTTP connection. This data belongs to the user and is not used in any way by the HTTP server module. It is available to the user by calling TCPIP_HTTP_NET_ConnectionUserDataGet.

Remarks

None.

Preconditions

None.

Example

```
uint32_t myConnData;

TCPIP_HTTP_NET_ConnectionUserDataSet(connHandle, (const void*)myConnData);
```

Parameters

Parameters	Description
connHandle	HTTP connection handle
uData	user supplied data

Function

void TCPIP_HTTP_NET_ConnectionUserDataSet(TCPIP_HTTP_NET_CONN_HANDLE

connHandle, const void* uData)

TCPIP_HTTP_NET_DynAcknowledge Function

Dynamic variable acknowledge function

File

http_net.h

C

```
void TCPIP_HTTP_NET_DynAcknowledge(TCPIP_HTTP_NET_CONN_HANDLE connHandle, const void* buffer, const struct
_tag_TCPIP_HTTP_NET_USER_CALLBACK* pCBack);
```

Returns

None.

Description

Functions in this style are implemented by the application developer. This function reports that a buffer that was passed as part of a dynamic variable callback (dynamicPrint) was processed and can be reused, freed, etc.

Remarks

The function is called only when TCPIP_HTTP_NET_DynamicWrite or TCPIP_HTTP_NET_DynamicWriteString was specified with a true needAck parameter.

The function is called from withing HTTP context. It should be kept as short as possible.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle
buffer	the processed buffer
pCBack	user TCPIP_HTTP_NET_USER_CALLBACK pointer

Function

void TCPIP_HTTP_NET_DynAcknowledge(TCPIP_HTTP_NET_CONN_HANDLE connHandle,

const void* buffer,

const struct _tag_TCPIP_HTTP_NET_USER_CALLBACK* pCBack);

TCPIP_HTTP_NET_DynamicWrite Function

Writes a data buffer to the current connection

File

http_net.h

C

```
bool TCPIP_HTTP_NET_DynamicWrite(const TCPIP_HTTP_DYN_VAR_DCPT* varDcpt, const void * buffer, uint16_t
size, bool needAck);
```

Returns

True if the data buffer has been queued for output. False if an invalid buffer was provided or the buffer could not be queued because of the lack of resources (descriptors).

Description

This function takes a buffer and sends it over the HTTP connection as part of the HTTP dynamic variable processing

Remarks

The buffer passed in by the user with this call is queued internally using an available dynamic variable buffer descriptor. That means that the buffer has to be persistent. Once the buffer is processed and sent to output, the dynamicAck callback will be called, to inform the user that the corresponding buffer can be reused/freed.

When multiple connections output their dynamic content concurrently the HTTP may run out of dynamic variable buffer descriptors that are used in queuing the requests and the call may fail. If the call failed, because the buffer could not be queued, it may be retried using by returning TCPIP_HTTP_DYN_PRINT_RES_AGAIN in the TCPIP_HTTP_NET_DynPrint callback.

If sequential write calls are done from within the same TCPIP_HTTP_NET_DynPrint call the HTTP module will try to append the new dynamic data to the existent one.

The number of internal HTTP dynamic variables buffer descriptors is controlled by TCPIP_HTTP_NET_DYNVAR_DESCRIPTORS_NUMBER. It can be obtained at run-time using the TCPIP_HTTP_NET_ConnectionDynamicDescriptors function.

Preconditions

varDcpt - a valid dynamic variable descriptor.

Parameters

Parameters	Description
varDcpt	dynamic variable descriptor as passed in the TCPIP_HTTP_NET_DynPrint function
buffer	The pointer to the persistent buffer to be written to the HTTP connection as part of this dynamic variable callback
size	The number of bytes to be written
needAck	if true, once the buffer is processed internally, TCPIP_HTTP_NET_DynAcknowledge will be called

Function

bool TCPIP_HTTP_NET_DynamicWrite(const TCPIP_HTTP_DYN_VAR_DCPT* varDcpt,

const void * buffer, uint16_t size, bool needAck);

TCPIP_HTTP_NET_DynamicWriteString Function

Helper for writing a string within a dynamic variable context.

File

http_net.h

C

```
bool TCPIP_HTTP_NET_DynamicWriteString(const TCPIP_HTTP_DYN_VAR_DCPT* varDcpt, const char* str, bool needAck);
```

Returns

True if the data buffer has been queued for output. False if an invalid buffer was provided or the buffer could not be queued because of the lack of resources (descriptors).

Description

This function takes a 0 terminated ACII string and sends it to the HTTP connection as part of the HTTP dynamic variable processing

Remarks

This is just a helper. The actual function called is still TCPIP_HTTP_NET_DynamicWrite. That means that the supplied string has to be persistent.

See the remarks for TCPIP_HTTP_NET_DynamicWrite.

Preconditions

varDcpt - a valid dynamic variable descriptor.

Parameters

Parameters	Description
varDcpt	dynamic variable descriptor as passed in the TCPIP_HTTP_NET_DynPrint function
str	The string to be written
needAck	if true, once the buffer is processed internally, TCPIP_HTTP_NET_DynAcknowledge will be called

Function

bool TCPIP_HTTP_NET_DynamicWriteString(const TCPIP_HTTP_DYN_VAR_DCPT* varDcpt,

const char* str, bool needAck);

TCPIP_HTTP_NET_DynPrint Function

Inserts dynamic content into a web page

File

http_net.h

C

```
TCPIP_HTTP_DYN_PRINT_RES TCPIP_HTTP_NET_DynPrint(TCPIP_HTTP_NET_CONN_HANDLE connHandle, const
TCPIP_HTTP_DYN_VAR_DCPT* varDcpt, const TCPIP_HTTP_NET_USER_CALLBACK* pCBack);
```

Returns

TCPIP_HTTP_DYN_PRINT_RES_PROCESS_AGAIN/TCPIP_HTTP_DYN_PRINT_RES_AGAIN. Typically this is used when outputting large amounts of data that cannot fit into one single buffer write operation or when the data is not available all at once.

An alternative (legacy) mechanism for that, is using the connection callbackPos calls: (TCPIP_HTTP_NET_ConnectionCallbackPosGet/TCPIP_HTTP_NET_ConnectionCallbackPosSet). This value will be set to zero before the function is called. If the function is managing its output state, it must set this to a non-zero value before returning. If the connection callbackPos is non-zero, the function will be called again after the current data is processed (equivalent to returning TCPIP_HTTP_DYN_PRINT_RES_PROCESS_AGAIN). Once the callback completes, set the callback value back to zero and return TCPIP_HTTP_DYN_PRINT_RES_DONE to resume normal servicing of the request.

If the function does not process this dynamic variable callback (or it wants the default action to be performed), it should return TCPIP_HTTP_DYN_PRINT_RES_DEFAULT. Then the default action for that variable will be performed by the HTTP module.

Note that this is an advanced feature and will be used for processing of HTTP dynamic variable keywords. No implementation currently exists for user added variables and the default action in this case will do nothing.

A TCPIP_HTTP_DYN_PRINT_RES specifying the action to be taken. See the TCPIP_HTTP_DYN_PRINT_RES definition for a list of allowed actions

Description

Functions in this style are implemented by the application developer. This function generates dynamic content to be inserted into web pages.

The function of this type is called when a dynamic variable is located in a web page. (i.e., ~varname~) The name between the tilde '~' characters is passed as the dynamic variable name.

The function currently supports int32_t and string parameters. The dynamic variable parameters are included in the varDcpt data structure that's passed at the time of the call. For example, the variable "~myArray(2,6)~" will generate the call with: varDcpt.dynName = "myArray"; varDcpt.nArgs = 2; varDcpt.dynArgs->argType = TCPIP_HTTP_DYN_ARG_TYPE_INT32; varDcpt.dynArgs->argInt32 = 2; (varDcpt.dynArgs + 1)->argType = TCPIP_HTTP_DYN_ARG_TYPE_INT32; (varDcpt.dynArgs + 1)->argInt32 = 6;

When called, this function should write its output to the HTTP connection using the TCPIP_HTTP_NET_DynamicWrite/TCPIP_HTTP_NET_DynamicWriteString functions.

In situations where the dynamic variable print function needs to perform additional write operations, or simply needs to be called again, it must

Remarks

This function may service multiple HTTP requests simultaneously, especially when managing its output state. Exercise caution when using global or static variables inside this routine. Use the connection callbackPos or the connection data buffer for storage associated with individual requests.

The varDcpt variable descriptor is valid only in the context of this call. Any parameters that are needed for further processing should be copied to user storage.

The varDcpt variable descriptor is constant and should not be modified in any way by the callback.

If the callback returned TCPIP_HTTP_DYN_PRINT_RES_DEFAULT, no further calls will be made to the callback function.

Returning TCPIP_HTTP_DYN_PRINT_RES_PROCESS_AGAIN/TCPIP_HTTP_DYN_PRINT_RES_AGAIN is an alternative mechanism to manipulation the connection status with TCPIP_HTTP_NET_ConnectionCallbackPosSet/TCPIP_HTTP_NET_ConnectionCallbackPosGet functions (which mechanism is still valid).

- If the TCPIP_HTTP_NET_DynPrint() returned TCPIP_HTTP_DYN_PRINT_RES_PROCESS_AGAIN, the HTTP server will start sending the dynamic variable buffer (invoked by TCPIP_HTTP_NET_DynamicWrite/TCPIP_HTTP_NET_DynamicWriteString). Once sending is done, the HTTP server will again call TCPIP_HTTP_NET_DynPrint regardless of the value set with the callback position.
- If the TCPIP_HTTP_NET_DynPrint() returned TCPIP_HTTP_DYN_PRINT_RES_AGAIN, there will be no processing of dynamic variable data (potentially written to the connection) but the TCPIP_HTTP_NET_DynPrint will be invoked again. Returning TCPIP_HTTP_DYN_PRINT_RES_AGAIN is needed when TCPIP_HTTP_NET_DynamicWrite failed or some condition is not satisfied and the TCPIP_HTTP_NET_DynPrint needs to be called again.

The callback position mechanism will be evaluated after the TCPIP_HTTP_NET_DynPrint returns TCPIP_HTTP_DYN_PRINT_RES_DONE.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle
varDcpt	pointer to a variable descriptor containing the dynamic variable name and arguments valid within this call context only.
pCBack	user TCPIP_HTTP_NET_USER_CALLBACK pointer

Function

```
TCPIP_HTTP_DYN_PRINT_RES TCPIP_HTTP_NET_DynPrint(TCPIP_HTTP_NET_CONN_HANDLE connHandle,
const                    TCPIP_HTTP_DYN_VAR_DCPT* varDcpt,
const                    TCPIP_HTTP_NET_USER_CALLBACK* pCBack);
```

TCPIP_HTTP_NET_EventReport Function

Reports an event that occurred in the processing of a HTTP web page

File

http_net.h

C

```
void TCPIP_HTTP_NET_EventReport(TCPIP_HTTP_NET_CONN_HANDLE connHandle, TCPIP_HTTP_NET_EVENT_TYPE evType,
const void* evInfo, const struct _tag_TCPIP_HTTP_NET_USER_CALLBACK* pCBack);
```

Returns

None.

Description

Functions in this style are implemented by the application developer. This function reports an event that occurred when processing a file, dynamic variable, etc.

Remarks

The evInfo parameter is valid only in the context of this call. Any data that is needed for further processing should be copied to user storage.

This function may NOT write to the network transport buffer.

Preconditions

None.

Parameters

Parameters	Description
connHandle	HTTP connection handle
evType	the HTTP event that occurred

evInfo	additional info for that particular event • TCPIP_HTTP_NET_EVENT_FS_UPLOAD_COMPLETE: file name pointer • TCPIP_HTTP_NET_EVENT_FILE_OPEN_ERROR: file name pointer • TCPIP_HTTP_NET_EVENT_FILE_NAME_ERROR: 0 • TCPIP_HTTP_NET_EVENT_FILE_NAME_SIZE_ERROR: file name pointer • TCPIP_HTTP_NET_EVENT_FILE_SIZE_ERROR: file name pointer • TCPIP_HTTP_NET_EVENT_FILE_READ_ERROR: file name pointer • TCPIP_HTTP_NET_EVENT_DEPTH_ERROR: file name pointer • TCPIP_HTTP_NET_EVENT_DYNVAR_PARSE_ERROR: dynamic variable name pointer • TCPIP_HTTP_NET_EVENT_FS_WRITE_ERROR: file name pointer • TCPIP_HTTP_NET_EVENT_FS_MOUNT_ERROR: file name pointer • TCPIP_HTTP_NET_EVENT_CHUNK_POOL_ERROR: file name pointer • TCPIP_HTTP_NET_EVENT_FILE_BUFFER_POOL_ERROR: file name pointer • TCPIP_HTTP_NET_EVENT_DYNVAR_ALLOC_ERROR: dynamic variable name pointer • TCPIP_HTTP_NET_EVENT_UPLOAD_ALLOC_ERROR: file name pointer • TCPIP_HTTP_NET_EVENT_SSI_PARSE_ERROR: SSI command pointer • TCPIP_HTTP_NET_EVENT_SSI_COMMAND_ERROR: SSI command pointer • TCPIP_HTTP_NET_EVENT_SSI_ATTRIB_ERROR: SSI command pointer • TCPIP_HTTP_NET_EVENT_SSI_ALLOC_DESCRIPTOR_ERROR: SSI command pointer • TCPIP_HTTP_NET_EVENT_DYNVAR_ARG_NAME_TRUNCATED: dynamic variable name pointer • TCPIP_HTTP_NET_EVENT_DYNVAR_ARG_NUMBER_TRUNCATED: dynamic variable name pointer • TCPIP_HTTP_NET_EVENT_DYNVAR_RETRIES_EXCEEDED: dynamic variable name pointer • TCPIP_HTTP_NET_EVENT_SSI_ATTRIB_NUMBER_TRUNCATED: SSI argument pointer • TCPIP_HTTP_NET_EVENT_SSI_ATTRIB_UNKNOWN: SSI attribute pointer • TCPIP_HTTP_NET_EVENT_SSI_ATTRIB_NUMBER_MISMATCH: SSI command pointer • TCPIP_HTTP_NET_EVENT_SSI_VAR_NUMBER_EXCEEDED: SSI variable pointer • TCPIP_HTTP_NET_EVENT_SSI_VAR_UNKNOWN: SSI variable pointer • TCPIP_HTTP_NET_EVENT_SSI_VAR_VOID: SSI variable pointer • TCPIP_HTTP_NET_EVENT_SSI_VAR_DELETED: SSI variable pointer • TCPIP_HTTP_NET_EVENT_CHUNK_POOL_EMPTY: file name pointer • TCPIP_HTTP_NET_EVENT_FILE_BUFFER_POOL_EMPTY: file name pointer • TCPIP_HTTP_NET_EVENT_PEEK_BUFFER_SIZE_EXCEEDED: string with excess number of bytes that cannot be read Valid within this call context only!
pCBack	user TCPIP_HTTP_NET_USER_CALLBACK pointer

Function

void TCPIP_HTTP_NET_EventReport(TCPIP_HTTP_NET_CONN_HANDLE connHandle,
TCPIP_HTTP_NET_EVENT_TYPE evType, const void* evInfo,
const struct _tag_TCPIP_HTTP_NET_USER_CALLBACK* pCBack);

TCPIP_HTTP_NET_Task Function

Standard TCP/IP stack module task function.

File

http_net.h

C

```
void TCPIP_HTTP_NET_Task();
```

Returns

None.

Description

This function performs HTTP module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The HTTP module should have been initialized.

Function

void TCPIP_HTTP_NET_Task(void)

TCPIP_HTTP_NET_URLDecode Function

Parses a string from URL encoding to plain text.

File

http_net.h

C

```
uint8_t* TCPIP_HTTP_NET_URLDecode(uint8_t* cData);
```

Returns

A pointer to the last null terminator in data, which is also the first free byte for new data.

Description

This function parses a string from URL encoding to plain text. The following conversions are made: ‘=’ to ‘0’, ‘&’ to ‘0’, ‘+’ to ‘ ‘, and “%xx” to a single hex byte.

After completion, the data has been decoded and a null terminator signifies the end of a name or value. A second null terminator (or a null name parameter) indicates the end of all the data.

Remarks

This function is called by the stack to parse GET arguments and cookie data. User applications can use this function to decode POST data, but first need to verify that the string is null-terminated.

Preconditions

The data parameter is null terminated and has at least one extra byte free.

Parameters

Parameters	Description
cData	The string which is to be decoded in place.

Function

uint8_t* TCPIP_HTTP_NET_URLDecode(uint8_t* cData)

TCPIP_HTTP_NET_UserHandlerDeregister Function

Deregisters a previously registered HTTP user handler.

File

http_net.h

C

```
bool TCPIP_HTTP_NET_UserHandlerDeregister(TCPIP_HTTP_NET_USER_HANDLE hHttp);
```

Returns

- true - if the call succeeds
- false - if no such handler is registered or there are active connections

Description

This function deregisters a HTTP user callback handler.

Remarks

The call will fail if there is active HTTP traffic. The handler cannot be deregistered while HTTP traffic is in progress.

Preconditions

The HTTP server module properly initialized.

Parameters

Parameters	Description
hHttp	A handle returned by a previous call to TCPIP_HTTP_NET_UserHandlerRegister

Function

TCPIP_HTTP_NET_UserHandlerDeregister(TCPIP_HTTP_NET_USER_HANDLE hHttp)

TCPIP_HTTP_NET_UserHandlerRegister Function

Registers a user callback structure with the HTTP server

File

http_net.h

C

```
TCPIP_HTTP_NET_USER_HANDLE TCPIP_HTTP_NET_UserHandlerRegister(const TCPIP_HTTP_NET_USER_CALLBACK*
userCallback);
```

Returns

Returns a valid handle if the call succeeds, or a null handle if the call failed (out of memory, for example).

Description

The function registers a user callback data structure with the HTTP server. The HTTP server will call the user supplied callbacks at run-time when processing the web pages.

Remarks

Currently only one user callback structure could be registered. The call will fail if a user callback structure is already registered.

Preconditions

The HTTP server module properly initialized.

Example

Parameters

Parameters	Description
userCallback	user callback to be registered with the HTTP server

Function

TCPIP_HTTP_NET_USER_HANDLE TCPIP_HTTP_NET_UserHandlerRegister
(const TCPIP_HTTP_NET_USER_CALLBACK* userCallback);

TCPIP_HTTP_NET_ConnectionDataBufferSizeGet Function

Returns the size of the connection general purpose data buffer.

File

http_net.h

C

```
uint16_t TCPIP_HTTP_NET_ConnectionDataBufferSizeGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

Size of the connection's general purpose data buffer.

Description

This function returns the size of the HTTP connection internal data buffer.

Remarks

This is the parameter that was used for HTTP initialization in TCPIP_HTTP_NET_MODULE_CONFIG::dataLen.

Preconditions

None.

Example

```
  // Read a name
  uint8_t* httpDataBuff = TCPIP_HTTP_NET_ConnectionDataBufferGet(connHandle);
  uint16_t httpDataLen = TCPIP_HTTP_NET_ConnectionDataBufferSizeGet(connHandle);
  if(TCPIP_HTTP_NET_ConnectionPostNameRead(connHandle, httpDataBuff, httpDataLen) ==
TCPIP_HTTP_NET_READ_INCOMPLETE)
  {
      return TCPIP_HTTP_NET_IO_RES_NEED_DATA;
  }
```

Parameters

Parameters	Description
connHandle	HTTP connection handle

Function

uint16_t TCPIP_HTTP_NET_ConnectionDataBufferSizeGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle);

TCPIP_HTTP_NET_ConnectionDynamicDescriptors Function

Returns the number of dynamic variable descriptors

File

http_net.h

C

```
int TCPIP_HTTP_NET_ConnectionDynamicDescriptors();
```

Returns

The number of descriptors allocated by the HTTP module.

Description

This function returns the number of the dynamic variable buffer descriptors that are allocated by the HTTP for dynamic variable processing.

Remarks

Currently the dynamic variable descriptors are allocated at the HTTP initialization and cannot be changed at run-time.

Preconditions

None

Function

int TCPIP_HTTP_NET_ConnectionDynamicDescriptors(void);

TCPIP_HTTP_NET_SSINotification Function

Reports an SSI processing event that occurs in the processing of a HTTP web page

File

http_net.h

C

```
bool TCPIP_HTTP_NET_SSINotification(TCPIP_HTTP_NET_CONN_HANDLE connHandle, TCPIP_HTTP_SSI_NOTIFY_DCPT*
pSSINotifyDcpt, const struct _tag_TCPIP_HTTP_NET_USER_CALLBACK* pCBack);
```

Returns

true - if the SSI processing is complete and no further action needs to be taken by the HTTP server false - the HTTP should process the SSI command

Description

Functions in this style are implemented by the application developer. This function is used by the HTTP server to report that an SSI command line was encountered while processing a file. The user has a chance to inspect the line and to provide custom action by using the SSI API functions.

Remarks

The ssiLine parameter is valid only in the context of this call. Any data that is needed for further processing should be copied to user storage.

This function could use the SSI API functions to alter/examine the value of SSI variables that are part of the ssiLine.

This function may NOT write to the network transport buffer. Possiblity to write to the transport channel could be eventually added, based on the dynamic variable model TCPIP_HTTP_NET_DynamicWrite.

The default return value should be false: the user function examines/adjusts value of SSI variables and instructs the HTTP module continue normally. However, the user has the option of supressing the output (SSI "echo") or override the value of a variable (SSI "set"), etc.

Preconditions

SSI processing should be enabled.

Parameters

Parameters	Description
connHandle	HTTP connection handle
pSSINotifyDcpt	pointer to a SSI notification descriptor containing:
fileName	the name of the file the SSI command belongs to
ssiCommand	the SSI command parsed from the command line
nAttribs	number of attribute descriptors in the command
pAttrDcpt	pointer to an array of descriptors parsed from this SSI command
pCBack	user TCPIP_HTTP_NET_USER_CALLBACK pointer

Function

bool TCPIP_HTTP_NET_SSINotification(TCPIP_HTTP_NET_CONN_HANDLE connHandle, TCPIP_HTTP_SSI_NOTIFY_DCPT* pSSINotifyDcpt, const struct _tag_TCPIP_HTTP_NET_USER_CALLBACK* pCBack);

TCPIP_HTTP_NET_SSIVariableDelete Function

Function to delete an SSI variable.

File

http_net.h

C

```
bool TCPIP_HTTP_NET_SSIVariableDelete(const char* varName);
```

Returns

true - if the variable existed and was deleted false - the variable didn't exist

Description

This function deletes an SSI variable if it exists.

Remarks

None.

Preconditions

The HTTP module should have been initialized. SSI should be enabled.

Parameters

Parameters	Description
varName	the SSI variable name

Function

bool TCPIP_HTTP_NET_SSIVariableDelete(const char* varName);

TCPIP_HTTP_NET_SSIVariableGet Function

Function to get access to an existing SSI variable.

File

http_net.h

C

```
const char* TCPIP_HTTP_NET_SSIVariableGet(const char* varName, TCPIP_HTTP_DYN_ARG_TYPE* pVarType, int32_t*
pVarInt);
```

Returns

a valid pointer to the SSI variable string representation if the variable was found 0 if there is no variable with such name

Description

This function performs a search for the corresponding SSI variable name and returns a pointer to the variable string representation.

Remarks

The returned value points to the internal SSI variable representation. This pointer should not be used for changing the SSI variable value.

Preconditions

The HTTP module should have been initialized. SSI should be enabled.

Parameters

Parameters	Description
varName	the SSI variable to search for
pVarType	address to store the type of the SSI variable
pVarInt	address to store the integer value of this variable, if the variable exists and is an integer else this address won't be modified Could be NULL if not needed

Function

const char* TCPIP_HTTP_NET_SSIVariableGet(const char* varName, TCPIP_HTTP_DYN_ARG_TYPE* pVarType, int32_t* pVarInt);

TCPIP_HTTP_NET_SSIVariableGetByIndex Function

Function to get access to an existing SSI variable.

File

http_net.h

C

```
const char* TCPIP_HTTP_NET_SSIVariableGetByIndex(int varIndex, const char** pVarName,
TCPIP_HTTP_DYN_ARG_TYPE* pVarType, int32_t* pVarInt);
```

Returns

a valid pointer to the SSI variable string representation if the variable was found 0 if there is no variable with such name

Description

This function accesses the corresponding SSI variable by its index and returns a pointer to the variable string representation.

Remarks

The returned value points to the internal SSI variable representation. This pointer should not be used for changing the SSI variable value.

The pVarName points to the internal SSI variable name representation. This pointer MUST NOT be used for changing the SSI variable name.

None.

Preconditions

The HTTP module should have been initialized. SSI should be enabled.

Parameters

Parameters	Description
varIndex	the index of the SSI variable to search for Should be < TCPIP_HTTP_NET_SSIVariablesNumberGet()
pVarName	address to store a pointer to the variable name
pVarType	address to store the type of the SSI variable
pVarInt	address to store the integer value of this variable, if the variable exists and is an integer else this address won't be modified Could be NULL if not needed

Function

const char* TCPIP_HTTP_NET_SSIVariableGetByIndex(int varIndex, const char** pVarName, TCPIP_HTTP_DYN_ARG_TYPE* pVarType, int32_t* pVarInt);

TCPIP_HTTP_NET_SSIVariableSet Function

Function to set an SSI variable.

File

http_net.h

C

```
bool TCPIP_HTTP_NET_SSIVariableSet(const char* varName, TCPIP_HTTP_DYN_ARG_TYPE varType, const char* strValue, int32_t intValue);
```

Returns

true - if the variable was updated or created successfully false - the variable didn't exist and the attempt to create it failed (all slots already in use. Increase TCPIP_HTTP_NET_SSI_VARIABLES_NUMBER).

Description

This function sets the new values for an SSI variable. If a variable with such name does not exist, it is created.

Remarks

The string variable interpretation is needed even if the variable is of integer type. HTTP module will use that representation instead of doing an itoa conversion on intValue. value points to the internal SSI variable representation.

The string representation should not exceed TCPIP_HTTP_NET_SSI_VARIABLE_STRING_MAX_LENGTH. Any excess variables will be truncated.

Preconditions

The HTTP module should have been initialized. SSI should be enabled.

Parameters

Parameters	Description
varName	the SSI variable name
varType	the type of the SSI variable
strValue	pointer to the string representation of the variable
intValue	the integer value of the variable, if the type is integer.

Function

bool TCPIP_HTTP_NET_SSIVariableSet(const char* varName, TCPIP_HTTP_DYN_ARG_TYPE varType, const char* strValue, int32_t intValue);

TCPIP_HTTP_NET_SSIVariablesNumberGet Function

Function to get the number of the current SSI variables.

File

http_net.h

C

```
int TCPIP_HTTP_NET_SSIVariablesNumberGet(int* pMaxNo);
```

Returns

The number of current SSI variables that are in use

Description

This function returns the number of SSI variables that currently exist. It will also return the maximum number of variables that the SSI can hold.

Remarks

None.

Preconditions

The HTTP module should have been initialized. SSI should be enabled.

Parameters

Parameters	Description
pMaxNo	pointer to store the maximum number of SSI variables that can exist Can be NULL if not needed

Function

int TCPIP_HTTP_NET_SSIVariablesNumberGet(int* pMaxNo);

TCPIP_HTTP_NET_ConnectionHandleGet Function

Gets the connection handle of a HTTP connection.

File

http_net.h

C

```
TCPIP_HTTP_NET_CONN_HANDLE TCPIP_HTTP_NET_ConnectionHandleGet(int connIx);
```

Returns

A valid connection handle if the connection index is valid 0 if there is no such connection

Description

This function will return the connection handle of the requested HTTP connection index.

Remarks

None

Preconditions

None.

Example

```
TCPIP_HTTP_NET_CONN_HANDLE connHandle;

connHandle = TCPIP_HTTP_NET_ConnectionHandleGet(0);
```

Parameters

Parameters	Description
connIx	the HTTP connection ix.

Function

TCPIP_HTTP_NET_CONN_HANDLE TCPIP_HTTP_NET_ConnectionHandleGet(int connIx);

TCPIP_HTTP_NET_ConnectionIndexGet Function

Gets the index of the HTTP connection.

File

http_net.h

C

```
int TCPIP_HTTP_NET_ConnectionIndexGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle);
```

Returns

The connection index.

Description

This function will return the index of the requested HTTP connection.

Remarks

None

Preconditions

None.

Example

```
int connIx;

connIx = TCPIP_HTTP_NET_ConnectionIndexGet(connHandle);
```

Parameters

Parameters	Description
connHandle	the HTTP connection handle.

Function

int TCPIP_HTTP_NET_ConnectionIndexGet(TCPIP_HTTP_NET_CONN_HANDLE connHandle);

b) Data Types and Constants

TCPIP_HTTP_DYN_ARG_DCPT Structure

HTTP dynamic argument descriptor.

File

http_net.h

C

```
typedef struct {
  uint16_t argType;
  uint16_t argFlags;
  union {
    int32_t argInt32;
    const char* argStr;
  }
} TCPIP_HTTP_DYN_ARG_DCPT;
```

Members

Members	Description
uint16_t argType;	a TCPIP_HTTP_DYN_ARG_TYPE value
uint16_t argFlags;	extra argument flags
int32_t argInt32;	use this member when the arg type is INT32
const char* argStr;	use this member when the arg type is string

Description

Data structure: TCPIP_HTTP_DYN_ARG_DCPT

This data type defines the structure of a HTTP dynamic variable argument. It is used for describing the dynamic variables arguments.

Remarks

The argument flags are currently not used. They are meant for further extensions.

TCPIP_HTTP_DYN_ARG_TYPE Enumeration

HTTP supported dynamic variables argument types.

File

http_net.h

C

```
typedef enum {
  TCPIP_HTTP_DYN_ARG_TYPE_INVALID = 0,
  TCPIP_HTTP_DYN_ARG_TYPE_INT32,
  TCPIP_HTTP_DYN_ARG_TYPE_STRING
} TCPIP_HTTP_DYN_ARG_TYPE;
```

Members

Members	Description
TCPIP_HTTP_DYN_ARG_TYPE_INVALID = 0	invalid argument type
TCPIP_HTTP_DYN_ARG_TYPE_INT32	the dynamic variable argument is a int32_t
TCPIP_HTTP_DYN_ARG_TYPE_STRING	the dynamic variable argument is a ASCII string

Description

Enumeration: TCPIP_HTTP_DYN_ARG_TYPE

This enumeration defines the types of the HTTP supported dynamic variables arguments.

Remarks

Currently a dynamic variable can have either string or int32_t parameters.

Only 16 bit values are currently supported.

TCPIP_HTTP_DYN_PRINT_RES Enumeration

Dynamic print result when a dynamic variable print callback function returns;

File

http_net.h

C

```
typedef enum {
  TCPIP_HTTP_DYN_PRINT_RES_DONE = 0,
  TCPIP_HTTP_DYN_PRINT_RES_DEFAULT,
  TCPIP_HTTP_DYN_PRINT_RES_PROCESS_AGAIN,
  TCPIP_HTTP_DYN_PRINT_RES_AGAIN
} TCPIP_HTTP_DYN_PRINT_RES;
```

Members

Members	Description
TCPIP_HTTP_DYN_PRINT_RES_DONE = 0	dynamic callback is done
TCPIP_HTTP_DYN_PRINT_RES_DEFAULT	no implementation supported for this dynamic variable, call the default action
TCPIP_HTTP_DYN_PRINT_RES_PROCESS_AGAIN	process the action of this call and then call again data written to the HTTP connection but more data is pending
TCPIP_HTTP_DYN_PRINT_RES_AGAIN	do not process any action just call again no data was available to be written to the connection or the written data should be ignored this turn

Description

Enumeration: TCPIP_HTTP_DYN_PRINT_RES

This enumeration defines the results associated with the HTTP dynamic variables callbacks (TCPIP_HTTP_NET_DynPrint).

Remarks

Currently the default action for a user defined dynamic variable is "do nothing". Keywords like "inc" have an internal implementation and don't need to be processed by the user.

TCPIP_HTTP_DYN_VAR_DCPT Structure

HTTP dynamic variable descriptor.

File

http_net.h

C

```
typedef struct {
  const char* dynName;
  const char* fileName;
  uint16_t callbackID;
  uint8_t dynFlags;
  uint8_t nArgs;
  TCPIP_HTTP_DYN_ARG_DCPT* dynArgs;
  const void* dynContext;
} TCPIP_HTTP_DYN_VAR_DCPT;
```

Members

Members	Description
const char* dynName;	ASCII string storing the dynamic variable name
const char* fileName;	ASCII string storing the file name the dynamic variable belongs to
uint16_t callbackID;	Call back ID: the dynamic variable index within the file
uint8_t dynFlags;	a TCPIP_HTTP_DYN_VAR_FLAGS value
uint8_t nArgs;	number of arguments that the variable has
TCPIP_HTTP_DYN_ARG_DCPT* dynArgs;	array of argument descriptors carrying the dynamic variable arguments
const void* dynContext;	dynamic context of the callback. This context is used by the HTTP server and is irrelevant to the user.

Description

Data structure: TCPIP_HTTP_DYN_VAR_DCPT

This data type defines the structure of a HTTP dynamic variable descriptor. When the user registers a TCPIP_HTTP_NET_DynPrint function for dynamic variable processing, this callback will receive the dynamic variable descriptor as a parameter.

Remarks

None.

TCPIP_HTTP_DYN_VAR_FLAGS Enumeration

HTTP supported dynamic variables flags.

File

http_net.h

C

```
typedef enum {
  TCPIP_HTTP_DYN_VAR_FLAG_NONE = 0,
  TCPIP_HTTP_DYN_VAR_FLAG_NAME_TRUNCATED = 0x01,
  TCPIP_HTTP_DYN_VAR_FLAG_ARG_NAME_TRUNCATED = 0x02,
  TCPIP_HTTP_DYN_VAR_FLAG_ARG_NO_TRUNCATED = 0x04
} TCPIP_HTTP_DYN_VAR_FLAGS;
```

Members

Members	Description
TCPIP_HTTP_DYN_VAR_FLAG_NONE = 0	no flag associated with this dynamic variable
TCPIP_HTTP_DYN_VAR_FLAG_NAME_TRUNCATED = 0x01	dynamic variable field exceeded available parsing space the dynamic variable name has been truncated

TCPIP_HTTP_DYN_VAR_FLAG_ARG_NAME_TRUNCATED = 0x02	dynamic variable field exceeded available parsing space the dynamic variable arguments have been truncated
TCPIP_HTTP_DYN_VAR_FLAG_ARG_NO_TRUNCATED = 0x04	dynamic variable arguments exceeded available buffering space the number of arguments of the dynamic variable has been truncated

Description

Enumeration: TCPIP_HTTP_DYN_VAR_FLAGS

This enumeration defines the flags associated with the HTTP supported dynamic variables.

Remarks

Multiple flags con be set simultaneously. New flags will be eventually added. Only 16-bit values are currently supported.

TCPIP_HTTP_NET_CONN_HANDLE Type

File

http_net.h

C

```
typedef const void* TCPIP_HTTP_NET_CONN_HANDLE;
```

Description

HTTP connection identifier, handle of a HTTP connection

TCPIP_HTTP_NET_EVENT_TYPE Enumeration

HTTP reported run-time events.

File

http_net.h

C

```
typedef enum {
  TCPIP_HTTP_NET_EVENT_NONE = 0,
  TCPIP_HTTP_NET_EVENT_FS_UPLOAD_COMPLETE,
  TCPIP_HTTP_NET_EVENT_FILE_OPEN_ERROR = -1,
  TCPIP_HTTP_NET_EVENT_FILE_NAME_ERROR = -2,
  TCPIP_HTTP_NET_EVENT_FILE_NAME_SIZE_ERROR = -3,
  TCPIP_HTTP_NET_EVENT_FILE_SIZE_ERROR = -4,
  TCPIP_HTTP_NET_EVENT_FILE_READ_ERROR = -5,
  TCPIP_HTTP_NET_EVENT_FILE_PARSE_ERROR = -6,
  TCPIP_HTTP_NET_EVENT_DEPTH_ERROR = -7,
  TCPIP_HTTP_NET_EVENT_DYNVAR_PARSE_ERROR = -8,
  TCPIP_HTTP_NET_EVENT_FS_WRITE_ERROR = -9,
  TCPIP_HTTP_NET_EVENT_FS_MOUNT_ERROR = -10,
  TCPIP_HTTP_NET_EVENT_CHUNK_POOL_ERROR = -11,
  TCPIP_HTTP_NET_EVENT_FILE_BUFFER_POOL_ERROR = -12,
  TCPIP_HTTP_NET_EVENT_DYNVAR_ALLOC_ERROR = -13,
  TCPIP_HTTP_NET_EVENT_UPLOAD_ALLOC_ERROR = -14,
  TCPIP_HTTP_NET_EVENT_SSI_PARSE_ERROR = -15,
  TCPIP_HTTP_NET_EVENT_SSI_COMMAND_ERROR = -16,
  TCPIP_HTTP_NET_EVENT_SSI_ATTRIB_ERROR = -17,
  TCPIP_HTTP_NET_EVENT_SSI_ALLOC_DESCRIPTOR_ERROR = -18,
  TCPIP_HTTP_NET_EVENT_DYNVAR_ARG_NAME_TRUNCATED = 0x8001,
  TCPIP_HTTP_NET_EVENT_DYNVAR_ARG_NUMBER_TRUNCATED = 0x8002,
  TCPIP_HTTP_NET_EVENT_DYNVAR_RETRIES_EXCEEDED = 0x8003,
  TCPIP_HTTP_NET_EVENT_SSI_ATTRIB_NUMBER_TRUNCATED = 0x8004,
  TCPIP_HTTP_NET_EVENT_SSI_ATTRIB_UNKNOWN = 0x8005,
  TCPIP_HTTP_NET_EVENT_SSI_ATTRIB_NUMBER_MISMATCH = 0x8006,
  TCPIP_HTTP_NET_EVENT_SSI_VAR_NUMBER_EXCEEDED = 0x8007,
  TCPIP_HTTP_NET_EVENT_SSI_VAR_UNKNOWN = 0x8008,
  TCPIP_HTTP_NET_EVENT_SSI_VAR_VOID = 0x8009,
  TCPIP_HTTP_NET_EVENT_SSI_HASH_CREATE_FAILED = 0x800a,
  TCPIP_HTTP_NET_EVENT_SSI_VAR_DELETED = 0x800b,
  TCPIP_HTTP_NET_EVENT_CHUNK_POOL_EMPTY = 0x8020,
  TCPIP_HTTP_NET_EVENT_FILE_BUFFER_POOL_EMPTY = 0x8021,
  TCPIP_HTTP_NET_EVENT_PEEK_BUFFER_SIZE_EXCEEDED = 0x8030
} TCPIP_HTTP_NET_EVENT_TYPE;
```

Members

Members	Description
TCPIP_HTTP_NET_EVENT_NONE = 0	no event
TCPIP_HTTP_NET_EVENT_FS_UPLOAD_COMPLETE	Notification that a FS upload operation was completed successfully
TCPIP_HTTP_NET_EVENT_FILE_OPEN_ERROR = -1	errors an error occurred when opening a HTTP file
TCPIP_HTTP_NET_EVENT_FILE_NAME_ERROR = -2	a file name was not specified
TCPIP_HTTP_NET_EVENT_FILE_NAME_SIZE_ERROR = -3	a file name was longer than the HTTP storage space
TCPIP_HTTP_NET_EVENT_FILE_SIZE_ERROR = -4	file size error
TCPIP_HTTP_NET_EVENT_FILE_READ_ERROR = -5	file read error
TCPIP_HTTP_NET_EVENT_FILE_PARSE_ERROR = -6	file parse error: line too long
TCPIP_HTTP_NET_EVENT_DEPTH_ERROR = -7	the depth allowed for a recursive call was exceeded
TCPIP_HTTP_NET_EVENT_DYNVAR_PARSE_ERROR = -8	an error occurred when parsing: dynamic variable name terminator could not be found, for example
TCPIP_HTTP_NET_EVENT_FS_WRITE_ERROR = -9	a write error was reported while performing an FS upload
TCPIP_HTTP_NET_EVENT_FS_MOUNT_ERROR = -10	a write error was reported while mounting after an FS upload
TCPIP_HTTP_NET_EVENT_CHUNK_POOL_ERROR = -11	the number of retries for getting a chunk from the pool has been exceeded
TCPIP_HTTP_NET_EVENT_FILE_BUFFER_POOL_ERROR = -12	the number of retries for getting a file buffer has been exceeded
TCPIP_HTTP_NET_EVENT_DYNVAR_ALLOC_ERROR = -13	out of memory when trying to allocate space for a dynamic variable descriptor Note that for the dynamic variable descriptor allocation the system heap is used: • the TCPIP_STACK_MALLOC_FUNC/TCPIP_STACK_FREE_FUNC that's passed at the stack initialization

TCPIP_HTTP_NET_EVENT_SSI_PARSE_ERROR = -15	an error occurred when parsing an SSI command: SSI terminator could not be found, for example
TCPIP_HTTP_NET_EVENT_SSI_COMMAND_ERROR = -16	an unknown/unsupported SSI command
TCPIP_HTTP_NET_EVENT_SSI_ATTRIB_ERROR = -17	a SSI attribute error : command w/o attribute, etc.
TCPIP_HTTP_NET_EVENT_SSI_ALLOC_DESCRIPTOR_ERROR = -18	out of memory when trying to allocate space for a SSI command descriptor Note that for the SSI commands the system heap is used: • the TCPIP_STACK_MALLOC_FUNC/TCPIP_STACK_FREE_FUNC that's passed at the stack initialization
TCPIP_HTTP_NET_EVENT_DYNVAR_ARG_NAME_TRUNCATED = 0x8001	warning: a dynamic variable argument name too long, truncated
TCPIP_HTTP_NET_EVENT_DYNVAR_ARG_NUMBER_TRUNCATED = 0x8002	warning: too many arguments for a dynamic variable, truncated
TCPIP_HTTP_NET_EVENT_DYNVAR_RETRIES_EXCEEDED = 0x8003	warning: too many retries for a dynamic variable, stopped
TCPIP_HTTP_NET_EVENT_SSI_ATTRIB_NUMBER_TRUNCATED = 0x8004	warning: too many attributes for a SSI command, truncated
TCPIP_HTTP_NET_EVENT_SSI_ATTRIB_UNKNOWN = 0x8005	warning: unrecognized/unsupported SSI command attribute
TCPIP_HTTP_NET_EVENT_SSI_ATTRIB_NUMBER_MISMATCH = 0x8006	warning: wrong number of SSI command attributes
TCPIP_HTTP_NET_EVENT_SSI_VAR_NUMBER_EXCEEDED = 0x8007	warning: number of SSI set variables exceeded
TCPIP_HTTP_NET_EVENT_SSI_VAR_UNKNOWN = 0x8008	warning: SSI variable does not exist
TCPIP_HTTP_NET_EVENT_SSI_VAR_VOID = 0x8009	warning: SSI variable is void: not echoed
TCPIP_HTTP_NET_EVENT_SSI_HASH_CREATE_FAILED = 0x800a	warning: SSI variable hash could not be created, allocation failed Ther ewill be no run time SSI variable support
TCPIP_HTTP_NET_EVENT_SSI_VAR_DELETED = 0x800b	event: SSI variable deleted
TCPIP_HTTP_NET_EVENT_CHUNK_POOL_EMPTY = 0x8020	warning: allocation from the HTTP chunk pool failed (the allocation will be retried)

TCPIP_HTTP_NET_EVENT_FILE_BUFFER_POOL_EMPTY = 0x8021	warning: allocation from the HTTP file buffers pool failed (the allocation will be retried)
TCPIP_HTTP_NET_EVENT_PEEK_BUFFER_SIZE_EXCEEDED = 0x8030	warning: the HTTP peek buffer is too small and cannot contain all the data available in the transport socket buffer and a HTTP search operation may fail This will happen only for transport sockets that do not support peek operation with an offset parameter

Description

Enumeration: TCPIP_HTTP_NET_EVENT_TYPE

This enumeration defines the types of the HTTP reported events when processing dynamic variables, files, etc.

Remarks

Multiple warnings can be set simultaneously.

TCPIP_HTTP_NET_IO_RESULT Enumeration

File

http_net.h

C

```
typedef enum {
  TCPIP_HTTP_NET_IO_RES_DONE = 0u,
  TCPIP_HTTP_NET_IO_RES_NEED_DATA,
  TCPIP_HTTP_NET_IO_RES_WAITING,
  TCPIP_HTTP_NET_IO_RES_ERROR
} TCPIP_HTTP_NET_IO_RESULT;
```

Members

Members	Description
TCPIP_HTTP_NET_IO_RES_DONE = 0u	Finished with procedure
TCPIP_HTTP_NET_IO_RES_NEED_DATA	More data needed to continue, call again later
TCPIP_HTTP_NET_IO_RES_WAITING	Waiting for asynchronous process to complete, call again later
TCPIP_HTTP_NET_IO_RES_ERROR	Some error has occurred, operation will be aborted

Description

Result states for execution callbacks

TCPIP_HTTP_NET_MODULE_CONFIG Structure

File

http_net.h

C

```
typedef struct {
  uint16_t nConnections;
  uint16_t dataLen;
  uint16_t sktTxBuffSize;
  uint16_t sktRxBuffSize;
  uint16_t listenPort;
  uint16_t nDescriptors;
  uint16_t nChunks;
  uint16_t maxRecurseLevel;
  uint16_t configFlags;
  uint16_t nFileBuffers;
  uint16_t fileBufferSize;
  uint16_t chunkPoolRetries;
  uint16_t fileBufferRetries;
  uint16_t dynVarRetries;
} TCPIP_HTTP_NET_MODULE_CONFIG;
```

Members

Members	Description
uint16_t nConnections;	number of simultaneous HTTP connections allowed

uint16_t dataLen;	size of the data buffer for reading cookie and GET/POST arguments (bytes)
uint16_t sktTxBuffSize;	size of TX buffer for the associated socket; leave 0 for default
uint16_t sktRxBuffSize;	size of RX buffer for the associated socket; leave 0 for default
uint16_t listenPort;	HTTP listening port: 80, 443, etc.
uint16_t nDescriptors;	how many buffers descriptors for dynamic variable processing to create they are independent of the HTTP connection number all the HTTP connections use from the dynamic descriptors pool
uint16_t nChunks;	maximum number of chunks that are created It depends on the TCPIP_HTTP_NET_MAX_RECURSE_LEVEL and on the number of connections Maximum number should be TCPIP_HTTP_NET_MAX_CONNECTIONS * TCPIP_HTTP_NET_MAX_RECURSE_LEVEL All the chunks are in a pool and are used by all connections
uint16_t maxRecurseLevel;	The maximum depth of recursive calls for serving a web page: • files without dynvars: 1 • file including another file: + 1 • file including a dynamic variable: + 1 etc.
uint16_t configFlags;	a TCPIP_HTTP_NET_MODULE_FLAGS value.
uint16_t nFileBuffers;	number of file buffers to be created; These buffers are used to store data while file processing is done They are organized in a pool Each file being processed needs a file buffer and tries to get it from the pool If a buffer is not available, the HTTP conenction will wait for one to become available. Once the file is done the file buffer is released and could be used by a different file The number depends on the number of files that are processed in parallel To avoid deadlock the number should be >= than the number of maximum files that can be open simultaneously: i.e. for file1 ->include file2 -> include file3 you'll need >= 3 file process buffers
uint16_t fileBufferSize;	size of each of these file buffers should correspond to TCPIP_HTTP_NET_FILE_PROCESS_BUFFER_SIZE
uint16_t chunkPoolRetries;	how many retries to get chunk from the pool before giving up
uint16_t fileBufferRetries;	how many retries to get a fileBuffer before giving up
uint16_t dynVarRetries;	how many retries to have for a dynamic variable dynamicPrint function before calling it done

Description

HTTP module dynamic configuration data

TCPIP_HTTP_NET_MODULE_FLAGS Enumeration

File

http_net.h

C

```
typedef enum {
  TCPIP_HTTP_NET_MODULE_FLAG_DEFAULT = 0x00,
  TCPIP_HTTP_NET_MODULE_FLAG_NON_PERSISTENT = 0x01,
  TCPIP_HTTP_NET_MODULE_FLAG_NO_DELAY = 0x02,
  TCPIP_HTTP_NET_MODULE_FLAG_SECURE_ON = 0x10,
  TCPIP_HTTP_NET_MODULE_FLAG_SECURE_OFF = 0x20,
  TCPIP_HTTP_NET_MODULE_FLAG_SECURE_DEFAULT = 0x00
} TCPIP_HTTP_NET_MODULE_FLAGS;
```

Members

Members	Description
TCPIP_HTTP_NET_MODULE_FLAG_DEFAULT = 0x00	Default flags value
TCPIP_HTTP_NET_MODULE_FLAG_NON_PERSISTENT = 0x01	Use non-persistent connections This flag will cause the HTTP connections to be non-persistent and closed after serving each request to the client By default the HTTP connections are persistent
TCPIP_HTTP_NET_MODULE_FLAG_NO_DELAY = 0x02	Create the HTTP sockets with NO-DELAY option. It will flush data as soon as possible.
TCPIP_HTTP_NET_MODULE_FLAG_SECURE_ON = 0x10	All HTTP connections have to be secure (supposing the network presentation layer supports encryption) Cannot be used together with TCPIP_HTTP_NET_MODULE_FLAG_SECURE_OFF
TCPIP_HTTP_NET_MODULE_FLAG_SECURE_OFF = 0x20	HTTP connections will be non-secure Cannot be used together with TCPIP_HTTP_NET_MODULE_FLAG_SECURE_ON

TCPIP_HTTP_NET_MODULE_FLAG_SECURE_DEFAULT = 0x00	HTTP security is based on the port numbers

Description

HTTP module configuration flags Multiple flags can be OR-ed

TCPIP_HTTP_NET_READ_STATUS Enumeration

File

http_net.h

C

```
typedef enum {
  TCPIP_HTTP_NET_READ_OK = 0,
  TCPIP_HTTP_NET_READ_TRUNCATED,
  TCPIP_HTTP_NET_READ_INCOMPLETE
} TCPIP_HTTP_NET_READ_STATUS;
```

Members

Members	Description
TCPIP_HTTP_NET_READ_OK = 0	Read was successful
TCPIP_HTTP_NET_READ_TRUNCATED	Buffer overflow prevented by truncating value
TCPIP_HTTP_NET_READ_INCOMPLETE	Entire object is not yet in the buffer. Try again later.

Description

Result states for TCPIP_HTTP_NET_ConnectionPostNameRead, TCPIP_HTTP_NET_ConnectionPostValueRead and TCPIP_HTTP_NET_ConnectionPostReadPair

TCPIP_HTTP_NET_STATUS Enumeration

File

http_net.h

C

```
typedef enum {
  TCPIP_HTTP_NET_STAT_GET = 0u,
  TCPIP_HTTP_NET_STAT_POST,
  TCPIP_HTTP_NET_STAT_BAD_REQUEST,
  TCPIP_HTTP_NET_STAT_UNAUTHORIZED,
  TCPIP_HTTP_NET_STAT_NOT_FOUND,
  TCPIP_HTTP_NET_STAT_OVERFLOW,
  TCPIP_HTTP_NET_STAT_INTERNAL_SERVER_ERROR,
  TCPIP_HTTP_NET_STAT_NOT_IMPLEMENTED,
  TCPIP_HTTP_NET_STAT_REDIRECT,
  TCPIP_HTTP_NET_STAT_TLS_REQUIRED,
  TCPIP_HTTP_NET_STAT_UPLOAD_FORM,
  TCPIP_HTTP_NET_STAT_UPLOAD_STARTED,
  TCPIP_HTTP_NET_STAT_UPLOAD_WRITE,
  TCPIP_HTTP_NET_STAT_UPLOAD_WRITE_WAIT,
  TCPIP_HTTP_NET_STAT_UPLOAD_OK,
  TCPIP_HTTP_NET_STAT_UPLOAD_ERROR
} TCPIP_HTTP_NET_STATUS;
```

Members

Members	Description
TCPIP_HTTP_NET_STAT_GET = 0u	GET command is being processed
TCPIP_HTTP_NET_STAT_POST	POST command is being processed
TCPIP_HTTP_NET_STAT_BAD_REQUEST	400 Bad Request will be returned
TCPIP_HTTP_NET_STAT_UNAUTHORIZED	401 Unauthorized will be returned
TCPIP_HTTP_NET_STAT_NOT_FOUND	404 Not Found will be returned
TCPIP_HTTP_NET_STAT_OVERFLOW	414 Request-URI Too Long will be returned
TCPIP_HTTP_NET_STAT_INTERNAL_SERVER_ERROR	500 Internal Server Error will be returned

TCPIP_HTTP_NET_STAT_NOT_IMPLEMENTED	501 Not Implemented (not a GET or POST command)
TCPIP_HTTP_NET_STAT_REDIRECT	302 Redirect will be returned
TCPIP_HTTP_NET_STAT_TLS_REQUIRED	403 Forbidden is returned, indicating TLS is required
TCPIP_HTTP_NET_STAT_UPLOAD_FORM	Show the Upload form
TCPIP_HTTP_NET_STAT_UPLOAD_STARTED	An upload operation is being processed
TCPIP_HTTP_NET_STAT_UPLOAD_WRITE	An upload operation is currently writing
TCPIP_HTTP_NET_STAT_UPLOAD_WRITE_WAIT	An upload operation is currently waiting for the write completion
TCPIP_HTTP_NET_STAT_UPLOAD_OK	An Upload was successful
TCPIP_HTTP_NET_STAT_UPLOAD_ERROR	An Upload was not a valid image

Description

Supported Commands and Server Response Codes

TCPIP_HTTP_NET_USER_CALLBACK Structure

HTTP user implemented callback data structure.

File

http_net.h

C

```
typedef struct _tag_TCPIP_HTTP_NET_USER_CALLBACK {
  TCPIP_HTTP_NET_IO_RESULT (* getExecute)(TCPIP_HTTP_NET_CONN_HANDLE connHandle, const struct
_tag_TCPIP_HTTP_NET_USER_CALLBACK* pCBack);
  TCPIP_HTTP_NET_IO_RESULT (* postExecute)(TCPIP_HTTP_NET_CONN_HANDLE connHandle, const struct
_tag_TCPIP_HTTP_NET_USER_CALLBACK* pCBack);
  uint8_t (* fileAuthenticate)(TCPIP_HTTP_NET_CONN_HANDLE connHandle, const char* cFile, const struct
_tag_TCPIP_HTTP_NET_USER_CALLBACK* pCBack);
  uint8_t (* userAuthenticate)(TCPIP_HTTP_NET_CONN_HANDLE connHandle, const char* cUser, const char* cPass,
const struct _tag_TCPIP_HTTP_NET_USER_CALLBACK* pCBack);

void (* dynamicAck)(TCPIP_HTTP_NET_CONN_HANDLE connHandle, const void* buffer, const struct _tag_TCPIP_HTTP_NET_USER_CALLBACK* pCBack);	TCPIP_HTTP_NET_DynAcknowledge Dynamic variable acknowledge function
void (* eventReport)(TCPIP_HTTP_NET_CONN_HANDLE connHandle, TCPIP_HTTP_NET_EVENT_TYPE evType, const void* evInfo, const struct _tag_TCPIP_HTTP_NET_USER_CALLBACK* pCBack);	TCPIP_HTTP_NET_EventReport run-time HTTP processing report
bool (* ssiNotify)(TCPIP_HTTP_NET_CONN_HANDLE connHandle, TCPIP_HTTP_SSI_NOTIFY_DCPT* pSSINotifyDcpt, const struct _tag_TCPIP_HTTP_NET_USER_CALLBACK* pCBack);	TCPIP_HTTP_NET_SSINotification run-time HTTP SSI processing

Description

Structure: TCPIP_HTTP_NET_USER_CALLBACK

This data structure defines the user callbacks that are implemented by the user and the HTTP server calls at run-time.

Remarks

See the detailed explanation for each callback in the callback templates section.

The extra pCBack parameter is passed back for allowing the user to store additional info in the supplied TCPIP_HTTP_NET_USER_CALLBACK data structure that could be used at run-time.

TCPIP_HTTP_NET_USER_HANDLE Type

HTTP user handle.

File

http_net.h

C

```
typedef const void* TCPIP_HTTP_NET_USER_HANDLE;
```

Description

Type: TCPIP_HTTP_NET_USER_HANDLE

A handle that a client can use after the HTTP user callback has been registered.

TCPIP_HTTP_NET_ConnectionPostReadPair Macro

Reads a name and value pair from a URL encoded string in the network transport buffer.

File

http_net.h

C

```
#define TCPIP_HTTP_NET_ConnectionPostReadPair(connHandle, cData, wLen) \
        TCPIP_HTTP_NET_ConnectionPostValueRead(connHandle, cData, wLen)
```

Returns

- TCPIP_HTTP_NET_READ_OK - name and value were successfully read
- TCPIP_HTTP_NET_READ_TRUNCTATED - entire name and value could not fit in the buffer, so input was truncated and data has been lost
- TCPIP_HTTP_NET_READ_INCOMPLETE - entire name and value was not yet in the buffer, so call this function again later to retrieve

Description

Reads a name and value pair from a URL encoded string in the network transport buffer. This function is meant to be called from an TCPIP_HTTP_NET_ConnectionPostExecute callback to facilitate easier parsing of incoming data. This function also prevents buffer overflows by forcing the programmer to indicate how many bytes are expected. At least 2 extra bytes are needed in cData over the maximum length of data expected to be read.

This function will read until the next '&' character, which indicates the end of a value parameter. It assumes that the front of the buffer is the

beginning of the name parameter to be read.

This function properly updates the connection byteCount (see TCPIP_HTTP_NET_ConnectionByteCountGet) by decrementing it by the number of bytes read. It also removes the delimiting '&' from the buffer.

Once complete, two strings will exist in the cData buffer. The first is the parameter name that was read, while the second is the associated value.

Remarks

This function is aliased to TCPIP_HTTP_NET_ConnectionPostValueRead, since they effectively perform the same task. The name is provided only for completeness.

Preconditions

The front of the network transport buffer is the beginning of a name parameter, and the rest of the network transport buffer contains a URL-encoded string with a name parameter terminated by a '=' character and a value parameter terminated by a '&'.

Parameters

Parameters	Description
connHandle	HTTP connection handle
cData	where to store the name and value strings once they are read
wLen	how many bytes can be written to cData

Function

TCPIP_HTTP_NET_READ_STATUS TCPIP_HTTP_NET_ConnectionPostReadPair(TCPIP_HTTP_NET_CONN_HANDLE connHandle, uint8_t* cData, uint16_t wLen)

TCPIP_HTTP_SSI_ATTR_DCPT Structure

HTTP SSI attribute descriptor.

File

http_net.h

C

```
typedef struct {
  const char* attribute;
  char* value;
} TCPIP_HTTP_SSI_ATTR_DCPT;
```

Members

Members	Description
const char* attribute;	the SSI attribute of the command
char* value;	the SSI value

Description

Data structure: TCPIP_HTTP_SSI_ATTR_DCPT

This data type defines the structure of a SSI command attribute descriptor. When the user registers a TCPIP_HTTP_NET_SSINotification function for SSI processing, this callback will receive info about the SSI attribute descriptors.

Remarks

The SSI commands consist of pairs of (attribute, value) tokens. For example: <!--#set var="varname" value="varvalue" --> has 2 pairs: pair 1 - attribute = var value = varname pair 2 - attribute = value value = varvalue

TCPIP_HTTP_SSI_NOTIFY_DCPT Structure

HTTP SSI notification descriptor.

File

http_net.h

C

```
typedef struct {
  const char* fileName;
  char* ssiCommand;
  int nAttribs;
```

```
  TCPIP_HTTP_SSI_ATTR_DCPT* pAttrDcpt;
} TCPIP_HTTP_SSI_NOTIFY_DCPT;
```

Members

Members	Description
const char* fileName;	the file containing the SSI command
char* ssiCommand;	the SSI command parsed from the command line
int nAttribs;	number of attributes descriptors in the command
TCPIP_HTTP_SSI_ATTR_DCPT* pAttrDcpt;	pointer to an array of descriptors parsed from this SSI command

Description

Data structure: TCPIP_HTTP_SSI_NOTIFY_DCPT

This data type defines the structure of a SSI notification descriptor. When the user registers a TCPIP_HTTP_NET_SSINotification function for SSI processing, this callback will receive a SSI descriptor as a parameter.

Remarks

None.

http_net.h	The HTTP web server module together with a file system (SYS_FS) allow the board to act as a web server. This module uses the network presentation layer to allow for encrypted connections.
http_net_config.h	HTTP Net configuration file

Description

This section lists the source and header files used by the library.

http_net.h

The HTTP web server module together with a file system (SYS_FS) allow the board to act as a web server. This module uses the network presentation layer to allow for encrypted connections.

Enumerations

	Name	Description
	TCPIP_HTTP_DYN_ARG_TYPE	HTTP supported dynamic variables argument types.
	TCPIP_HTTP_DYN_PRINT_RES	Dynamic print result when a dynamic variable print callback function returns;
	TCPIP_HTTP_DYN_VAR_FLAGS	HTTP supported dynamic variables flags.
	TCPIP_HTTP_NET_EVENT_TYPE	HTTP reported run-time events.
	TCPIP_HTTP_NET_IO_RESULT	Result states for execution callbacks
	TCPIP_HTTP_NET_MODULE_FLAGS	HTTP module configuration flags Multiple flags can be OR-ed
	TCPIP_HTTP_NET_READ_STATUS	Result states for TCPIP_HTTP_NET_ConnectionPostNameRead, TCPIP_HTTP_NET_ConnectionPostValueRead and TCPIP_HTTP_NET_ConnectionPostReadPair
	TCPIP_HTTP_NET_STATUS	Supported Commands and Server Response Codes

Functions

	Name	Description
	TCPIP_HTTP_NET_ActiveConnectionCountGet	Gets the number of active (and inactive) connections.
	TCPIP_HTTP_NET_ArgGet	Locates a form field value in a given data array.
	TCPIP_HTTP_NET_ConnectionByteCountDec	Decrements the connection byte count.
	TCPIP_HTTP_NET_ConnectionByteCountGet	Returns how many bytes have been read so far.
	TCPIP_HTTP_NET_ConnectionByteCountSet	Sets how many bytes have been read so far.
	TCPIP_HTTP_NET_ConnectionCallbackPosGet	Returns the callback position indicator.
	TCPIP_HTTP_NET_ConnectionCallbackPosSet	Sets the callback position indicator.
	TCPIP_HTTP_NET_ConnectionDataBufferGet	Returns pointer to connection general purpose data buffer.

	TCPIP_HTTP_NET_ConnectionDataBufferSizeGet	Returns the size of the connection general purpose data buffer.
	TCPIP_HTTP_NET_ConnectionDiscard	Discards any pending data in the connection RX buffer.
	TCPIP_HTTP_NET_ConnectionDynamicDescriptors	Returns the number of dynamic variable descriptors
	TCPIP_HTTP_NET_ConnectionFileAuthenticate	Determines if a given file name requires authentication
	TCPIP_HTTP_NET_ConnectionFileGet	Get handle to current connection's file.
	TCPIP_HTTP_NET_ConnectionFileInclude	Writes a file to the HTTP connection.
	TCPIP_HTTP_NET_ConnectionFlush	Immediately transmits all connection pending TX data.
	TCPIP_HTTP_NET_ConnectionGetExecute	Processes GET form field variables and cookies.
	TCPIP_HTTP_NET_ConnectionHandleGet	Gets the connection handle of a HTTP connection.
	TCPIP_HTTP_NET_ConnectionHasArgsGet	Checks whether there are get or cookie arguments.
	TCPIP_HTTP_NET_ConnectionHasArgsSet	Sets whether there are get or cookie arguments.
	TCPIP_HTTP_NET_ConnectionIndexGet	Gets the index of the HTTP connection.
	TCPIP_HTTP_NET_ConnectionIsAuthorizedGet	Gets the authorized state for the current connection.
	TCPIP_HTTP_NET_ConnectionIsAuthorizedSet	Sets the authorized state for the current connection.
	TCPIP_HTTP_NET_ConnectionNetHandle	Returns the network handle of the current connection.
	TCPIP_HTTP_NET_ConnectionPeek	Reads a specified number of data bytes from the connection RX buffer without removing them from the buffer.
	TCPIP_HTTP_NET_ConnectionPostExecute	Processes POST form variables and data.
	TCPIP_HTTP_NET_ConnectionPostNameRead	Reads a name from a URL encoded string in the network transport buffer.
	TCPIP_HTTP_NET_ConnectionPostSmGet	Get the POST state machine state.
	TCPIP_HTTP_NET_ConnectionPostSmSet	Set the POST state machine state.
	TCPIP_HTTP_NET_ConnectionPostValueRead	Reads a value from a URL encoded string in the network transport buffer.
	TCPIP_HTTP_NET_ConnectionRead	Reads an array of data bytes from a connection's RX buffer.
	TCPIP_HTTP_NET_ConnectionReadBufferSize	Returns the size of the connection RX buffer.
	TCPIP_HTTP_NET_ConnectionReadIsReady	Determines how many bytes can be read from the connection RX buffer.
	TCPIP_HTTP_NET_ConnectionSocketGet	Get the socket for the current connection.
	TCPIP_HTTP_NET_ConnectionStatusGet	Gets HTTP status.
	TCPIP_HTTP_NET_ConnectionStatusSet	Sets HTTP status.
	TCPIP_HTTP_NET_ConnectionStringFind	Helper to find a string of characters in an incoming connection buffer.
	TCPIP_HTTP_NET_ConnectionUserAuthenticate	Performs validation on a specific user name and password.
	TCPIP_HTTP_NET_ConnectionUserDataGet	Gets the user data parameter for the current connection.
	TCPIP_HTTP_NET_ConnectionUserDataSet	Sets the user data parameter for the current connection.
	TCPIP_HTTP_NET_DynAcknowledge	Dynamic variable acknowledge function
	TCPIP_HTTP_NET_DynamicWrite	Writes a data buffer to the current connection
	TCPIP_HTTP_NET_DynamicWriteString	Helper for writing a string within a dynamic variable context.
	TCPIP_HTTP_NET_DynPrint	Inserts dynamic content into a web page
	TCPIP_HTTP_NET_EventReport	Reports an event that occurred in the processing of a HTTP web page
	TCPIP_HTTP_NET_SSINotification	Reports an SSI processing event that occurs in the processing of a HTTP web page
	TCPIP_HTTP_NET_SSIVariableDelete	Function to delete an SSI variable.
	TCPIP_HTTP_NET_SSIVariableGet	Function to get access to an existing SSI variable.
	TCPIP_HTTP_NET_SSIVariableGetByIndex	Function to get access to an existing SSI variable.
	TCPIP_HTTP_NET_SSIVariableSet	Function to set an SSI variable.
	TCPIP_HTTP_NET_SSIVariablesNumberGet	Function to get the number of the current SSI variables.
	TCPIP_HTTP_NET_Task	Standard TCP/IP stack module task function.
	TCPIP_HTTP_NET_URLDecode	Parses a string from URL encoding to plain text.
	TCPIP_HTTP_NET_UserHandlerDeregister	Deregisters a previously registered HTTP user handler.
	TCPIP_HTTP_NET_UserHandlerRegister	Registers a user callback structure with the HTTP server

Macros

	Name	Description
	TCPIP_HTTP_NET_ConnectionPostReadPair	Reads a name and value pair from a URL encoded string in the network transport buffer.

Structures

	Name	Description
	_tag_TCPIP_HTTP_NET_USER_CALLBACK	HTTP user implemented callback data structure.
	TCPIP_HTTP_DYN_ARG_DCPT	HTTP dynamic argument descriptor.
	TCPIP_HTTP_DYN_VAR_DCPT	HTTP dynamic variable descriptor.
	TCPIP_HTTP_NET_MODULE_CONFIG	HTTP module dynamic configuration data
	TCPIP_HTTP_NET_USER_CALLBACK	HTTP user implemented callback data structure.
	TCPIP_HTTP_SSI_ATTR_DCPT	HTTP SSI attribute descriptor.
	TCPIP_HTTP_SSI_NOTIFY_DCPT	HTTP SSI notification descriptor.

Types

	Name	Description
	TCPIP_HTTP_NET_CONN_HANDLE	HTTP connection identifier, handle of a HTTP connection
	TCPIP_HTTP_NET_USER_HANDLE	HTTP user handle.

Description

HTTP Headers for Microchip TCP/IP Stack

The HTTP module runs a web server within the TCP/IP stack. This facilitates an easy method to view status information and control applications using any standard web browser.

File Name

http_net.h

Company

Microchip Technology Inc.

http_net_config.h

HTTP Net configuration file

Macros

	Name	Description
	TCPIP_HTTP_NET_CACHE_LEN	Max lifetime (sec) of static responses as string
	TCPIP_HTTP_NET_CHUNK_RETRIES	retry limit for allocating a chunk from the pool If more retries are not successful the operation will be aborted
	TCPIP_HTTP_NET_CHUNKS_NUMBER	number of chunks that are created It depends on the TCPIP_HTTP_NET_MAX_RECURSE_LEVEL and on the number of connections Maximum number should be TCPIP_HTTP_NET_MAX_CONNECTIONS * TCPIP_HTTP_NET_MAX_RECURSE_LEVEL i.e. TCPIP_HTTP_NET_MODULE_CONFIG::nConnections * TCPIP_HTTP_NET_MODULE_CONFIG::nChunks All the chunks are in a pool and are used by all connections
	TCPIP_HTTP_NET_CONFIG_FLAGS	Define the HTTP module configuration flags Use 0 for default See HTTP_MODULE_FLAGS definition for possible values
	TCPIP_HTTP_NET_COOKIE_BUFFER_SIZE	Size of the buffer used for sending the cookies to the client. Should be able to accommodate the longest cookie response. Otherwise the cookies will be truncated.
	TCPIP_HTTP_NET_DEFAULT_FILE	Indicate what HTTP file to serve when no specific one is requested
	TCPIP_HTTP_NET_DYNVAR_ARG_MAX_NUMBER	maximum number of arguments for a dynamic variable
	TCPIP_HTTP_NET_DYNVAR_DESCRIPTORS_NUMBER	how many buffers descriptors for dynamic variable processing they are independent of the HTTP connection number all the HTTP connections use from the dynamic descriptors pool
	TCPIP_HTTP_NET_DYNVAR_MAX_LEN	maximum size for a complete dynamic variable: name + args must be <= TCPIP_HTTP_NET_FILE_PROCESS_BUFFER_SIZE! If it is much larger than needed then inefficiency occurs when reading data from the file and then discarding it because a much larger than needed data buffer was read

	TCPIP_HTTP_NET_DYNVAR_PROCESS	This symbol enables the processing of dynamic variables Make it evaluate to false (0) if dynamic variables are not needed All the following symbols referring to dynamic variables are relevant only when TCPIP_HTTP_NET_DYNVAR_PROCESS != 0
	TCPIP_HTTP_NET_DYNVAR_PROCESS_RETRIES	retry limit for a dynamic variable processing ths puts a limit on the number of times a dynamic variable "dynamicPrint" function can return TCPIP_HTTP_DYN_PRINT_RES_AGAIN/TCPIP_HTTP_DYN_PRINT_RES_PROCESS_AGAIN and avoids having the HTTP code locked up forever. If more retries are attempted the processing will be considered done and dynamicPrint function will not be called again
	TCPIP_HTTP_NET_FILE_PROCESS_BUFFER_RETRIES	Retry limit for allocating a file buffer from the pool. If more retries are not successful the operation will be aborted.
	TCPIP_HTTP_NET_FILE_PROCESS_BUFFER_SIZE	Size of the buffer used for processing HTML, dynamic variable and binary files. For dynamic variable files it should be able to accommodate the longest HTML line size, including CRLF!
	TCPIP_HTTP_NET_FILE_PROCESS_BUFFERS_NUMBER	Number of file buffers to be created; These buffers are used to store data while file processing is done They are organized in a pool Each file being processed needs a file buffer and tries to get it from the pool If a buffer is not available, the HTTP conenction will wait for one to become available. Once the file is done the file buffer is released and could be used by a different file The number depends on the number of files that are processed in parallel To avoid deadlock the number should be >= than the number of... more
	TCPIP_HTTP_NET_FILE_UPLOAD_ENABLE	Configure MPFS over HTTP updating Comment this line to disable updating via HTTP
	TCPIP_HTTP_NET_FILE_UPLOAD_NAME	This is macro TCPIP_HTTP_NET_FILE_UPLOAD_NAME.
	TCPIP_HTTP_NET_FILENAME_MAX_LEN	maximum size of a HTTP file name with the path removed from the file name one extra char added for the string terminator
	TCPIP_HTTP_NET_FIND_PEEK_BUFF_SIZE	Size of the peek buffer to perform searches into. If the underlying transport layer supports offset peak operation with a offset, value could be smaller (80 characters, for example); otherwise, a one time peek is required and the buffer should be larger - 512 bytes recommended.
	TCPIP_HTTP_NET_MAX_CONNECTIONS	Maximum numbers of simultaneous supported HTTP connections.
	TCPIP_HTTP_NET_MAX_DATA_LEN	Define the maximum data length for reading cookie and GET/POST arguments (bytes)
	TCPIP_HTTP_NET_MAX_HEADER_LEN	The length of longest header string that can be parsed
	TCPIP_HTTP_NET_MAX_RECURSE_LEVEL	The maximum depth of recursive calls for serving a web page: • no dynvars files: 1 • file including a file: 2 • if the include file includes another file: +1 • if a dyn variable: +1 Default value is 3;
	TCPIP_HTTP_NET_RESPONSE_BUFFER_SIZE	Size of the buffer used for sending the response messages to the client. Should be able to accommodate the longest server response: Default setting should be 300 bytes
	TCPIP_HTTP_NET_SKT_RX_BUFF_SIZE	Define the size of the RX buffer for the HTTP socket Use 0 for default TCP socket value The default recommended value for high throughput is > 2MSS (3 KB). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput.
	TCPIP_HTTP_NET_SKT_TX_BUFF_SIZE	Define the size of the TX buffer for the HTTP socket Use 0 for default TCP socket value The default recommended value for high throughput is > 2MSS (3 KB). The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput.
	TCPIP_HTTP_NET_SSI_ATTRIBUTES_MAX_NUMBER	maximum number of attributes for a SSI command most SSI commands take just one attribute/value pair per line but multiple attribute/value pairs on the same line are allowed where it makes sense

	TCPIP_HTTP_NET_SSI_CMD_MAX_LEN	maximum size for a SSI command line: command + attribute/value pairs must be <= TCPIP_HTTP_NET_FILE_PROCESS_BUFFER_SIZE! If it is much larger than needed then inefficiency occurs when reading data from the file and then discarding it because a much larger than needed data buffer was read
	TCPIP_HTTP_NET_SSI_ECHO_NOT_FOUND_MESSAGE	message to echo when echoing a not found variable
	TCPIP_HTTP_NET_SSI_PROCESS	This symbol enables the processing of SSI commands Make it evaluate to false (0) if SSI commands are not needed All the following symbols referring to SSI commands are relevant only when TCPIP_HTTP_NET_SSI_PROCESS != 0
	TCPIP_HTTP_NET_SSI_STATIC_ATTTRIB_NUMBER	number of static attributes associated to a SSI command if the command has more attributes than this number the excess will be allocated dynamically
	TCPIP_HTTP_NET_SSI_VARIABLE_NAME_MAX_LENGTH	maximum length of a SSI variable name any excess characters will be truncated Note that this can result in multiple variables being represented as one SSI variable
	TCPIP_HTTP_NET_SSI_VARIABLE_STRING_MAX_LENGTH	maximum size of a SSI string variable value any excess characters will be truncated Note that the variable value requires SSI storage that's allocated dynamically Also, this value determines the size of an automatic (stack) buffer when the variable is echoed. If this value is large, make sure you have enough stack space.
	TCPIP_HTTP_NET_SSI_VARIABLES_NUMBER	maximum number of SSI variables that can be created at run time These variables are stored in an internal hash. For max. efficiency this number should be a prime.
	TCPIP_HTTP_NET_TASK_RATE	The HTTP task rate, ms The default value is 33 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_HTTP_NET_TIMEOUT	Max time (sec) to await more data before timing out and disconnecting the socket
	TCPIP_HTTP_NET_USE_AUTHENTICATION	Enable basic authentication support
	TCPIP_HTTP_NET_USE_COOKIES	Enable cookie support
	TCPIP_HTTP_NET_USE_POST	Define which HTTP modules to use If not using a specific module, comment it to save resources Enable POST support

Description

ICMP Module

This section describes the TCP/IP Stack Library ICMP module.

Introduction

TCP/IP Stack Library Internet Control Message Protocol (ICMP) Module for Microchip Microcontrollers

This library provides the API of the ICMP module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

The Internet Control Message Protocol is used to send error and status messages and requests. The ICMP module implements the Echo Reply message type (commonly referred to as a ping) which can be used to determine if a specified host is reachable across an IP network from a device running the TCP/IP stack. An ICMP server is also supported to respond to pings from other devices.

Using the Library

This topic describes the basic architecture of the ICMP TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `icmp.h`

The interface to the ICMP TCP/IP Stack library is defined in the `icmp.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the ICMP TCP/IP Stack library should include `tcpip.h`.

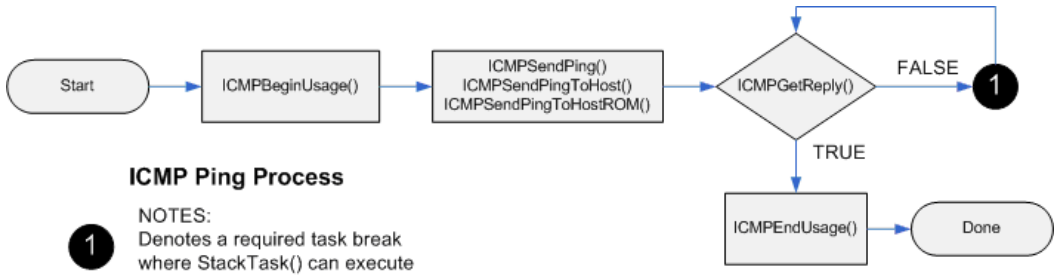
Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

This library provides the API of the ICMP TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

ICMP Software Abstraction Block Diagram



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the ICMP module.

Library Interface Section	Description
Functions	This section provides general interface routines
Data Types and Constants	This section provides various definitions describing this API

Configuring the Library

Macros

	Name	Description
	TCPIP_ICMP_CLIENT_USER_NOTIFICATION	allow ICMP client user notification if enabled, the TCPIP_ICMP_CallbackRegister/TCPIP_ICMP_CallbackDeregister functions exist and can be used Note that if disabled, the tcpip console ping command won't be available
	TCPIP_ICMP_ECHO_REQUEST_TIMEOUT	Timeout for a request that was sent and no reply was received milliseconds
	TCPIP_ICMP_TASK_TICK_RATE	The ICMP task processing rate: number of milliseconds to generate an ICMP tick. This is the tick that advances the ICMP state machine. The default value is around 30 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

Description

The configuration of the ICMP TCP/IP Stack is based on the file `tcpip_config.h`.

This header file contains the configuration selection for the ICMP TCP/IP Stack. Based on the selections made, the ICMP TCP/IP Stack may support the selected features. These configuration settings will apply to all instances of the ICMP TCP/IP Stack.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_ICMP_CLIENT_USER_NOTIFICATION Macro

File

icmp_config.h

C

```
#define TCPIP_ICMP_CLIENT_USER_NOTIFICATION true
```

Description

allow ICMP client user notification if enabled, the TCPIP_ICMP_CallbackRegister/TCPIP_ICMP_CallbackDeregister functions exist and can be used Note that if disabled, the tcpip console ping command won't be available

TCPIP_ICMP_ECHO_REQUEST_TIMEOUT Macro

File

icmp_config.h

C

```
#define TCPIP_ICMP_ECHO_REQUEST_TIMEOUT 500
```

Description

Timeout for a request that was sent and no reply was received milliseconds

TCPIP_ICMP_TASK_TICK_RATE Macro

File

icmp_config.h

C

```
#define TCPIP_ICMP_TASK_TICK_RATE 33
```

Description

The ICMP task processing rate: number of milliseconds to generate an ICMP tick. This is the tick that advances the ICMP state machine. The default value is around 30 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

Building the Library

This section lists the files that are available in the ICMP module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/icmp.c`	ICMP implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The ICMP module depends on the following modules:

- TCP/IP Stack Library
- IPv4 Module

Library Interface

a) Functions

	Name	Description
	TCPIP_ICMP_CallbackDeregister	Deregisters the ICMP callback function.
	TCPIP_ICMP_CallbackRegister	Registers a callback to allow the application layer to process incoming ICMPv4 packets
	TCPIP_ICMP_EchoRequestSend	Sends an ICMP echo request to a remote node.
	TCPIP_ICMP_Task	Standard TCP/IP stack module task function.
	TCPIP_ICMP_EchoRequest	Sends an ICMP echo request containing user supplied data
	TCPIP_ICMP_EchoRequestCancel	Cancels a previously sent ICMP echo request

b) Data Types and Constants

	Name	Description
	ICMP_ECHO_RESULT	result of an ICMP Echo Request call
	ICMP_HANDLE	a handle that a client can use after the event handler has been registered
	TCPIP_ICMP_MODULE_CONFIG	Placeholder for ICMP module configuration.
	_tag_TCPIP_ICMP_ECHO_REQUEST	Contains the data needed for an ICMP request operation
	TCPIP_ICMP_ECHO_REQUEST	Contains the data needed for an ICMP request operation
	TCPIP_ICMP_ECHO_REQUEST_RESULT	A result code for an Echo Request callback (as a result of an ICMP TCPIP_ICMP_EchoRequest call)
	TCPIP_ICMP_REQUEST_HANDLE	This is type TCPIP_ICMP_REQUEST_HANDLE.

Description

This section describes the Application Programming Interface (API) functions of the ICMP module.

Refer to each section for a detailed description.

a) Functions

TCPIP_ICMP_CallbackDeregister Function

Deregisters the ICMP callback function.

File

icmp.h

C

```
bool TCPIP_ICMP_CallbackDeregister(ICMP_HANDLE hIcmp);
```

Returns

- true - if the notification handler has been successfully removed
- false - if such a notification handler could not be found

Description

This function notifies a stack client to remove its former registered notification handler. After this operation the client will no longer be notified about the receiving of replies to the ICMP requests.

Remarks

None.

Preconditions

The TCP/IP Stack must be initialized and up and running. A previous successful call to TCPIP_ICMP_CallbackRegister has been done.

Example

```
void MyICMPCallbackFunction(TCPIP_NET_HANDLE hNetIf, IPV4_ADDR * remoteIP, void * data);
ICMP_HANDLE hIcmp = TCPIP_ICMP_CallbackRegister(&MyICMPCallbackFunction);
if(hIcmp != 0)
{
    // successfully registered my handler
    // send requests and process the incoming results
    // ...
    // later on, once we're done, remove the notification handler
    TCPIP_ICMP_CallbackDeregister(hIcmp);
}
```

Parameters

Parameters	Description
hIcmp	an ICMP handle obtained by TCPIP_ICMP_CallbackRegister

Function

bool TCPIP_ICMP_CallbackDeregister(ICMP_HANDLE hIcmp)

TCPIP_ICMP_CallbackRegister Function

Registers a callback to allow the application layer to process incoming ICMPv4 packets

File

icmp.h

C

```
ICMP_HANDLE TCPIP_ICMP_CallbackRegister(void (*callback)(TCPIP_NET_HANDLE hNetIf, IPV4_ADDR * remoteIP,
void * data));
```

Returns

- A non-null handle if the registration succeeded
- 0 if the registration operation failed (for example, out of memory)

Description

Allows a stack client to be notified of the receiving of a response from an ICMP query. Once an Echo request reply is received, the notification handler callback will be called, letting the client know of the result of the query. The callback will contain as parameters:

- the network interface handle on which the query reply was received
- the remote host IP address
- a 32-bit value containing the sequence number in the low 16-bit part and the identifier value in the high 16-bit part.

Remarks

None.

Preconditions

The TCP/IP Stack must be initialized and up and running.

Example

```
// Callback function prototype
void MyICMPCallbackFunction(TCPIP_NET_HANDLE hNetIf, IPV4_ADDR * remoteIP, void * data);

// ******************************************************************************
// Register callback function
ICMP_HANDLE hIcmp = TCPIP_ICMP_CallbackRegister(&MyICMPCallbackFunction);
if(hIcmp == 0)
{
    // process error; couldn't register a handler
```

```
}

// success; I can send an Echo request and receive notification

// ******************************************************************************
IPV4_ADDR remoteIP = 0xc0a00101;
uint16_t mySequenceNumber = 1;
uint16_t myId = 0x1234;
// send an ICMP query request
TCPIP_ICMP_EchoRequestSend(&remoteIP, mySequenceNumber, myId);

// ******************************************************************************
// process the ICMP reply in the callback function
void MyICMPCallbackFunction(TCPIP_NET_HANDLE hNetIf, IPV4_ADDR * remoteIP, void * data)
{
    // process request from interface hNetIf and remoteIP address
    uint16_t* pReply = (uint16_t*)data;
    uint16_t myRecvId = *pReply;
    uint16_t myRecvSequenceNumber = *(pReply + 1);

    // check that the sequence number, ID and IP address match, etc.
}
```

Parameters

Parameters	Description
callback	notification function to be registered. This function will be called when an echo request reply is received.

Function

ICMP_HANDLE TCPIP_ICMP_CallbackRegister (void (*callback)(TCPIP_NET_HANDLE hNetIf,
IPV4_ADDR * remoteIP, void * data))

TCPIP_ICMP_EchoRequestSend Function

Sends an ICMP echo request to a remote node.

File

icmp.h

C

```
ICMP_ECHO_RESULT TCPIP_ICMP_EchoRequestSend(TCPIP_NET_HANDLE netH, IPV4_ADDR * targetAddr, uint16_t
sequenceNumber, uint16_t identifier);
```

Returns

- ICMP_ECHO_OK - Indicates the query request was successfully sent
- ICMP_ECHO_RESULT - The query request was unsuccessfully sent, which results in an error code (interface not ready for transmission, allocation error, etc.)

Description

This function allows a stack client to send an ICMP query message to a remote host. The supplied sequence number and identifier will be used in the query message. The user will be notified by the result of the query using a notification handle registered by using the TCPIP_ICMP_CallbackRegister function.

Remarks

This function does not allow the user to specify a data buffer to be sent as part of the request. The preferred function to use is TCPIP_ICMP_EchoRequest.

This function will eventually be obsoleted.

Preconditions

The TCP/IP Stack must be initialized and up and running.

Example

```
IPV4_ADDR remoteAddress = 0xc0a00101;
```

```
uint16_t mySequenceNumber = 1;
uint16_t myId = 0x1234;

if(TCPIP_ICMP_EchoRequestSend(0, &remoteAddress, mySequenceNumber, myId) == ICMP_ECHO_OK )
{
    // successfully sent the ICMP request
    //
}
else
{
    // process the error
}
```

Function

ICMP_ECHO_RESULT TCPIP_ICMP_EchoRequestSend (TCPIP_NET_HANDLE netH, IPV4_ADDR * targetAddr, uint16_t sequenceNumber, uint16_t identifier)

TCPIP_ICMP_Task Function

Standard TCP/IP stack module task function.

File

icmp.h

C

```
void TCPIP_ICMP_Task();
```

Returns

None.

Description

This function performs ICMPv4 module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The ICMP module should have been initialized.

Function

void TCPIP_ICMP_Task(void)

TCPIP_ICMP_EchoRequest Function

Sends an ICMP echo request containing user supplied data

File

icmp.h

C

```
ICMP_ECHO_RESULT TCPIP_ICMP_EchoRequest(TCPIP_ICMP_ECHO_REQUEST* pEchoRequest, TCPIP_ICMP_REQUEST_HANDLE* pHandle);
```

Returns

- ICMP_ECHO_OK - Indicates the query request was successfully sent
- ICMP_ECHO_RESULT - The query request was unsuccessfully sent, which results in an error code (interface not ready for transmission, allocation error, etc.)

Description

This function allows a stack client to send an ICMP query message to a remote host. The supplied sequence number and identifier will be used in the query message. The request will also contain user supplied data. The request is scheduled and the user will be notified of the outcome of the query using the callback function that's specified in the call.

Remarks

The data buffer that's passed as part of the callback routine is no longer available after the callback routine returns control.

This routine is more generic than TCPIP_ICMP_EchoRequestSend and is preferred.

The user has to enforce the fact that the "identifier" field has to be unique per (destination address, source address) pair.

Currently there could be only one ping/echo request active at a time. If another echo request is active, a ICMP_ECHO_BUSY code will be returned.

Once the callback notification occurs, the echo request is completed and the icmpHandle is invalidated.

Preconditions

The TCP/IP Stack must be initialized and up and running.

Example

```
  uint8_t  myDataBuffer[200];     // buffer for the ping data
  void EchoCallback(TCPIP_ICMP_ECHO_REQUEST* pReqData, TCPIP_ICMP_REQUEST_HANDLE icmpHandle,
TCPIP_ICMP_ECHO_REQUEST_RESULT result);    // callback function to be called

  TCPIP_ICMP_ECHO_REQUEST myEchoRequest;
  myEchoRequest.netH  = 0;
  myEchoRequest.targetAddr  = 0xc0a00101;
  myEchoRequest.sequenceNumber = 1;
  myEchoRequest.identifier     = 0x1234;
  myEchoRequest.pData          = myDataBuffer;
  myEchoRequest.dataSize       = sizeof(myDataBuffer);
  myEchoRequest.callback       = EchoCallback;

  if(TCPIP_ICMP_EchoRequest(&myEchoRequest, 0) == ICMP_ECHO_OK )
  {
      // successfully sent the ICMP request
      //
      // EchoCallback() will be called and data can be examined
  }
  else
  {
      // process the error
  }
```

Function

ICMP_ECHO_RESULT TCPIP_ICMP_EchoRequest (TCPIP_ICMP_ECHO_REQUEST* pEchoRequest, TCPIP_ICMP_REQUEST_HANDLE* pHandle);

TCPIP_ICMP_EchoRequestCancel Function

Cancels a previously sent ICMP echo request

File

icmp.h

C

```
ICMP_ECHO_RESULT TCPIP_ICMP_EchoRequestCancel(TCPIP_ICMP_REQUEST_HANDLE icmpHandle);
```

Returns

- ICMP_ECHO_OK - Indicates the cancel request was successful
- ICMP_ECHO_BAD_HANDLE - No such request is currently scheduled Invalid handle

Description

This function allows a stack client to cancel a pending ICMP echo request. The request should have been previously scheduled with TCPIP_ICMP_EchoRequest.

Remarks

None

Preconditions

The TCP/IP Stack must be initialized and up and running. Valid handle obtained using TCPIP_ICMP_EchoRequest.

Example

Function

ICMP_ECHO_RESULT TCPIP_ICMP_EchoRequestCancel (TCPIP_ICMP_REQUEST_HANDLE icmpHandle);

b) Data Types and Constants

ICMP_ECHO_RESULT Enumeration

File

icmp.h

C

```
typedef enum {
  ICMP_ECHO_OK = 0,
  ICMP_ECHO_ALLOC_ERROR = -1,
  ICMP_ECHO_ROUTE_ERROR = -2,
  ICMP_ECHO_TRANSMIT_ERROR = -3,
  ICMP_ECHO_PARAMETER_ERROR = -4,
  ICMP_ECHO_BUSY = -5,
  ICMP_ECHO_BAD_HANDLE = -6
} ICMP_ECHO_RESULT;
```

Members

Members	Description
ICMP_ECHO_OK = 0	operation successful error codes, < 0
ICMP_ECHO_ALLOC_ERROR = -1	could not allocate memory
ICMP_ECHO_ROUTE_ERROR = -2	could not find a route to destination
ICMP_ECHO_TRANSMIT_ERROR = -3	could not transmit (dead interface, etc.)
ICMP_ECHO_PARAMETER_ERROR = -4	null pointer, etc.
ICMP_ECHO_BUSY = -5	module currently busy
ICMP_ECHO_BAD_HANDLE = -6	invalid handle, no such request exist

Description

result of an ICMP Echo Request call

ICMP_HANDLE Type

File

icmp.h

C

```
typedef const void* ICMP_HANDLE;
```

Description

a handle that a client can use after the event handler has been registered

TCPIP_ICMP_MODULE_CONFIG Structure

Placeholder for ICMP module configuration.

File

icmp.h

C

```
typedef struct {
} TCPIP_ICMP_MODULE_CONFIG;
```

Description

ICMP Module Configuration Structure Typedef

Provides a placeholder for ICMP module configuration.

Remarks

None.

TCPIP_ICMP_ECHO_REQUEST Structure

Contains the data needed for an ICMP request operation

File

icmp.h

C

```
typedef struct _tag_TCPIP_ICMP_ECHO_REQUEST {
  TCPIP_NET_HANDLE netH;
  IPV4_ADDR targetAddr;
  uint16_t sequenceNumber;
  uint16_t identifier;
  uint8_t* pData;
  uint16_t dataSize;
  void (* callback)(const struct _tag_TCPIP_ICMP_ECHO_REQUEST* pReqData, TCPIP_ICMP_REQUEST_HANDLE
icmpHandle, TCPIP_ICMP_ECHO_REQUEST_RESULT result);
} TCPIP_ICMP_ECHO_REQUEST;
```

Description

ICMP Request Data Structure

This structure defines the information required for sending an ICMP request that contains user data.

Remarks

When the callback is made with an error result, the TCPIP_ICMP_ECHO_REQUEST structure may identify the request, if no reply was received (for example timeout)

TCPIP_ICMP_ECHO_REQUEST_RESULT Enumeration

File

icmp.h

C

```
typedef enum {
  TCPIP_ICMP_ECHO_REQUEST_RES_OK = 0,
  TCPIP_ICMP_ECHO_REQUEST_RES_TMO = -1
} TCPIP_ICMP_ECHO_REQUEST_RESULT;
```

Members

Members	Description
TCPIP_ICMP_ECHO_REQUEST_RES_OK = 0	a reply has been successfully received error codes, < 0
TCPIP_ICMP_ECHO_REQUEST_RES_TMO = -1	no reply received; the current request timed out and will be deleted

Description

A result code for an Echo Request callback (as a result of an ICMP TCPIP_ICMP_EchoRequest call)

TCPIP_ICMP_REQUEST_HANDLE Type

File

icmp.h

C

```
typedef const void* TCPIP_ICMP_REQUEST_HANDLE;
```

Description

This is type TCPIP_ICMP_REQUEST_HANDLE.

Files

Files

Name	Description
icmp.h	The Internet Control Message Protocol is used to send error and status messages and requests.
icmp_config.h	ICMP configuration file

Description

This section lists the source and header files used by the library.

icmp.h

The Internet Control Message Protocol is used to send error and status messages and requests.

Enumerations

	Name	Description
	ICMP_ECHO_RESULT	result of an ICMP Echo Request call
	TCPIP_ICMP_ECHO_REQUEST_RESULT	A result code for an Echo Request callback (as a result of an ICMP TCPIP_ICMP_EchoRequest call)

Functions

	Name	Description
	TCPIP_ICMP_CallbackDeregister	Deregisters the ICMP callback function.
	TCPIP_ICMP_CallbackRegister	Registers a callback to allow the application layer to process incoming ICMPv4 packets
	TCPIP_ICMP_EchoRequest	Sends an ICMP echo request containing user supplied data
	TCPIP_ICMP_EchoRequestCancel	Cancels a previously sent ICMP echo request
	TCPIP_ICMP_EchoRequestSend	Sends an ICMP echo request to a remote node.
	TCPIP_ICMP_Task	Standard TCP/IP stack module task function.

Structures

ICMPv6 Module

This section describes the TCP/IP Stack Library ICMPv6 module.

Introduction

TCP/IP Library ICMPv6 Module for Microchip Microcontrollers

This library provides the API of the ICMPv6 module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

This document specifies a set of APIs of Internet Control Message Protocol (ICMP) messages for use with version 6 of the Internet Protocol (IPv6).

The Internet Protocol, version 6 (IPv6) is a new version of IP, uses the Internet Control Message Protocol (ICMP) as defined for IPv4

[RFC-792], with a number of changes. It is called ICMPv6, and has an IPv6 Next Header value of 58.

ICMPv6 messages are used by IPv6 nodes to report *error messages* and *information messages*. ICMPv6 is also used for Ipv6 node diagnostic (i.e., IPv6 ping).

The ICMPv6 protocol also provides a framework for the following:

Neighbor Discovery

Neighbor Discovery is a series of five ICMPv6 messages that manage node-to-node communication on a link. Neighbor Discovery replaces Address Resolution Protocol (ARP), ICMP (IPv4) Router Discovery, and the ICMP (IPv4) Redirect message.

Multicast Listener Discovery (MLD)

Multicast Listener Discovery is a series of three ICMP messages that manage subnet multicast membership. Multicast Listener Discovery replaces version 2 of the Internet Group Management Protocol (IGMP) for IPv4.

Path MTU Discovery

The maximum transmission unit (MTU) for a path is the minimum link MTU of all links on a path between a source and a destination. IPv6 packets that are smaller than the path MTU do not require fragmentation by the host and are successfully forwarded by all routers on the path. To discover the path MTU, the sending host uses the receipt of **ICMPv6 Packet Too Big messages**.

ICMPv6 Common Messages	Functions
Echo Request	Sent to check IPv6 connectivity to a particular host.
Echo Reply	Sent in response to an ICMPv6 Echo Request.
Destination Unreachable	Sent by a router or the destination host to inform the sending host that the packet or payload cannot be delivered.
Packet to big	Sent by a router to inform a sending host that a packet is too large to forward.
Time exceeded	Sent by a router to inform a sending host that the Hop Limit of an IPv6 packet has expired.
Parameter Problem	Sent by a router to inform a sending host that an error was encountered in processing the IPv6 header or an IPv6 extension header.

Using the Library

This topic describes the basic architecture of the ICMPv6 TCP/IP Library and provides information and examples on its use.

Description

Interface Header File: `icmpv6.h`

The interface to the ICMPv6 TCP/IP library is defined in the `icmpv6.h` header file. Any C language source (`.c`) file that uses the ICMPv6 TCP/IP library should include `ipv6.h` , `icmpv6.h`, and `ndp.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

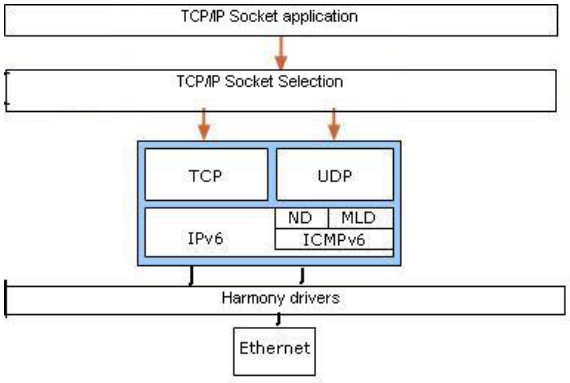
This library provides the API of the ICMPv6 TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

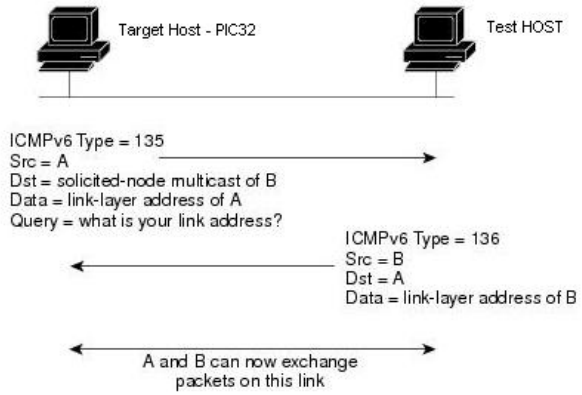
ICMPv6 Software Abstraction Block Diagram

This module provides software abstraction of the IPv6 module existent in any TCP/IP Stack implementation. It removes the overhead of address resolution from all other modules in the stack.

IPv6 Block Diagram



ICMPv6 message communication



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the IPv6 and ICMPv6 module.

Library Interface Section	Description
Functions	This section provides general interface routines
Data Types and Constants	This section provides various definitions describing this API

Configuring the Library

The configuration of the ICMPv6 TCP/IP Stack is based on the file `icmpv6_config.h`.

This header file contains the configuration selection for the ICMPv6 TCP/IP Stack. Based on the selections made, the ICMPv6 TCP/IP Stack IP may support the selected features. These configuration settings will apply to all instances of the ICMPv6 TCP/IP Stack.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build.

Building the Library

This section lists the files that are available in the ICMPv6 module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/icmpv6.c`	ICMPv6 implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The ICMPv6 module depends on the following modules:

- TCP/IP Stack Library
- IPv6 Module

Library Interface

a) Functions

	Name	Description
	TCPIP_ICMPV6_CallbackDeregister	Deregisters an upper-layer function from ICMPv6 callback.
	TCPIP_ICMPV6_Flush	Flushes a ICMPv6 packet.
	TCPIP_ICMPV6_HeaderEchoRequestPut	Allocates a packet, IPv6 Header, and Upper-layer header for an ICMPv6 echo request.
	TCPIP_ICMPV6_EchoRequestSend	Sends an ICMPv6 echo request to a remote node.
	TCPIP_ICMPV6_CallbackRegister	Registers an upper-layer function for ICMPv6 callback.

b) Data Types and Constants

	Name	Description
	ICMPV6_ERR_PTB_CODE	ICMPv6 Packet Too Big error code.
	ICMPV6_INFO_EREQ_CODE	ICMPv6 Packet Echo Request information code.
	ICMPV6_INFO_ERPL_CODE	ICMPv6 Packet Echo Reply information code.
	TCPIP_ICMPV6_PutHeaderEchoReply	This is macro TCPIP_ICMPV6_PutHeaderEchoReply.
	ICMPV6_ERR_DU_CODE	ICMPv6 Destination Unreachable error code.
	ICMPV6_ERR_PP_CODE	ICMPv6 Parameter Problem error code.
	ICMPV6_ERR_TE_CODE	ICMPv6 Time Exceeded error code.
	ICMPV6_HANDLE	ICMPv6 handle.
	ICMPV6_HEADER_ECHO	Header for an ICMPv6 Echo Request/Reply packet
	ICMPV6_HEADER_ERROR	Header for an ICMPv6 Error packet.
	ICMPV6_PACKET_TYPES	ICMPv6 packet types.
	TCPIP_ICMPV6_CLIENT_USER_NOTIFICATION	allow ICMPV6 client user notification if enabled, the TCPIP_ICMPV6_CallbackRegister/TCPIP_ICMPV6_CallbackDeregister functions exist and can be used Note that if disabled, the tcpip console ping6 command won't be available

Description

This section describes the Application Programming Interface (API) functions of the ICMPv6 module.

Refer to each section for a detailed description.

a) Functions

TCPIP_ICMPV6_CallbackDeregister Function

Deregisters an upper-layer function from ICMPv6 callback.

File

icmpv6.h

C

```
bool TCPIP_ICMPV6_CallbackDeregister(ICMPV6_HANDLE hIcmpv6);
```

Returns

- true - On Success
- false - On Failure (If no such handler registered)

Description

This function deregisters a previously registered function from the ICMPv6 register list.

Remarks

None.

Preconditions

IPv6 and ICMPv6 are initialized.

Parameters

Parameters	Description
hIcmpv6	ICMPv6 handler

Function

ICMPV6_HANDLE TCPIP_ICMPV6_CallbackRegister (void (*callback)(TCPIP_NET_HANDLE hNetIf, uint8_t type, IPV6_ADDR * localIP, IPV6_ADDR * remoteIP, void * header))

TCPIP_ICMPV6_Flush Function

Flushes a ICMPv6 packet.

File

icmpv6.h

C

```
bool TCPIP_ICMPV6_Flush(IPV6_PACKET * pkt);
```

Returns

- true - if the packet was flushed
- false - if the packet was queued

Description

Transmit out a ICMPv6 packet.

Remarks

None.

Preconditions

IPv6 and ICMPv6 are initialized.

Parameters

Parameters	Description
pkt	The packet to flush

Function

bool TCPIP_ICMPV6_Flush (IPV6_PACKET * pkt)

TCPIP_ICMPV6_HeaderEchoRequestPut Function

Allocates a packet, IPv6 Header, and Upper-layer header for an ICMPv6 echo request.

File

icmpv6.h

C

```
IPV6_PACKET * TCPIP_ICMPV6_HeaderEchoRequestPut(TCPIP_NET_HANDLE hNetIf, const IPV6_ADDR * localIP, const
IPV6_ADDR * remoteIP, uint8_t type, uint16_t identifier, uint16_t sequenceNumber);
```

Returns

IPV6_PACKET * - The constructed error packet or NULL

Description

This function allocates a packet using TCPIP_ICMPV6_Open() and updates local and remote addresses. Updates IPv6 Header with ICMPv6 type and upper-layer header for an ICMPv6 echo request.

Remarks

None.

Preconditions

IPv6 and ICMPv6 are initialized.

Parameters

Parameters	Description
pNetIf	The interface for the outgoing packet.
localIP	The local address that should be used for this packet.
remoteIP	The packet's destination address
type	Echo Request or Echo Reply
identifier	The Echo Request id.
sequenceNumber	The Echo request sequence number

Function

IPV6_PACKET * TCPIP_ICMPV6_HeaderEchoRequestPut (TCPIP_NET_HANDLE hNetIf,
IPV6_ADDR * localIP, IPV6_ADDR * remoteIP, uint8_t type,
uint16_t identifier, uint16_t sequenceNumber)

TCPIP_ICMPV6_EchoRequestSend Function

Sends an ICMPv6 echo request to a remote node.

File

icmpv6.h

C

```
bool TCPIP_ICMPV6_EchoRequestSend(TCPIP_NET_HANDLE netH, IPV6_ADDR * targetAddr, uint16_t sequenceNumber,
uint16_t identifier, uint32_t packetSize);
```

Returns

- true - if the query request was successfully sent
- false - otherwise (interface not ready for transmission, allocation error, etc.)

Description

This function allows a stack client to send an ICMPv6 Echo request message to a remote host. The supplied sequence number and identifier will be used in the query message. The user will be notified by the result of the query using a notification handle registered by using the TCPIP_ICMPV6_CallbackRegister function.

Remarks

None.

Preconditions

The TCP/IP Stack is initialized and up and running. IPv6 and ICMPv6 are initialized.

Function

bool TCPIP_ICMPV6_EchoRequestSend(TCPIP_NET_HANDLE netH, IPV6_ADDR * targetAddr,
uint16_t sequenceNumber, uint16_t identifier,uint32_t packetSize);

TCPIP_ICMPV6_CallbackRegister Function

Registers an upper-layer function for ICMPv6 callback.

File

icmpv6.h

C

```
ICMPV6_HANDLE TCPIP_ICMPV6_CallbackRegister(void (*callback)(TCPIP_NET_HANDLE hNetIf, uint8_t type, const
IPV6_ADDR * localIP, const IPV6_ADDR * remoteIP, void * header));
```

Returns

ICMPV6_HANDLE

- Success - Returns a valid handle
- Failure - Null handle

Description

This function registers an upper-layer function to handle ICMPv6 messages that may require action at the application layer (Echo Replies, Error messages)

Remarks

None.

Preconditions

IPv6 and ICMPv6 are initialized.

Parameters

Parameters	Description
type	ICMPv6 header type
localIP	IPv6 destination address of the incoming message
remoteIP	IPv6 address of the node that originated the incoming message
header	Pointer to the ICMPv6 header

Function

ICMPV6_HANDLE TCPIP_ICMPV6_CallbackRegister (void (*callback)(TCPIP_NET_HANDLE hNetIf,
uint8_t type, IPV6_ADDR * localIP, IPV6_ADDR * remoteIP, void * header))

b) Data Types and Constants

ICMPV6_ERR_PTB_CODE Macro

ICMPv6 Packet Too Big error code.

File

icmpv6.h

C

```
#define ICMPV6_ERR_PTB_CODE 0u
```

Description

Macro: ICMPV6_ERR_PTB_CODE

ICMPv6 packet too big error code value is 0 generated by the originator and ignored by the receiver.

Remarks

A Packet Too Big MUST be sent by a router in response to a packet that it cannot forward because the packet is larger than the MTU of the outgoing link. The information in this message is used as part of the Path MTU Discovery process [PMTU].

More details on RFC - 4446.

ICMPV6_INFO_EREQ_CODE Macro

ICMPv6 Packet Echo Request information code.

File

icmpv6.h

C

```
#define ICMPV6_INFO_EREQ_CODE 0u
```

Description

Macro: ICMPV6_INFO_EREQ_CODE

Definition for ICMPv6 Packet Echo Request information code.

Remarks

More details on RFC - 4446.

ICMPV6_INFO_ERPL_CODE Macro

ICMPv6 Packet Echo Reply information code.

File

icmpv6.h

C

```
#define ICMPV6_INFO_ERPL_CODE 0u
```

Description

Macro: ICMPV6_INFO_ERPL_CODE

Definition for ICMPv6 Packet Echo Reply information code.

Remarks

More details on RFC - 4446.

TCPIP_ICMPV6_PutHeaderEchoReply Macro

File

icmpv6.h

C

```
#define TCPIP_ICMPV6_PutHeaderEchoReply TCPIP_ICMPV6_HeaderEchoRequestPut
```

Description

This is macro TCPIP_ICMPV6_PutHeaderEchoReply.

ICMPV6_ERR_DU_CODE Enumeration

ICMPv6 Destination Unreachable error code.

File

icmpv6.h

C

```
typedef enum {
  ICMPV6_ERR_DU_NO_ROUTE = 0u,
  ICMPV6_ERR_DU_PROHIBITED = 1u,
  ICMPV6_ERR_DU_OUTSIDE_SCOPE = 2u,
  ICMPV6_ERR_DU_ADDR_UNREACHABLE = 3u,
  ICMPV6_ERR_DU_PORT_UNREACHABLE = 4u,
  ICMPV6_ERR_DU_SRC_FAILED_INGRESS_POLICY = 5u,
  ICMPV6_ERR_DU_REJECT_ROUTE = 6u
} ICMPV6_ERR_DU_CODE;
```

Members

Members	Description
ICMPV6_ERR_DU_NO_ROUTE = 0u	No route to destination
ICMPV6_ERR_DU_PROHIBITED = 1u	Communication with destination administratively prohibited
ICMPV6_ERR_DU_OUTSIDE_SCOPE = 2u	Beyond scope of source address

ICMPV6_ERR_DU_ADDR_UNREACHABLE = 3u	Address unreachable
ICMPV6_ERR_DU_PORT_UNREACHABLE = 4u	Port unreachable
ICMPV6_ERR_DU_SRC_FAILED_INGRESS_POLICY = 5u	Source address failed ingress/egress policy
ICMPV6_ERR_DU_REJECT_ROUTE = 6u	Reject route to destination

Description

Enumeration: ICMPV6_ERR_DU_CODE

Defines different type of ICMPv6 Destination Unreachable error code.

Remarks

A Destination Unreachable message should be generated by a router, or by the IPv6 layer in the originating node, in response to a packet that cannot be delivered to its destination address for reasons other than congestion. An ICMPv6 message MUST NOT be generated if a packet is dropped due to congestion.

More details on RFC - 4446.

ICMPV6_ERR_PP_CODE Enumeration

ICMPv6 Parameter Problem error code.

File

icmpv6.h

C

```
typedef enum {
  ICMPV6_ERR_PP_ERRONEOUS_HEADER = 0u,
  ICMPV6_ERR_PP_UNRECOGNIZED_NEXT_HEADER = 1u,
  ICMPV6_ERR_PP_UNRECOGNIZED_IPV6_OPTION = 2u
} ICMPV6_ERR_PP_CODE;
```

Members

Members	Description
ICMPV6_ERR_PP_ERRONEOUS_HEADER = 0u	Erroneous header field encountered
ICMPV6_ERR_PP_UNRECOGNIZED_NEXT_HEADER = 1u	Unrecognized Next Header type encountered
ICMPV6_ERR_PP_UNRECOGNIZED_IPV6_OPTION = 2u	Unrecognized IPv6 option encountered

Description

Enumeration: ICMPV6_ERR_PP_CODE

Definitions for ICMPv6 Parameter Problem error code.

Remarks

More details on RFC - 4446.

ICMPV6_ERR_TE_CODE Enumeration

ICMPv6 Time Exceeded error code.

File

icmpv6.h

C

```
typedef enum {
  ICMPV6_ERR_TE_HOP_LIMIT_EXCEEDED = 0u,
  ICMPV6_ERR_TE_FRAG_ASSEMBLY_TIME_EXCEEDED = 1u
} ICMPV6_ERR_TE_CODE;
```

Members

Members	Description
ICMPV6_ERR_TE_HOP_LIMIT_EXCEEDED = 0u	Hop limit exceeded in transit

ICMPV6_ERR_TE_FRAG_ASSEMBLY_TIME_EXCEEDED = 1u	Fragment reassembly time exceeded

Description

Enumeration: ICMPV6_ERR_TE_CODE

Definitions for ICMPv6 Time Exceeded error code. An ICMPv6 Time Exceeded message with Code 1 is used to report fragment reassembly time out.

Remarks

More details on RFC - 4446.

ICMPV6_HANDLE Type

ICMPv6 handle.

File

icmpv6.h

C

```
typedef const void* ICMPV6_HANDLE;
```

Description

Type: ICMPV6_HANDLE

A handle that a client needs to use when deregistering a notification handler.

Remarks

This handle can be used by the client after the event handler has been registered.

ICMPV6_HEADER_ECHO Structure

File

icmpv6.h

C

```
typedef struct {
  uint8_t vType;
  uint8_t vCode;
  uint16_t wChecksum;
  uint16_t identifier;
  uint16_t sequenceNumber;
} ICMPV6_HEADER_ECHO;
```

Members

Members	Description
uint8_t vType;	icmpV6 request or reply type
uint8_t vCode;	Error code
uint16_t wChecksum;	Packet TX and RX checksum
uint16_t identifier;	incoming and outgoing packet identifier
uint16_t sequenceNumber;	request and reply sequence number

Description

Header for an ICMPv6 Echo Request/Reply packet

ICMPV6_HEADER_ERROR Structure

Header for an ICMPv6 Error packet.

File

icmpv6.h

C

```
typedef struct {
  uint8_t vType;
  uint8_t vCode;
  uint16_t wChecksum;
  uint32_t additionalData;
} ICMPV6_HEADER_ERROR;
```

Members

Members	Description
uint8_t vType;	icmpV6 request or reply type
uint8_t vCode;	error code
uint16_t wChecksum;	Packet TX and RX checksum
uint32_t additionalData;	Unused for Destination. Unreachable and Time Exceeded. MTU for MTU. Pointer for Parameter Problem.

Description

Structure: ICMPV6_HEADER_ERROR

ICMPv6 different code and type error messages (Range 0 to 127).

Remarks

More details on RFC - 4446.

ICMPV6_PACKET_TYPES Enumeration

ICMPv6 packet types.

File

icmpv6.h

C

```
typedef enum {
  ICMPV6_ERROR_DEST_UNREACHABLE = 1u,
  ICMPV6_ERROR_PACKET_TOO_BIG = 2u,
  ICMPV6_ERROR_TIME_EXCEEDED = 3u,
  ICMPV6_ERROR_PARAMETER_PROBLEM = 4u,
  ICMPV6_INFO_ECHO_REQUEST = 128u,
  ICMPV6_INFO_ECHO_REPLY = 129u,
  ICMPV6_INFO_ROUTER_SOLICITATION = 133u,
  ICMPV6_INFO_ROUTER_ADVERTISEMENT = 134u,
  ICMPV6_INFO_NEIGHBOR_SOLICITATION = 135u,
  ICMPV6_INFO_NEIGHBOR_ADVERTISEMENT = 136u,
  ICMPV6_INFO_REDIRECT = 137u
} ICMPV6_PACKET_TYPES;
```

Members

Members	Description
ICMPV6_ERROR_DEST_UNREACHABLE = 1u	Destination Unreachable error packet
ICMPV6_ERROR_PACKET_TOO_BIG = 2u	Packet Too Big error packet
ICMPV6_ERROR_TIME_EXCEEDED = 3u	Time Exceeded error packet
ICMPV6_ERROR_PARAMETER_PROBLEM = 4u	Parameter Problem error packet
ICMPV6_INFO_ECHO_REQUEST = 128u	Echo Request packet
ICMPV6_INFO_ECHO_REPLY = 129u	Echo Reply packet
ICMPV6_INFO_ROUTER_SOLICITATION = 133u	Router solicitation NDP packet
ICMPV6_INFO_ROUTER_ADVERTISEMENT = 134u	Router advertisement NDP packet
ICMPV6_INFO_NEIGHBOR_SOLICITATION = 135u	Neighbor Solicitation NDP packet
ICMPV6_INFO_NEIGHBOR_ADVERTISEMENT = 136u	Neighbor Advertisement NDP packet
ICMPV6_INFO_REDIRECT = 137u	Redirect NDP packet

Description

Enumeration: ICMPV6_PACKET_TYPES

Defines different type of ICMPv6 message. Values in the range from 0 to 127 indicate an error type of messages. Values in the range 128 to 255 indicate an information message.

Remarks

None.

TCPIP_ICMPV6_CLIENT_USER_NOTIFICATION Macro

File

icmpv6_config.h

C

```
#define TCPIP_ICMPV6_CLIENT_USER_NOTIFICATION true
```

Description

allow ICMPV6 client user notification if enabled, the TCPIP_ICMPV6_CallbackRegister/TCPIP_ICMPV6_CallbackDeregister functions exist and can be used Note that if disabled, the tcpip console ping6 command won't be available

Files

Files

Iperf Module

This section describes the TCP/IP Stack Library Iperf Module.

Introduction

This library provides the API of the Iperf module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

Iperf is a networking tool that helps to measure networking bandwidth and performance.

Using the Library

This topic describes the basic architecture of the Iperf TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `iperf.h`

The interface to the Iperf TCP/IP Stack library is defined in the `iperf.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the Iperf TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Using Iperf

Describes how to use in the TCP/IP Stack Library Iperf module.

Description

Iperf is a networking tool that helps to measure networking bandwidth and performance. The Iperf module can act as both a client and server for testing. Iperf has the ability to test both UDP and TCP. In the case of UDP, you can specify the size of the UDP datagrams. For TCP, Iperf measures the throughput of the payload.

To run Iperf, you will need a personal computer that has an Iperf application installed. There is an open source version that is maintained, as well as many other variants across the Internet.

Iperf is meant to be run on the command line. On the PIC32 MPLAB Harmony TCP/IP Stack device side, there is also a built-in command console that can accept your different Iperf settings from a system console, such as the UART.

Iperf measures performance data in a unidirectional format. Therefore, the side that the server is running on is considered the receiver, and provides the most accurate performance values.

Command Synopsis

```
iperf [ -s|-c <IP addr> ]
[ -u ]
[ -i <sec> ]
[ -b <bandwidth> ]
[ -t <time> ]
```

`-s`	Runs the Iperf server. No IP address needs to be specified.
`-c <IP addr>`	Runs the Iperf client. The IP address is the IP address of the server.
`-u`	Sends UDP datagrams.
`-i <sec>`	Specified the time interval, in seconds, that the display will be updated.
`-b <bandwidth>`	Specifies the amount of data to try and send. This option is only valid with UDP datagrams.
`-t <time>`	Amount of time, in seconds, to run the test.

Note: The socket size of TCP/UDP (especially TCP) will affect the benchmark result. In addition, activated TCP/IP modules will also consume CPU and Ethernet load. The traffic load in your test network environment will also affect the benchmark test.

To get a reasonable maximum benchmark/evaluation data for a PIC32 device target, it is recommended to disable other modules, such as HTTP, client example, server example, etc., and find a uncongested network.

Running the Demonstration

1. First, make sure the Iperf module and the System Console are enabled in your project.
2. Then, rebuild and program your project into target board.
3. After powering on the development board and associating the connected network, start the server side Iperf application first. If you start Iperf as a server on the development board in the console, this implies that you are trying to measure the PIC32 device Ethernet receiver performance. If you start the Iperf server on a personal computer, you will be measuring PIC Ethernet transmit performance.

PIC32 Ethernet Starter Kit Example

The following tests show receiver and transmitter performance, respectively on the PIC32 Ethernet Starter Kit with the following settings

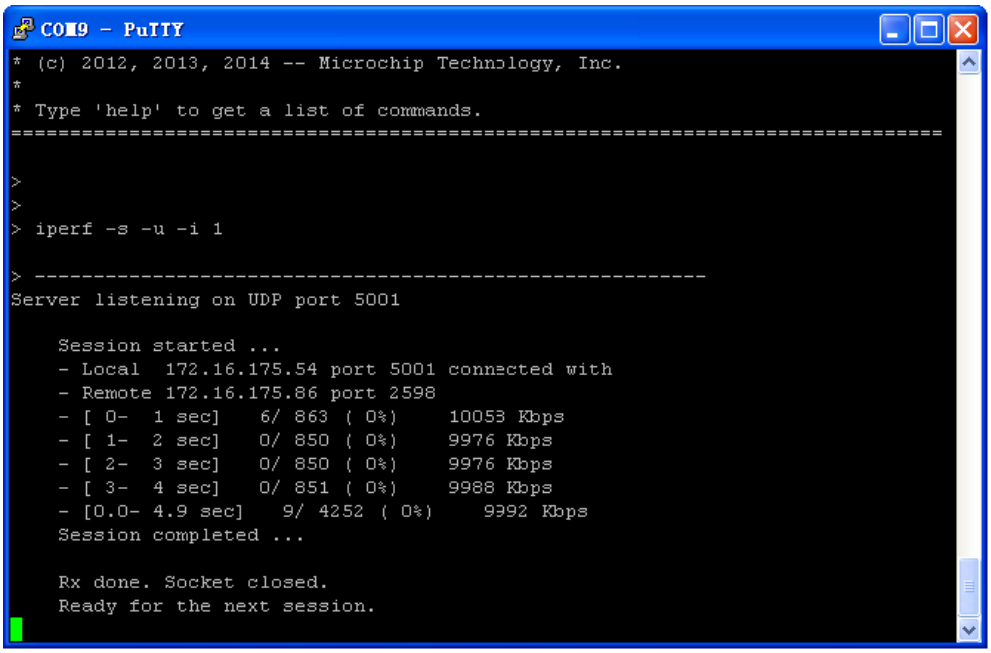
Note: The data does NOT show the maximum throughput of the PIC32 device as the settings are not optimized for that. Only the DHCP client, and the TCP and UDP modules are enabled in this example:

- TCP TX and RX Socket Size = 512
- UDP TX and RX Socket Size = 512
- Built by MPLAB XC32 C/C++ Compiler without any optimization
- Personal Computer IP Address: 172.16.175.86
- PIC32 Ethernet Starter Kit IP Address: 172.16.175.54

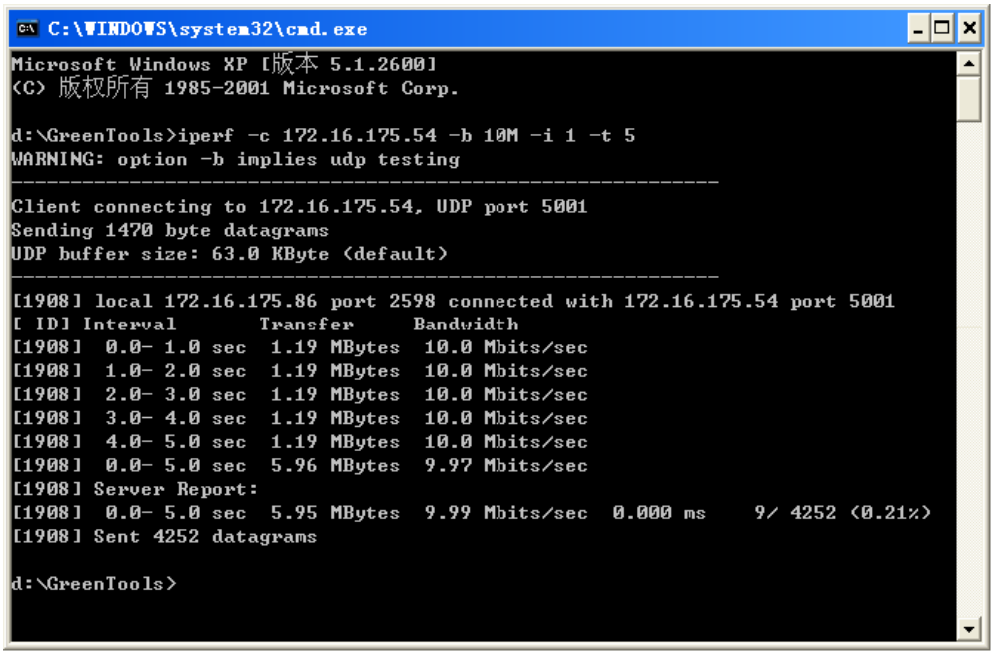
UDP Test

PIC32 ESK as UDP server (PIC32 receive):

- Command on the PIC32 device: `iperf -s -u -i 1`

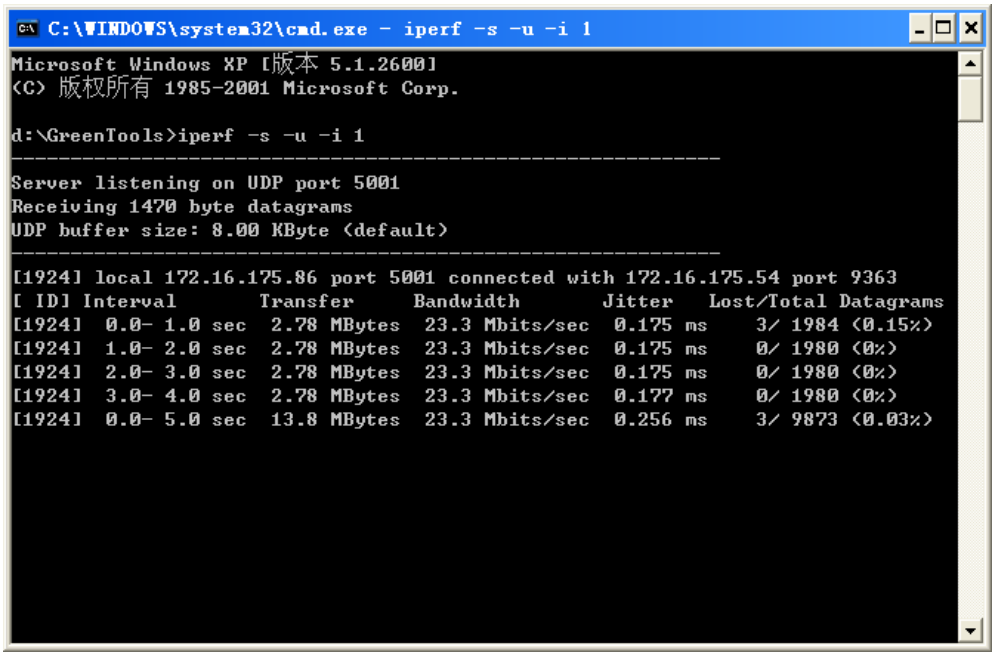


- Command on personal computer: `iperf -c 172.16.175.54 -b 10M -i 1 -t 5`

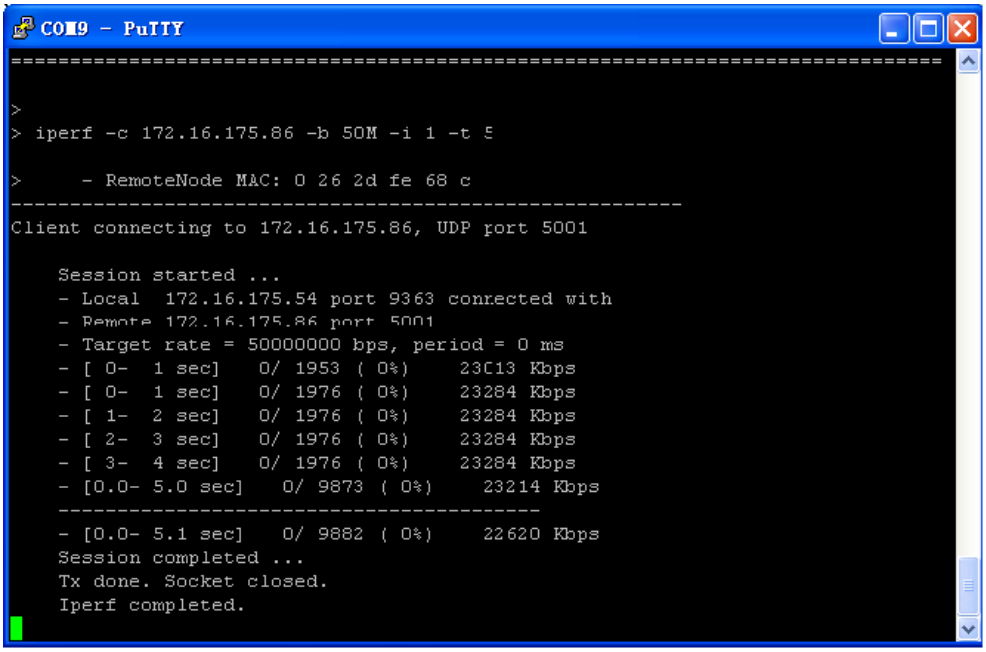


Personal computer as UDP server (PIC32 transmit)

- Command on personal computer: `iperf -s -u -i 1`

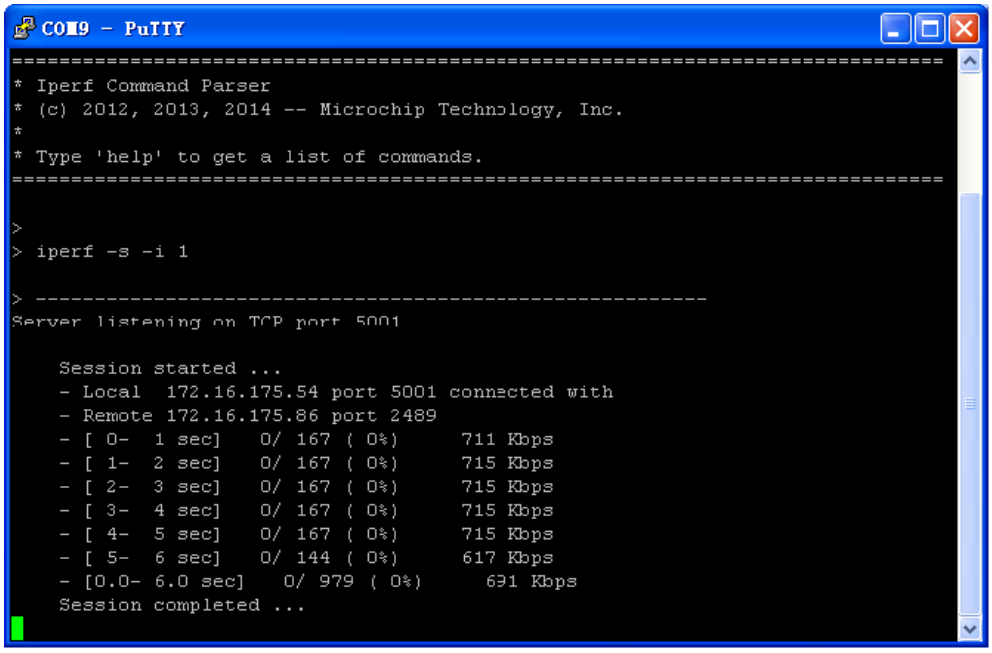


- Command on the PIC32 device: `iperf -c 172.16.175.86 -b 50M -i 1 -t 5`

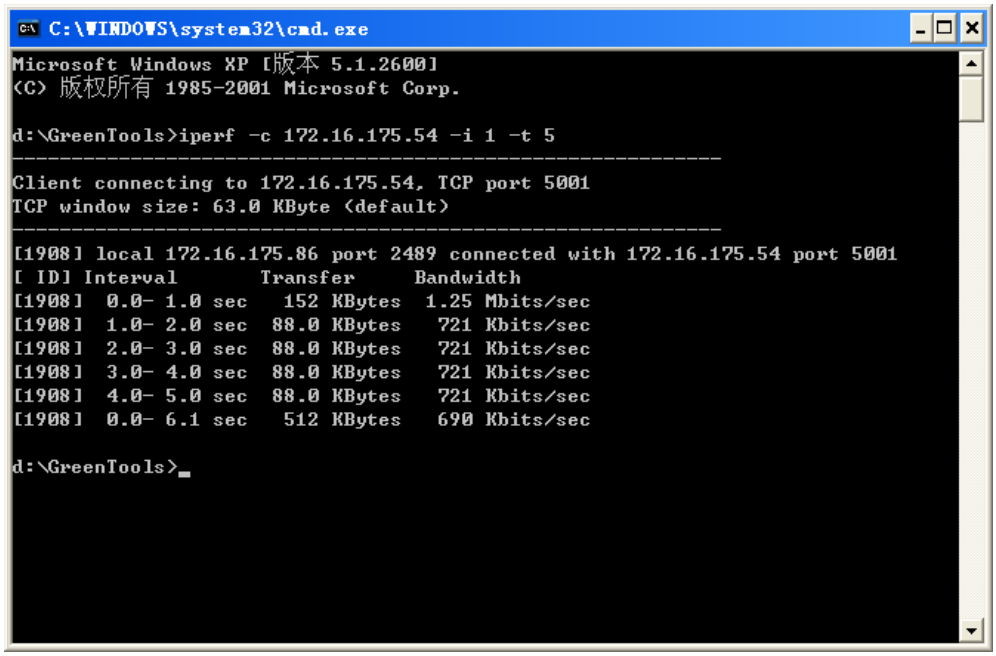


PIC32 ESK as TCP server (PIC32 receiving):

- Command on the PIC32 device: `iperf -s -i 1`

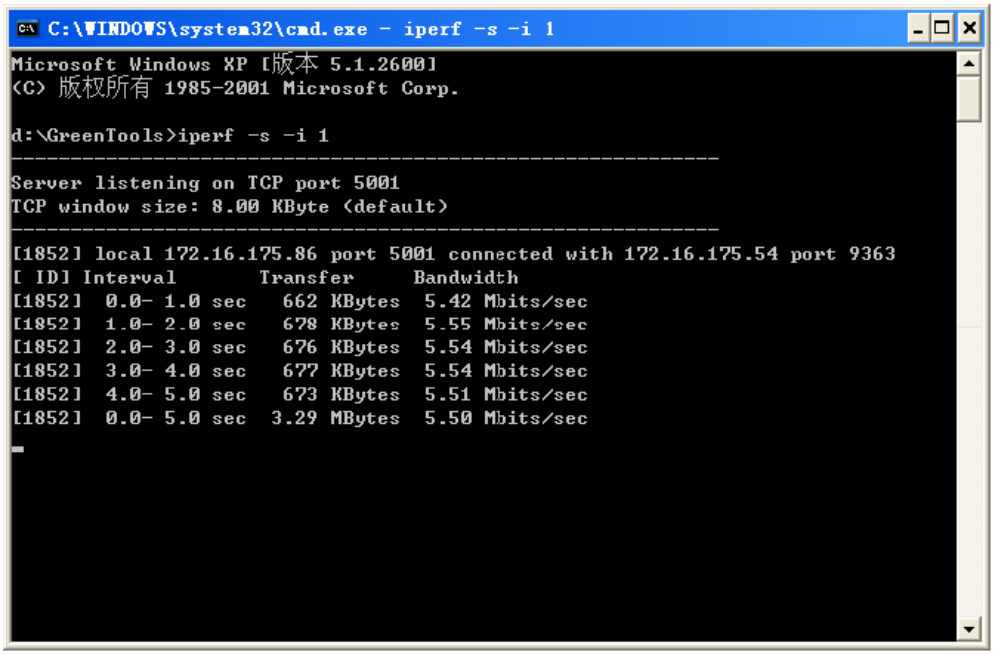


- Command on personal computer: `iperf -c 172.16.175.54 -i 1 -t 5`

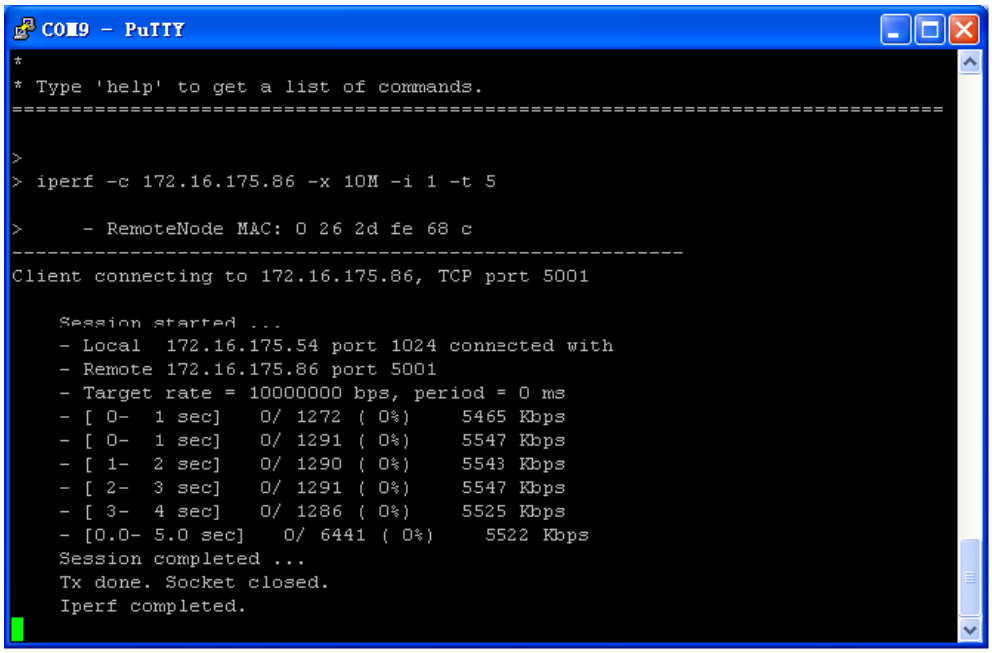


Personal computer as TCP server (PIC32 transmit):

- Command on personal computer: `iperf -s -i 1`



- Command on the PIC32 device: `iperf -c 172.16.175.86 -x 10M -i 1 -t 5`



Configuring the Module

Macros

	Name	Description
	TCPIP_IPERF_RX_BUFFER_SIZE	Default size of the Iperf RX buffer The default value is 4KB. The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput. Bigger buffers will help obtain higher performance numbers
	TCPIP_IPERF_TX_BUFFER_SIZE	Default size of the Iperf TX buffer The default value is 4KB. The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput. Bigger buffers will help obtain higher performance numbers
	TCPIP_IPERF_TX_QUEUE_LIMIT	for Iperf UDP client, the limit to set to avoid memory allocation overflow on slow connections
	TCPIP_IPERF_TX_WAIT_TMO	timeout to wait for TX channel to be ready to transmit a new packet; ms depends on the channel bandwidth

	TCPIP_IPERF_MAX_INSTANCES	maximum number of simultaneously running iperf instances
	TCPIP_IPERF_TIMING_ERROR_MARGIN	iperf timing error, ms. Accounts for timing uncertainty The higher the value, the more relaxed is the iperf timing Lower limit is 0

Description

The configuration of the Iperf TCP/IP Stack is based on the template file `iperf_config.h` with the actual symbols generated in the `system_config.h` file.

This header file contains the configuration selection for the Iperf TCP/IP Stack. Based on the selections made, the Iperf TCP/IP Stack may support the selected features.

TCPIP_IPERF_RX_BUFFER_SIZE Macro

File

iperf_config.h

C

```
#define TCPIP_IPERF_RX_BUFFER_SIZE 4096
```

Description

Default size of the Iperf RX buffer The default value is 4KB. The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput. Bigger buffers will help obtain higher performance numbers

TCPIP_IPERF_TX_BUFFER_SIZE Macro

File

iperf_config.h

C

```
#define TCPIP_IPERF_TX_BUFFER_SIZE 4096
```

Description

Default size of the Iperf TX buffer The default value is 4KB. The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput. Bigger buffers will help obtain higher performance numbers

TCPIP_IPERF_TX_QUEUE_LIMIT Macro

File

iperf_config.h

C

```
#define TCPIP_IPERF_TX_QUEUE_LIMIT 2
```

Description

for Iperf UDP client, the limit to set to avoid memory allocation overflow on slow connections

TCPIP_IPERF_TX_WAIT_TMO Macro

File

iperf_config.h

C

```
#define TCPIP_IPERF_TX_WAIT_TMO 100
```

Description

timeout to wait for TX channel to be ready to transmit a new packet; ms depends on the channel bandwidth

TCPIP_IPERF_MAX_INSTANCES Macro

File

iperf_config.h

C

```
#define TCPIP_IPERF_MAX_INSTANCES 1
```

Description

maximum number of simultaneously running iperf instances

TCPIP_IPERF_TIMING_ERROR_MARGIN Macro

File

iperf_config.h

C

```
#define TCPIP_IPERF_TIMING_ERROR_MARGIN 0
```

Description

iperf timing error, ms. Accounts for timing uncertainty The higher the value, the more relaxed is the iperf timing Lower limit is 0

Building the Library

This section lists the files that are available in the Iperf module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (.h) and source (.c) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.
`/iperf.h`	Header file for the Iperf module.

Required File(s)

MHC ***All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.***

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/iperf.c`	Iperf implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The Iperf module depends on the following modules:

- TCP/IP Stack Library

Files

Files

Name	Description
iperf_config.h	Iperf configuration file

Description

This section lists the source and header files used by the module.

iperf_config.h

Iperf configuration file

Macros

	TCPIP_IPERF_RX_BUFFER_SIZE	Default size of the Iperf RX buffer The default value is 4KB. The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput. Bigger buffers will help obtain higher performance numbers
	TCPIP_IPERF_TIMING_ERROR_MARGIN	iperf timing error, ms. Accounts for timing uncertainty The higher the value, the more relaxed is the iperf timing Lower limit is 0
	TCPIP_IPERF_TX_BUFFER_SIZE	Default size of the Iperf TX buffer The default value is 4KB. The performance of a socket is highly dependent on the size of its buffers so it's a good idea to use as large as possible buffers for the sockets that need high throughput. Bigger buffers will help obtain higher performance numbers
	TCPIP_IPERF_TX_QUEUE_LIMIT	for Iperf UDP client, the limit to set to avoid memory allocation overflow on slow connections
	TCPIP_IPERF_TX_WAIT_TMO	timeout to wait for TX channel to be ready to transmit a new packet; ms depends on the channel bandwidth

IPv4 Module

This section describes the TCP/IP Stack Library IPv4 module.

Introduction

TCP/IP Stack Library IPv4 Module for Microchip Microcontrollers

This library provides the API of the IPv4 module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

IP is the workhorse protocol of the TCP/IP protocol suite. All TCP, UDP, and ICMP data gets transmitted as IP datagrams. IP provides an unreliable, connectionless datagram delivery service.

IP provides a best effort service. When something goes wrong, such as a router temporarily running out of buffers, IP has a simple error handling algorithm: throw away the datagram and try to send an ICMP message back to the source. Any required reliability must be provided by the upper layers (e.g., TCP).

The term connectionless means that IP does not maintain any state information about successive datagrams. Each datagram is handled independently from all other datagrams. This also means that IP datagrams can get delivered out of order. If a source sends two consecutive datagrams (first A, and then B) to the same destination, each is routed independently and can take different routes, with B arriving before A.

Using the Library

This topic describes the basic architecture of the IP TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `ipv4.h`

The interface to the IPv4 TCP/IP Stack library is defined in the ipv4.h header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the IPv4 TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

Abstraction Model

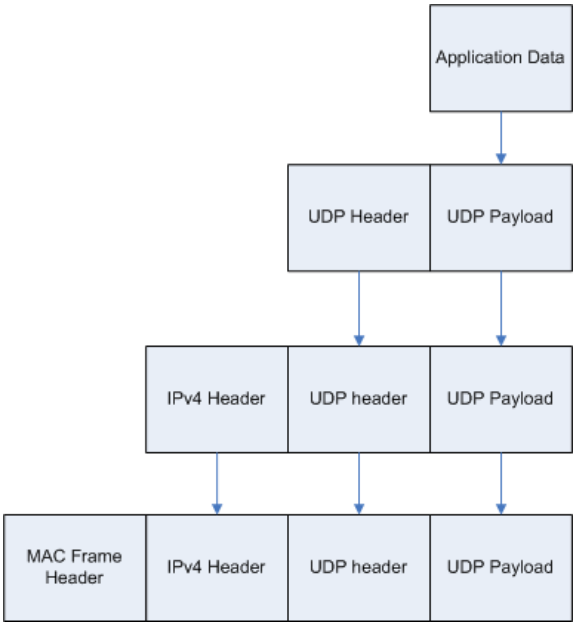
This library provides the API of the IPv4 TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

This module provides software abstraction of the IPv4 module existent in any TCP/IP Stack implementation.

The typical usage of the IP layer in a TCP/IP stack for transmitting a packet is shown in the following diagram:

IPv4 Software Abstraction Block Diagram



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the IPv4 module.

Library Interface Section	Description
Functions	Routines for configuring IPv4
Data Types and Constants	This section provides various definitions describing this API

How the Library Works

This topic describes how the IP TCP/IP Stack Library works.

Description

On the transmit side, the IP layer is responsible for routing and forwarding the IP datagrams to the required destination host. To do that, the IP layer has internal functionality that allows the selection of the proper network interface and destination hardware address of a packet.

Based on the destination of a packet/datagram, the IP layer will send the packet to either a host on the network or to a gateway if either is available. To accomplish this, the IP module works closely with the ARP layer from which it requests the destination hardware addresses for

outgoing packets. If the destination address of a packet is not known, the IP module will request an ARP probe and will wait for the ARP module reply. Whenever ARP signals that the solicited address is available, the IP module will send the packet over the network. If a time-out is reported (no such host could be found on that particular network), the packet is silently discarded.

On the receive side, the IP module processes all the incoming IPv4 packets and performs a basic sanity check of the packet checksum and other attributes. If the packet check fails, the packet is simply discarded. Otherwise, it is dispatched for further processing to the appropriate module (UDP, TCP, ICMP, etc.).

The IP layer operation within the TCP/IP stack is transparent to the applications using the preferred socket API (MCHP UDP, TCP or BSD). This means that normally an application does not need to interface directly to the IP layer. However, the IP module exposes an API that can be used by the application for sending IP datagrams directly, bypassing the normal higher layer protocols (UDP, TCP).

Notes:

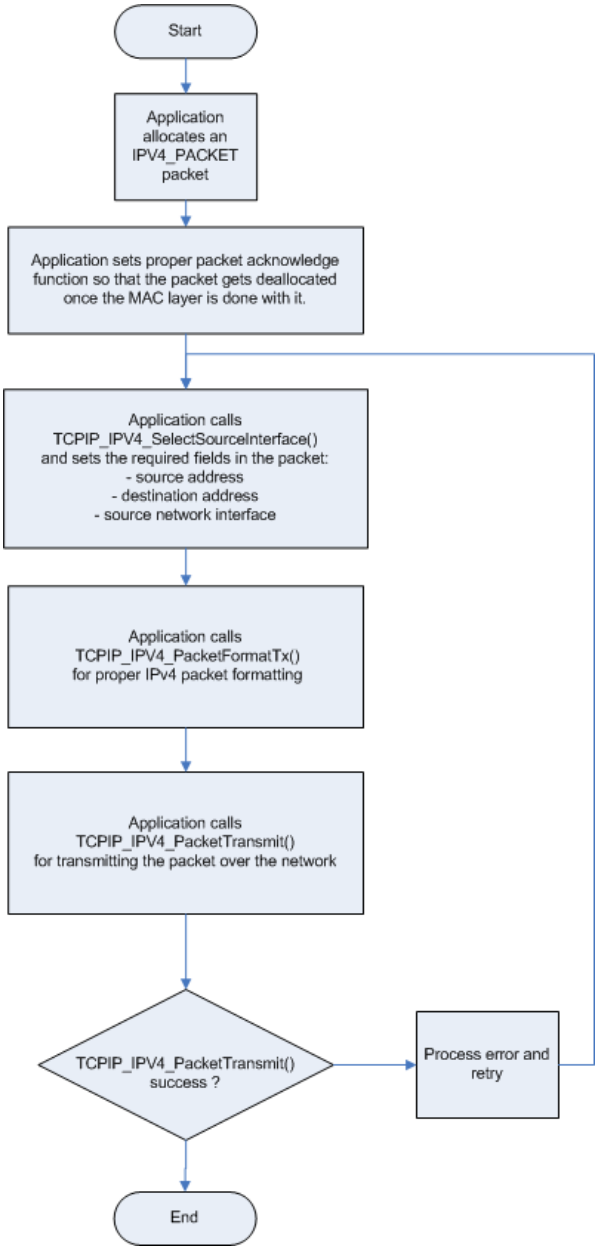
1. Currently, it is not possible for an application to intercept the incoming IP datagrams and interfere with the default IP processing. However, this may change in the future and support can be added for the receive side.
2. For a detailed description of the IP layer functionality, please consult RFC 791, RFC 1122, RFC 2474, etc.
3. This implementation does not support packet fragmentation (neither on transmit or receive).

Core Functionality

This topic describes the core functionality of the IP TCP/IP Stack Library.

Description

IP Connection Flow



To transmit an IP packet over the network, the application has to prepare an IPV4_PACKET data structure and properly format it so that the recipients of this packet (the IP and the MAC layers) can process the packet.

The TCP/IP Stack modules allocate the IPV4_PACKET data structures dynamically using the TCP/IP Stack private heap using packet allocation functions.

Note: Currently, the packet and heap allocation functions are not exposed as public APIs as they are meant for stack's private usage. This may change in the future.

The IPV4_PACKET packet can be allocated statically by the application.

When the IPV4_PACKET is constructed an important thing to remember is to fill in the appropriate packet acknowledge function. Once the MAC layer/driver is done with processing the packet (successfully or not) it will call the IPV4_PACKET acknowledge function, indicating that the packet is now available (and could be freed or reused).

The next step is to fill in the packet source and destination addresses, as well as the outgoing interface (please keep in mind that the TCP/IP stack supports multiple network interfaces).

This could be done with a call to TCPIP_IPV4_SelectSourceInterface or the application can select all these addresses manually.

All that's left before handing the packet is to call TCPIP_IPV4_PacketFormatTx. This call fills in the supplied packet with the IP header structure and updates the IP checksum. Please note that this function expects a properly formatted packet, with the source and destination addresses filled in.

After this, the application can call TCPIP_IPV4_PacketTransmit. This function does some basic packet checks and expects that the packet has a valid network interface selected otherwise the call will fail.

After further formatting (with the MAC required headers), the IP layer will try to send the packet over the network. If the destination hardware

address is known (the ARP resolve call succeeds) the packet is handed over to the MAC. Otherwise, the IP will insert the packet into a queue, waiting for the ARP resolution. When ARP signals that the request is done (either success or timeout) the IP layer intercepts the signal and removes the packet from the wait queue: either hands it over to the MAC for transmission or it discards it if the ARP resolution failed.

The MAC layer/driver in its turn can transmit it immediately, queue the packet for transmission or discard it (if, for example the network link is down). Regardless, once the packet is processed, the packet acknowledge function is called with an updated acknowledge result. This informs the owner of the packet about the result of the operation and also that the packet is no longer in traffic.

Note: Transmission of chained packets is not supported. Each packet has to be transmitted individually.

Configuring the Library

Macros

	Name	Description
	TCPIP_IPV4_FRAGMENT_MAX_NUMBER	Upper limit for the number of fragments in a fragmented stream This also imposes a limit on how large a packet could be depending on the MTU and fragmentations that occur If more fragments received for a certain stream, the stream will be discarded
	TCPIP_IPV4_FRAGMENT_MAX_STREAMS	Upper limit for the number of fragmented streams that could be handled simultaneously
	TCPIP_IPV4_FRAGMENT_TIMEOUT	Initial fragment timeout, in seconds Timer Lower Bound (RFC 791) The RFC states this value to be 15 seconds
	TCPIP_IPV4_FRAGMENTATION	If 1, enable IPv4 fragmentation processing, RX + TX If 0 (default), IPv4 fragmentation not supported
	TCPIP_IPV4_TASK_TICK_RATE	The IP task processing rate: number of milliseconds to generate an IP tick. This is the tick that advances the IP state machine. The default value is around 30 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE. The IP state machine tick is used only when fragmentation is enabled.

Description

The configuration of the IPv4 TCP/IP Stack is based on the file `system_config.h` (which may include `ip_config.h`).

This header file contains the configuration selection for the IPv4 TCP/IP Stack. Based on the selections made, the IPv4 TCP/IP Stack may support the selected features. Currently, there are no configuration parameters for the IP module.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_IPV4_FRAGMENT_MAX_NUMBER Macro

File

ip_config.h

C

```
#define TCPIP_IPV4_FRAGMENT_MAX_NUMBER 4
```

Description

Upper limit for the number of fragments in a fragmented stream This also imposes a limit on how large a packet could be depending on the MTU and fragmentations that occur If more fragments received for a certain stream, the stream will be discarded

TCPIP_IPV4_FRAGMENT_MAX_STREAMS Macro

File

ip_config.h

C

```
#define TCPIP_IPV4_FRAGMENT_MAX_STREAMS 3
```

Description

Upper limit for the number of fragmented streams that could be handled simultaneously

TCPIP_IPV4_FRAGMENT_TIMEOUT Macro

File

ip_config.h

C

```
#define TCPIP_IPV4_FRAGMENT_TIMEOUT 15
```

Description

Initial fragment timeout, in seconds Timer Lower Bound (RFC 791) The RFC states this value to be 15 seconds

TCPIP_IPV4_FRAGMENTATION Macro

File

ip_config.h

C

```
#define TCPIP_IPV4_FRAGMENTATION 1
```

Description

If 1, enable IPv4 fragmentation processing, RX + TX If 0 (default), IPv4 fragmentation not supported

TCPIP_IPV4_TASK_TICK_RATE Macro

File

ip_config.h

C

```
#define TCPIP_IPV4_TASK_TICK_RATE 37
```

Description

The IP task processing rate: number of milliseconds to generate an IP tick. This is the tick that advances the IP state machine. The default value is around 30 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE. The IP state machine tick is used only when fragmentation is enabled.

Building the Library

This section lists the files that are available in the IPv4 module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
`/src/ipv4.c`	IPv4 implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The IPv4 module depends on the following modules:

- TCP/IP Stack Library

Library Interface

a) Functions

	Name	Description
	TCPIP_IPV4_PacketGetDestAddress	Returns the IPv4 destination address associated with a TCPIP_MAC_PACKET
	TCPIP_IPV4_PacketGetSourceAddress	Returns the IPv4 source address associated with a TCPIP_MAC_PACKET
	TCPIP_IPV4_PacketTransmit	Transmits an IPV4 packet over the network.
	TCPIP_IPV4_SelectSourceInterface	Selects a source address and an interface based on the IPv4 destination address
	TCPIP_IPV4_Task	Standard TCP/IP stack module task function.
	TCPIP_IPV4_PacketFilterClear	Clears the IPV4 packet filters
	TCPIP_IPV4_PacketFilterSet	Sets the IPV4 packet filters
	TCPIP_IPV4_MacPacketTransmit	Transmits a fully constructed MAC packet over the network.
	TCPIP_IPV4_PacketFormatTx	Formats an IPV4 packet and makes it ready for transmission.

b) Data Types and Constants

	Name	Description
	IPV4_HEADER	This is type IPV4_HEADER.
	IPV4_HEADER_TYPE	List of supported protocols.
	IPV4_PACKET	IPv4 packet structure.
	TCPIP_IPV4_FILTER_TYPE	List of supported IPv4 packet filters.
	TCPIP_IPV4_MODULE_CONFIG	This is type TCPIP_IPV4_MODULE_CONFIG.
	IPV4_FRAGMENT_INFO	Structure of an IPv4 header.

Description

This section describes the Application Programming Interface (API) functions of the IPv4 module.

Refer to each section for a detailed description.

a) Functions

TCPIP_IPV4_PacketGetDestAddress Function

Returns the IPv4 destination address associated with a TCPIP_MAC_PACKET

File

ipv4.h

C

```
__inline__ const IPV4_ADDR* TCPIP_IPV4_PacketGetDestAddress(TCPIP_MAC_PACKET* pPkt);
```

Returns

- A valid pointer to an IPV4_ADDR - if it succeeds
- 0 - if call failed

Description

The function will return a pointer to where the IPv4 destination address is located in the TCPIP_MAC_PACKET. The TCPIP_MAC_PACKET is

supposed to be a valid IPv4 packet that has destination address properly set.

Remarks

This function is primarily meant for RX packets.

Preconditions

pPkt - valid IPv4 packet, pNetLayer filed properly set.

Parameters

Parameters	Description
pPkt	packet to query

Function

const IPV4_ADDR* TCPIP_IPV4_PacketGetDestAddress(TCPIP_MAC_PACKET* pPkt);

TCPIP_IPV4_PacketGetSourceAddress Function

Returns the IPv4 source address associated with a TCPIP_MAC_PACKET

File

ipv4.h

C

```
__inline__ const IPV4_ADDR* TCPIP_IPV4_PacketGetSourceAddress(TCPIP_MAC_PACKET* pPkt);
```

Returns

- A valid pointer to an IPV4_ADDR - if it succeeds
- 0 - if call failed

Description

The function will return a pointer to where the IPv4 source address is located in the TCPIP_MAC_PACKET. The TCPIP_MAC_PACKET is supposed to be a valid IPv4 packet that has properly source address set.

Remarks

This function is primarily meant for RX packets.

Preconditions

pPkt - valid IPv4 packet, pNetLayer filed properly set

Parameters

Parameters	Description
pPkt	packet to query

Function

const IPV4_ADDR* TCPIP_IPV4_PacketGetSourceAddress(TCPIP_MAC_PACKET* pPkt);

TCPIP_IPV4_PacketTransmit Function

Transmits an IPV4 packet over the network.

File

ipv4.h

C

```
bool TCPIP_IPV4_PacketTransmit(IPV4_PACKET* pPkt);
```

Returns

- true - if the packet was handed to the MAC or is queued for transmission
- false - the packet cannot be transmitted (wrong interface, etc.)

Description

The IPv4 packet is sent to the MAC for transmission.

Remarks

Only single packets can be transmitted. Chained packets are not supported for now.

Preconditions

pPkt should have been properly formatted with TCPIP_IPV4_PacketFormatTx(). The packet interface should be updated.

Parameters

Parameters	Description
pPkt	the packet to be transmitted

Function

bool TCPIP_IPV4_PacketTransmit(IPV4_PACKET* pPkt);

TCPIP_IPV4_SelectSourceInterface Function

Selects a source address and an interface based on the IPv4 destination address

File

ipv4.h

C

```
TCPIP_NET_HANDLE TCPIP_IPV4_SelectSourceInterface(TCPIP_NET_HANDLE netH, IPV4_ADDR* pDestAddress,
IPV4_ADDR* pSrcAddress, bool srcSet);
```

Returns

- A valid interface - if it succeeds and a valid source interface selected
- 0 - interface selection failed

Description

Updates the pSrcAddress and returns the needed interface, if successful:

- if srcSet == 1 and netH != 0, the function will not change anything
- if srcSet == 1 and netH == 0, the call will never fail it will use whatever value in pSrcAddress (even 0) and will try to come up with an appropriate interface
- if srcSet == 0 and netH == 0, it will use the destination address
- if srcSet == 0 and netH != 0, it will use the address of that interface

Remarks

None.

Preconditions

netH has to be valid (if non-0).

Parameters

Parameters	Description
netH	network interface handle
pDestAddress	pointer to destination address
pSrcAddress	pointer to source address
srcSet	boolean; true if address pointed by pSrcAddress is valid

Function

TCPIP_NET_HANDLE TCPIP_IPV4_SelectSourceInterface(TCPIP_NET_HANDLE netH,
IPV4_ADDR* pDestAddress, IPV4_ADDR* pSrcAddress, bool srcSet)

TCPIP_IPV4_Task Function

Standard TCP/IP stack module task function.

File

ipv4.h

C

```
void TCPIP_IPV4_Task();
```

Returns

None.

Description

This function performs IPv4 module tasks in the TCP/IP stack.

Remarks

None.

Preconditions

The IPv4 module should have been initialized.

Function

void TCPIP_IPV4_Task(void)

TCPIP_IPV4_PacketFilterClear Function

Clears the IPV4 packet filters

File

ipv4.h

C

```
TCPIP_IPV4_FILTER_TYPE TCPIP_IPV4_PacketFilterClear(TCPIP_IPV4_FILTER_TYPE filtType);
```

Returns

- the current value of the IPV4 packet filters after this mask was applied.

Description

The function will clear the IPv4 packet filters. The filters that are present in the mask will be cleared. Other filters won't be touched.

Remarks

None.

Preconditions

filtType - valid IPv4 filter IPv4 properly initialiazed

Parameters

Parameters	Description
filtType	packet filter mask to clear

Function

TCPIP_IPV4_FILTER_TYPE TCPIP_IPV4_PacketFilterClear(TCPIP_IPV4_FILTER_TYPE filtType);

TCPIP_IPV4_PacketFilterSet Function

Sets the IPV4 packet filters

File

ipv4.h

C

```
TCPIP_IPV4_FILTER_TYPE TCPIP_IPV4_PacketFilterSet(TCPIP_IPV4_FILTER_TYPE filtType);
```

Returns

- the current value of the IPV4 packet filters after this mask was applied.

Description

The function will set the IPv4 packet filters. The filters that are present in the mask will be set. Other filters won't be touched.

Remarks

None.

Preconditions

filtType - valid IPv4 filter IPv4 properly initialiazed

Parameters

Parameters	Description
filtType	packet filter mask to set

Function

TCPIP_IPV4_FILTER_TYPE TCPIP_IPV4_PacketFilterSet(TCPIP_IPV4_FILTER_TYPE filtType);

TCPIP_IPV4_MacPacketTransmit Function

Transmits a fully constructed MAC packet over the network.

File

ipv4.h

C

```
bool TCPIP_IPV4_MacPacketTransmit(TCPIP_MAC_PACKET* pPkt, TCPIP_NET_HANDLE hNet, IPV4_ADDR* pDestAddress);
```

Returns

- true - if the packet was handed to the MAC or queued internally
- false - the packet cannot be transmitted (wrong interface, etc.)

Description

The function is a helper to transmit a fully constructed MAC packet over an interface. The MAC packet is supposed to have all the fields properly constructed (including the TCPIP_MAC_ETHERNET_HEADER fields). The MAC packet does not need ARP resolution since the DestMACAddr is already known. The packet acknowledge function should be properly set (it will be called by the MAC driver once the packet is transmitted).

Remarks

Only single packets can be transmitted. Chained packets are not supported for now.

The packet could be composed of multiple fragments. If the transmission fails, some fragments could have been transmitted while other failed. The flag TCPIP_MAC_PKT_FLAG_QUEUED could be used to determine which fragments didn't make it through.

Preconditions

pPkt should have been properly formatted and constructed into a valid MAC packet that can go out over an interface pDestAddress - valid pointer

Parameters

Parameters	Description
pPkt	the packet to be transmitted
hNet	interface over which the packet is to be transmitted
pDestAddress	the IPv4 packet destination address It is used only for routing purposes, to decide if the packet is routed internally or sent to the network interface

Function

bool TCPIP_IPV4_MacPacketTransmit(TCPIP_MAC_PACKET* pPkt, TCPIP_NET_HANDLE hNet, IPV4_ADDR* pDestAddress);

TCPIP_IPV4_PacketFormatTx Function

Formats an IPV4 packet and makes it ready for transmission.

File

ipv4.h

C

```
void TCPIP_IPV4_PacketFormatTx(IPV4_PACKET* pPkt, uint8_t protocol, uint16_t ipLoadLen, uint8_t ttl);
```

Returns

None

Description

The necessary fields are set into the IPv4 packet.

Remarks

The segments should be properly updated with the right number of bytes (segLen). The IP payload length (ipLoadLen) is added only to the 1st segment of the packet! Other segments (for packets having multiple packets) are not touched.

Preconditions

Properly allocated pPkt. The source and destination addresses should be updated in the packet.

Parameters

Parameters	Description
pPkt	the packet to be formatted
protocol	the protocol associated with the packet
ipLoadLen	the IPv4 packet payload length
ttl	the Time to Live of the packet If 0, then the default value will be used Otherwise the passed in parameter

Function

TCPIP_IPV4_PacketFormatTx(IPV4_PACKET* pPkt, uint8_t protocol, uint16_t ipLoadLen, uint8_t ttl);

b) Data Types and Constants

IPV4_HEADER Structure

File

ipv4.h

C

```
typedef struct {
  uint8_t VersionIHL;
  uint8_t TypeOfService;
  uint16_t TotalLength;
  uint16_t Identification;
  IPV4_FRAGMENT_INFO FragmentInfo;
  uint8_t TimeToLive;
  uint8_t Protocol;
  uint16_t HeaderChecksum;
  IPV4_ADDR SourceAddress;
  IPV4_ADDR DestAddress;
} IPV4_HEADER;
```

Description

This is type IPV4_HEADER.

IPV4_HEADER_TYPE Enumeration

List of supported protocols.

File

ipv4.h

C

```
typedef enum {
  IP_PROT_ICMP = (1u),
```

```
  IP_PROT_IGMP = (2u),
  IP_PROT_TCP = (6u),
  IP_PROT_UDP = (17u)
} IPV4_HEADER_TYPE;
```

Description

IPv4 supported protocols

This is the list of the protocols that are supported by this IPv4 implementation.

Remarks

None.

IPV4_PACKET Structure

IPv4 packet structure.

File

ipv4.h

C

```
typedef struct {
  TCPIP_MAC_PACKET macPkt;
  IPV4_ADDR srcAddress;
  IPV4_ADDR destAddress;
  TCPIP_NET_HANDLE netIfH;
  IPV4_ADDR arpTarget;
} IPV4_PACKET;
```

Members

Members	Description
TCPIP_MAC_PACKET macPkt;	standard MAC packet header safe cast to TCPIP_MAC_PACKET
IPV4_ADDR srcAddress;	packet source
IPV4_ADDR destAddress;	packet destination
TCPIP_NET_HANDLE netIfH;	packet interface
IPV4_ADDR arpTarget;	ARP resolution target

Description

IPv4 packet structure definition

This is the structure of an IPv4 packet for transmission over the network.

Remarks

None.

TCPIP_IPV4_FILTER_TYPE Enumeration

List of supported IPv4 packet filters.

File

ipv4.h

C

```
typedef enum {
  TCPIP_IPV4_FILTER_NONE = 0x00,
  TCPIP_IPV4_FILTER_UNICAST = 0x01,
  TCPIP_IPV4_FILTER_BROADCAST = 0x02,
  TCPIP_IPV4_FILTER_MULTICAST = 0x04
} TCPIP_IPV4_FILTER_TYPE;
```

Members

Members	Description
TCPIP_IPV4_FILTER_NONE = 0x00	no packet filter active. All packets are accepted
TCPIP_IPV4_FILTER_UNICAST = 0x01	unicast packets will be filtered out
TCPIP_IPV4_FILTER_BROADCAST = 0x02	broadcast packets will be filtered out

TCPIP_IPV4_FILTER_MULTICAST = 0x04	multicast packets will be filtered out

Description

IPv4 packet filters

This is the list of the packet filters that are supported by this IPv4 implementation. There are 3 types of IPv4 packets currently supported:

- unicast
- broadcast
- multicast

An IPV4 packet is accepted if the filter corresponding to the packet type is not set

Remarks

Multiple filters can be set

If no filter is set, all packets are accepted this is the default case.

TCPIP_IPV4_MODULE_CONFIG Structure

File

ipv4.h

C

```
typedef struct {
} TCPIP_IPV4_MODULE_CONFIG;
```

Description

This is type TCPIP_IPV4_MODULE_CONFIG.

IPV4_FRAGMENT_INFO Union

Structure of an IPv4 header.

File

ipv4.h

C

```
typedef union {
  uint16_t val;
  struct {
    uint16_t fragOffset : 13;
    uint16_t MF : 1;
    uint16_t DF : 1;
    uint16_t reserved : 1;
  }
} IPV4_FRAGMENT_INFO;
```

Members

Members	Description
uint16_t fragOffset : 13;	fragment offset
uint16_t MF : 1;	more fragments
uint16_t DF : 1;	don't fragment

Description

IPv4 packet header definition

This is the structure of an IPv4 packet header.

Remarks

None.

Files

IPv6 Module

This section describes the TCP/IP Stack Library IPv6 module.

Introduction

TCP/IP Stack Library IPv6 Module for Microchip Microcontrollers

This library provides the API of the IPv6 module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP Stack.

Description

IPv6 is the workhorse protocol of the TCP/IP protocol suite. All TCP, UDP, ICMP, and IGMP data gets transmitted as IP datagrams. IP provides an reliable, connectionless datagram delivery service.

IPv6 provides a best effort service. When something goes wrong, such as a router temporarily running out of buffers, IPv6 has a simple error handling algorithm: throw away the datagram and try to send an ICMP message back to the source. Any required reliability must be provided by the upper layers (e.g., TCP).

The term connectionless means that IPv6 does not maintain any state information about successive datagrams. Each datagram is handled independently from all other datagrams. This also means that IPv6 datagrams can get delivered out of order. If a source sends two consecutive datagrams (first A, and then B) to the same destination, each is routed independently and can take different routes, with B arriving before A.

Using the Library

This topic describes the basic architecture of the IPv6 TCP/IP Stack Library and provides information and examples on its use.

Description

Interface Header File: `ipv6.h`

The interface to the IPv6 TCP/IP Stack library is defined in the `ipv6.h` header file. This file is included by the `tcpip.h` file. Any C language source (`.c`) file that uses the IPv6 TCP/IP Stack library should include `tcpip.h`.

Please refer to the What is MPLAB Harmony? section for how the TCP/IP Stack interacts with the framework.

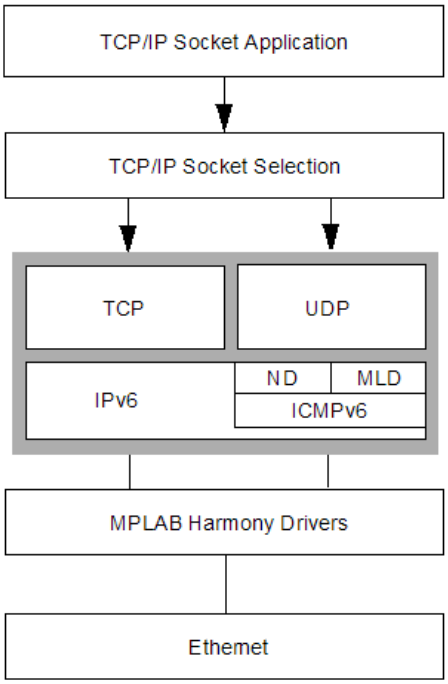
Abstraction Model

This library provides the API of the IP TCP/IP Module that is available on the Microchip family of microcontrollers with a convenient C language interface. It is a module that belongs to the TCP/IP stack.

Description

IP Software Abstraction Block Diagram

This module provides software abstraction of the IP module existent in any TCP/IP Stack implementation. It removes the overhead of address resolution from all other modules in the stack.



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the IPv6 module.

Library Interface Section	Description
Functions	Routines for configuring IPv6
Data Types and Constants	This section provides various definitions describing this API

Configuring the Library

Macros

	Name	Description
	TCPIP_IPV6_DEFAULT_ALLOCATION_BLOCK_SIZE	Sets the minimum allocation unit for the payload size
	TCPIP_IPV6_DEFAULT_BASE_REACHABLE_TIME	Default 30 seconds , Router advertisement reachable time
	TCPIP_IPV6_DEFAULT_CUR_HOP_LIMIT	IPv4 Time-to-Live parameter
	TCPIP_IPV6_DEFAULT_LINK_MTU	Default Maximum Transmission Unit
	TCPIP_IPV6_DEFAULT_RETRANSMIT_TIME	1 second, Process the router advertisement's retransmission time
	TCPIP_IPV6_FRAGMENT_PKT_TIMEOUT	Fragmentation packet time-out value. default value is 60 .
	TCPIP_IPV6_INIT_TASK_PROCESS_RATE	IPv6 initialize task processing rate, milliseconds The default value is 32 milliseconds.
	TCPIP_IPV6_MINIMUM_LINK_MTU	Sets the lower bounds of the Maximum Transmission Unit
	TCPIP_IPV6_NEIGHBOR_CACHE_ENTRY_STALE_TIMEOUT	10 minutes
	TCPIP_IPV6_QUEUE_MCAST_PACKET_LIMIT	This option defines the maximum number of multicast queued IPv6 If an additional packet is queued, the oldest packet in the queue will be removed.
	TCPIP_IPV6_QUEUE_NEIGHBOR_PACKET_LIMIT	This option defines the maximum number of queued packets per remote. If an additional packet needs to be queued, the oldest packet in the queue will be removed.

	TCPIP_IPV6_QUEUED_MCAST_PACKET_TIMEOUT	This option defines the number of seconds an IPv6 multicast packet will remain in the queue before being timed out
	TCPIP_IPV6_RX_FRAGMENTED_BUFFER_SIZE	RX fragmented buffer size should be equal to the total original packet size of ICMPv6 ECHO request packets . ex - Let Transmit ICMPv6 Echo request packet whose original packet size is 1500byte from the Global address of HOST1 to the global address of HOST2 and if the packet is going to be fragmented then packet will be broken more than packets. Each packet will have IPv6 header(40 bytes)+ Fragmentation header (8 bytes) + ICMPv6 Echo request header(8 bytes) • Payload (data packet).PING6(1500=40+8+8+1452 bytes). Here data packet size is 1452. If the data packet size is getting changed then this... more
	TCPIP_IPV6_TASK_PROCESS_RATE	IPv6 task processing rate, milliseconds The default value is 1000 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.
	TCPIP_IPV6_ULA_NTP_ACCESS_TMO	NTP access time-out for the IPv6 ULA address generation, ms
	TCPIP_IPV6_ULA_NTP_VALID_WINDOW	the NTP time stamp validity window, ms if a stamp was obtained outside this interval from the moment of the request a new request will be issued

Description

The configuration of the IPv6 TCP/IP Stack is based on the file `system_config.h`.

This header file contains the configuration selection for the IPv6 TCP/IP Stack. Based on the selections made, the IPv6 TCP/IP Stack may support the support selected features. These configuration settings will apply to all instances of the IPv6 TCP/IP Stack.

This header can be placed anywhere; however, the path of this header needs to be present in the include search path for a successful build. Refer to the Applications Help section for more details.

TCPIP_IPV6_DEFAULT_ALLOCATION_BLOCK_SIZE Macro

File

ipv6_config.h

C

```
#define TCPIP_IPV6_DEFAULT_ALLOCATION_BLOCK_SIZE (64u)
```

Description

Sets the minimum allocation unit for the payload size

TCPIP_IPV6_DEFAULT_BASE_REACHABLE_TIME Macro

File

ipv6_config.h

C

```
#define TCPIP_IPV6_DEFAULT_BASE_REACHABLE_TIME 30u
```

Description

Default 30 seconds , Router advertisement reachable time

TCPIP_IPV6_DEFAULT_CUR_HOP_LIMIT Macro

File

ipv6_config.h

C

```
#define TCPIP_IPV6_DEFAULT_CUR_HOP_LIMIT 64u
```

Description

IPv4 Time-to-Live parameter

TCPIP_IPV6_DEFAULT_LINK_MTU Macro

File

ipv6_config.h

C

```
#define TCPIP_IPV6_DEFAULT_LINK_MTU 1500u
```

Description

Default Maximum Transmission Unit

TCPIP_IPV6_DEFAULT_RETRANSMIT_TIME Macro

File

ipv6_config.h

C

```
#define TCPIP_IPV6_DEFAULT_RETRANSMIT_TIME 1000u
```

Description

1 second, Process the router advertisement's retransmission time

TCPIP_IPV6_FRAGMENT_PKT_TIMEOUT Macro

File

ipv6_config.h

C

```
#define TCPIP_IPV6_FRAGMENT_PKT_TIMEOUT 60
```

Description

Fragmentation packet time-out value. default value is 60 .

TCPIP_IPV6_INIT_TASK_PROCESS_RATE Macro

File

ipv6_config.h

C

```
#define TCPIP_IPV6_INIT_TASK_PROCESS_RATE (32)
```

Description

IPv6 initialize task processing rate, milliseconds The default value is 32 milliseconds.

TCPIP_IPV6_MINIMUM_LINK_MTU Macro

File

ipv6_config.h

C

```
#define TCPIP_IPV6_MINIMUM_LINK_MTU 1280u
```

Description

Sets the lower bounds of the Maximum Transmission Unit

TCPIP_IPV6_NEIGHBOR_CACHE_ENTRY_STALE_TIMEOUT Macro

File

ipv6_config.h

C

```
#define TCPIP_IPV6_NEIGHBOR_CACHE_ENTRY_STALE_TIMEOUT 600ul           // 10 minutes
```

Description

10 minutes

TCPIP_IPV6_QUEUE_MCAST_PACKET_LIMIT Macro

File

ipv6_config.h

C

```
#define TCPIP_IPV6_QUEUE_MCAST_PACKET_LIMIT 4
```

Description

This option defines the maximum number of multicast queued IPv6 If an additional packet is queued, the oldest packet in the queue will be removed.

TCPIP_IPV6_QUEUE_NEIGHBOR_PACKET_LIMIT Macro

File

ipv6_config.h

C

```
#define TCPIP_IPV6_QUEUE_NEIGHBOR_PACKET_LIMIT 1
```

Description

This option defines the maximum number of queued packets per remote. If an additional packet needs to be queued, the oldest packet in the queue will be removed.

TCPIP_IPV6_QUEUED_MCAST_PACKET_TIMEOUT Macro

File

ipv6_config.h

C

```
#define TCPIP_IPV6_QUEUED_MCAST_PACKET_TIMEOUT 10u
```

Description

This option defines the number of seconds an IPv6 multicast packet will remain in the queue before being timed out

TCPIP_IPV6_RX_FRAGMENTED_BUFFER_SIZE Macro

File

ipv6_config.h

C

```
#define TCPIP_IPV6_RX_FRAGMENTED_BUFFER_SIZE 1514
```

Description

RX fragmented buffer size should be equal to the total original packet size of ICMPv6 ECHO request packets . ex - Let Transmit ICMPv6 Echo request packet whose original packet size is 1500byte from the Global address of HOST1 to the global address of HOST2 and if the packet is going to be fragmented then packet will be broken more than packets. Each packet will have IPv6 header(40 bytes)+ Fragmentation header (8

bytes) + ICMPv6 Echo request header(8 bytes)

- Payload (data packet).PING6(1500=40+8+8+1452 bytes). Here data packet size is 1452. If the data packet size is getting changed

then this following macro should be rectified to get proper ICMPv6 ECHO response. This is the Maximum RX fragmented buffer size.

TCPIP_IPV6_TASK_PROCESS_RATE Macro

File

ipv6_config.h

C

```
#define TCPIP_IPV6_TASK_PROCESS_RATE (1000)
```

Description

IPv6 task processing rate, milliseconds The default value is 1000 milliseconds. The lower the rate (higher the frequency) the higher the module priority and higher module performance can be obtained The value cannot be lower than the TCPIP_STACK_TICK_RATE.

TCPIP_IPV6_ULA_NTP_ACCESS_TMO Macro

File

ipv6_config.h

C

```
#define TCPIP_IPV6_ULA_NTP_ACCESS_TMO (12000)
```

Description

NTP access time-out for the IPv6 ULA address generation, ms

TCPIP_IPV6_ULA_NTP_VALID_WINDOW Macro

File

ipv6_config.h

C

```
#define TCPIP_IPV6_ULA_NTP_VALID_WINDOW (1000)
```

Description

the NTP time stamp validity window, ms if a stamp was obtained outside this interval from the moment of the request a new request will be issued

Building the Library

This section lists the files that are available in the IPv6 module of the TCP/IP Stack Library.

Description

The following three tables list and describe the header (`.h`) and source (`.c`) files that implement this library. The parent folder for these files is `<install-dir>/framework/tcpip`.

Interface File(s)

This table lists and describes the header files that must be included (i.e., using `#include`) by any code that uses this library.

Source File Name	Description
`/tcpip.h`	Header file that includes all of the TCP/IP modules.

Required File(s)

All of the required files listed in the following table are automatically added into the MPLAB X IDE project by the MHC when the library is selected for use.

This table lists and describes the source and header files that must *always* be included in the MPLAB X IDE project to build this library.

Source File Name	Description
/src/ipv6.c	IPv6 implementation file.

Optional File(s)

This table lists and describes the source and header files that may optionally be included if required for the desired implementation.

Source File Name	Description
N/A	No optional files are available for this library.

Module Dependencies

The IPv6 module depends on the following modules:

- TCP/IP Stack Library
- NDP Module
- SNTP Module

Library Interface

a) Functions

	Name	Description
	TCPIP_IPV6_AddressUnicastRemove	Removed a configured unicast address from an interface.
	TCPIP_IPV6_ArrayGet	Reads the next byte of data from the specified MAC.
	TCPIP_IPV6_ArrayPutHelper	Helper function to write data to a packet.
	TCPIP_IPV6_DASSourceAddressSelect	Determines the appropriate source address for a given destination address.
	TCPIP_IPV6_DestAddressGet	Gets the destination address for a IPv6 packet.
	TCPIP_IPV6_DestAddressSet	Sets the destination address for a IPv6 packet.
	TCPIP_IPV6_Flush	Flushes a IP TX packet.
	TCPIP_IPV6_Get	Reads the next byte of data from the specified MAC.
	TCPIP_IPV6_HandlerDeregister	Deregisters an IPv6 event handler callback function.
	TCPIP_IPV6_HandlerRegister	Registers an IPv6 event handler callback function.
	TCPIP_IPV6_InterfaceIsReady	Determines if an interface is ready for IPv6 transactions.
	TCPIP_IPV6_MulticastListenerAdd	Adds a multicast listener to an interface.
	TCPIP_IPV6_MulticastListenerRemove	Removes a multicast listener from a given interface.
	TCPIP_IPV6_PacketFree	Frees a TCP/IP Packet structure from dynamic memory.
	TCPIP_IPV6_PayloadSet	Allocates a segment on the end of a packet segment chain and uses it to address prebuffered data.
	TCPIP_IPV6_Put	Writes a character of data to a packet.
	TCPIP_IPV6_SourceAddressGet	Gets the source address for an IPv6 packet.
	TCPIP_IPV6_SourceAddressSet	Sets the source address for a IPv6 packet.
	TCPIP_IPV6_TxIsPutReady	Determines whether a TX packet can be written to.
	TCPIP_IPV6_TxPacketAllocate	Dynamically allocates a packet for transmitting IP protocol data.
	TCPIP_IPV6_UniqueLocalUnicastAddressAdd	Adds a Unique Local Unicast Address (ULA) to a specified interface.
	TCPIP_IPV6_UnicastAddressAdd	Adds a unicast address to a specified interface
	TCPIP_IPV6_RouterAddressAdd	Adds a new router address to a specified interface.
	TCPIP_IPV6_DefaultRouterDelete	Deletes the current router list for a specified interface
	TCPIP_IPV6_DefaultRouterGet	Returns the current router address for a specified interface.
	TCPIP_IPV6_Task	Standard TCP/IP stack module task function.

b) Data Types and Constants

	Name	Description
	IP_VERSION_4	Using IPv4
	IP_VERSION_6	Using IPv6
	IPV6_DATA_DYNAMIC_BUFFER	Data to transmit is allocated in dynamically allocated RAM
	IPV6_DATA_NETWORK_FIFO	Data to transmit is stored in the Network Controller's FIFOs
	IPV6_DATA_NONE	The data segment is unused

	IPV6_DATA_PIC_RAM	Data to transmit is stored in PIC RAM
	IPV6_HEADER_OFFSET_DEST_ADDR	Header offset for destination address
	IPV6_HEADER_OFFSET_NEXT_HEADER	Header offset for next header
	IPV6_HEADER_OFFSET_PAYLOAD_LENGTH	Header offset for payload length
	IPV6_HEADER_OFFSET_SOURCE_ADDR	Header offset for source address
	IPV6_NO_UPPER_LAYER_CHECKSUM	Value flag for no upper layer checksum
	IPV6_TLV_HBHO_PAYLOAD_JUMBOGRAM	IPv6 Type-length-value type code for the Hop-by-hop "Jumbo-gram Payload" option
	IPV6_TLV_HBHO_ROUTER_ALERT	IPv6 Type-length-value type code for the Hop-by-hop "Router Alert" option
	IPV6_TLV_PAD_1	IPv6 Type-length-value type code for the Pad 1 option
	IPV6_TLV_PAD_N	IPv6 Type-length-value type code for the Pad N option
	IPV6_TLV_UNREC_OPT_DISCARD_PP	IPv6 action code for the unrecognized option reaction to discard the packet and send an ICMP parameter problem message
	IPV6_TLV_UNREC_OPT_DISCARD_PP_NOT_MC	IPv6 action code for the unrecognized option reaction to discard the packet and send an ICMP parameter problem message is the destination address isn't a multicast address
	IPV6_TLV_UNREC_OPT_DISCARD_SILENT	IPv6 action code for the unrecognized option reaction to discard the packet silently
	IPV6_TLV_UNREC_OPT_SKIP_OPTION	IPv6 action code for the unrecognized option reaction to skip the option
	TCPIP_IPV6_PutArray	Writes data to a packet
	IPV6_ACTION	Provides a list of possible IPv6 actions.
	IPV6_ADDRESS_POLICY	Data structure for IPv6 address policy.
	IPV6_ADDRESS_PREFERENCE	Provides selection of public versus temporary addresses.
	IPV6_ADDRESS_TYPE	Data structure for IPv6 address types.
	IPV6_DATA_SEGMENT_HEADER	Data structure for IPv6 Data Segment header.
	_IPV6_DATA_SEGMENT_HEADER	Data structure for IPv6 Data Segment header.
	IPV6_EVENT_HANDLER	Clients can register a handler with the IPv6 service.
	IPV6_EVENT_TYPE	This enumeration is used to notify IPv6 client applications.
	IPV6_FRAGMENT_HEADER	Data structure for IPv6 fragment header.
	IPV6_HANDLE	Pointer to IPv6 object
	IPV6_HEADER	IPv6 packet header definition.
	IPV6_NEXT_HEADER_TYPE	Defines a list of IPv6 next header types.
	IPV6_PACKET	Packet structure/state tracking for IPv6 packets.
	_IPV6_PACKET	Packet structure/state tracking for IPv6 packets.
	IPV6_PACKET_ACK_FNC	Packet allocation and deallocation acknowledgment callback function.
	IPV6_RX_FRAGMENT_BUFFER	Data structure for IPv6 Received fragmented packet.
	_IPV6_RX_FRAGMENT_BUFFER	Data structure for IPv6 Received fragmented packet.
	IPV6_SEGMENT_TYPE	Provides an enumeration of IPv6 segment types.
	IPV6_TLV_OPTION_TYPE	Data structure for IPv6 TLV options.
	IPV6_ULA_FLAGS	Provides a list of possible ULA action flags.
	IPV6_ULA_RESULT	Provides a list of possible ULA results.
	TCPIP_IPV6_MODULE_CONFIG	Provides a place holder for IPv6 configuration.

Description

This section describes the Application Programming Interface (API) functions of the IPv6 module.

Refer to each section for a detailed description.

a) Functions

TCPIP_IPV6_AddressUnicastRemove Function

Removed a configured unicast address from an interface.

File

ipv6.h

C

```
void TCPIP_IPV6_AddressUnicastRemove(TCPIP_NET_HANDLE netH, IPV6_ADDR * address);
```

Returns

None.

Description

This function is used to remove a configured unicast address from an interface.

Remarks

None.

Preconditions

TCPIP_IPV6_Initialize should be called. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
netH	The interface to remove the address
address	The address

Function

void TCPIP_IPV6_AddressUnicastRemove(TCPIP_NET_HANDLE netH, IPV6_ADDR * address)

TCPIP_IPV6_ArrayGet Function

Reads the next byte of data from the specified MAC.

File

ipv6.h

C

```
uint8_t TCPIP_IPV6_ArrayGet(TCPIP_MAC_PACKET* pRxPkt, uint8_t * val, uint16_t len);
```

Returns

- > 0 - The number of bytes read
- 0 - No byte is available to read

Description

Reads a character of data from a packet.

Remarks

None

Preconditions

TCPIP_IPV6_Initialize is required. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
pRxPkt	The MAC RX packet to read data from
val	The buffer to store the data
len	The amount of data to read

Function

uint8_t TCPIP_IPV6_ArrayGet (TCPIP_MAC_PACKET* pRxPkt, uint8_t *val,
uint16_t len);

TCPIP_IPV6_ArrayPutHelper Function

Helper function to write data to a packet.

File

ipv6.h

C

```
unsigned short TCPIP_IPV6_ArrayPutHelper(IPV6_PACKET * pkt, const void * dataSource, uint8_t dataType,
unsigned short len);
```

Returns

unsigned short - The number of bytes of data written.

Description

This is a helper function for writing data to a packet.

Remarks

None.

Preconditions

TCPIP_IPV6_Initialize is required. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
ptrPacket	The packet
dataSource	The address of the data on its medium
dataType	Descriptor of the data type (dynamic memory on PIC, in a network FIFO, in static PIC RAM)
len	Length of the data

Function

unsigned short TCPIP_IPV6_ArrayPutHelper (IPV6_PACKET * ptrPacket,

const void * dataSource, uint8_t dataType, unsigned short len)

TCPIP_IPV6_DASSourceAddressSelect Function

Determines the appropriate source address for a given destination address.

File

ipv6.h

C

```
IPV6_ADDR_STRUCT * TCPIP_IPV6_DASSourceAddressSelect(TCPIP_NET_HANDLE hNetIf, const IPV6_ADDR * dest,
IPV6_ADDR * requestedSource);
```

Returns

- On Success - Pointer to the selected source address
- On Failure - NULL

Description

The IPv6 policy table is used to select the destination address. The destination address selection algorithm takes a list of IPv6 addresses (gPolicyTable) and sorts the linked list. There are eight sorting rules. Starting with the last rule and working to the most important, using a stable sorting algorithm, will produce a sorted list most efficiently. The best average run time we'll get with a stable sort with O(1) memory usage is O(n^2), so we'll use an insertion sort. This will usually be most efficient for small lists (which should be the typical case). If a rule determines a result, then the remaining rules are not relevant and should be ignored.

Remarks

None.

Preconditions

TCPIP_IPV6_Initialize is required. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
hNetIf	The given interface

dest	The destination address
requestedSource	A specified source

Function

IPV6_ADDR_STRUCT * TCPIP_IPV6_DASSourceAddressSelect (TCPIP_NET_HANDLE hNetIf,
IPV6_ADDR * dest, IPV6_ADDR * requestedSource)

TCPIP_IPV6_DestAddressGet Function

Gets the destination address for a IPv6 packet.

File

ipv6.h

C

```
IPV6_ADDR * TCPIP_IPV6_DestAddressGet(IPV6_PACKET * p);
```

Returns

IPV6_ADDR *

- On Success - Get a valid IPv6 Destination address
- On Failure - NULL

Description

This function is used to get the destination address for a IPv6 packet.

Remarks

None.

Preconditions

TCPIP_IPV6_Initialize should be called. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
p	pointer to IPv6 packet

Function

IPV6_ADDR * TCPIP_IPV6_DestAddressGet(IPV6_PACKET * p)

TCPIP_IPV6_DestAddressSet Function

Sets the destination address for a IPv6 packet.

File

ipv6.h

C

```
void TCPIP_IPV6_DestAddressSet(IPV6_PACKET * p, const IPV6_ADDR * addr);
```

Returns

None.

Description

This API is used to configure the destination address for a IPv6 packet.

Remarks

None.

Preconditions

TCPIP_IPV6_Initialize should be called. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
p	pointer to IPv6 packet
addr	destination address

Function

void TCPIP_IPV6_DestAddressSet(IPV6_PACKET * p, const IPV6_ADDR * addr)

TCPIP_IPV6_Flush Function

Flushes a IP TX packet.

File

ipv6.h

C

```
int TCPIP_IPV6_Flush(IPV6_PACKET * pkt);
```

Returns

- 1 - if the packet has been transmitted
- 0 - if the packet has been queued
- <0 - if the packet has been discarded for some error

Description

This function flushes a IP TX packet. Determines the link-layer address, if necessary and calculates the upper-layer checksum, if necessary.

Remarks

None.

Preconditions

TCPIP_IPV6_Initialize should be called. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
ptrPacket	The packet to flush

Function

int TCPIP_IPV6_Flush (IPV6_PACKET * ptrPacket)

TCPIP_IPV6_Get Function

Reads the next byte of data from the specified MAC.

File

ipv6.h

C

```
uint8_t TCPIP_IPV6_Get(TCPIP_MAC_PACKET* pRxPkt, uint8_t* pData);
```

Returns

- 1 - On Successful read
- 0 - No byte is available to read

Description

This function is used to read the next byte of data from a packet.

Remarks

None.

Preconditions

TCPIP_IPV6_Initialize should be called. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
pRxPkt	The MAC RX packet to read data from
pData	Byte data to be read

Function

uint8_t TCPIP_IPV6_Get (TCPIP_MAC_PACKET* pRxPkt, uint8_t* pData)

TCPIP_IPV6_HandlerDeregister Function

Deregisters an IPv6 event handler callback function.

File

ipv6.h

C

```
bool TCPIP_IPV6_HandlerDeregister(IPV6_HANDLE hIpv6);
```

Returns

- true - if deregister successful
- false - if deregister is not successful

Description

This function deregisters a previously registered IPv6 event handler callback function.

Remarks

None.

Preconditions

The IPv6 stack is initialized and the interface is up and configured.

Parameters

Parameters	Description
hIpv6	Handle to registered callback

Function

bool TCPIP_IPV6_HandlerDeregister(IPV6_HANDLE hIpv6)

TCPIP_IPV6_HandlerRegister Function

Registers an IPv6 event handler callback function.

File

ipv6.h

C

```
IPV6_HANDLE TCPIP_IPV6_HandlerRegister(TCPIP_NET_HANDLE hNet, IPV6_EVENT_HANDLER handler, const void*
hParam);
```

Returns

Handle to registered callback.

- On Success - Returns a valid handle
- On Failure - null handle

Description

This function is used to register a notification handler with the IPv6 module.

Remarks

None.

Preconditions

The IPv6 stack is initialized and the interface is up and configured.

Parameters

Parameters	Description
netH	Specifies interface to register on.
handler	Handler to be called for event.
hParam	The hParam is passed by the client and will be used by the IPv6 when the notification is made. It is used for per-thread content or if more modules, for example, share the same handler and need a way to differentiate the callback.

Function

IPV6_HANDLE TCPIP_IPV6_HandlerRegister(TCPIP_NET_HANDLE hNet,
IPV6_EVENT_HANDLER handler, const void* hParam)

TCPIP_IPV6_InterfaceIsReady Function

Determines if an interface is ready for IPv6 transactions.

File

ipv6.h

C

```
bool TCPIP_IPV6_InterfaceIsReady(TCPIP_NET_HANDLE netH);
```

Returns

- true - if the interface has IPv6 functionality available
- false - if the interface does not have IPv6 functionality available

Description

Returns the current state of the IPv6 interface (i.e., determines if an interface is ready for IPv6 transactions).

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
netH	The interface to check

Function

bool TCPIP_IPV6_InterfaceIsReady (TCPIP_NET_HANDLE netH)

TCPIP_IPV6_MulticastListenerAdd Function

Adds a multicast listener to an interface.

File

ipv6.h

C

```
IPV6_ADDR_STRUCT * TCPIP_IPV6_MulticastListenerAdd(TCPIP_NET_HANDLE hNet, IPV6_ADDR * address);
```

Returns

IPV6_ADDR_STRUCT *

- On Success - Pointer to the new listener
- On Failure - NULL

Description

This function is used to add the IPv6 multicast address to an interface.

Remarks

None.

Preconditions

TCPIP_IPV6_Initialize should be called. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
hNet	The interface to add the address
address	The new listener

Function

IPV6_ADDR_STRUCT * TCPIP_IPV6_MulticastListenerAdd(TCPIP_NET_HANDLE hNet, IPV6_ADDR * address)

TCPIP_IPV6_MulticastListenerRemove Function

Removes a multicast listener from a given interface.

File

ipv6.h

C

```
void TCPIP_IPV6_MulticastListenerRemove(TCPIP_NET_HANDLE netH, IPV6_ADDR * address);
```

Returns

None.

Description

This function removes a multicast listener from a given interface.

Remarks

None.

Preconditions

TCPIP_IPV6_Initialize should be called. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
netH	The interface
address	The address

Function

void TCPIP_IPV6_MulticastListenerRemove (TCPIP_NET_HANDLE netH, IPV6_ADDR * address)

TCPIP_IPV6_PacketFree Function

Frees a TCP/IP Packet structure from dynamic memory.

File

ipv6.h

C

```
void TCPIP_IPV6_PacketFree(IPV6_PACKET * pkt);
```

Returns

None.

Description

This function frees a TCP/IP Packet structure from dynamic memory.

Remarks

None.

Preconditions

TCPIP_IPV6_Initialize is required. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
ptrPacket	The packet to free.

Function

void TCPIP_IPV6_PacketFree (IPV6_PACKET * ptrPacket)

TCPIP_IPV6_PayloadSet Function

Allocates a segment on the end of a packet segment chain and uses it to address prebuffered data.

File

ipv6.h

C

```
unsigned short TCPIP_IPV6_PayloadSet(IPV6_PACKET * pkt, uint8_t* payload, unsigned short len);
```

Returns

- On Success - The amount of data added to the packet length
- On Failure - 0

Description

This function will allocate a data segment header and append it to the end of a chain of segments in a TX packet. It will set the data pointer in the packet segment to a pre-existing buffer of data.

Remarks

This function is useful for adding payloads to outgoing packets without copying them if the data is in another pre-existing buffer (i.e., TCP).

Preconditions

TCPIP_IPV6_Initialize should be called. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
ptrPacket	The packet
payload	Address of the data payload
len	Length of the data payload

Function

unsigned short TCPIP_IPV6_PayloadSet (IPV6_PACKET * ptrPacket, uint8_t* payload,

unsigned short len)

TCPIP_IPV6_Put Function

Writes a character of data to a packet.

File

ipv6.h

C

```
bool TCPIP_IPV6_Put(IPV6_PACKET * pkt, unsigned char v);
```

Returns

- true - if the character was written
- false - if the character was not written

Description

This function writes a character of data to a packet.

Remarks

None.

Preconditions

TCPIP_IPV6_Initialize is required. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
pkt	The packet
v	The character

Function

bool TCPIP_IPV6_Put (IPV6_PACKET * pkt, unsigned char v)

TCPIP_IPV6_SourceAddressGet Function

Gets the source address for an IPv6 packet.

File

ipv6.h

C

```
IPV6_ADDR * TCPIP_IPV6_SourceAddressGet(IPV6_PACKET * p);
```

Returns

IPV6_ADDR *

- On Success - Get a valid IPv6 Source address
- On Failure - NULL

Description

This API is used to get the source address for an IPv6 packet.

Remarks

None.

Preconditions

TCPIP_IPV6_Initialize should be called. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
p	pointer to IPv6 packet

Function

IPV6_ADDR * TCPIP_IPV6_SourceAddressGet(IPV6_PACKET * p)

TCPIP_IPV6_SourceAddressSet Function

Sets the source address for a IPv6 packet.

File

ipv6.h

C

```
void TCPIP_IPV6_SourceAddressSet(IPV6_PACKET * p, const IPV6_ADDR * addr);
```

Returns

None.

Description

This function is used to configure the source address for a IPv6 packet.

Remarks

None.

Preconditions

TCPIP_IPV6_Initialize should be called. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
p	pointer to IPv6 packet
addr	source address

Function

void TCPIP_IPV6_SourceAddressSet(IPV6_PACKET * p, const IPV6_ADDR * addr)

TCPIP_IPV6_TxIsPutReady Function

Determines whether a TX packet can be written to.

File

ipv6.h

C

```
unsigned short TCPIP_IPV6_TxIsPutReady(IPV6_PACKET * pkt, unsigned short count);
```

Returns

- On Success - The amount of space available
- On Failure - 0

Description

This function determines whether a TX packet can be written to. This function will allocate additional space to the packet to accommodate the user.

Remarks

None.

Preconditions

TCPIP_IPV6_Initialize is required. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
ptrPacket	The packet to check
count	The amount of writable space to check for

Function

unsigned short TCPIP_IPV6_TxIsPutReady (IPV6_PACKET * ptrPacket,
unsigned short count)

TCPIP_IPV6_TxPacketAllocate Function

Dynamically allocates a packet for transmitting IP protocol data.

File

ipv6.h

C

```
IPV6_PACKET * TCPIP_IPV6_TxPacketAllocate(TCPIP_NET_HANDLE netH, IPV6_PACKET_ACK_FNC ackFnc, void*
ackParam);
```

Returns

- On Success - Pointer to the allocated packet
- On Failure - NULL

Description

This function dynamically allocates a packet for transmitting IP protocol data and sets the packet IPv6 protocol for a TX packet.

Remarks

None.

Preconditions

TCPIP_IPV6_Initialize is required. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
netH	Interface of the outgoing packet.
ackFnc	function to be called when IP is done with the TX packet (finished transmitting)
ackParam	parameter to be used for this callback This has meaning only for the caller of the TCPIP_IPV6_TxPacketAllocate

Function

IPV6_PACKET * TCPIP_IPV6_TxPacketAllocate (TCPIP_NET_HANDLE netH,
IPV6_PACKET_ACK_FNC ackFnc, void* ackParam);

TCPIP_IPV6_UniqueLocalUnicastAddressAdd Function

Adds a Unique Local Unicast Address (ULA) to a specified interface.

File

ipv6.h

C

```
IPV6_ULA_RESULT TCPIP_IPV6_UniqueLocalUnicastAddressAdd(TCPIP_NET_HANDLE netH, uint16_t subnetID,
IPV6_ULA_FLAGS genFlags, IP_MULTI_ADDRESS* ntpAddress);
```

Returns

- IPV6_ULA_RES_BUSY - address generation module is busy
- IPV6_ULA_RES_IF_ERR - IPv6 interface is not up
- IPV6_ULA_RES_OK - if the call succeeded and the generation process was started

Description

This function starts the process of adding an ULA address to the specified interface. The segments of the generated address are as follows:

- FC00::/7 - ULA prefix
- L - 1 bit set to 1, locally assigned
- Global ID - 40 bit random generated identifier
- subnet ID - 16 bit subnet identifier
- Interface ID - 64 bit interface identifier generated as a EUI64 from the specified interface MAC

The randomness of the "Global ID" prefix of the generated IPv6 address is obtained by using an NTP server. The supplied NTP server will be

contacted to obtain an NTP time stamp. This time stamp together with the EUI64 identifier obtained from the interface MAC are passed through a 160 bits hash algorithm (SHA1) and the least significant 40 bits are used as the GlobalID of the interface.

Remarks

Only one address generation at a time is supported for now. Before attempting a new address generation the previous operation has to be completed, otherwise the call will fail.

This function requires that the NTP client is enabled in the stack. If not, the call will fail.

The caller will be notified by the outcome of the operation by the stack using the standard IPv6 notification handler (registered by TCPIP_IPV6_HandlerRegister call).

Preconditions

The IPv6 stack is initialized and the interface is up and configured.

Parameters

Parameters	Description
netH	The interface to add the address to.
subnetID	The subnet ID to be used.
genFlags	Address generation flags: • IPV6_ULA_FLAG_NTPV4 - if set, the ntpAddress is an IPv4 address and the NTP server will be contacted over an IPv4 connection. Otherwise, a default IPv6 connection will be attempted • IPV6_ULA_FLAG_GENERATE_ONLY - if set, the address will not be added to the list of the addresses for the specified interface • IPV6_ULA_FLAG_SKIP_DAD - if set, the DAD processing will be skipped
ntpAddress	The NTP server address - it is an IPv4/IPv6 address as selected by the IPV6_ULA_FLAG_NTPV4 flag (the IP address could be obtained with an DNS call into the stack)

Function

IPV6_ULA_RESULT TCPIP_IPV6_UniqueLocalUnicastAddressAdd (TCPIP_NET_HANDLE netH,
uint16_t subnetID, IPV6_ULA_FLAGS genFlags, IP_MULTI_ADDRESS* ntpAddress)

TCPIP_IPV6_UnicastAddressAdd Function

Adds a unicast address to a specified interface

File

ipv6.h

C

```
IPV6_ADDR_STRUCT * TCPIP_IPV6_UnicastAddressAdd(TCPIP_NET_HANDLE netH, IPV6_ADDR * address, int prefixLen,
uint8_t skipProcessing);
```

Returns

IPV6_ADDR_STRUCT *

- On Success - Pointer to the structure of the newly allocated address
- On Failure - NULL

Description

Adds a unicast address to a specified interface. Starts duplicate address detection if necessary.

Remarks

The RFC (4291) requires the interface ID for all unicast addresses, (except those that start with the binary value 000) to be 64 bits long and to be constructed in Modified EUI-64 format. Therefore the prefixLen parameter should probably always be 64.

Preconditions

TCPIP_IPV6_Initialize is required. TCPIP_IPV6_InterfaceIsReady should be true.

Parameters

Parameters	Description
netH	The interface to which the the address is to be addded

address	The address to add
prefixLen	The prefix length associated to this static address (providing the subnet prefix length). If 0, the default value of 64 will be used
skipProcessing	true to skip Duplicate address detection; otherwise, false

Function

IPV6_ADDR_STRUCT * TCPIP_IPV6_UnicastAddressAdd (TCPIP_NET_HANDLE netH,
IPV6_ADDR * address, int prefixLen, uint8_t skipProcessing)

TCPIP_IPV6_RouterAddressAdd Function

Adds a new router address to a specified interface.

File

ipv6.h

C

```
bool TCPIP_IPV6_RouterAddressAdd(TCPIP_NET_HANDLE netH, IPV6_ADDR * rAddress, unsigned long validTime, int flags);
```

Returns

- true - operation succeeded
- false - operation failed (interface not valid, interface still configuring, no memory, etc.)

Description

This function adds a unicast address as a routing address to a specified interface.

Remarks

The validTime parameter is relevant for an existent router on the network. If such router does not exist the stack will eventually discard the entry automatically.

Preconditions

rAddress pointer to a valid IPv6 router address IPv6 stack initialized, interface up and configured

Parameters

Parameters	Description
netH	The interface to which the address is to be added
rAddress	The router address to add
validTime	The time this valid will be valid, seconds. If 0, the entry will be valid forever.
flags	Creation flags (not used for now, should be 0)

Function

bool TCPIP_IPV6_RouterAddressAdd(TCPIP_NET_HANDLE netH, IPV6_ADDR * rAddress,
unsigned long validTime, int flags);

TCPIP_IPV6_DefaultRouterDelete Function

Deletes the current router list for a specified interface

File

ipv6.h

C

```
